The overall employment density in cities with different land use intensity does not change significantly, as the percent changes in total employment density in all areas are less than 0.1%. This indicates that although SAVs are likely to change the spatial distribution of jobs by industry sectors, the firms are not going to sprawl outside of the city, due to the agglomeration effects.

However, it appears that SAV may further segregate different types of jobs in the region. For instance, manufacturing, construction, TCU, and wholesale jobs will migrate to cities in the outer ring. While, sectors such as FIRE, service, and public will become more dominant in the cities in the core of the urban region.

MODEL VALIDATION AND VERIFICATION

We validate the developed models by comparing the results from the 2015 BAU scenario with the 2015 ESRI observed business data. The estimated Spearman correlations by industry sectors, as shown in Figure 4, indicate that BAU simulation results are highly correlated with 2015 observed TAZ level employment counts across industries. The estimated correlations for manufacturing, wholesale, and services sectors are the lowest, at 0.72. The correlation is the strongest for the TCU sector, which is 0.84. The high correlations between the simulated BAU results and the observed 2015 employment distribution, to some extent, validate the model framework and the estimated coefficients from the employment location choice models. The discrepancies between the simulated results and the observed data can be attributed to (1) the changes in location preferences over time and (2) the missing control variables in the employment location choice models.

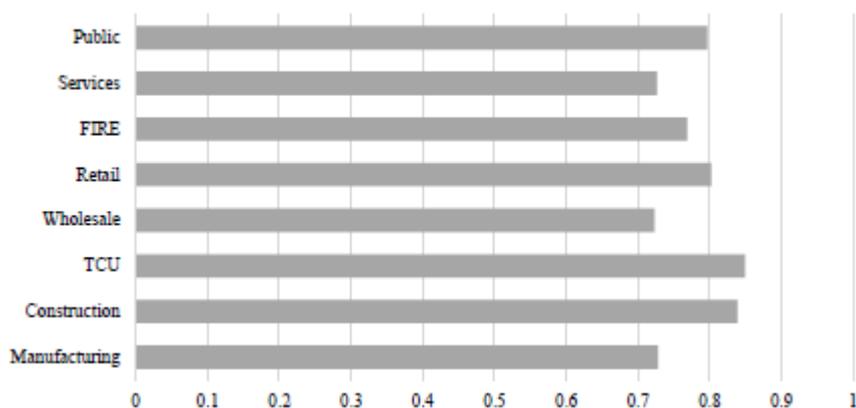

Figure 4: Correlations between BAU results and observed 2015 ESRI business data by sector

We also verify the model by conducting a series of sensitivity tests. First, several parking lots conversion rates, including 25% and 50%, are examined and compared with the 90% conversion scenario. The results, as displayed in Table 6, suggest that different parking conversion rates are not going to change the trends in employment relocation choices across sectors, as the signs of differences between SAV and BAU employment densities are stable across scenarios. Some sectors, such as retail, services, and wholesales are less sensitive to the variations of parking conversion rates, as the estimated coefficients for the commercial and industrial land density variable in these sector-specific location choice models are either not significant or small in magnitude.

For sectors that are sensitive to changes in parking conversion rate, the variations in model outputs are not linear. For instance, the downtown employment density for the construction sector decreases by 11.6% in the scenario where 25% parking are converted into commercial or industrial use. The reduction rate only increases to 14.2% when the parking conversion rate is doubled to 50%. Further, the reduction rate is merely 15.6% when the parking conversion rate rises to 90%. This is because the utilities of location choices are not linearly associated with the commercial and industrial land density variable but the log-transformed variable. As a result, the reduction in construction employment density diminishes when increasing the parking conversion rate from 25% to 90%.

Table 6: Changes in Employment Density (vs. BAU results) by Different Parking Conversion Rates

Industry Sectors	Parking Conversion Rates	Downtown	Inner City	Inner Suburban	RingOuter Suburban	Ring
Construction	25% Conversion	-11.59%	-10.30%	7.16%	3.49%	
	50% Conversion	-14.22%	-13.67%	10.09%	4.32%	
	90% Conversion	-15.60%	-16.70%	10.53%	4.39%	

Manufacture	25% Conversion	-2.92%	-2.29%	0.07%	0.32%
	50% Conversion	-5.28%	-4.84%	0.16%	0.83%
	90% Conversion	-6.90%	-6.00%	0.20%	1.00%
TCU	25% Conversion	-7.60%	-4.53%	0.21%	1.94%
	50% Conversion	-12.36%	-7.42%	0.36%	3.82%
	90% Conversion	-17.50%	-9.40%	0.50%	4.50%
Wholesale	25% Conversion	-10.26%	-1.65%	5.81%	6.96%
	50% Conversion	-11.36%	-1.58%	6.16%	7.97%
	90% Conversion	-12.00%	-1.80%	6.60%	8.30%
Retail	25% Conversion	0.84%	4.53%	0.00%	0.52%
	50% Conversion	0.69%	4.64%	0.00%	0.56%
	90% Conversion	0.80%	4.90%	0.00%	0.60%
FIRE	25% Conversion	4.13%	0.00%	-3.85%	-0.76%
	50% Conversion	9.30%	0.00%	-6.51%	-2.02%
	90% Conversion	11.80%	0.00%	-7.80%	-2.50%
Service	25% Conversion	1.01%	0.52%	-4.19%	-1.94%
	50% Conversion	1.17%	0.63%	-5.21%	-2.31%
	90% Conversion	1.40%	0.70%	-5.90%	-2.70%
Public	25% Conversion	1.40%	0.10%	-3.38%	-3.22%
	50% Conversion	2.28%	0.22%	-6.31%	-5.80%
	90% Conversion	3.10%	0.30%	-7.40%	-6.90%

Finally, the assumption that no IVTT costs will be perceived by SAV users is relaxed. Two additional scenarios, where SAV clients are charged with an additional 25% and 50% of IVTT costs, are developed. Access to labor are then re-estimated given the updated assumptions. Some sectors, such as construction, TCU, FIRE, and public are sensitive to changes in IVTT costs, as shown in Table 7. The results are as expected, as the larger portion of perceived IVTT costs, the less changes in employment distribution compared with BAU results are observed.

Moreover, changes in employment density are not linearly correlated with the percentage of charged IVTT costs. Meanwhile, the results for sectors, such as manufacturing, wholesale, and retail, do not vary significantly across different sensitivity tests, because the labor accessibility related variables are not significant in the corresponding location choice models. The changes in these sectors stem primarily from variations in other sectors that are sensitive to changes in human capital accessibility related variables.

Table 7: Changes in Employment Density (vs. BAU results) by Different Percent of Charged IVTT

Industry Sectors	Charged Percent of IVTT	Ring			
		Downtown	Inner City	Inner Suburban	RingOuter Suburban
Construction	0% IVTT	-15.60%	-16.70%	10.53%	4.39%
	25% IVTT	-12.88%	-14.77%	7.75%	3.47%
	50% IVTT	-2.82%	-2.86%	1.98%	0.65%
Manufacture	0% IVTT	-6.90%	-6.00%	0.20%	1.00%

	50% IVTT	1.77%	0.22%	-5.25%	-4.47%

CONCLUSIONS

The results of our study suggest that different economic sectors may move in different directions in the SAV scenario. Secondary economic sectors, including manufacturing, construction, TCU, and wholesale sectors, are more likely to concentrate in cities at the periphery of the urban region. Meanwhile, tertiary sectors, such as FIRE, service, and public, are going to agglomerate more densely in cities at the core of the region. The density of retail employment will increase slightly in all cities, but the ones in the core of the region will gain more. This is because retail sector follows the

distribution of markets or population in the region more closely than other sectors. Most large cities in the U.S. have started deindustrialization decades ago, i.e., the employment density of secondary sectors have declined together with increasing employment in the tertiary sectors. The vast literature on this subject have identified several causes, including globalization and robotic automation technologies. The results from this study indicate that the introduction of the SAVs will accelerate the existing deindustrialization trends in major U.S. cities.

The simulation results together with the sensitivity tests also offer insights on how variations in labor accessibility and parking space redevelopment will influence the spatial distribution of employment across different sectors. The agglomeration patterns are not linearly correlated with job accessibility or parking space redevelopment. The marginal effects of variations diminish with the increase in these factors. Moreover, our research suggests that the changes in labor accessibility and parking land use redevelopment induced by SAVs will not significantly alter the trends in industrial agglomeration in the future.

The model validation results suggest that the developed employment location choice and relocation choice models are robust, given the high correlation between the results obtained in business-as-usual scenario for 2015 and the 2015 observed employment distribution.

Additionally, the sensitivity tests also validate the design of the model, as the outputs change in expected directions given changes in various model assumptions. Finally, the sensitivity test results also indicate that the changes in access to human capital and commercial and industrial land density will not affect all industry sectors equally. For instance, the location choice in the retail sector is not sensitive to both variables. Firms in the manufacturing and wholesale sectors are only sensitive to commercial and industrial land density.

The developed model has limitations that merit future research. First, this model only considers the demand side of the location decision making; the supply side is not considered in the model. Therefore, the model results cannot provide insights on land value changes, which may influence the landscape of firms in the long run. Additionally, this study only examines the impact of SAVs on employment patterns. However, there are some other AV deployment models, such as privately-owned AVs (PAVs) and transit complementary AVs (TCAVs) and separate studies are needed to explore the impacts of alternative AV business models on the spatial distribution of employment in the region. Finally, this study does not provide insights regarding the employment distribution in the transition period. More research should be dedicated to examining potential changes in scenarios where the AVs co-exists with conventional vehicles (CVs).

1622 AN ANALYSIS OF PERFORMANCE OF INDIAN LEATHER INDUSTRY ACROSS STATES, ORGANIZATIONAL STRUCTURES AND LOCATION OF THE FIRMS

ABSTRACT

The Indian leather industry holds a place of prominence in the economy by meeting two important policy goals of employment and export generation. Recognizing its potential to generate 250 jobs for every INR 1 crore investment, the central government has put the leather industry under the focus areas of 'Make in India' scheme with the aim to increase leather exports to \$15 billion by 2020 from the current \$6 billion. However, the industry is facing issues of access to high-quality raw materials, and loss of competitiveness in the international leather market. The leather exports fell by 10% (value terms) in 2015 relative to 2014 which was one of the worst drops after 2008 global crisis. In addition, the pollution-intensive nature of leather tanning industry has created a negative impact on the society. With increased competition from China, Bangladesh and Vietnam, it is imperative for the industry to become more efficient in order to maximize its returns from the given resources. This requires a study of its production performance and to determine factors that can boost its potential in the future. The present paper evaluates its economic performance across different states, organizational structures, urban/rural location, and sub industrial groups using Meta- Group frontier DEA framework for measuring technical efficiency of the leather firms in India. Plant-level data from Annual Survey of Industries post 2000-01 is used for the study. The efficiency analysis shows a relatively poor performance of leather industry post-crisis period of 2008-09. Efficiency differs between different organizational structures, location, and sub industrial groups of the leather industry. Tamil Nadu and Uttar Pradesh leather clusters are found to be less efficient relative to other states. Firms from rural location experience infrastructural constraint and have shown low efficiency. The public and private limited companies perform relatively worse in comparison to the individual proprietorship or partnership firms. While examining factors to enhance technical efficiency, the paper suggests investing in skilled labors, new plant and machinery, pollution abatement equipment, higher vertical integration, and merging of small firms to take advantage of economies of scale. Further, reducing energy consumption by leather firms will not only boost the overall efficiency of the leather industry but also reduce carbon emissions.

- Preliminary and incomplete version – please do not quote -

ABSTRACT

This paper investigates changes in the spatial concentration of economic activities in East Germany between 1992 and 2010. To this I draw on detailed plant data for manufacturing and services. Overall, East Germany features a substantial degree of concentration that strongly decreased until 1998 and since then slowly increased again. This pattern is consistent with the profound structural changes going along since German reunification. Concentration in manufacturing is substantially higher than in services. The main drivers of the deconcentration process in the 1990s were contracting plants within agglomerations. Since then, their impact diminished. A crucial role can be ascertained towards the closure of plants in agglomerations, which greatly reduced the overall degree of concentration. Evidently, the profound process of restructuring the East German economy brought along massive changes in the industrial location patterns. The results also provide evidence that agglomerative forces might have (re-)developed to some extent, which might also foster the emergence of successful economic clusters.

1. INTRODUCTION

This paper investigates changes in the spatial concentration of economic activity in East Germany between 1992 and 2010. During Socialism, location decisions of firms were strongly influenced by political reasoning. In the course of the German reunification and the exposure to free market forces, the East German economy was struck by a massive shock (Burda 2006). As a consequence, many formerly large combines were closed down or broken up into several smaller firms. At the same time, many new plants were being set up. On the one hand, the economic upheavals brought along profound changes in the location patterns of single industries. On the other hand, some industries have retained their concentration in space, successfully adapting to the new economic environment.

So far, the few studies investigating the changes in location patterns in East Germany have mainly dealt with single industries or undertaken case studies (see Heimpold 2015, 2016a, 2016b, 2016c). A comprehensive investigation of the overall processes and the underlying determinants is still missing (see, e.g., Rosenfeld/Franz/Heimpold 2007; Kosfeld/Titze 2015). The present paper aims at filling this research gap. For the measurement of concentration, I relate to the index of Ellison/Glaeser (1997) (EG index) and draw on detailed plant data of 187 industries at the district (NUTS-3) level. The data comes from the Establishment History Panel of the Institute for Employment Research, which comprises information on all German establishments with at least one employee required to make social security contributions. I assess the patterns and changes between 1992 and 2010 in all economic industries and in manufacturing and services separately. Furthermore, I also shed light on which mechanisms drive the long-run changes in geographical concentration. In line with Dumais/Ellison/Glaeser (2002), I decompose aggregate concentration changes into portions attributable to plant births, expansions, contractions, and closures. These dynamics act together in changing the level of industrial concentration over time. Last, the results are contrasted to those for West Germany (Dauth/Fuchs/Otto 2016). This provides evidence as to how the East Germany's economic structure still deviates from that in West Germany and how much its economic landscape has possibly converged.

The results show a strong decline of geographic concentration in East Germany until around 1998 in all sectors under consideration. Since then, the EG index has slowly increased again to an overall value of 0.046 in the year 2010, with concentration in manufacturing higher than in services. According to first results, the main drivers of the deconcentration process in the 1990s were contracting plants within agglomerations. Since then, their impact diminished. A crucial role can be ascertained towards the closure of plants in agglomerations, which greatly reduced the overall degree of concentration until 2008. Plant expansions, in contrast, play only a minor role. Evidently, the profound process of restructuring the East German economy brought along massive changes in the industrial location patterns.

The paper is structured as follows. In chapter 2, a short overview over the theoretical background and the related empirical literature is provided. Chapter 3 contains information on the data set and the EG index. Empirical results for East Germany are at the center of chapter 4, and chapter 5 draws conclusions.

2 THEORETICAL BACKGROUND AND RELATED LITERATURE

The question why economic activity is not evenly distributed across space has been subject to intense theoretical thought. A substantial part of the observed geographical concentration can be traced back to so-called first-nature forces. Firms that rely on natural advantages such as fertile soil, raw materials or the existence of navigable waterways locate close to

where these are abundant (Krugman 1993).²³¹ The other explanation for geographic concentration are economies of scale, external to individual firms but internal to co-located firms. These centripetal forces lead to a concentration of economic activities in space. In contrast, centrifugal forces or urban congestion costs act as agglomeration disadvantages that negatively influence benefits and profits. Economic agents have incentives to avoid proximity, which ultimately results in the geographical dispersion of economic activities.

There are several theoretical explanations as to the causes of agglomeration economies (for an overview, see Duranton/Puga 2004). Rooted in the seminal work of Alfred Marshall (1890), three agglomeration forces have become prominent. First, the proximity of firms reduces transport costs and enables them to benefit from sharing suppliers producing with increasing returns. Second, the local concentration of firms of one sector creates a pool of skilled personnel, reducing search costs for qualified labor and enhancing the probability and quality of successful matches. Third, geographical proximity promotes the flow of knowledge and technology spillovers between firms and people. Knowledge and ideas can be transmitted through formal and informal channels fostering innovation and technological change. Jacobs (1969), on the other hand, emphasizes the importance of the exchange of ideas between economic agents from different sectors that inspire each other.

The existence and the sources of agglomeration economies are generally scrutinized for the manufacturing sector (see, e.g., Rosenthal/Strange 2001). For the service sector, much less evidence is available in both theoretical and empirical terms. Kolko (2010) argues that services are more urbanized, but also less agglomerated than manufacturing. He stresses that services rely much less on physical inputs than manufacturing, thereby reducing the necessity to locate near natural resources. In addition, transports costs for services output and the necessity of face-to-face contact with customers make it important for some service industries to be close to their customers. Moreover, for those firms that serve customers across different industries, the optimal location choice is within a dense and diverse net of businesses that also provides a thick labor market. In his empirical analysis for the USA, Kolko (2010) confirms that services are less concentrated than manufacturing at the county level and much less so at the state level. Natural resources do not statistically explain the location of service firms, whereas the share of workers with graduate degrees as proxy for knowledge spillovers is the only measure that is positive and significant. For Germany, Alecke/Untiedt (2008) and Koh/Riedel (2014) find that the vast majority of service industries is strongly localized and that agglomeration forces play an equally important role as in manufacturing.

From a static point of view, agglomeration advantages provide an answer as to why firms locate close to each other, which explains the geographical concentration of economic activities. However, there is no reason to assume that positive external effects prevail in the same magnitude or even increase over time. In the long run, agglomeration advantages may alter due to technological progress or structural or geopolitical changes. For example, because of the rapid technological progress especially in the telecommunications sector, the way individuals or firms can interact has changed fundamentally in the last decades. Likewise, improvements in traffic infrastructure have resulted in much lower transport costs of goods. Moreover, vertical disintegration of production has led to outsourcing parts of the production process to intermediate suppliers that may even be located in different countries. These latter developments might well foster the dispersion of once concentrated structures.

Based on the concept of agglomeration economies, several theoretical models have been developed to explain changes in the geographical concentration of economic activities. One explanation in this respect is provided by the industry life cycle framework (Klepper 1997). As Neffke et al. (2011: 53) note, industries have different agglomeration needs in different stages of their life cycles because their mode of competition, innovation intensity, and learning opportunities change over time. During its growth phase, an industry can be expected to benefit from agglomeration advantages, and hence firms seek mutual proximity. As a consequence, the industry becomes geographically concentrated. When the maturity phase is reached and positive externalities eventually cease to exist, concentration remains simply because it would be too costly to relocate. In traditional manufacturing industries, for example, past agglomeration patterns might still be in place, whereas specific externalities have become obsolete due to declining demand and modern production technologies. When finally demand decreases too strongly, establishments die and concentration dissolves. In the same vein, Audretsch/Feldman (1996) link the propensity for innovative activity to spatially cluster to the different stages of the industry life cycle. They argue that location matters most during the early stages, whereas the positive agglomeration effects become replaced by congestion effects during later stages. Similarly, in outlining an evolutionary agglomeration theory, Potter/Watts (2011: 419) argue that the Marshallian forces create larger economic performance and increasing returns at the start of the industry life cycle, but declining economic performance and diminishing returns during the later stages. This focus on the development of the economic landscape is also at the heart of the evolutionary economic geography that deals with the processes by which the spatial organization of economic production, distribution and consumption is transformed over time (Boschma/Martin 2007: 539).

A slightly different way to catch the dynamics of geographical concentration is taken by Dumais/Ellison/Glaeser (2002). They define concentration as the outcome of a life cycle process in which new plants are created, existing plants expand and contract, and ultimately plants are closed down. Decomposing the EG index into these four components, they account for the fact that the aggregate trends in geographical concentration change only slowly, whereas there is a high degree of employment turnover at the level of the individual plants. Knowledge on the precise channels through which localization

²³¹ Ellison/Glaeser (1999) find that at least half of the observed geographical concentration in the USA is due to natural advantages. For Germany, Roos (2005) attributes about one third of the agglomeration of economic activity to natural features.

patterns remain constant is important for various reasons. For example, the EG index might not change simply because the employment decrease due to plants closing down is substituted by employment needs of newly created plants. This provides evidence for a process of creative destruction within the industry with links to the theoretical approaches mentioned above.

3 EMPIRICAL STRATEGY

In this section, the data set used for the empirical analysis will be presented as well as information on the EG index.

3.1 The Ellison-Glaeser index

Several measures can be used to analyze the geographical concentration of industries (see Combes/Overman 2004 for a discussion). I resort to the agglomeration measure proposed by Ellison/Glaeser (1997, henceforth EG) that is widely used in empirical research on assessing geographical concentration. EG begin by constructing a measure of an industry's 'raw' geographical concentration defined as $G = \sum_{r=1}^N (s_r - x_r)^2$, where s_r is the share of the industry's employment in region r , and x_r is the share of total employment in that region. G is very similar to the Gini coefficient and measures concentration relative to total employment. It takes the value of one if an industry is located in a single regions and zero if it is distributed across regions according to each region's size.

The raw concentration index G does not yet control for the structure of the respective industry, because it cannot distinguish between internal and external economies of scale. If an industry in a region consisted of one large establishment instead of a number of smaller establishments, G would still indicate geographical concentration. EG take this into account by deriving their index from a model of location choice.²³² They assume that, in the absence of agglomeration forces, firms choose their location as if dartboards were thrown at a map and that there exists an allocation process that yields the observed employment distribution in expectation. Under these assumptions, $E(G) = (1 - \sum_{r=1}^R x_r^2)(\gamma + (1 - \gamma)H)$, where γ is a combined measure of the strength of natural advantages and spillovers between firms in a broad sense. H is the industry's Herfindahl index $H = \sum_{j=1}^B z_j^2$, with z_j denoting firm j 's share of the industry's employment. Solving for γ yields the EG index of geographical concentration:

$$\gamma \stackrel{\text{def}}{=} \frac{G - (1 - \sum_{r=1}^N x_r^2)H}{(1 - \sum_{r=1}^N x_r^2)(1 - H)}$$

γ is a sophisticated measure of the geographical concentration of an industry that explicitly takes into account its establishment size structure and the aggregate distribution of economic activity. Unlike other measures of geographical concentration, it also allows to test if the observed spatial concentration is significantly stronger than what would be expected by a purely random location choice where positive externalities due to locational advantages do not play a role. In the absence of agglomeration effects, γ would be equal to zero, and consequently, $E(G) = (1 - \sum_{r=1}^R x_r^2)H$. Assuming normality, EG propose that, in the case of significant concentration, G is at least two standard deviations larger than its expected value $E(G)$.²³³ This offers the unique possibility to test the significance of geographical concentration, which distinguishes the EG index from comparable measures.

There are several restrictions of the EG index that should be kept in mind. From a theoretical point of view, the EG index does not distinguish between concentration due to natural advantages and due to true spillovers. This must be taken into account when concentration patterns of different industries are compared. Moreover, it is difficult to interpret absolute index values. Even though Ellison/Glaeser (1997: 890) argue that their index is designed to facilitate comparisons between countries and different levels of aggregation, one should be careful when comparing countries with huge disparities in their economic structure. From a methodological point of view, it should be noted that the EG index neither controls for the relative position of geographical units in space nor for the size of an industry.

3.2 Data

The Establishment History Panel (EHP) of the Institute for Employment Research (IAB) is a comprehensive database that comprises information on the full universe of German establishments with at least one employee required to make social security contributions as of June 30 of a given year (see Gruhl/Schmucker/Seth 2012 for further details). From 1999 onwards, the EHP also contains plants with at least one marginal part-time employee not obliged to pay social security contributions. To obtain consistent time series data, they are excluded from the analysis. The EHP consists of worker-level information from the social security insurance system, aggregated to the establishment level via unique firm-specific identifiers. Due to its original use to calculate retirement pensions, this data is highly reliable. I refer to a time span of 12 years that covers the years from 1992 to 2010.

The industrial classification system in the EHP has undergone several revisions. The greatest change took place when the WZ 1973 (up to the 3-digit level) was replaced by the more disaggregated German versions of the NACE classifications (up to the 5-digit level) from 1999 onwards: NACE 1.0 (1999-2003), NACE 1.1 rev (2003-2008) and NACE 2.0 rev (since 2008). To obtain a consistent industry coding system over time, the NACE 1.0 classification is used as reference. Following the method of Eberle et al. (2011), correspondence tables are constructed between the different classifications and, subsequently, to each plant one unique industry code of the NACE 1.0 is assigned that covers the entire time period. I disregard the primary sector, since agriculture and fishing are made up largely by self-employed persons who are not

²³² Maurel/Sédillot (1999) develop an alternative index of geographical concentration that also takes account of the firm size structure.

²³³ The variance of G can be obtained as $\sigma_G^2 = 2H^2[\sum_{r=1}^N x_r^2 - 2\sum_{r=1}^N x_r^3 + (\sum_{r=1}^N x_r^2)^2] - 2\sum_{j=1}^B z_j^4[\sum_{r=1}^N x_r^2 - 4\sum_{r=1}^N x_r^3 + 3(\sum_{r=1}^N x_r^2)^2]$.

covered by the EHP, and since mining plants are clearly primarily subject to first-nature forces. I also disregard the public sector, as location decisions are only remotely subject to market-based forces and agglomeration economies. In addition, the 3-digit industries ‘Processing of nuclear fuel’ (class 233), ‘Space transport’ (class 623), and ‘Other computer-related activities’ (class 726) are excluded, because they consist for most of the years of only one firm. The final sectoral setting consists of a total of 187 3-digit industries.

Table 1: Descriptive statistics by sectors, 1992 and 2010

Number of...	Total	Manufacturing	Services
1992			
industries	187	102	76
employees	5.898.899	1.169.703	2.033.742
plants	359.910	45.440	200.322
employees per plant	16.4	25.7	10.2
2010			
industries	187	102	76
employees	4.432.015	803.047	2.013.218
plants	521.360	40.103	313.063
employees per plant	8.5	20.0	6.4
Δ employees	-24.9	-31.3	-1.0
Δ plants	44.0	-11.7	56.3

Source: Establishment History Panel; own calculations.

The final data set contains information on half a million firms and up to 5.8 million full-time equivalent employees per year in East Germany (see table 1). In 2010, the service (manufacturing) sector accounted for 45.4 (18.1) % of total employment. Its prevalence is the result of a dynamic employment growth and to a simultaneous decline in manufacturing. The average number of employees per firm in manufacturing clearly exceeds the mean firm size in services.

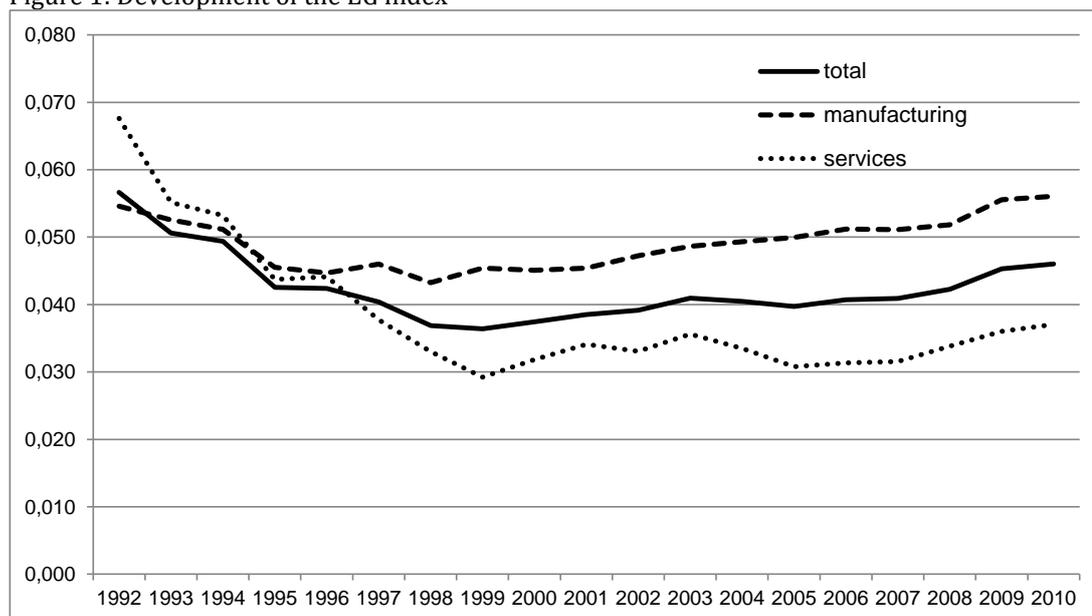

4 RESULTS

4.1 Overall development

The size of the EG index yields information on the degree of an industry's concentration and allows a comparison of different industries. For East Germany, the average EG index amounts to 0.057. This points towards a much higher degree of geographical concentration than in West Germany, where the comparable EG index took on a value of 0.016 in 1990 (Dauth/Fuchs/Otto 2016). Over time, its value decreased to 0.036 in 1999 and since then increased again (see figure 1). In 2010, it amounted to 0.046.

There are distinct differences between the three sectors under consideration. As can be seen in figure 1, the EG index fell until 1999 and since then roughly remained around a value of 0.05. The EG index in manufacturing is higher than in services. In both sectors, the large decrease in geographic concentration becomes evident until 1999, implying that the profound structural changes in the course of transformation also influenced the spatial distribution of economic activities.

Figure 1: Development of the EG index

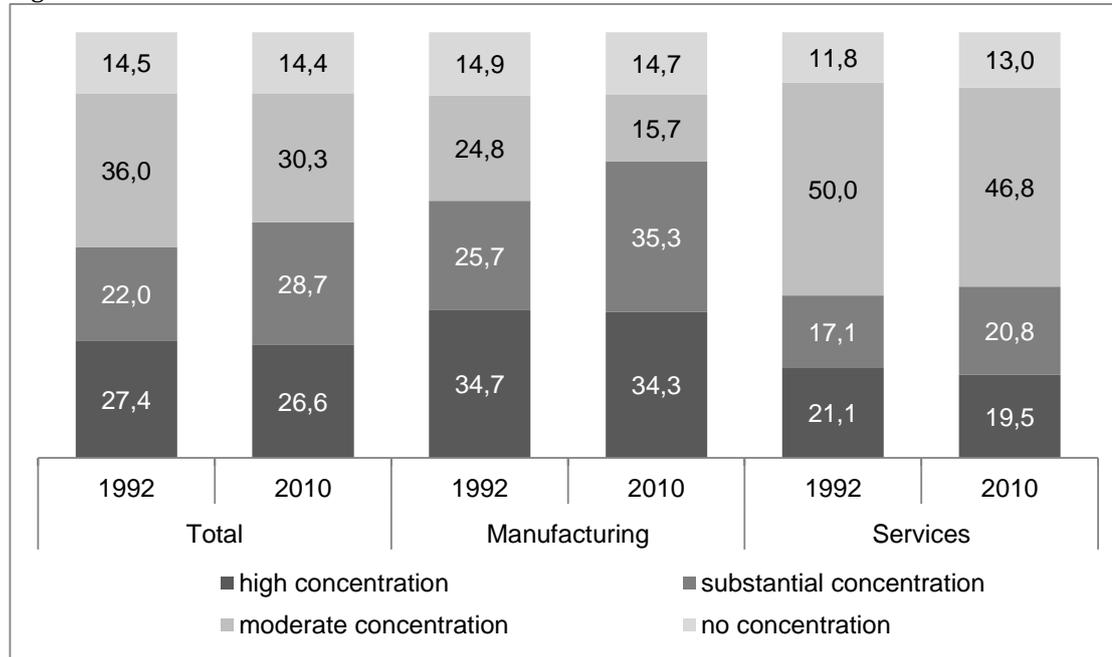

Source: Establishment History Panel; own calculations.

Alterations in the spatial patterns of economic activities become even more visible when comparing the respective fractions of concentrated and non-concentrated industries. Following Ellison/Glaeser (1997), I categorize industries as

highly concentrated if the EG index is higher than 0.05, and as substantially concentrated if it is between a range of 0.05 and 0.02. If the EG-Index is equal or lower than 0.02, there is only moderate concentration, and for values smaller than 0, the industry is not concentrated. Figure 2 depicts the resulting distributions. According to this classification, about half of all industries were not or only moderately concentrated in 1992. This share declined until 2010, with the share of substantially concentrated 3-digit industries increasing. In services, the proportion of the moderately concentrated industries is highest.

4.2 Agglomeration patterns in individual industries

In this section, the agglomeration of individual industries is explored. Table 3 lists those 3-digit industries that were most strongly concentrated in 2010. As evidenced for other countries, agglomeration patterns vary widely between the single industries. The highest degree of geographical concentration can be ascertained for the manufacture of watches and clocks. In 2010, the EG index reached a value of 0.753. Since 1992, it had increased considerably. It is followed by sea and coastal water transport that is traditionally found on selected maritime sites.

Table 2: The 20 most concentrated industries, 1992 and 2010

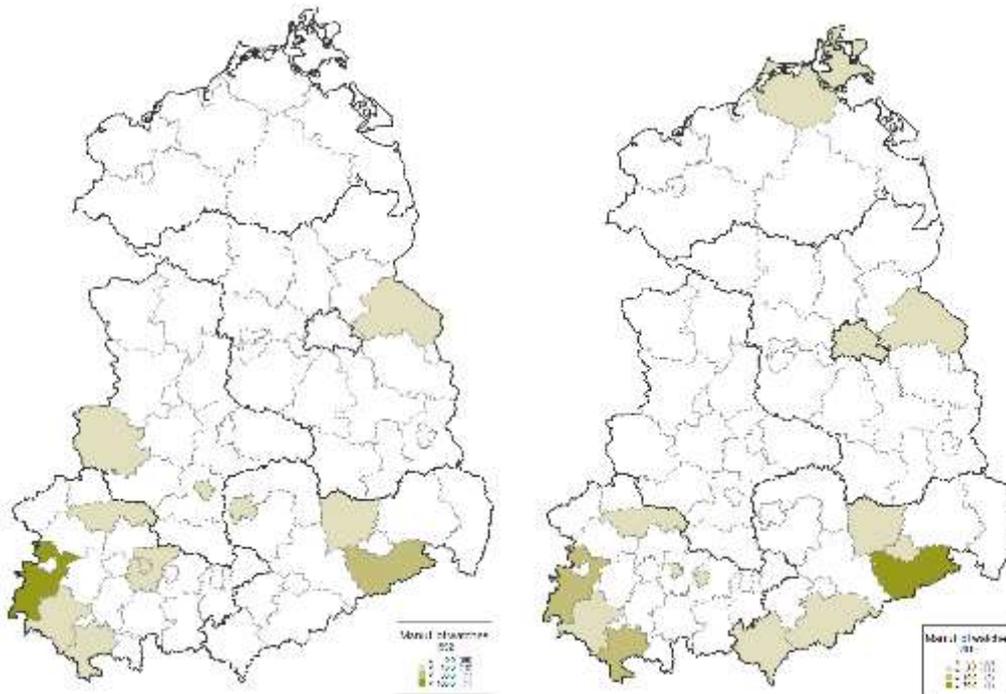

3-digit industry	2010				1992		
	sector	rank	EG	employment	rank	EG	employment
335 Manufacture of watches and clocks	m	1	0.753	1,011	5	0.331	2,305
611 Sea and coastal water transport	s	2	0.716	2,359	3	0.791	7,294
363 Manufacture of musical instruments	m	3	0.287	1,731	29	0.109	2,155
176 Manufacture of knitted and crocheted fabrics	m	4	0.239	1,511	23	0.125	8,433
177 Manufacture of knitted and crocheted articles	m	5	0.234	464	53	0.049	613
724 Database activities	s	6	0.199	1,035	1	1.075	25
622 Non-scheduled air transport	s	7	0.197	323	2	0.809	165
365 Manufacture of games and toys	m	8	0.197	1,954	19	0.155	4,212
921 Motion picture and video activities	s	9	0.188	11,676	27	0.111	7,061
296 Manufacture of weapons and ammunition	m	10	0.168	314	12	0.226	1,720
174 Manufacture of made-up textile articles	m	11	0.143	2,828	13	0.199	3,032
193 Manufacture of footwear	m	12	0.126	1,732	50	0.052	5,308
172 Textile weaving	m	13	0.124	1,946	42	0.076	6,992
181 Manufacture of leather clothes	m	14	0.115	170	14	0.192	313
924 News agency activities	s	15	0.102	3,305	4	0.400	1,379
175 Manufacture of other textiles	m	16	0.099	4,715	17	0.155	9,917
232 Manufacture of refined petroleum products	m	17	0.096	3,135	28	0.110	8,394
152 Processing and preserving of fish and fish products	m	18	0.095	1,601	68	0.033	2,311
732 R&D on social sciences and humanities	s	19	0.095	2,820	34	0.097	2,279
241 Manufacture of basic chemicals	m	20	0.950	15,219	6	0.299	37,235

m: manufacturing, s: services.

The strong concentration of the manufacturing of watches and clocks is visualized in figure 3. It contains the location coefficient based on the number of employees across the East German districts in the years 1992 and 2010. It becomes evident that production is mainly concentrated in two regions, namely the *Wartburgkreis* in Thuringia and the *Erzgebirgskreis* in Saxony. Manufacturing of watches in the city of *Glashütte* in Saxony has a long tradition (see Neiberger 2014).

Source: Establishment History Panel; own calculations.

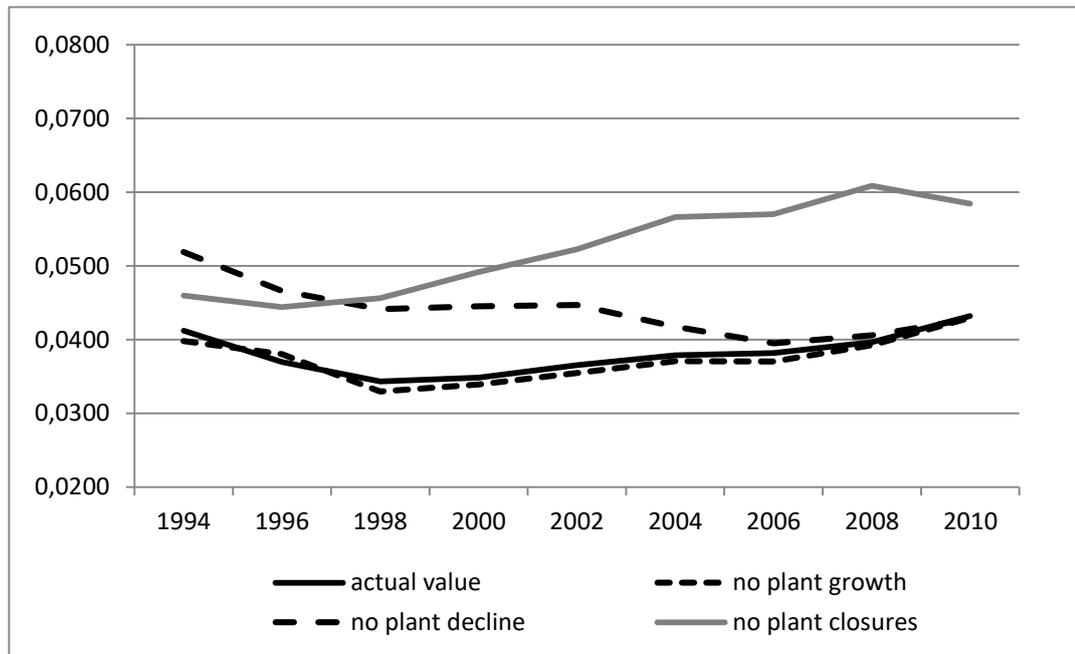

4.3 What drives the changes in concentration?

Which forces have driven the large changes in concentration in East Germany? To shed light on the underlying mechanisms, I decompose the aggregate concentration changes into the four factors constituting the life cycle of plants as applied by Dumais/Ellison/Glaeser (2002). They encompass the entire 'life' of a firm from its creation on to the subsequent stages of (employment) growth until (employment) decline and firm closure.

Intuitively, the formation of a new plant could contribute to concentration or dispersion depending on where it is established. If a new firm is opened in a region where others are already located, the industry's concentration increases and vice versa. Analogously, a plant closure has the opposing effect on the industry's overall concentration.

To implement the plant life cycle concept into our analysis, four counterfactual plant distributions for manufacturing and for services, respectively, are constructed. Each counterfactual mirrors the geographical distribution of an industry if the respective factor would not have been drawn upon by the firms. Figure \{fig5\} displays how the EG index would have developed if there were no plant creation, plant growth, plant decline, plant closure, respectively, between 1992 and 2010. Figure 4 contains first preliminary results. They provide tentative evidence that, obviously, plant closures contributed profoundly to the decrease of geographic concentration especially since 1996, whereas in the first years under observation it was rather the declining plants that exerted an influence on changes in the geographical setting of economic activities. Plant growth virtually played no role. These first results hint towards grave impacts of structural change in the course of transformation on the spatial distribution of economic activities.

Figure 4: Counterfactual EG indices in the absence of plant growth, decline and closure

5 CONCLUSIONS

This paper has investigated the geographical concentration of economic activities in East Germany, using the index developed by Ellison/Glaeser (1997). We have assessed the changes between 1992 and 2010 in all economic sectors and in manufacturing, services, and the knowledge-intensive sector separately. We have also shed light on which mechanisms drive the long-run changes in geographical concentration. The results yield, as we believe, first-time information on the development of agglomeration for several sectors simultaneously over such a long time span of 30 years, thereby expanding the existing empirical literature on location patterns and their dynamics over time.

Evidently, the profound process of restructuring the East German economy brought along massive changes in the industrial location patterns. First tentative results show that plant contractions and closures worked together in reducing the degree of concentration until the late 1990s. Since then, the results provide evidence that agglomerative forces might have (re-)developed to some extent, which might also foster the emergence of successful economic clusters.

1125 GEOGRAPHY OF CREATIVE FIRMS IN ISTANBUL

ABSTRACT

Creative economy has become a key feature of the landscape of urban politics. Recent studies have stressed the importance of creativity for the economic development and competitiveness of cities. Therefore, if cities want to increase their competitiveness they need to attract firms and employees who belong to the creative economy. In this paper, creative firms in Istanbul are analyzed by examining their location in accordance with the characteristics of firms. The analysis of firm location has been attracting a growing interest from scholars in recent years. The main objective is to analyze creative activities regarding to creative firms for understanding trends of geography. It aims to contribute to the creative economy debate by discussing the relationships between the creative firms and the space in the city. Based on questionnaire surveys conducted in 2016, the results offer an insight into the preferences of the geography of creative industries. Determinants of the firm location accordingly creative clusters, are different depending on the characteristics of the firm. It is aimed to provide some empirical basis for the urban development policies of creative based urban spaces. Keywords: Creative economy, creative firms, creative industries, creative cities, Istanbul

1238 SPACES OF CIRCULAR ECONOMY: FROM GLOBAL VALUE CHAINS TO CLOSING THE LOOP AND CLOSE PROXIMITY

ABSTRACT

Circular Economy represents a promising approach to a sustainable transition from the linear socioeconomic paradigm. As such, it entails the necessity to address some specific challenges. In particular, the objective of the Circular Economy is to maintain and to share value along the time, rather than adding value. Systemic change may be addressed from different perspectives, usually top-down and bottom-up approaches are distinguished. The important aspect that emerges from the literature overview is that the shift towards Circular Economy requires taking into account systemic thinking, especially to note the importance of synergies, cooperation and rebound effects. The apparently positive effects need to be contrasted with rebound effects such as increased consumption of the same or new products, the transference of impacts from one stage of the supply chain to another one, and the green consumerism linked to planned obsolescence. In order to pave the way to Circular Economy business models are considered a key instrument. The business model is seen as a holistic approach towards the way of doing business. Overall it is defined as the way of creating, producing and delivering value. From the spatial perspective, a business model needs to add ecological and social value to the value proposal and changing the producer and the consumer practices. The spatial set-up of business model is key to evaluate the ecological (material and energy) and social impacts of the logistic-transport activities along the Global Value Chain, the distribution and consumption patterns and the management of post-consumption activities devoted to re-using, repairing, remanufacturing and recycling products and components. Circular Economy business models should be focused on activities that follow the hierarchy reuse, repair, remanufacture and recycle, consider the geographical dimension and trying to increase value preservation as much as possible. The objectives of closing the loop are clearly linked to the spatial proximity (clustering) of activities and also the proximity of production-consumption and the subsequent activities. The present globalisation patterns poses a clear concern for the widespread diffusion of Circular Economy Business Models. For business models to work and to foster real shift towards Circular Economy, important changes are need both at international and national level.

1760 FACTORS AFFECTING THE SPATIAL DISTRIBUTION OF HOSPITALS: THE CASE OF ISTANBUL

Muhammed Ziya Paköz¹, Numan Kiliç²

1 Assoc. Prof. Department of Architecture, Abdullah Gul University, Kayseri/Turkey. E-mail: mzpaköz@gmail.com

2 Research Assistant, Department of City and Regional Planning, Istanbul Technical University, Beyoğlu, 34367, Istanbul, Turkey. E-mail: kilincnum@itu.edu.tr

ABSTRACT

Healthy is indispensable for human and states must supply healthy services to everybody. Turkish healthy system is insufficient in comparison to developed countries. Public and private sector work together in healthy services. Public sector aims to efficient and accessibility, so these factors affect public hospitals' location decision. On the other hand private sector aims to maximize profit and it prefers high income residential areas.

Location decisions, which may be made by individuals, companies and public institutions, play an essential role in how the urban form is shaped. While the location decisions made by the private sector prioritize profit maximization, the maximization of social benefit is aimed when selecting the locations of public facilities. On the other hand, due to the constraints on budget and the necessity to avoid the waste of resources, the spatial distribution of public facilities and how 'equity/efficiency' will be achieved remain on the agenda.

Accessibility is the most important for healthy services, so most of hospitals located in high accessible areas, highways, main roads, subways. Private hospitals prefer being near public hospitals. Most of them are Fatih and Şişli area which have large public hospitals.

During the last 35 years, Istanbul's population has increased unexpected values, and governments was not efficient for supplying public services. In 1980s public hospitals' locations were not efficient and equal. For instance, Sultanbeyli, Pendik, Avclar were residential areas, but there were any public and private hospitals, people had to go far away, when they were ill. On the other hand first private hospitals were racial minority hospitals. Between 1980 and 1990 private hospitals number increased by effects of globalization. In 1990s, neoliberal economic policies affected private sectors, 72 private hospitals were opened between 1990 and 2000. Private hospitals located in high income districts such as Kadıköy, Şişli, Bakırköy. In these years public hospitals began to spread out to peripheries. In the beginning of 2000s, Adapazarı earthquake and economic crisis affect private sectors, the ratio increasing of private hospitals number began to fall. Transformation in Health Program (government decision, 2003) is important for private hospitals. These decisions encouraged public sectors and private hospitals began to trigger again after 2006. Today's, total public hospitals' bed number and total private hospitals' bed number are very closest. Private hospitals are opened not only high income residential areas but also middle income districts no longer.

1 INTRODUCTION

Health is the most important element of our life. In every breath and step we take, health is our constant element in the whole life. Health is a birth-right and this right is emphasized by WHO with the "health for everyone" motto in 2000. There is a need for effective health treatment and efficient patient examination processes to realize WHO's health policies.

The purpose of this paper is to determine distribution of public and private hospitals in Istanbul, between 1980 and 2014. Especially to analyse private hospitals' location decisions. The scope is; researching the existing spatial distribution of the hospitals in Istanbul.

Limitations, firstly, instead of the entire health system, the research only addresses healthcare services. Secondly, it only focuses on hospitals instead of all of the healthcare facilities in Istanbul. Finally, the evaluations and proposals expressed in the research were developed on a district basis.

In my case study, I used Esri Maps and GIS to show how is the public and private hospitals' locations.

The questions that I want to prove are;

- 'How is the distribution of public and private hospitals in Istanbul?'
- 'Is there any relation between location public hospitals and private hospitals?'
- 'Is there any increase number of private hospitals after 2003 government decision?'

2 METHODOLOGY

In order to achieve the study and find out the answers of the question, I assessed addresses establish years of public and private hospitals. I used ESRI Maps and GIS programme to indicate the distribution of hospitals location in Istanbul.

Legal/administrative framework and health policies in Turkey and the distribution of healthcare services and Istanbul's position within this distribution. The characteristics of and the relation between the distribution of healthcare supply (hospitals) and demand for healthcare services (population) in Istanbul. Statistical data reveals that healthcare services in Istanbul are accumulated in districts which have higher accessibility and/or higher income.

Such a distribution causes certain areas in the city to be deprived of using the healthcare services supplied. The deprivation is more significant in areas which developed recently.

3 HOSPITAL LOCATION

Location decisions, which may be made by individuals, companies and public institutions, play an essential role in how the urban form is shaped. While the location decisions made by the private sector prioritize profit maximization, the maximization of social benefit is aimed when selecting the locations of public facilities. On the other hand, due to the constraints on budget and the necessity to avoid the waste of resources, the spatial distribution of public facilities and how 'equity/efficiency' will be achieved remain on the agenda.

The behavioral evolution of location decision-making and the diversification of the factors which influence the location decisions should be tackled in parallel to the transformation of settlements. Globalization and technological advances are the dynamics behind this transformation. In recent years, location processes are influenced by not only economic concerns but also social, spatial and cultural factors. The role and importance of planning during this process still constitute a primary topic of debate.

'Health geography' is among the major areas on which the location theory is focused. Access to healthcare services and achieving a healthy environment are still current topics and keep on drawing further attention. The location theory is based on the understanding that increased distance leads to decreased human interaction. As healthcare services are space/time dependent, it becomes more important that healthcare facilities are located in order to optimize the distance between healthcare demand and supply. In addition, it is necessary to consider the needs and preferences of the patients.

Although administrative bodies take regulatory precautions in order to steer the facility location decisions for healthcare services in Turkey and Istanbul, increased number of healthcare facilities owned by private entities and non-profit organizations (such as foundations, associations, NGOs) impair accessibility, and consequently, the spatial distribution presents an increasingly uneven structure. In spatial orders which achieve a higher quality of life, it is important to locate healthcare facilities so that they are easily accessible by all segments of society while they also function efficiently.

4 CURRENT HEALTHY SITUATION OF TURKEY

Our country with a 75.627 million population is one of the twenty most crowded countries in the world. There exists a young population as a result of high fertility and growing rates in the past. 30% population is below the age of 15 and 11% of the population is below the age of 5. More than 28.7 million (38%) women are in the fertile period (15-49 years) (TUIK, 2012).

However, a decreasing trend observed in these rates. Total fertility number was 5 children per woman at the beginning of 1970s and less than 3 in 1990s (Transformation in healthy report, 2003).

As of December 2013 a total of 129 383 doctors in Turkey is actively working. 74.562 doctors work in Ministry of Health, 28.283 doctors work in university hospitals, and the others (26.538) work in private hospitals. (Health education and health status report of manpower in turkey, 2013).

171 doctors per 100.000 fall in Turkey. This ratio is 346 doctors per 100.000 EU and 334 doctors are the average of WHO European district. 15.870 doctors (6.272 public hospitals,

7.315 private hospitals, 2.283 university hospitals) work in Istanbul and total population of İstanbul is 13.854.740 people (TUIK, 2012), and 873 doctors per 100,000 fall in Istanbul. (Health education and health status report of manpower in turkey, 2013).

4.1.Spatial Distribution of Beds in Health Institutions in Turkey

As of the year 2012, According to TUIK data, there are 1.483 hospitals in Turkey, 832 of them are Ministry of Health, 45 are connected other public services, 65 are university and 541 of them are private hospitals.(TUIK,2012)

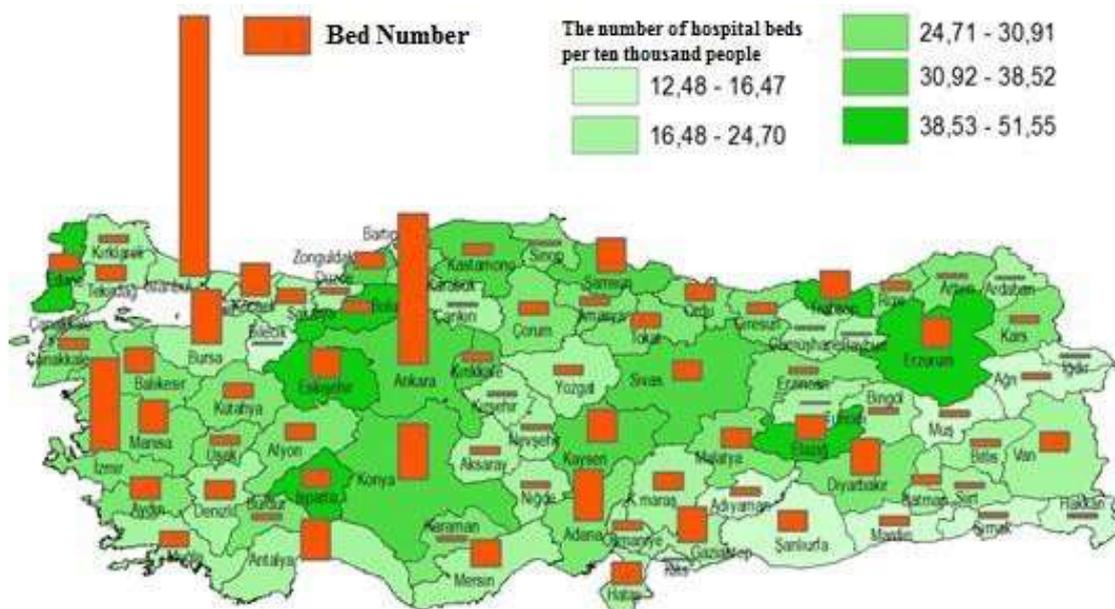

Figure 4.1: Distribution of hospital beds across Turkey

Total number of beds per ten thousand persons in a total of 34 provinces in Turkey Turkey, are higher average, which is on average 26.45.

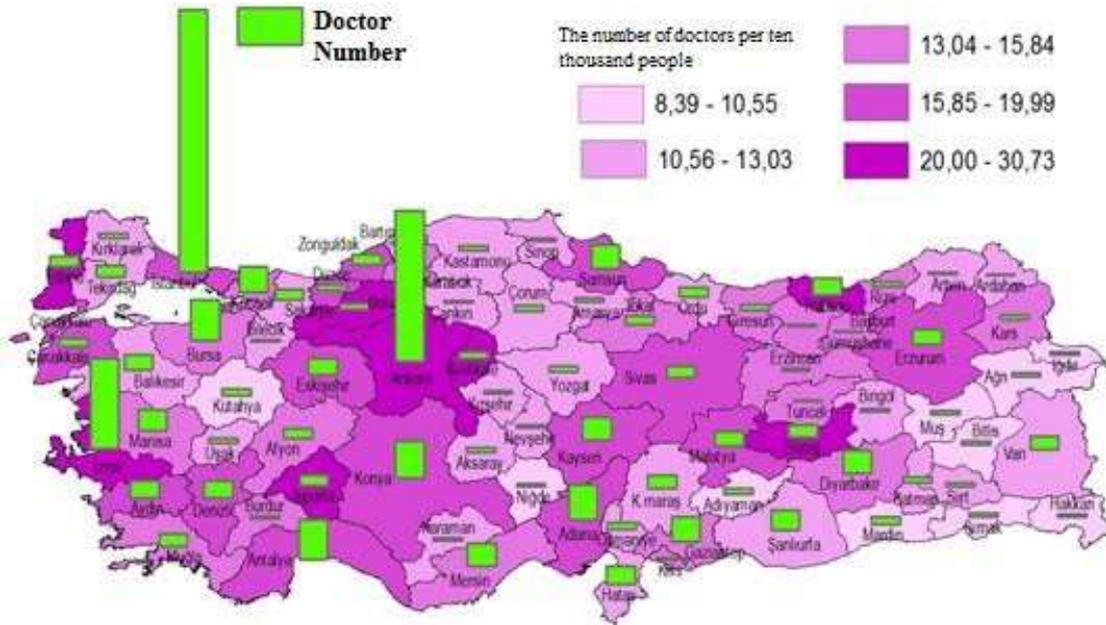

Figure 4.2: Distribution of doctor number across Turkey

The functioning of the private sector is based on the activity. Therefore, private hospitals want to make the choice in such a way to maximize profits. Multiple placements at the hospital opened the site selection behavior of private health institutions in Turkey, regional and urban scale, guiding with a hospital site selection model. This settlement is connected to the central hospital of the health care provider are shown in Table 4.1.

Table 4.1: Distribution of some private healthy group hospitals and branches in Turkey and Istanbul

Source: It has been compiled from hospitals' official website. (Access date: 26.12.2014)

As seen in the table, the first site selection choice of almost every health group is in Istanbul. Respectively in Istanbul, major cities follow İstanbul such as, Ankara, Antalya, Adana, Bursa, Izmir, İstanbul, İzmir, Konya, Kayseri, İzmir, Eskişehir, Diyarbakır. It is observed that, public hospitals chose regional district such as Erzurum, Elazığ, Van, Malatya and touristic district such as Tarsus, Bodrum, Kuşadası.

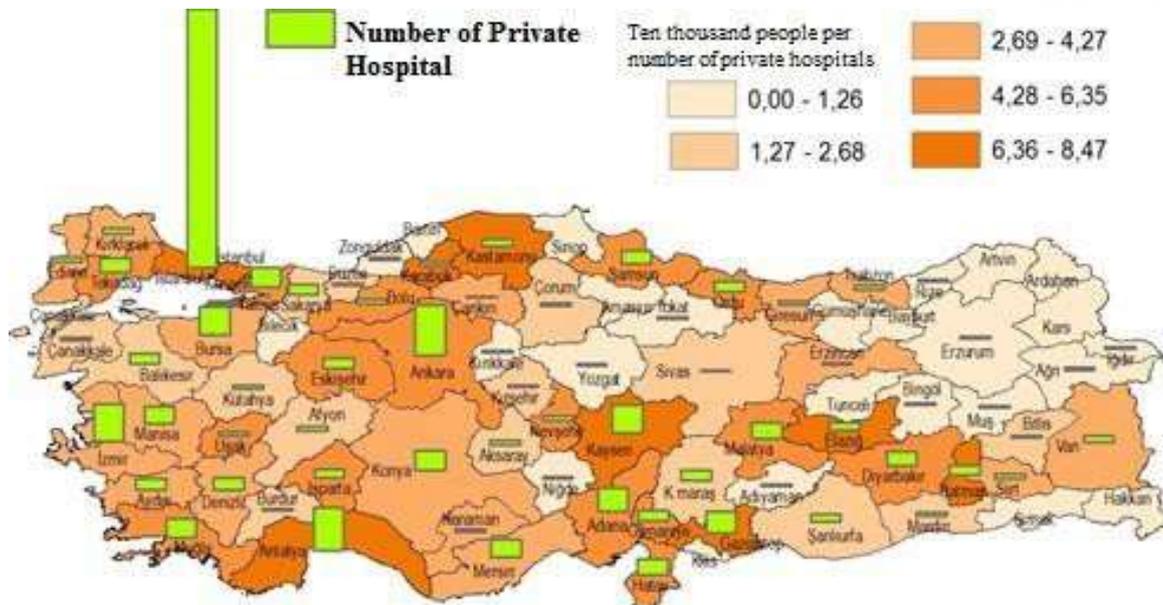

Figure 4.3: Distribution of Private Hospitals across Turkey (2012)

However, not all of the private hospitals are in the same capacity and capabilities. Therefore, the number of private hospital beds in the province and the total number of beds in the ratio of this number is important. The provinces that have the highest number of private hospitals' bed respectively Batman (0.42), Istanbul (0.36), Antalya (0.34) are the provinces.

5 CASE STUDY AREA: ISTANBUL

5.1 General Information

Istanbul is the most developed city in the Turkey. Most of government and private investments locate in Istanbul because of its attractiveness. Major health investment is to place in Istanbul, as well.

Istanbul is Turkey's most populous and dynamic city. In the city, both of the public and private sectors, from the local level up to the international level, take place every hospital and city's multicultural and complex character which represent all Turkey, makes important that understanding spatial distribution of health services and hospital locations.

15.870 doctors (6.272 public hospitals, 7.315 private hospitals, 2.283 university hospitals) work in Istanbul and total population of İstanbul is 13.854.740 people (TUIK, 2012), and 873 doctors per 100,000 fall in Istanbul. (Health education and health status report of manpower in turkey, 2013).

5.2 Hospitals in the historical process (between 1980-2014)

In this paper situations of public and private hospitals, between 1980 and 2014, were explored.

5.2.1 Hospitals' Location at 1980

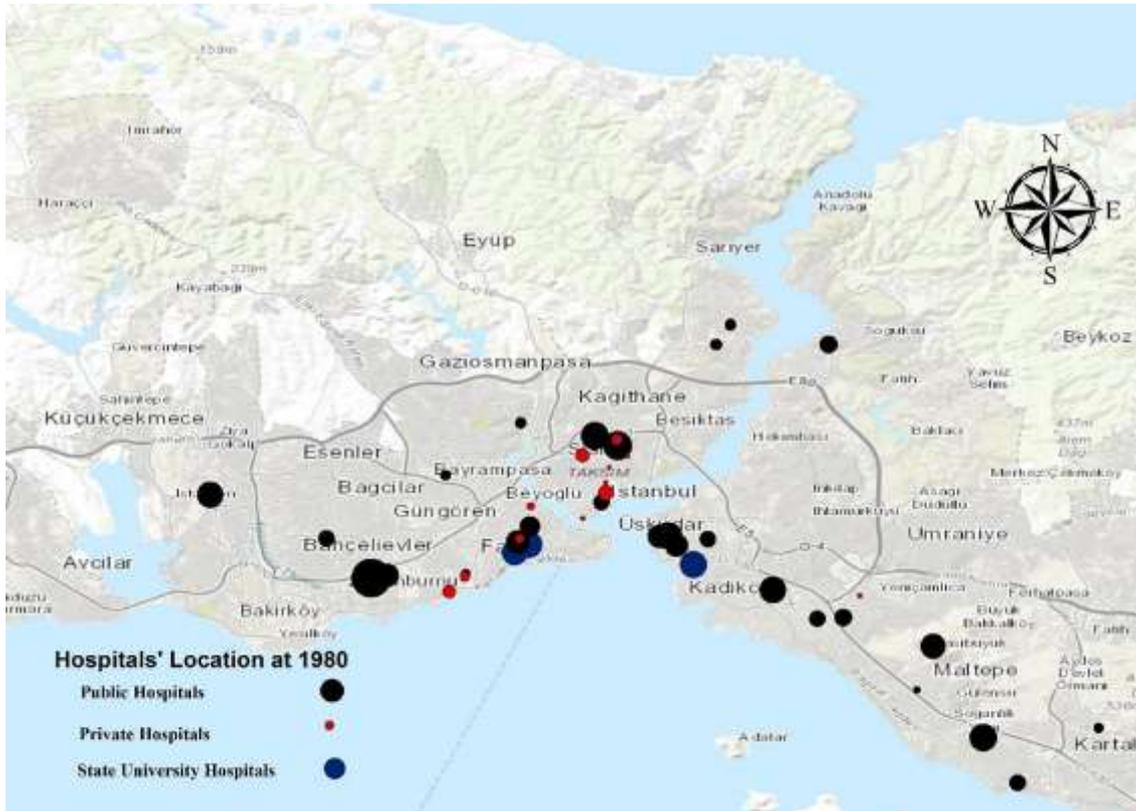

Figure 5.1: Distribution of public and private hospitals in Istanbul in 1980

In 1980, total population of Istanbul was 2.772.708 (Seçilmiş göstergelerle İstanbul, 2012). There was 29 public hospitals and public hospitals' bed number is 11.809. 3 university hospitals (İstanbul Fakültesi Hastanesi, İstanbul Cerrahpaşa Tıp Fakültesi Hastanesi and Marmara Üniversitesi Tıp Fakültesi Hastanesi) were located in Istanbul. On the other hand 12 private hospitals were in İstanbul. Private İstanbul Balıklı Rum Hospital is the first private hospital in Istanbul. It opened in Zeytinburnu district in 1753. The first private hospitals in Istanbul were racial minorities hospitals like Private Austria You Jorj Hospital, Private German Hospital, Private Surp Agop Hospital, ext.

Most of public hospitals were in high population district especially European Part. After construction of highway hospitals spread out periphery. Private hospitals preferred parts of Istanbul, which mostly racial minorities lived.

5.2.2 Hospitals' Location at 1985

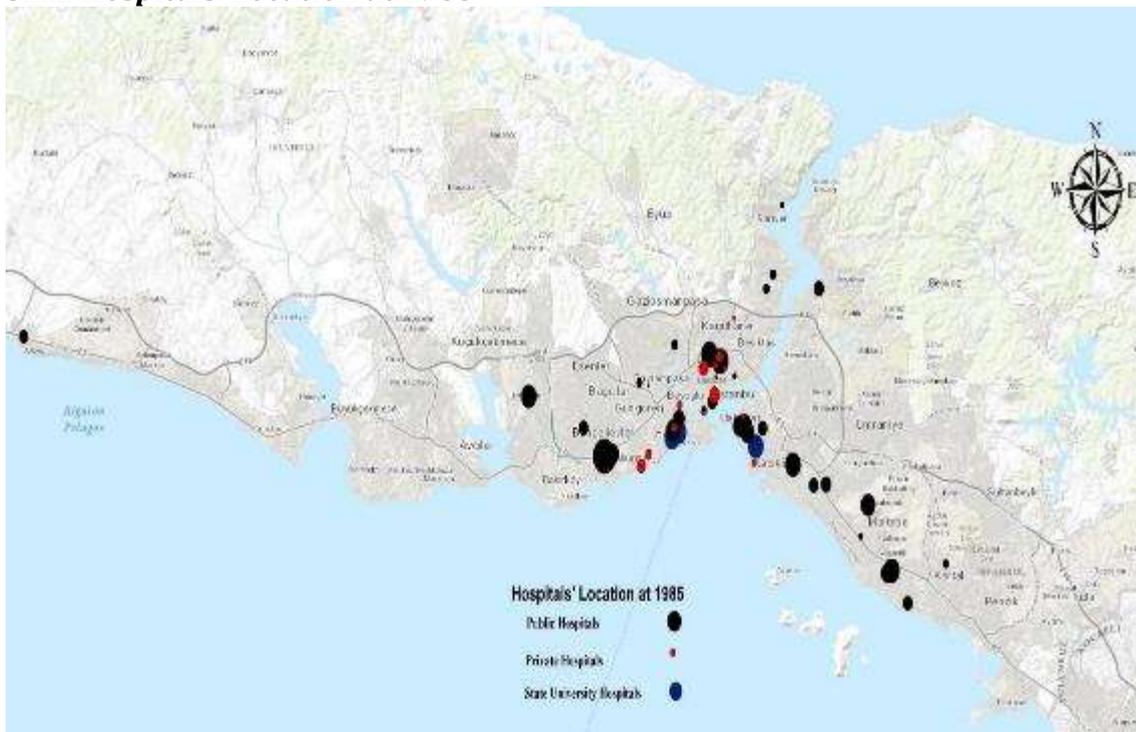

Figure 5.2: Distribution of public and private hospitals in Istanbul in 1985

In 1985, the population of Istanbul increased double, it was 5.475.982 (Seçilmiş göstergelerle İstanbul, 2012) there were 35 public hospitals versus 18 private hospitals. 6 private hospitals were opened in a 5 years. Increase in population

triggered both public hospitals and private hospitals. The other important effect of increasing hospital number was 1. And 2. Bridges and connection roads.

Private hospitals were not only racial minorities hospitals. Globalization affected most private investment and number of private hospitals increased in high income districts like Kadıköy, Şişli.

5.2.3 Hospitals' Location at 1990

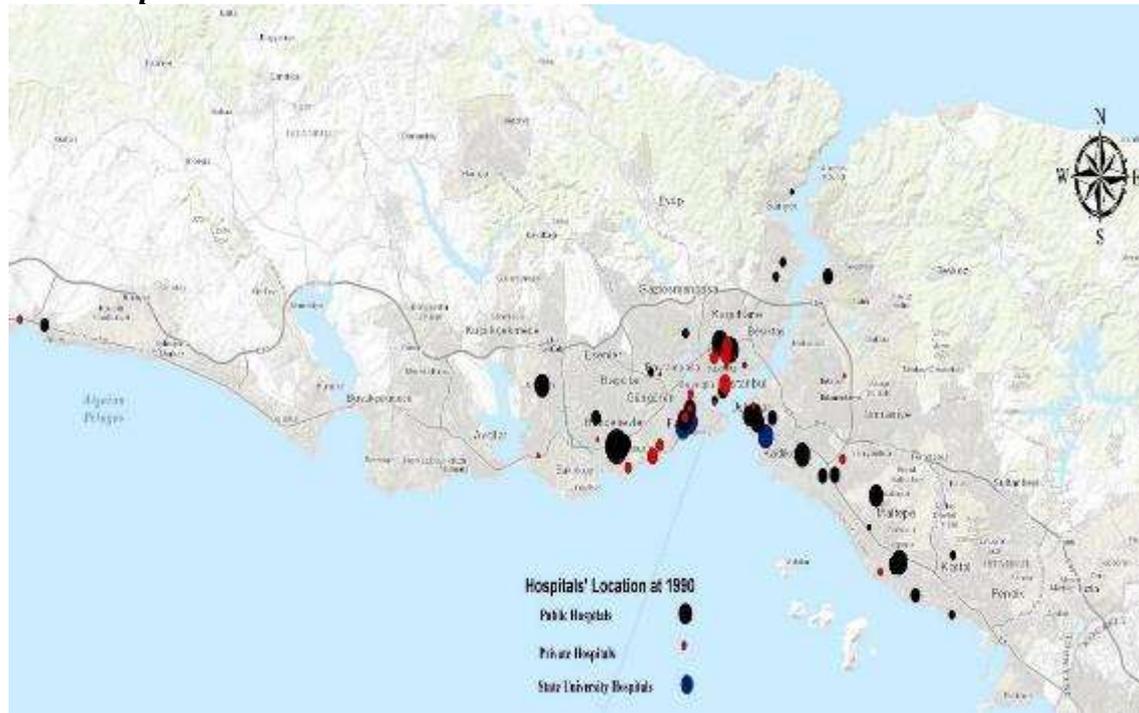

Figure 5.3: Distribution of public and private hospitals in Istanbul in 1990

In 1990, total population of Istanbul was 6.629.431 (Seçilmiş göstergelerle İstanbul, 2012). Increasing public hospital number was only 1. On the other hand this ratio was 8 in private hospitals. Total private hospitals number was 26. Private hospitals began to spread out new residential areas like Bahçelievler, Kartal, Ümraniye, but most of them preferred old and high income locations Beyoğlu and Fatih districts.

5.2.4 Hospitals' Location at 1995

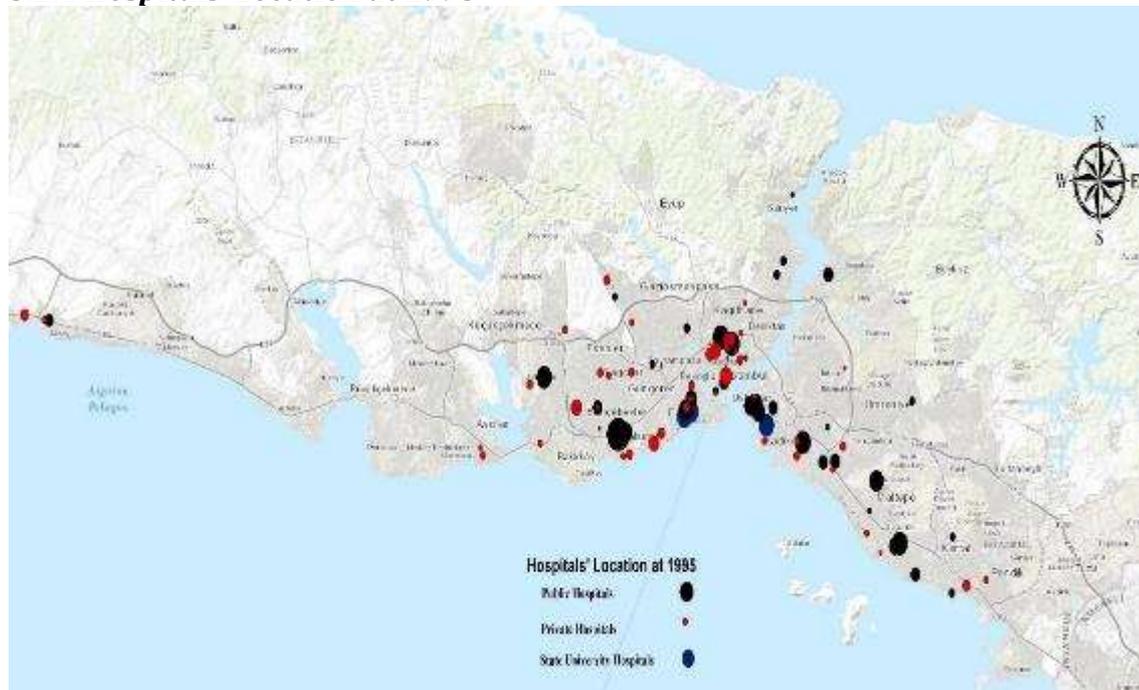

Figure 5.4: Distribution of public and private hospitals in Istanbul in 1995

In 1995, population of Istanbul was 9.260.438 people (Seçilmiş göstergelerle İstanbul, 2012). Public Hospitals number was 39, 4 new hospitals were opened in developing periphery areas, such as Çatalca, Sultanbeyli, Sultangazi. In 1990s Neoliberal Economies began to affect private sectors. Government has undertaken the task of establishing the legal framework only. Private sector began to make investment and to operate. In other words, private sectors gained strength.

In terms of hospitals, it verifies Neoliberal Economies, because number of private hospitals increased. 27 new private hospitals began to work between 1990 and 1995. Total Private hospitals number was 53 in 1995.

5.2.5 Hospitals' Location at 2000

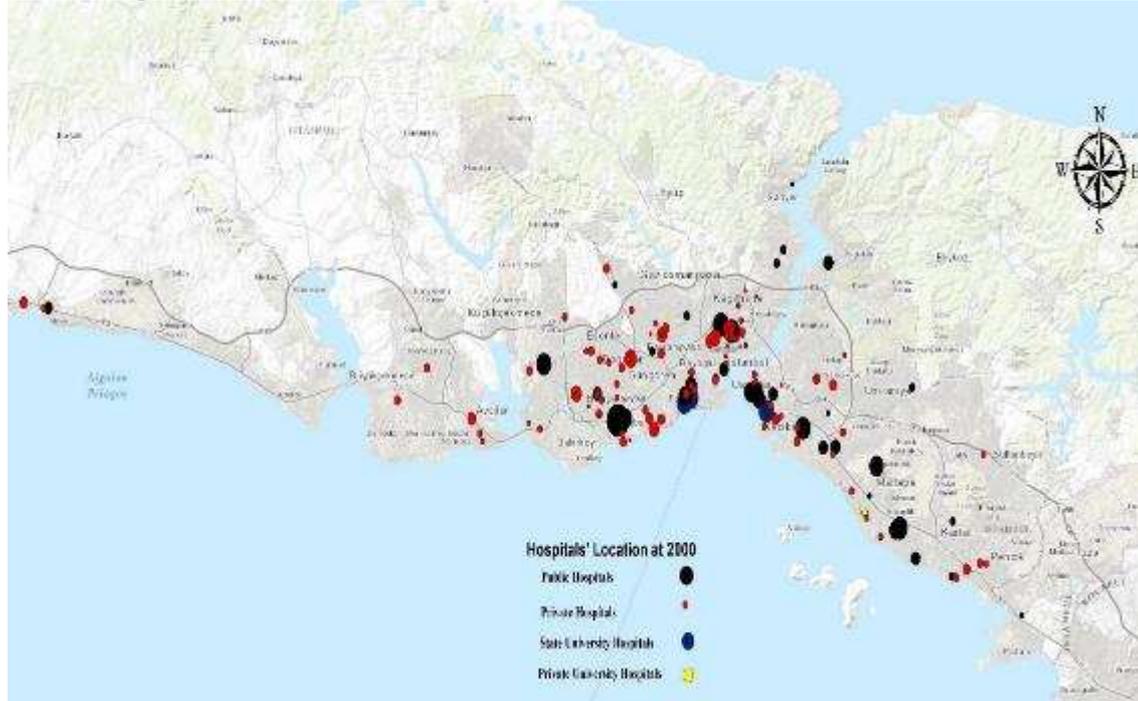

Figure 5.5: Distribution of public and private hospitals in Istanbul in 2000

In 2000, Istanbul's total population was 8.803.468 people (Seçilmiş göstergelerle İstanbul, 2012). Only Tuzla State Hospital was opened and total public hospital number was 40. It means that government began to be far from building new public hospitals. On the other hand total private hospitals number was 98. 45 private hospitals were done between 1995 and 2000. It is obvious that new economic situations encouraged private sectors. Private hospitals began to open middle income districts such as Bayrampaşa, Bahçelievler, Güngören. In addition first private university (Private Maltepe University Hospital) was established in 1997.

5.2.6 Hospitals' Location at 2005

Figure 5.6: Distribution of public and private hospitals in Istanbul in 2005

In 2005, the population of Istanbul was 9.260.438 people (Seçilmiş göstergelerle İstanbul, 2012). Total public hospitals number was 43 and total private hospitals number was 120. Increasing public hospitals number was normal, but increase ratio of private hospitals were law according to previous time periods. It might be because of 1999 earthquake and 2001 economic crisis. In 2002 a new one (Private Yeditepe University Hospital) private university hospital was opened. Most

of private hospitals which opened between 2000-2005 were located middle income residential areas such as Pendik, Kağthane, Esenler.

5.2.7 Hospitals' Location at 2010

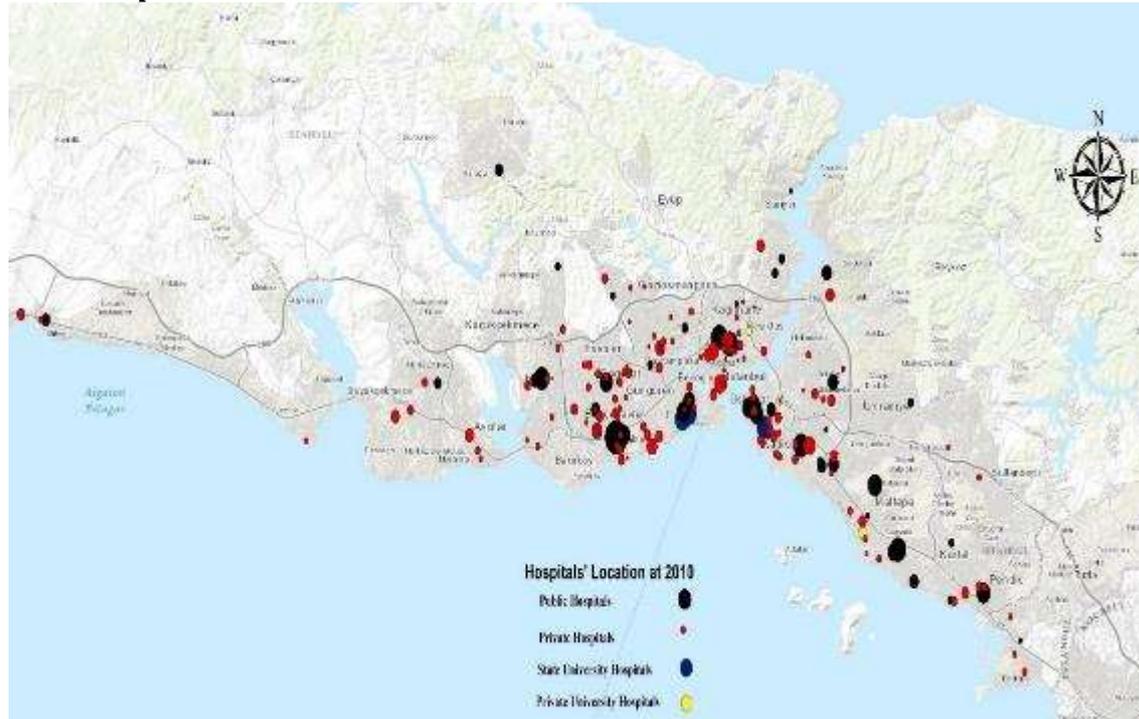

Figure 5.7: Distribution of public and private hospitals in Istanbul in 2010

In 2010, total population of Istanbul was 12.782.960 people (Seçilmiş göstergelerle İstanbul, 2012). There were 49 public hospitals versus 148 private hospitals. Private university hospitals number was 4. While government opening 6 new hospitals in the past 5 years period, private sectors opened 28 new private hospitals and 2 new private university hospitals were added existings. 2003 is an intersection year in terms of healthy sector, because of government's decisions (Transformation in Health). Briefly private healthy investments were encourage via this programme, it's effects began to be in sight after 2005 and will be continue to being seen.

5.2.8 Hospitals' Location at 2014

Figure 5.8: Distribution of public and private hospitals in Istanbul in 2010

Current population of Istanbul is 13.854.740 people (TUIK,2012). 52 public hospitals are exist in Istanbul. There are 164 private hospitals and 6 private university hospitals. Only 3 state university hospitals are located in Istanbul. In 2010 Marmara Satate University Hospital was hold on Health Minister and the same year, Bezm-i Alem Valide Sultan Hospital happened state university hospital. Namely number of state university hospitals are not changed. Current situation public

hospitals' bed number is 15.422, state university hospitals' bed number is 3.535 and private hospitals' bed number is 12.146, private university hospitals' bed number is 571. In other words public sector has 18.957 beds versus private sector has 12.717 beds. It is clear that government decision in 2003 has enhanced private hospital sector. Changes of the delivery of health services according to the year(2000-2014)

Between 2000 and 2014, total number of beds offering health care has increased approximately 18%. Current hospital bed number is 34.672. Number of beds in 4474 with the largest share of this increase is the private hospitals. Number of beds in private hospitals showed an increase of 62.3% over the same period. Increase the number of beds in public hospitals of 1536, while the increase in the number of university hospital bed is 373. The main reason for the increase in university hospitals as well, is a common private university hospital. In Table 5.2, the change in the number of hospitals and beds in Istanbul between the years 2000 to 2014 are shown.

Table 5.2: Changes in the number of hospitals and beds in Istanbul.

	Total		Ministry of Health		University		Private		Other Public Services	
	Hospital	Bed Number	Hospital	Bed Number	Hospital	Bed Number	Hospital	Bed Number	Hospital	Bed Number

2014	228	31.674	52	15.422	9	4.106	166	12.146	1	100

Source: It has been compiled from www.tuik.gov.tr (Access date: 26.12.2014) and Istanbul Provincial Health Directorate (Access date: 05.11.2014)

Şentürk and others (2011) tested by using regression analysis that there is a significant relationship between characteristics of the district (population, income and education level), and state and private hospitals, number of beds in Istanbul. Study area Istanbul was divided into 3 zones, first zone is core area (3 km. radius), 1.ring (3-10 km radius) and 2. Ring (other zones). Spatial distribution of public and private hospitals were explored in these zones. As a result of this analysis, education and income are related to private hospitals' bed number and, the most significant factors affecting it. On the other hand according to results there is no meaningful relationship between public hospitals' bed and population, income and education. Generally, distribution of public and private hospitals are not proportional to population especially university hospitals affect the distribution of hospitals' beds number was emphasized.

Dökmeci (2002), analysed location decisions private surgeries and population density and income by using regression. According to Dökmeci, proximity to major transportation routes economic polarization (high income zones) and existing hospitals affect location decisions of private surgeries which are clustered mostly Şişli and Kadıköy districts.

In 2014, when distribution of hospital location is analysed, it can be understood that distribution indicates unbalanced character. Hospitals center European part, Şişli, Fatih, Bahçelievler and Bakırköy, Asian part Kadıköy and Üsküdar. These districts have high accessibility values. There is no hospital in Adalar and Çekmeköy. Table 5.3. shows that bed number of public, private and university hospitals; Table 5.4. shows that distribution of hospitals to districts.

Table 5.3: According to the district in Istanbul, the private, public and university hospitals and bed capacity

N.P.H.B.PR.T.P.: The number of private hospital beds per thousand people N.P.H.B.P.T.P.: The number of public hospital beds per thousand people N.T.H.B.P.T.P.: The number of total hospital beds per thousand people

It has been compiled from Istanbul Provincial Health Directorate (Access date: 05.11.2014).

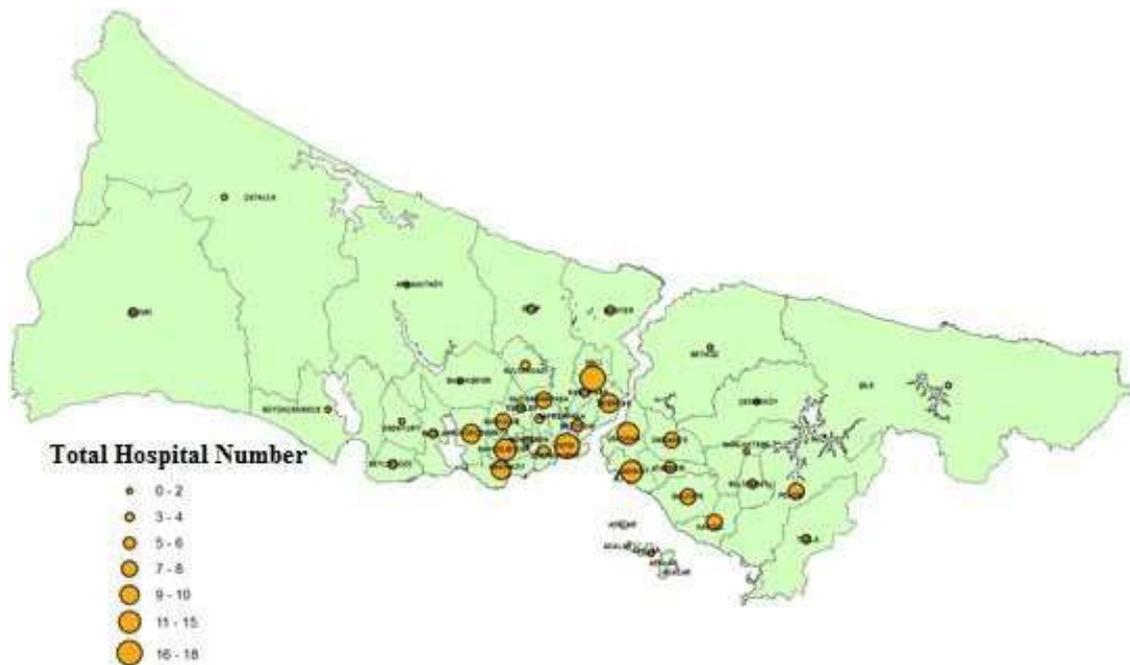

Figure 5.9: Distribution of hospitals in Istanbul(2014)

Distribution of hospitals' bed numbers are the same characters. European district, Şişli, Fatih, Bakırköy, Küçükçekmece, Bağcılar and Bahçelievler and Asian district Üsküdar, Kadıköy, Kartal and Pendik come forward. Locations of university and regional hospitals are decisive in distribution of hospitals. Figure 5.10 shows that distribution of bed number across counties.

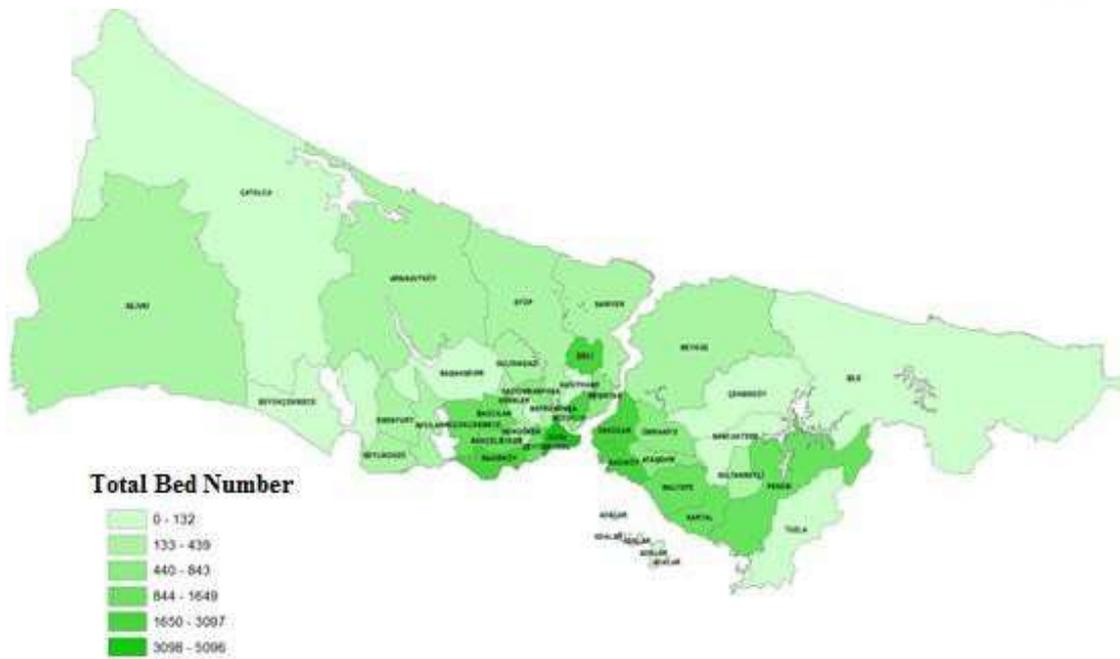

Figure 5.10: Distribution of bed number(2014)

To understand that, number of hospitals and bed numbers distribute proportional to counties or not, can be clear by analyzing number of hospital bed per ten thousand people. Fatih (118,83), Bakırköy (104,37) and Şişli (97,32) have highest hospital bed numbers, main cause is university hospitals and regional hospitals are located in these counties. Üsküdar, Kadıköy, Kartal, Zeytinburnu, Beyoğlu, Silivri and Beşiktaş, are the others counties which have high ratio up to Istanbul awarage. Distribution of hospitals bed numbers per ten thousand people is shown by Figure 5.11.

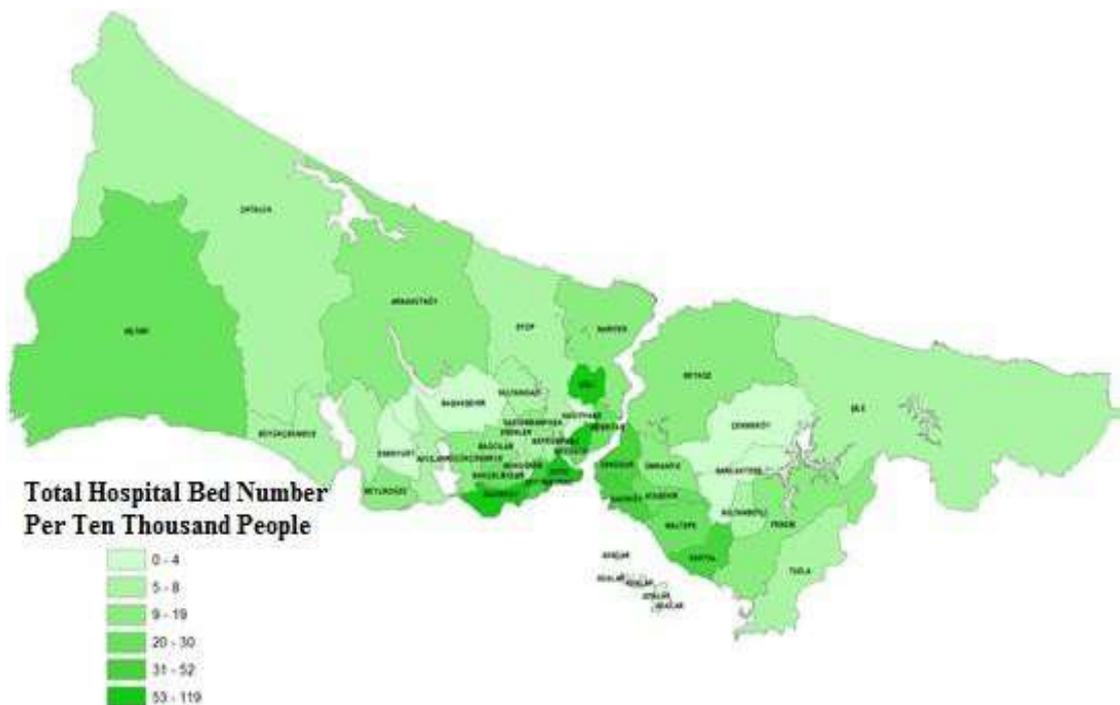

Figure 5.11: Distribution of hospitals bed number per ten thousand people

Spatial dispersions of private hospitals have more unbalanced character than public hospitals, because private hospitals' main purpose is effectiveness. Private hospitals are located in counties which have high accessibility and high income such as Şişli, Bahçelievler, Üsküdar, Kadıköy, Fatih, Beşiktaş and Bakırköy besides, they are located in high population density areas like Gaziosmanpaşa, Ümraniye and Pendik. There is no private hospital in Adalar, Çatalca, Çekmeköy, Başakşehir and Şile. Figure 5.12 indicates that distribution of private hospitals in Istanbul.

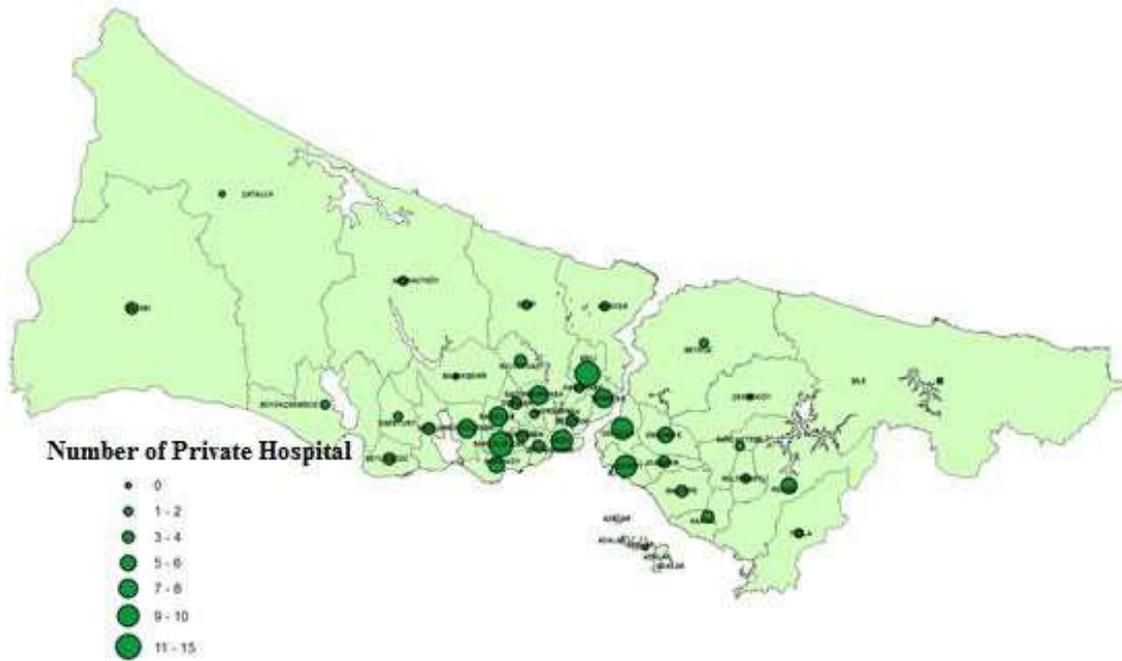

Figure 5.12: Distribution of private hospitals in Istanbul (2014)

Şişli county (1448 beds) has the highest number of private hospital bed. Bahçelievler, Kadıköy, Bağcılar and Üsküdar follow Şişli. Although Fatih and Beşiktaş counties have more private hospitals, hospital bed numbers are not more. On the other hand Zeytinburnu has less private hospital, but it has more hospital bed number.

The number of hospital bed number per ten thousand people in Istanbul is 8.41. Şişli county has the highest private bed number per ten thousand people via 45,5 ratio. Beşiktaş, Kadıköy, Zeytinburnu, Bakırköy, Beyoğlu, Bahçelievler, Silivri, Üsküdar, Beylikdüzü, Fatih, Gaziosmanpaşa, Bağcılar, Ataşehir and Pendik are the other counties which are up to Istanbul ratio. Figure 5.13 and Figure 5.14 show that dispersions of private hospitals' bed number across to counties in Istanbul.

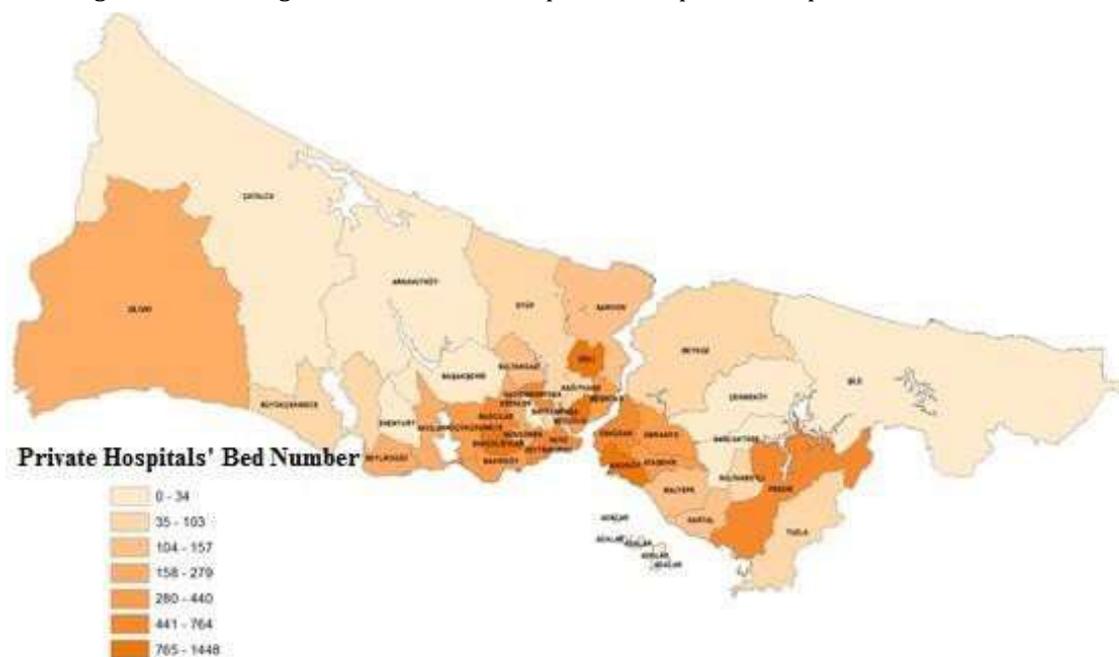

Figure 5.13: Distribution of private bed numbers (2014)

Figure 5.14: Distribution of private bed numbers per ten thousand people(2014)

Income level affects hospital preferences more than hospital admissions. Income level increases, the rate of private hospitals increase. On the other hand education level increases prevention of diseases and the consciousness of being treatment timely, and it affects hospital demand.

In 2009 The average annual income per person is 14.786 TL in Istanbul. (It has been produced from the results of household surveys conducted under Transportation Department İUAP, İBB). Huge income differences have seen between Adalar county (40.198 TL) which has highest income level and Sultanbeyli (8.103 TL) which has lowest income level. Other districts with above average income level in Istanbul are respectively Beşiktaş, Bakırköy, Kadıköy, Şişli, Beylikdüzü, Başakşehir, Sarıyer, Üsküdar, Ataşehir, Maltepe, Büyükçekmece and Kartal.

In general Istanbul, high school and college graduates over the age of 15 over the proportion of the total population is 0.38. The districts which have highest ratio are Beşiktaş (0,68), Kadıköy (0,66) and Bakırköy (0,62), the districts which have lowest ratio are Arnavutköy (0,18), Sultanbeyli (0,19) and Sultangazi (0,21).

In general in Istanbul, spatial distribution of education and income levels indicate parallelism. There is a highly correlation between education level and income level with 0.81ratio. Figure

5.15 and Figure 5.16 and Table 5.4 show that changes in income and education level in Istanbul.

6 EVOLUTIONS

Healthy is indispensable for human and states must supply healthy services to everybody. Turkish healthy system is insufficient in comparison to developed countries. Public and private sector work together in healthy services. Public sector aims to efficient and accessibility, so these factors affect public hospitals' location decision. On the other hand private sector aims to maximize profit and it prefers high income residential areas.

Accessibility is the most important for healthy services, so most of hospitals located in high accessible areas, highways, main roads, subways. Private hospitals prefer being near public hospitals. Most of them are Fatih and Şişli area which have large public hospitals.

During the last 35 years, Istanbul's population has increased unexpected values, and governments was not efficient for supplying public services. In 1980s public hospitals' locations were not efficient and equal. For instance, Sultanbeyli, Pendik, Avcılar were residential areas, but there were any public and private hospitals, people had to go far away, when they were ill. On the other hand first private hospitals were racial minority hospitals. Between 1980 and 1990 private hospitals number increased by effects of globalization. In 1990s, neoliberal economic policies affected private sectors, 72 private hospitals were opened between 1990 and 2000. Private hospitals located in high income districts such as Kadıköy, Şişli, Bakırköy. In these years public hospitals began to spread out to peripheries. In the beginning of 2000s, Adapazarı earthquake and economic crisis affect private sectors, the ratio increasing of private hospitals number began to fall. Transformation in Health Program (government decision, 2003) is important for private hospitals. These decisions encouraged public sectors and private hospitals began to trigger again after 2006. Today, total public hospitals' bed number and total private hospitals' bed number are very closest. Private hospitals are opened not only high income residential areas but also middle income districts no longer.

RS06.4. Location of Economic Activity

Tamás Vinkóczy

PhD student Széchenyi István University, Doctoral School for Regional Economic Sciences, 9026 Győr, Egyetem tér 1., vinkoczy.tamas@sze.hu

ABSTRACT

Firstly, I choose this topic, because I am interested in finance, but I would like to examine a complex system of the financial institutions. The local governments, financial institutions and inhabitants affected are essentially taking on the role of key factors, but the connection among them not always visible clearly. In my humble opinion, several (Hungarian) regional researchers do not devote enough time to attend to the impacts of finance. The problem with this mentality is that it does not take account of important financial factors. Why it is relevant to take account of finance in the regional science? In my esteem, financial institutions should be positioned as essential drivers of the settlements' economy. This sector of service gives many possibilities to the citizens as well as to small and medium-sized enterprises to save and invest their money or finance their purchases and projects. Secondly, the geography of finance is a new field of science which provides opportunities to examine the effects of financial institutions' strategic decisions. In my presentation/research paper, I would like to reveal the rising importance of this topic through the Hungarian example. In the course of my research, I would collect localization data from the financial institutions' websites, interview with at least two people (work in different financial institutions). After this, I would use the collected data to make illustrative diagrams and maps to make decisions. From my point of view location theories are play an important part of financial markets, thus I check in my study the positions and numbers of branches settlement by settlement in Hungary. There are two various types of financial institutions in the country because the Hungarian history caused different demands on financial services. The research shows that the differences between the mentality of the two main institutions have been being huge since their establishment of the second half of the twentieth century. All in all, I would like to present some of data and results of my research in this paper, because it provides curiosity for everyone who interested in financial or/and regional sciences.

Keywords: bank, financial geography, local government, regionalism, settlement

INTRODUCTION

Individual is meant to be a segment of the economic sector which is hard to be accessed and scrutinized, since everyone shares different ideas, habits of the mind and opinions. My research is partially linked to the analysis of savings and financial cultural habits of the individuals among the Hungarian population. At present, in another context – examining the territorial locations, penetration of banks and cooperative credit institutions – I tend to assess and scrutinize the geographic strategic parameters of these financial institutions. The survey, thanks to the triple typology of vicinity-distance-digitalization is closely connected to the demands of population, thus my research scope tends to focus on the factors of establishing banks or cooperative credit institutions. I would outline an important factor at this point, which in my opinion significantly affect the operational strategy of financial institutions and business corporations as well as the habits of the residential customers. The new informational technologies, digitalization, the internet's virtual reality, the cyber space do affect and inspire progress and development in such an incredible pace that we cannot simply bypass it without a word. I'd like to quote a few lines from the book of Thomas L. Friedman that had a really great impact upon me when reading, revealing the idea that corporations and individuals, as well must inevitably take the ride of progress: „It is important that we possess the knowledge and stay in the game ... the world is like a football pitch and we must perform well to remain in the team.. Unless you are good enough, you must watch the match from the side-line...” (Friedman 2005: 129.) The financial sector, nowadays is in the stage of quest for the right direction, since its traditional actors are facing brand new challenges.

BANKS AND COOPERATIVE CREDIT INSTITUTIONS

Before getting deeper into the theory and practice of choosing the right location for financial institutions, I need to present the brief history of the before-mentioned institutions, since their past formations can be traced back to different causes. In the aftermath of the devastating world wars, the economy of Hungary desperately needed development and rebuilding projects both in the field of agriculture and the corporate business world. By the second half of the 20th century – following the abolishment of the small credit institution-system – it became evident that the National Savings Bank (OTP) solely cannot satisfy the needs of the regions of the countryside. Due to the ensuing social, political changes the regional financial institutions catering for the needs of the country population ceded to exist. The needs of the rural people differ from those living in the cities, moreover the territorial distances used to play a significant role those days, so even besides modest profitability it was necessary to establish locally embedded and adoptive financial institutions, namely small cooperative credit institutions serving the special requirements of the local people. Thus, the rural cooperative credit institutions functioned as financial institutions serving the needs of the impoverished rural population, linked to more central rural locations with good agricultural and industrial connections. Following the political system-change, the operating financial institutions were also forced to change and transform themselves as a consequence of the ensuing alterations in the national banking system. The small cooperative credit institutions realized that centralization, the

²³⁴This research was supported by the „Internationalisation, initiatives to establish a new source of researchers and graduates and development of knowledge and technological transfer as instruments of intelligent specialisations at Széchenyi István University” EFOP-3.6.1.-16-2016-00017 Project.

continuous common development projects provide a more stable, cost-efficient and economical operation scheme for them. (Moizs 2012) The cooperative credit institutions in our country, based on the given territorial penetration of the share voucher-holders established the financial institutions since the owners' interest meant to be of utter importance in selecting the locations of the institutions. Their foundation – as we could witness – proved to be inevitable due to the local rural features so different from the urban conditions. The commercial banks, primarily were the Hungarian branches, affiliates of foreign banks, so their location selection would be a primarily a profit-driven choice, though for quite a long time, the cooperative credit institutions were to be the only genuinely Hungarian financial institutions. In my opinion, the operational schemes and strategies of these financial institutions must start to correlate and get closer as time goes by, and as their customers become basically the same. Their strategy must primarily rely and focus on the needs of the new generation for the sake of their future success.

It is also an interesting question the participation of a given bank-system in a special region in the regional economy as well as its dependency rate on the given region. Approaching this aspect from the before-mentioned vantage point, the current academic literature differentiates between two main trends. According to the neoclassic theory, we must focus on the integrated national banking system, thus taking advantage from sizeable economical measures flowing the capital towards the most appropriate targets. (Kohn, 1998) The other direction is that of the post-Keynesianism, which proclaims that the best thing for the capital is to remain at the location where it has been produced, promoting the embeddedness of the bank-system into the local economy. (Dow, 1994; Gál, 2010)

cooperative credit institutions do share this kind of locally embedded features, promoting and prioritizing the local interests, though their operations are significantly influenced by their popularity, good fame, as well. According to their core philosophy, they tend to promote and financially contribute to the success of the local regional interests. However, due to the current globalizing trends they could fulfill their mission in this respect only as being part of a national network. The residential as well as the corporate business clientele raise new challenging needs, while the continuously updated professional (technological) demands are getting higher and more complicated, too. Therefore, the cooperative credit institutions tend to create even bigger financial power-hubs through mergers in order to be able to keep afloat both on local and global level. (Kiss, 2009) Thus, in the following chapter, I tend to outline the impact of the institutional, regulatory as well technological changes upon the financial institutions.

THEORY OF BRANCH LOCATION SELECTION

I would like to present briefly the essential factors, elements of branch location selection displayed in the professional literatures. Within the regional way of thinking, even back in the 1700's *Johann Heinrich von Thünen* was meant to deal with regionalism, taking into account the importance of distance and location of marketplaces. Following the expansion and development of theories, Lengyel Imre et alia concluded that the economic actors when making a thorough decision take into account various business-specific criteria. Economic and even broader factors do altogether affect the ideas, projects of the business corporations, while the optimal conditions may vary based on their very own size, capacities and extension. (Lengyel 2004) It is quite difficult for an outsider to define the most appropriate choice for the various actors of an economy, though we must accept the fact that everyone should adopt and comply with the global changes of our world. Thanks to the continuity of the development processes, Manuel Castells back in 1996 called the attention upon the losing importance of time and distance in business, when the information society is about to expand in such an unprecedented pace and manner (Castells 1996). Shifting from the general theories to the world of financial markets, it can be observed that these institutions tend to pursue a trend-following attitude in this matter. With the prevalence of electronic banking transfer methods the time-frame barriers tend to disappear from business. Drawing into a closed network the remotest affiliates, branches is getting to be a routine furthermore the idea of vicinity/neighborhood is getting more room and importance. (Boschma 2005, Lengyel 2010).

It can be also observed the suspicious attitude of researchers concerning the emergence of newer and newer technologies, since they tend to highlight the importance of diminishing of time and space/distance. Peter Haggett in his book 'Geography global synthesis' argues about the idea that nowadays it is not geography which loses importance rather distance. The significance of geographic distance is undeniable, only the importance of distance diminished as a consequence of technological advancements. (Haggett 2006)

Based upon the literature analysis performed so far, I do consider that it is obvious that distance is losing ground as primary factor for establishing a branch or performing any kind of business activity, nowadays. Concerning the financial institutions, Gál Zoltán concluded a very sympathetic definition as follows: "By the implementation of info-communicational devices the capital markets witnessed the fastest transformations, predicting the 'likelihood' of the dawn of a virtual world without distances" (Gál 2014: 184.).

The diminishing importance of distances shared an outstanding attention in this chapter, since this is the topic I wish to highlight through my analyses, naturally paying attention to the other factors substituting distance when choosing a location for a depot or branch. I tend to present the branch network of the biggest financial institute of our country from a practical point of view, also dealing with the options of alternative agglomerations. In the forthcoming chapters, the great revelations and wisdoms of the above presented theories as well as the practically implemented strategic ideas are going to be supported by various maps, charts and interview findings carried out by the author.

THE PRACTICE OF CHOOSING A BRANCH LOCATION

Most of the researchers have created all sorts of theories concerning the definition of all those factors which may ensure the most benefitting positioning of the productive companies. In my opinion, the financial institutions play a significant role in fostering and developing economy, thus getting to know the set of criteria proves to be essential for them, too.

Interview findings

The discussions carried out with two interviewees of mine were related to the relationship and adaptation of financial institutions to the current economic conditions. Along the interviews, I asked 1-1 employee in mid-level manager position from a bank and from a cooperative credit institution, too, regarding the effects of digitalization, branch location selection and cooperative credit institution-mergers upon their own institutions. Along the discussions, inevitably we touched on issues of historic past, especially the events of the 1950's and of the 1990's. From the cooperative credit institutions' standpoint, the 1950-1960's were considered to be their peak, golden age ever since their foundations. From the banks vantage point, the abolishment of the small credit institutions and the establishment of a big state-owned bank proved to be of outstanding importance from that era. By the end of the 1990's the first really big challenge loomed in by the task of establishing a great, new unified data-base system. For the banks, this time period meant the 'overbanking' era of Hungary, since following the political system change the foreign banks considered a huge market opening in this sector. Thus, rationalizing the number of financial institutions and closing down the loss-producing branches goes on even nowadays in both financial sectors. Nevertheless, certain installation factors have also been revealed, which may be accounted as essential factors for preserving the operation and explaining the present location of the branches. From the banks point of view, the sales potential is supposed to be the most essential factor, which can also be considerably affected by the age, demographic and migratory trend as well as by the unemployment rate of the given settlement. The cooperative credit institutions are rather characterized by smaller scale profitability focus, thus even their less profitable branches can go on operating. The analyzed financial institutions were established in order to serve their residential customers' needs irrespective of their age. All the same, it can be stated that this primary goal currently seems to be unsustainable for the cooperative credit institutions because their residential customers are drastically aging. The younger and middle-aged customers generally choose the financial institutions closer to their workplaces or educational institutes instead of their permanent residential address. For the older generation customers trust, personal direct information-flow and local business management options are more important, therefore they tend to prefer the cooperative credit institutions' local branches.

Let's have a look at the picture deciphered by the two colleagues from the two financial institutions on the issue of cooperative credit institutions' merger presented in the media. From the part of the cooperative credit institutions, the initial goal is to create similar size branch mergers in all the regions with the headquarter being the Takarékbank (The Savings Bank). Later on it would be feasible to merge the cooperative credit institution branches into the Takarékbank, establishing a nationwide branch network with a regional penetration, size and capitalization similar to that of the National Savings Bank (OTP). The synergy effect linked to this merger would promote the creation of a territorial structure resembling to that of the big national banks, which would also imply the emergence of new competitive factor for those banks, too. It would also offer the option to lure away those customers rejecting the cooperative credit institutions merger and it would also be a challenge to decrease or neutralize the effect of the cooperative credit institutions' synergies.

Applying the new digital technologies for reaching out for the younger generation customers proves to be of utmost significance. Some parts of the regulations compiled by the Hungarian National Bank refer to this topic, consequently complying with these regulations and applying the new technologic developments²³⁵ (e.g. PSD2) are also meant to be organic part of the task allocation of the financial institutions. The envisaged development projects, most likely will not cause any disruption or problem for the banks or the cooperative credit institutions, either. The advantage of the impersonal banking services is also manifested in the decrease of importance of the geographic positioning of the branches.

Analysis of financial institutions data

I have collected the data concerning the geographic positioning of the branches of the 10 biggest Hungarian banks as well as of the currently operating cooperative credit institutions (61 altogether) in Hungary. In my study, I am going to present the various analyses of this data amount, which I presume contain really interesting information and results. Chart 1 illustrates the sphere of banks analyzed as well as all the settlements where these banks operate branches. The examined banks are present in several settlements, in the case of cooperative credit institutions this number is considerably higher, precisely there are 1,237 settlements in the country with operating cooperative credit institution branches.

Chart 1. Sphere of commercial banks analyzed (2017)

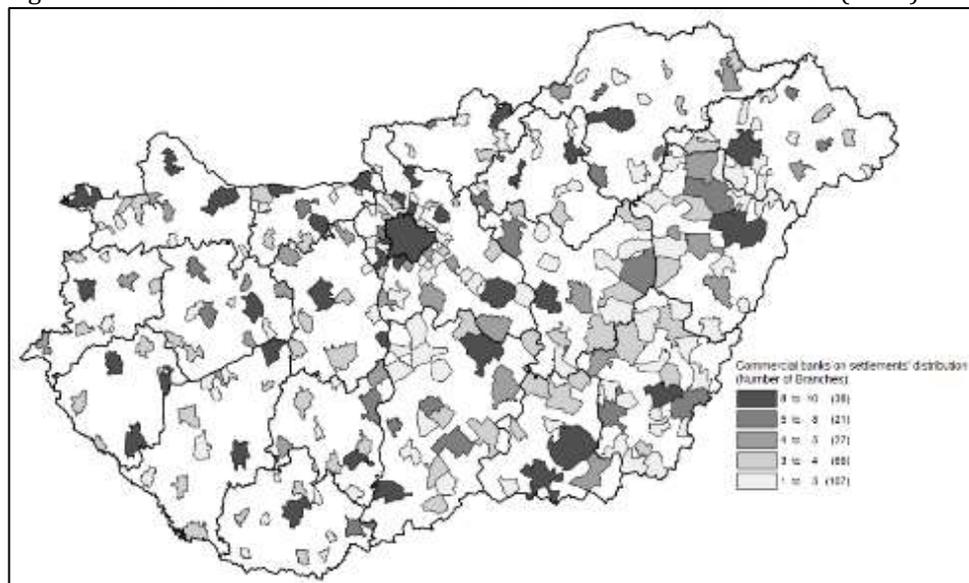

Bank	Budapest Bank	Erste Bank	Cib Bank	K&H Bank	FHB Bank	MKB Bank	Raiffaisen Bank	UniCredit Bank	Sber Bank	OTP bank
settlement (no.)	64	77	42	152	33	52	36	33	19	247

(own compilation based on data from the banks' websites)

²³⁵ See <https://www.mnb.hu/letoltes/az-azonnali-fizetesi-szolgaltatas-mukodesi-modellje-magyarorszagon.pdf> (downloaded on: May 06, 2017)

Cooperative credit institution branches can be found particularly in villages, while bank affiliates are present mostly in towns. Naturally, one reason for this penetration scale lies in the more profit-oriented strategy of the banks compared with the cooperative credit institutions, this way banks are quite unwilling to open branches in any small settlement. In figure 1. we can depict the distribution rate of the number of branches in a settlement of those banks mentioned above. It seems that the typically the capital city and the county towns share the biggest number of various commercial banks competing for the customers.

Figure 1.: Ratio of several commercial banks on settlements' distribution (2017)

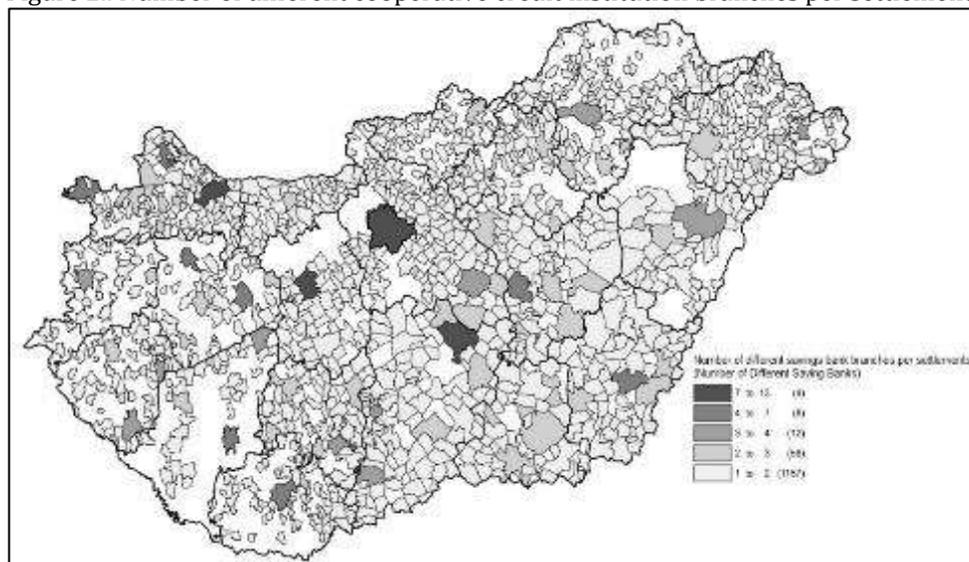

(own compilation based on the banks' websites)

Interesting detail reveals from the map concerning the western part of the country, which shares lower bank penetration scale than the southeastern region. One reason for this might be the fact that in the western countryside the settlements geographic location is more sporadic and scattered, and they also function as financial centers, agglomerations unlike the eastern settlements. Austria is neighboring Hungary from the west, thus the abundant potential workplaces over there may create customer migration to the Austrian bank branches, as well. For the more significant southeastern concentration another reason may be the bigger number of population in comparison with the rate of the central and southwestern region of the country.

For the financial institutions, the lack of hamlets and tiny rural areas may as well mean an advantage – contrary to the western region – since the infrastructural and economic development and benefits stemming from this fact prove to be positive factors for them. Consequently, the banks with bigger branch networks are also present in several settlements in the eastern region. In Figure 2. I tend to illustrate the number of cooperative credit institution branches with different names per settlements, thus we can compare it with the number of bank affiliates.

Figure 2.: Number of different cooperative credit institution branches per settlements (2017)

(own compilation on data driven from cooperative credit institutions websites)

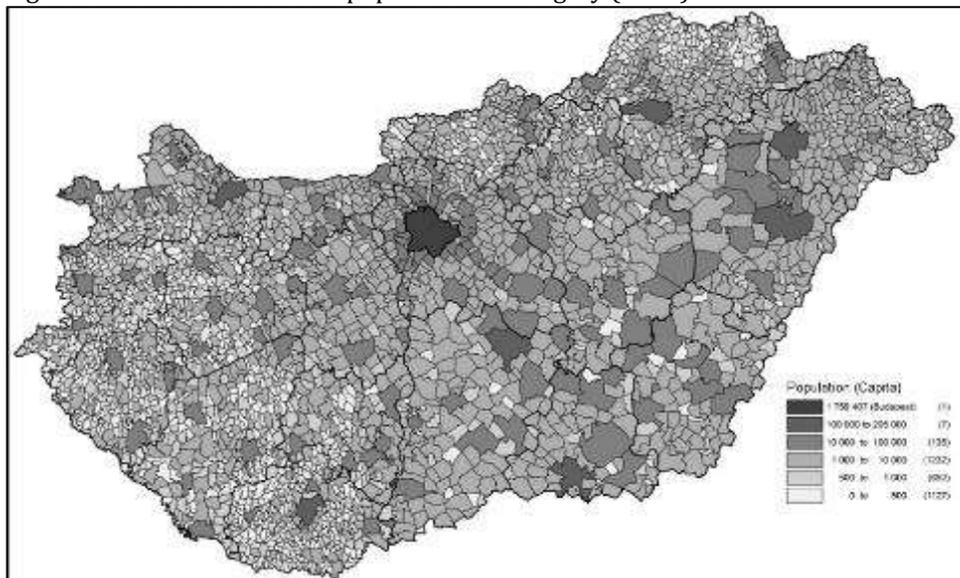

When interpreting the figures of the map, we should also take into account the fact that in 2013 the market penetration ratio of cooperative credit institutions in Hungary was merely 4-6% (Gál 2013), which I assume has not changed

considerably up to the present moment, yet in contrast to this fact, the size of the geographic area covered by their branch network is really enormous. The reasons for this disproportionateness may vary, separately operating cooperative credit institution branches which are present almost in one county thus they cannot provide a nationwide, single network penetration similar to the banks' networks. The significance of the capital and of the county towns is really striking, nevertheless the number of those settlements with only 1-2 operating cooperative credit institution branches is even higher, and thus their volatility must be rather symbolic. The difference of cooperative credit institution branch numbers on the East-West axis is also noteworthy, which may have a similar explanation to that of the banks and partly may be the consequence of the industrial and agricultural development projects prior to the political system change,

Supporting the data of the two previous figures, I'd like to present the Figure 3. illustrating the number of resident population of our country as of the latest 2015 survey, based on the data of the Central Bureau of Statistics (KSH) distribution per settlements.

The population distribution supports my assumption namely that its penetration on the western region of our country is much lower, partly due to the tiny village structure areas in that region. Examining the Western and South-TransDanubian region it is striking the great penetration of small and tiny rural settlements with 500 and 200 or even less population consequently, obviously the infrastructural build-up of the region is greatly affected by this condition. The analyzed financial institutions in the western region – particularly the banks – considered as their primary target to win over the potential customers from these areas rather than focusing on their local branch operations. Therefore, the relationship between the number of financial institution branches and the number of population proves to be deterministic, also supported by the revealed distinctions between the discussed branch number alterations on the east-west axis.

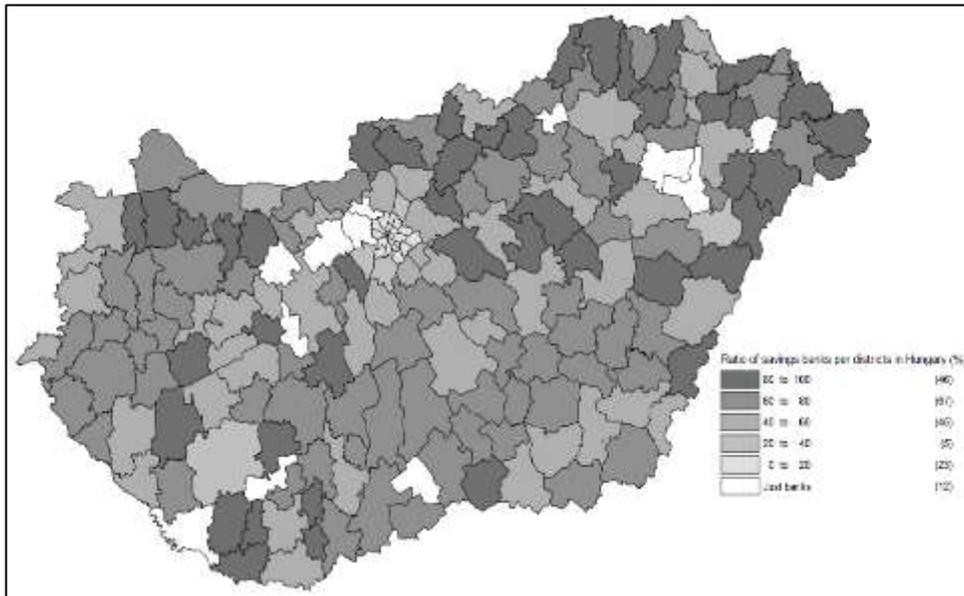

Figure 3.: Number of resident population in Hungary (2015)

(own compilation based on KSH website data)

After discussing the settlements level issues, let's have a look at the figures of the sub-regional districts in Hungary, where compiling my analysis I have taken into account the total number of financial institution branches. In figure 4. we can see the total number of cooperative credit institution branches in a district within the ratio of all the financial institutions examined in the area. Along my analysis I have taken into consideration the latest 2014 advancement, development ranking order of social and financial profiles of districts made by the Economy and Business Enterprise Research Institute of the Hungarian Chamber of Commerce and Industry. The research ranks the districts from 1 to 5 according to a 25 indicator-scale (HCCI IEER 2016).

Figure 4.: Ratio of cooperative credit institutions per districts in Hungary (2017)

(own compilation based on data from cooperative credit institutions and banks websites)

Having a closer look at the map, we can realize that 12 districts do not possess any cooperative credit institution branches only bank affiliates, while from these districts only 1 can be ranked into the 25 most developed districts based on the above-mentioned ranking scale. Four are listed among the 25 most advanced districts, and the remaining 7 are positioned in the mid-ranking field of districts. The map also suggests that, nevertheless even banks are willing to show up with branches in underdeveloped regions, too, to fill the market gap. Based upon the cooperative credit institution branches I need to emphasize the Northern-Hungarian and the Northern-Great Plain region, since their presence seem to be very significant in these regions. The two regions together with Southern Great Plain and Southern-TransDanubian regions, based on the statistic indices of the EUROSTAT 2015 GDP/capita²³⁶ accounts are supposed to be listed among the most under-developed and under-performing regions of the EU. Consequently, we can note that the cooperative credit institution network is typically present in the more under-developed regions. This revelation also makes us assume that the territorial economic development of the regions have not been transformed or restructured in our country, so far.

CONCLUSIONS

From the research findings we can assert that neither the commercial banks nor the cooperative credit institutions plan to open new branches, thus the branch-opening factors can be disregarded from this vantage point. Branch mergers and rationalization are meant to be those processes which do call need certain social, economic factors to be taken into account. Banks are featured by more profit-oriented traits contrary to the cooperative credit institutions operational style, which do share more locally embedded presence because they tend to operate and maintain their branches with margin-profitability rate. Due to the branch mergers, the cooperative credit institutions are facing tough challenging decisions to be made in the future concerning the allocation of regional financial centers (hubs) and partly on selecting the branches to be merged without problems. This process must necessarily involve the closure of certain branches with repositioning or laying off the present workforce, so these factors all must be taken into account by the management.

The future, likely national merger into the Takarékbank may have significant positive effects considering the profitability rate of the institutions. They could assume and benefit from the single network of non-competitive cooperating branches – similar to the efficient networks of banks –with significant amount of capital and effective institutional system. However, I would also highlight on the fact that the inspiring idea of this ambitious merger of the cooperative credit institution is basically historically missing from the set of thoughts from their part, not mentioning the really challenging, extremely time and energy-consuming task of transforming their business cultures.

The continuous advancement of the digital world and of globalization make some researchers consider the ensuing ‘death of geography’, since enormous transnational corporations may operate worldwide benefitting from this trend. (Morgan 2001) In my opinion, the financial institutions may launch the full access of impersonal digital financial services for their customers, although people will change their habits in this respect in quite a long time. Stemming from their personality traits trust and physical presence plays an important role for many customers when making decisions in this matter. My position is also supported by Graham and Morgan in this respect claiming that due to the high level of information carried by non-verbal communication tools the digital info-communication measures will not supplement personal appearance for the time being (Graham 1998, Morgan 2001).

Trust is particularly important factor both for the financial institutions and their clients – especially the corporate ones – since both parties share outstanding economic interests and cooperation in the background. For the inter-operating business parties the well-developed informational technological architecture is meant to be of key importance, and from

²³⁶<http://ec.europa.eu/eurostat/documents/2995521/7962764/1-30032017-AP-EN.pdf/4e9c09e5-c743-41a5-afc8-eb4aa89913f6> (downloaded on: May 08, 2017)

this respect I assume the bigger cities are in much more advantageous situation than the smaller settlements. Therefore, I consider the geographic space, physical location and territory will keep their significance even in new forms, yet these still tend to be important factors for the financial institutions as well as for their clients. Concerning the digitalization coverage and opportunities there are enormous regional differences in our country. Consequently, the banks and cooperative credit institutions when discuss their rationalization processes and branch mergers they must take this factor into account, as well. The applications and options offered by the digital world are getting ground and more importance for the customers, yet the total depersonalization of the financial services is not a current issue for the time being.

1 INTRODUCTION

Gujarat is one of the developed states of India but agriculture has been the major source of labor absorption with 70.5 per cent of the workers being rural based of which 52 per cent of the workers are cultivators and agricultural labourers (Swain *et.al*, 2012). Out of total geographical area of 196 lakh hectares, 99.66 lakh hectares is under net cultivable area which is 50 per cent of total geographical area. Total gross cropped area is about 122.11 lakh hectares of which total gross irrigated area is 56.14 lakhs hectares which is accounted for 45.97 per cent of total crop area. In the irrigated areas, cropping intensity is high (GoI, 2016).

Total operational land holders in the state are 48.86 lakh, who possess the cultivable land with an average of 2.03 hectares per land holders. Out of total land holders, 37.16 per cent are marginal farmers, 29.25 per cent are small farmers, 22.10 per cent are Semi-medium farmers, 10.49 per cent are medium farmers while only 1.00 per cent of farmers own large lands (Gujarat 2015). Agriculture in Gujarat is characterized by natural disparities such as (i) drought prone areas and lowest annual rainfall amounting to only about 345 mm at the North West end of the states; and assured and highest annual rainfall amounting to about 2500 mm at the South-East end; (ii) well drained deep fertile soils of central Gujarat and shallow and undulating soils with poor fertility in hilly rocky areas in the east; (iii) moisture starved degraded areas and low lying waterlogged and saline areas; (iv) areas prone to frequent scarcity and areas prone to frequent cyclone or floods or locusts hectares (Swain *et.al*, 2012).

Major agricultural products of the state include cotton, sugarcane, castor, ground nut, mustard etc. Gujarat is also known for its largest share in the production and productivity of cumin seeds, fennel and *isabgul* production in the country. However, the relative share of agriculture and allied sectors to both gross and net state domestic product has been declining significantly. Share of agriculture to Gross State Domestic Product (GSDP) (at current prices) which was at 19.8 per cent in 2010-11 has declined to 14.25 per cent in 2015-16. Gujarat, Goa, Kerala, Maharashtra, Sikkim, Uttarakhand, and Tamil Nadu are the few states where the contribution of agriculture to SDP has been less than 15 per cent (GoI, 2016).

The study report of The Agro-Economic Research Centre (AERC), observes that the share of area under cotton and wheat have been increasing in the past two decades. Particularly the area under wheat production accounts for 11.9 per cent of the total gross cropped area (Swain *et.al*, 2012). This paper focuses on wheat that is cultivated in rainfed saline areas known as Bhal region. The wheat cultivated here is very unique and has been appropriately registered with the Geographical Indications (GI) registry by the name Bhalia wheat in 2009-10. GI registration is conferred on those products which demonstrate a very strong link with the region where they are cultivated. This link could be the soil or water or any natural resources or climatic factor or the human skills that gives the uniqueness to the product either in the production or in the processing. Such location based goods are known for their uniqueness and have consumers who look for such uniqueness and are willing to pay a premium price for such unique products registered with GI. This paper looks into the economic challenges in the production of Bhalia wheat. In doing so this paper is organised in to the following sections. Section 2 following this introduction provides a discussion on GI products and their advantages. Section 3 and its sub sections discuss the case of Bhalia wheat. Section 4 presents the likely future scenario of Bhalia wheat, followed by Conclusion.

2. LOCATION BASED GOODS

Location based goods are also known as place goods like Darjeeling tea, Banarasi sari, Guntur Chili, Gir Kesar mango and other products. Since the (Trade-Related Aspects of Intellectual Property Rights) TRIPS Agreement, such place goods have been protected legally through appropriate framework. While the European nations protect with Appellation of Origin, some of the Asian countries have developed a sui-generis system of protection. Another choice exercised by a few countries is to use the Trade Mark or the certification mark route. There has been no separate legislation in India until the Geographical Indications of Goods (Registration and Protection Act), 1999 (GI Act) which came in to practice in 2003. Prior to this, GIs were governed by common law principles, which enabled the aggrieved person to file an action of 'passing off' for protection of his right. The sui-generis system provides protection to agriculture, handicrafts, natural and manufactured goods. It is important to note that agricultural products account for the highest proportion (33 per cent) of the total registered GIs in the country. As of March 2018, 320 products were protected with GI Registry, which includes the logo and products from foreign countries. Out of this, 28 per cent were agricultural/ horticultural products.

2.1. Advantages of Location Based Goods

The advantages of location based products registered with GI is that they help the producers to stand apart in a crowded market place of similar goods and enables the producer to make economic returns based on the uniqueness. Hence, GI registration provides the information and authenticates for the quality of the product and its origin.

The economic rationale for GIs is the correction of a market failure caused by an asymmetric information between sellers and buyers, where if the buyers are uncertain that the quality of product A is better than that of product B, buyers will not be willing to pay a higher price for product A. GI institutionalizes the reputation of a product, where due to information asymmetries free riding on reputation of a product happens. Thus it acts both as a consumer and a producer protection measure (Cerkia *et al.*, 2011) and has the potential to improve rural livelihoods emanating from local resources. Consumers revert to the making of repeat purchases, developing a strong sense of brand loyalty and also are willing to pay a premium for reputation. In response, producers adopt strategies for creating reputation in their products.

Cerkia *et al.* (2011) notes that in the context of European Union (EU) where more than 70 per cent of all registered GIs in the EU are linked with economically lagging regions and therefore, GIs are likely to support rural development in regions that are in most need of it. Lagging regions that focus on superior quality goods authenticated by geographical origin and traceability could be linked with the regional and national markets (Librey and Kneafsay, 1998). Librey and Kneafsay (1998) point out that after the 1990 Food Safety Act by the UK, emphasis on standards of production and traceability have become important aspects for the consumers and the producers. A GI certified product with the strong emphasis on the use of 'quality and local' resources in the making of the product, can reach a specific and sustainable market, which rewards with a premium price and recognition. Thus, the objectives of GI and rural development converge in realising the market potential of local resources through sustainable use. Moreover, the major concern of policy makers across the world today, is to mitigate out-migration from rural to urban areas especially distress migration and production and marketing of 'rural cultural distinction' has become a catchword in local development strategies (Coombe, 2005).

By enabling communities to continue producing their traditional products instead of finding alternative means for survival outside their traditional activities, GIs contribute to the preservation of cultural heritage. This factor, strengthens regional identity and again reinforces the inter linkages in support of rural development.

Sylvander (2004) cautions that the institutionalization of the resource origin does not *per se* set the conditions for development. Instead, he argues that it depends on how this process is developed and on the effectiveness of the valorisation strategies built upon it. These strategies could be defining production methods and area, quality standards, implementation, authentication and traceability enforced by institutions owned by the stakeholders themselves or external agencies (Hayes *et al.*, 2003; Soam and Sastry, 2008). In the EU and Latin American context, GI products have been linked to the rural development strategies and this has resulted in: (a) strengthening the producer associations who have filed the GI applications; (b) specific standards for production of the GI product that are strictly followed by all the identified authorized users; and (c) setting up quality councils that certify the products resulting in a highly distinguished premium market for the GI products. Depending on the rightful beneficiaries who develop or market the product and the relative reputation of the product (local, national, international), the need and efficacy of the protection is determined (Folkesson, 2005). In other words, creation of value, based on these regional identities are dependent on the ability of producers to coordinate the production process (capacity to form an association and implementing standards of production), strengthening vertical linkages and fostering trust through institutional mechanism (Lalitha, 2014; Vinayan, 2012; Rich, 2011; Bowen, 2010).

Reviron *et al.* (2009, p.12) positions GIs in the Maslow pyramid in the following way: with promise of origin, the immaterial component of the products increase and consumers move up the Maslow pyramid with "their hedonistic (taste), food safety (quality control), belonging (link with a territory and a social identity), beauty (aesthetic landscapes)" characteristics. As consumers' demand increase, self-actualization needs are also fulfilled through critique of mass production of food, concerns over environmental degradation leading to willingness to pay premium prices for such products. Thus, registration for GI with active labeling for origin coupled with other characteristics of the products can be a powerful marketing tool.

There are successful evidences from European countries, where GI for agricultural products originated. Champagne is a celebrated example from France, Columbian Coffee is an example from the developing country. Kintamani Bali coffee from Indonesia is another example. It is in this context of the advantages of the locational based goods, which have the potential to get higher returns based on their locational identity authenticated by GI registration, this paper is exploring the possibility whether Bhalia wheat protected by GI could reap such advantages.

3. BHALIA WHEAT IN THE STUDY AREA

The study on 'Bhalia wheat' is part of a larger study on GI registered agricultural products supported by the Indian Council of Social Science Research, New Delhi. The study area is in the 'bhal region' of Gujarat, also known as 'bhal area/ belt/ tract' which is located around the gulf of Khambhat. The 'bhal region' is only one of its kinds in the world, renowned for cultivating a unique variety of wheat known for its nutritional values. This tract is spread across six administrative districts in the state. The districts are Ahmedabad, Anand, Bharuch, Bhavnagar, Kheda and Surendranagar. 'Bhalia Wheat' or *GW-1* (an improved variety of durum wheat) is unique variety of its kind. The features of the grain are bold, very hard and vitreous (GoI, 2010).

3.1. The Study Area

The study area comprises of two districts viz. Ahmedabad and Surendranagar. The rationale behind the selection of these two districts was that they ranked higher in producing 'unirrigated wheat' (Table 1). Among the list of six districts falling under bhal region for the years 2010-11, 2011-12 and 2012-13. These years were taken into consideration for choosing the districts as this was the latest data available with the Directorate of Agriculture, Gujarat State. (Table 1).

Table 1: Averages of area, production and yield for unirrigated Wheat for the years 2010-11, 2011-12 and 2012-13 by districts in Gujarat

S.No.	District	Area*	Production#	Yield+

3.2. Objective and Methodology

The broad objective of the study was to look into a case of bhalia wheat cultivators to understand whether the GI registration of this location good would help in improving their economic returns. The discussion in this paper is based on the information drawn from the focus group discussions (FGDs) conducted in the 12 villages spread across the two districts of Ahmedabad and Surendranagar. The data is further supplemented by in-depth discussions and interviews with various stakeholders involved in Bhalia wheat production, distribution and technical support providers (like the Agriculture University staff including scientists based at Anand and Arnej Research Centre of Anand Agricultural University, Anand, Gujarat, mill owners, traders, retailers, Agricultural Produce Market Committee (APMC) Staff and the officials of Agriculture and Panchayat Departments respectively at village, taluka and district level in the state. Only those villages which were cultivating wheat entirely on unirrigated conditions were chosen for the study. The participants were selected randomly and all the participants were male farmers.

Table 2: Land Profile of the Farmers Participated in the FGD

S.No.	Name of the District	Name of the Taluk	Name of the Village	Total No. of Farmers Present in the FGD	Combined Land Holding	Land used for Bhalia Cultivation	Range-Yield per Ha.	Per cent of Land Share Cultivated for Bhalia
1.	Ahmedabad	Dhandhuka	Pachcham	8	NA	324	5-6	NA

3.3. Discussion

Among the 12 villages studied, eight villages fall under the administrative jurisdiction of Ahmedabad, while the other four belong to Surendranagar. Ahmedabad happens to be the major producer of Bhalia wheat both in terms of area and production. The main occupation of the people in the selected villages revolves around agriculture. Majority of land less people in the villages were agriculture labourers. However, there were about 10 per cent of the village population in the selected villages were artisans and others who were involved in non-farming activity or work in the pharmaceutical factories surrounding areas of Ahmedabad.

It is evident from Table 2 that in the chosen villages, out of the total land, 68 per cent of the land has been allocated for Bhalia wheat cultivation. The average yield for the FGD participants ranged between 1.65 on the lower side and 2.32 on the higher side. In contrast, the National level productivity of wheat is 2872 kg per hectare in 2014-15 (Government of India 2016). While this shows that the productivity is very low compared to the national average, even in comparison with the other varieties of wheat known as tukadi and sharbadi, which yield in the range of 10-13 quintals, Bhalia wheat yield is very low.

If the members present in the FGDs is taken as representation of the respective villages visited for the study, except for Ballol and Devpara villages, Bhalia wheat appears to be the most preferred crop by the farmers in the remaining 10 villages. The reason for this is not only lack of irrigation facility but also the characteristics of soil in the bhal tract. According to staff at Research Centre, Arnej, Anand Agricultural University (AAU) the bhal region is characterised by soil (top) that is medium to heavy black. In some of the areas the land is reddish or 'goralu' as local call it. This layer is about 1 to 1.5 meter deep and it can hold the water for about 6-7 months. The next layer of the soil is yellowish soil that is hard and then it is sand at the depth of 400-500 meters. This layer is highly saline as a result of minerals deposited over the years. The water is extremely saline and it cannot be used for drinking or agricultural purpose. Contrarily, if it is used,

the soil is bound for damage. The region also faces very erratic rainfall. This becomes a challenge for cultivation, hence the farmer has to depend only on rain water for his cultivation. Given such conditions, they don't see any alternative other than traditional Bhalia wheat.

However, there is also an acknowledgement by some section of farmers in the FGD to the fact that the preference for Bhalia wheat is gradually coming down since last decade for the reason that the famous bhal region in low land areas is now gradually receiving Narmada River through canals. Besides, every village has their own ponds (the government encourages the villages to maintain them by regularly de-silting them). All this is encouraging the traditional Bhalia wheat cultivators to move to other crops that fetch them lucrative prices. Besides, they get to grow those crops more than once in a year, leading to higher cropping intensity. In case of Bhalia wheat, it can be grown only once. This is again determined by how the monsoon has been in that particular year. Inroads made by irrigation have already lured away traditional Bhalia growing villages from following traditional method of cultivation. This has boosted the income as it provides them better yield. Tukdi 49 (a local variety of wheat) is the popular choice as alternative to Bhalia. This variety fetches them a yield of 12-14 quintals as compared to Bhalia's 0.1-0.15 quintals. The price for tukadi is Rs.1500 per quintal, while Bhalia wheat gets them a price of Rs. 3500-4000 per quintal.

The other crops grown in the region other than Bhalia are Chana (gram), Suvadana (Dill Seeds) and Indigenous Cotton (characterised by short staple). Gram yields Rs. 6000 per quintal and Suvadna yields between Rs.3500 to 4500 respectively. It is important to mention that, these crops are cultivated in only those villages where condition suits them. The special condition required for cultivating these crops is determined by the monsoon, irrigation facility and soil type. As narrated by the farmers, if the soil is slightly less black and less clay like, they by default cultivate chana. If the soil of their land happens to be black and clay like, then every farmer sows cotton in such land (majority of bhal region is comprised of this) in the beginning of the monsoon. However, if the monsoon remains moderate then the cotton automatically grows and farmers continue with it. If the monsoon is good then the cotton saplings gets submerged in the water and decay as in the saline areas, the water takes a long time to dry up. With no alternative left, the farmers sows Bhalia variety.

Challenges in Production, Storage and Value Chain

Explaining the production method and process, the farmers narrated how the land preparation begins by building a bund of 45-60 cms. height around the field. The first few days of rain water is collected and drained after a couple of days to wash off the top layer salinity. After this the rain water is collected and allowed to remain in the field by blocking the outlets. This helps in storing the water to increase moisture retaining capacity and decrease salinity. After three months, the water is drained. Here it may be noted that there has to be a good social cohesion among the producers as cooperation is required among the farmers to let go the drained water to reach a village pond. If there is no cooperation the water cannot be drained and the land will not be suitable for sowing the seeds. After draining the water, the land is left to dry for about 10 days. After this, the farmers using their traditional knowledge check the moisture content and the sowing takes place. It is important to mention that, not all villages follow this kind of practice. In fact, in most of the villages, the monsoon water evaporates on its own, so there is no need to follow such exercise rigorously.

Nevertheless, sowing of Bhalia wheat takes place either in the last week of October or in the first week or second week of November. To be precise, November 15 is the date, majority of the farmers' sow the Bhalia seeds, some of the farmers find this date auspicious, while some see scientific reason and ancestor's wisdom in suggesting this date. But if we look at it from the climate point of view, winter sets in properly at this point of time and it is conducive for the wheat crop cultivation.

The seeds that are used for sowing have to be preserved/ conserved in a moisture free condition. Farmers are required to change the seeds once in four years. Some of the farmers follow this practice while some farmers do not heed to the advice of the university and go on repeating the same seeds which results in lower yield. While sowing, heavy seed-drill or automatic seed drill fixed to tractor is used. The sowing has to be done in even and at uniform depth i.e. 75 cms deep at a space gap of 30 cms between two. For healthy growth, manure in organic form is used. Intercropping is normally followed while cultivating Bhalia wheat. This is with safflower in 3:1 row proportion²³⁷. If requirement of seeds for sowing is calculated, the average requirement amounts to 25 kgs per acre. The variation in the spacing of between the seeds determines the actual volume. The farmers cultivating Bhalia by treating one time irrigation usually applies urea along with the water.

The most common pest that destroys Bhalia in its initial stage of growth is grass hopper. This pest is predominantly found around Dhandhuka taluka. Other disease that affects Bhalia crop is what locally known as '*sukharo*', meaning drying up. This affects the root of the crop and the plant does not bear the grain and this found to happen in different parts of the same field. According to the farmers, nearly 2 per cent of the crop is lost to this disease all the time. '*Tidla*' is another disease, this disease happens within 15 days of sowing, wherein, in this condition, the crop is destroyed and this requires re-ploughing in the affected area for sowing the seeds afresh. Bhalia crop needs minimum follow-up as it does not require fertilising the field often or the use of any pesticides. Bhalia fields does require to maintain watch on the crop that is growing in the field to not only shoo away the stray animals like cows, wild boars but also the *chakli* (sparrows). According to the farmers, these birds destroy good amount of harvest that is still on plant if ignored. These birds not only

²³⁷ However, mixed cultivation is not practiced in every village, this is common only in the Dhandhuka region.

eat away a bulk of grains, they destroy the budding crops too. Due to sentiment value, the farmers do not use any chemicals to kill them even if they number around 200 in one drove.

The average yield is normally 8-10 quintals per acre when it had rained adequately and the farmers have changed the seeds every four years, otherwise the yield is less as reported in Table 2. Further, around January if the climate is cloudy for number of days or more often, then grain formation is less²³⁸ affecting the yield. Finally, the grains are stored after thoroughly drying. Grains with only 10 percent moisture qualify for storing which are done in pits, bins and moisture proof godowns.

Harvesting and Storage

The harvesting time begins after four months (in February-March). The Bhalia growers have to be contended with only one crop in a season. The harvesting is done either manually or with harvesting machines. If done with harvester, the grain is expected to lose a bit of shine. However, many farmers prefer it due to shortage of labour. Those not preferring harvester do it in traditional way which is known as '*uppani*'.

Storage is vital in the case of Bhalia wheat, explaining about the importance of preserving the product, the farmers and traders alike pointed to the fact that the shelf life of the grains is very poor. According to them, the wheat gets spoiled within one month if not properly stored. The wheat grains cannot be preserved with castor oil application, the normal practice followed in the state for other food grains as the flour tastes bitter. The big mill owners procure wheat directly from the farmers from their fields, and then they sort at their mills using high technology machines purchased from Japan and Korea known for its accuracy. Thereafter, from there on the grains are moved to cold storages.

The farmers in Limdi region who are affected regularly by flooding of water during monsoon prefer to harvest manually for two reasons: First they use the crop residue known as '*bhusa*' (hay/ Straws) as fodder for their cattle, and secondly the crop residue is also used for storing the harvested crop in a unique way. The farmers choose the elevated area in their house and prepare a makeshift pit and fill it up with the hay to a minimum height of one feet, then the wheat laced with the *neem* leaves is securely sealed in plastic bags. Then these bags are placed in the pit and insulated again with the hay covering it entirely. This is a fool proof practice being followed by them to keep away the moisture and dampness affecting the wheat to preserve it from decaying.

Challenges of Markets: Price Determinants: Marketing Channels, Prices in the last couple of years

Price

According to a Secretary of Grain Merchant Association, Ahmedabad it is economics that determine the choice of farmers and consumers alike. It is so because, consumers get Tukdi wheat (common brand) for just Rs. 2000 per quintal. But, for Bhalia one has to shell out Rs. 4000 per quintal. Price of Bhalia wheat is higher than Tukdi, though in terms of yield, 'Tukdi' yields much higher than Bhalia wheat. Another big trader in the market thought that, Bhalia wheat trade constitutes only one per cent of entire wheat trading in Ahmedabad. The views expressed by various stakeholders' only points to the fact that, there are committed consumers of the product in and around the Bhal producing region and beyond. Yet the production appears to be coming down. It is evident that, the availability of irrigation has prompted the farmers to opt for other crops and at the same time the Bhalia wheat yield per acre of land is too less. According to officials of Directorate of Agriculture at all three levels of taluka, district and state, this is natural tendency of the farmers, as they will always be interested in increasing their yield. And to attain the objective, the irrigation is vital; hence all the farmers demand irrigation for their agriculture. The point, the officials try to make is that, if at all, the uniqueness of Bhalia variety is at stake, it makes little difference to them.

Market

The Bhalia wheat farmers have choice of selling their produce to the following: 1) directly to the consumers, 2) traders, 3) mill owners and 4) APMC. Except for the last category, all the buyers purchase the product from the door steps of the farmers. For the traders and mill owners, Bhalia wheat is a one month business material. In the opinion of all the stakeholders, the market for Bhalia wheat is very unpredictable. The prices in the market are determined by the market forces. So, if there is a lot of supply and the demand is low then the prices fall and if the demand rises up and supply is stable then the prices shot up. According to a leading mill owner, presently the prices (in 2018) could reach all time low from Rs. 45-47 kg to Rs. 22-27 kg.

The superior quality of Bhalia wheat attracts huge demand. Majority of traders purchase directly from the farmers known for cultivating the crop traditionally. In fact, there are a very few farmers producing such quality of Bhalia wheat. Major market for Bhalia wheat is found in Ahmedabad, Bhavnagar, Baroda, Surat, Anand and Nadiad and Mumbai. The traders from these cities buy directly from the farmers. Arrangement to sell the produce at doorsteps saves the farmers time and money. With telephone network making inroads, some of the farmers are able to make good use of the technology, firstly, they use phone facility to find out the price at different places or even at APMCs, most of the farmers have the regular purchasers who contact the farmers when they require the commodity or as and when demand arises. The farmers leave the sample of their product with them. Since the price is negotiated on phone, the farmers do not incur much loss. Some of the enterprising farmers in Moti Boru have tried their luck successfully by taking the stock in their mini vans and trucks all the way to Surat and were able to sale at retail price within a week's time. It was also reported in the newspapers that

²³⁸ Reported by farmers in Koth village.

farmers instead of selling at a lower auction price at APMC, farmers in the Khambhat area took the grains in mini trucks and carts and sold it directly to the consumers at their door steps²³⁹.

There is also an online market for Bhalia wheat. An Ahmedabad based online business firm started dealing in organic farming products in 2015. Bhalia wheat is one of their products. On receiving orders, the product is sent to the consumers. The packaging and transporting costs are borne by the customers. According to its proprietor, the people residing in faraway places like Bangalore, Delhi and Mumbai place order with them for Bhalia wheat. More often, the extra cost of transportation is almost equal to the value of the product they are purchasing. The current price of Bhalia wheat through this source is Rs. 60/- per kg. It was Rs. 50/- per Kg last year.

According to the experts of Agriculture University, Anand, Bhalia wheat has very good potential for be recognised as organic. They also highlight to the fact that, Bhalia fits in ideally for national market since the timing of its harvest is unique (between February and March) and does not exports because it requires minimum fertilizers and pesticides so it fulfils the essentials required to run parallel to other famous brands produced in Punjab, Haryana, Utter Pradesh or Madhya Pradesh (between May and June) when it comes out in market and can get a higher price. But the yield is relatively less than the Tukdi wheat.

When the scientists at Krishi Vigyan Kendra, Arnej were asked about the value chain or the scope for by-products of Bhalia wheat, they pointed out that, Bhalia wheat could be used in baking industry. Therefore the baking industry should be established in these regions benefiting both the consumers and farmers. Further, a big retail trader in Ahmedabad was of the opinion that Bhalia flour will not be commercially beneficial unless it is sold with its own brand, but given the poor awareness level (uniqueness characteristics of the wheat) of the consumers, this is not possible. He thought that, it is not commercially beneficial also because; Bhalia wheat flour absorbs 10 times more addends while making the dough. The addends could be ghee, water, oil, or any other bakery related ingredients.

Functioning of APMCs: Farmers Experience

Visiting APMCs which are 30 Kms in distance on an average from the Bhalia producing villages does not guarantee the farmers an assured and desired price for their product. According to farmers in Pachham, the trading associations and form an informal cartel to set the price for the product for a particular season. Hence, they are discouraged to visit APMCs. Only marginal and small farmers sell their product for the poor price because by March end they would be desperate to have hard cash in hand to fulfil their domestic obligations or to repay the loans. A farmer, who is also a trader, however does not approve about this allegation as he feels this is not practically possible because there are so many traders at the auction, and not all of them could be united to carry out such manipulation, this paves a way for some other traders quoting a higher price. But during the trading season in February- March 2018, the price range in the APMCs of Bhavla ranged from Rs.320 to 400. Nearly 90 per cent of the farmers got price in this range and the remaining got more than Rs. 400. While some farmers decided to offload their harvest at the price quoted by the traders, some of the farmers did not sell their product and took it back with them which is a huge cost for the farmers. However, other issues like lack of storage facility in the villages to bank on to wait until they get a good price determine the farmers to choose the traders wishing to collect their produce from their fields.

4. FUTURE OF BHALIA WHEAT

The scientists at Agriculture University, Anand agreed that the Narmada canal has changed the scenario of agriculture in Gujarat as 60 per cent of the land has been converted into irrigated land which earlier was rain fed. They observed that, volume of Bhalia wheat grown entirely on rain water in the region has decreased a lot. However, the farmers explained that irrigating the land consecutively for more than three years will decrease the quality of soil to such an extent that soil becomes useless for agriculture in the subsequent season, hence, they have to discontinue using irrigation after a couple of years. When asked how they know about this, the farmers explained that, they have observed the experience of their neighbouring villagers where Narmada water through canal has already reached, so they could come to conclusion that to preserve the quality of their farm land, they have to follow the traditional techniques.

On prospects of retaining traditional method of Bhalia wheat cultivation, the farmers sounded optimistic of doing well in future if government intervenes. They expect the government to come up with the incentives to the farmers in the form of extending better prices than other crops grown in the region. This is not only for maintaining the organic qualities of the land that are required for growing Bhalia but also for cultivating the crop the way it has to be. This would provide a much needed assurance to the farmers to stick to its cultivation even if their region starts receiving irrigation facility. This was reflected in vociferous contention that was common among all the stakeholders.

When asked about specific support, the government can provide to Bhalia farmers, a farmer in Gamph expects the government to intervene and set up a special board for Bhalia wheat. The objectives of the Board should be to include buying the stock directly from the farmers by paying a suitable price. If quality strictures are laid and price is assured, he sees no reason for the farmers to cheat on the method of production instead they would stick to the traditional variety and traditional form of cultivation. He suggested above measure in the wake of irrigation reaching them. Besides, a common demand coming from all the farmers involved in Bhalia wheat cultivation was construction of warehouses in each village or gram panchayat. According to the scientists at Krishi Vigyan Kendra, Arnej, promoting contract farming and establishing co-operatives will act as encouragement to the farmers to continue with Bhalia cultivation.

²³⁹ Reported in Sandesh on 7th April. 2018.

Minimum Support Price (MSP) is another important area that requires an urgent look-in from the government according to a mill owner based in Khambat. It is because; least respect is shown for following MSP during auction while buying not only Bhalia wheat but other agriculture products too. The traders offer prices below MSP on the pretext of lower quality of the grain. Hence, he recommends, the Food Corporation of India (FCI) to intervene and buy the entire stock when the prices go below MSP. In reality, one cannot find the representatives from the corporation when auctions are in the process. However, the official at District Agriculture Office in Ahmedabad was of the opinion that, MSP concept does not work for sustaining the endangered variety of crops like Bhalia wheat.

On insurance, none of the farmers spoken to were not highly impressed with the present mechanism as the insurance process and premium is decided by the banks, that too when loans are taken through them, hence, they want government to come up with sound policy. One farmer thought, the insurance on the lines of 'life insurance policy' would help farmers in improving their economic lives and provides much needed psychological security.

An interesting theory was presented by a taluka official of agriculture office on the future of Bhalia, his observation was that, the variety of Bhalia may not remain same over a period of time because there is strong chance of it getting pollinated because lot of other variety is grown around in the region, he doesn't see this problem affecting kesar mango because the area exclusively grows same variety in the region. Besides, in case of mango, the tree remains useful for 15-20 years.

Future of Agriculture

A farmer with good educational background in one of the FGDs opined that, if the government does not come up with special policy to address farmer's concerns like availing better prices for all the products, the agriculture sector could go down to an unprecedented low. He was not interested particularly with Bhalia wheat and it being registered as GI, he was concerned about the plight of farmers in general and feared that, very soon the members in the villages will move to the cities leaving agriculture activity altogether. He finds it difficult to carry on with farming given the poor market price, labour problem and interestingly society per se becoming indifferent towards looking at the farmers in terms of social status. Many examples are recorded during the FGD where farmers have given account of how their brethren's are abandoning agriculture for assured jobs that they get in the pharmaceutical companies that have come up nearby Ahmedabad. It is different issue that the salaries they get are meagre. Some of the bigger farmers especially belonging to Patel community are said to have selling good chunk of their land to buy flats in Ahmedabad to see their children educated in good schools and colleges so as to prepare them for better life than theirs as farmers.

Geographical Indication (GI)

When the farmers in the FGDs and the local agriculture officials in the villages visited for the study alike were enquired about GI, not a single respondent among them acknowledged to have heard about it before us introducing about it. It appeared that neither Agriculture University nor agriculture department have ever apprised about GI to the farmers in the Bhalia growing belt. The top most retailer in Ahmedabad too was found to be totally unaware of GI. On explaining its importance, he opined that, farmers go only by price factor and it determines their choice of crop they would cultivate. The owner of the online dealer in organic products had learnt about GI very recently when they exhibited Bhalia wheat along with other organic products they sell at a University in Ahmedabad.

However, more than half of the respondents were aware of organic farming and use of its logo. When the staffs working at Research Centre, Arnej were queried about GI, they agreed they have knowledge about it to the extent that, application process was underway, but it was surprising to learn from them that, they had no idea about its registry which had happened long back in 2009 itself. However, they opined that until the government comes up with wide publicity to create awareness among the masses, the benefits of GI will not reach the farmers and consumers alike. They pointed to lack of authority and institutional set-up devoted exclusively for its implementation. On asking, which department would be ideal to take GI implementation effectively, they thought Gujarat Agro Industries Corporation Limited (GAIC) as the nodal agency, should take initiatives for implementation of the GI. They are the agency at the state level which can take all the required responsibilities viz. organizing training programs, creating farmer's associations, overseeing code of practices and marketing. A senior scientist at the office of Directorate of Agriculture was hopeful of GI recognition helping the Bhalia farmers in the future if awareness is effectively created extensively including consumers. Spreading awareness will also increase the market and the continuous demand for the unique wheat will incentivise the farmers to continue cultivation. If adequate measures are not taken, the area will reduce drastically as only farmers who want this wheat for their self-consumption would cultivate it.

5. CONCLUSION

The results of the study illustrates that the production of Bhalia wheat is unique because it is grown exclusively on rain fed water. The 'bhal region' is only one of its kinds in the World, renowned for its uniqueness including its nutritional values. There are committed consumers of the product in and around the bhal producing region. However, the production of Bhalia wheat is gradually coming down since last decade for the reason that the famous bhal region is now receiving irrigation facility as canal water is slowly reaching the area. This is encouraging the traditional bhal wheat cultivators to move to other crops that fetch them lucrative prices. Besides, they get to grow those crops more than once in a year. In case of Bhalia wheat, it can be grown only once. This is again determined by how the monsoon has been in that particular year. Yet, the traditional Bhalia wheat cultivators are optimistic of doing well in future if government intervenes. They expect the government to come up with the incentives for the farmers in the form of extending better prices than other crops grown in the region. This is not only for maintaining the organic qualities of the land that are required for growing

Bhalia but also for cultivating the crop the way it has to be. This would provide a much needed assurance to the farmers to stick to its cultivation even if their region starts receiving irrigation facility. Besides, GI supporting institutions needs to be set-up strategically to help the farmers to promote a sense of regional pride and identity about the product and also to enhance a wide market for the product. It could be done by setting up a separate arena for Bhalia wheat at APMCs and facilitate them with all the required support to market their produce by using the GI logo and boost the marketability of Bhalia wheat. For this to happen on ground, the active and collective efforts of the farmers is equally important. Towards achieving this goal, they can form an organisation of their own which will give them the bargaining power to determine the price for their product. GAIC too can play its role in achieving common as a party for having GI registry in its name. All this exercise will ultimately boost the local economy by attracting the local populace to involve in the value chain of the product.

1615 MEASURING THE CONNECTION BETWEEN CITIES' AND COMPANIES' COMPETITIVENESS - A HUNGARIAN CASE STUDY

Veronika Poreisz

Assistant lecturer of Széchenyi István University, Hungary, PHD candidate in Doctoral School in Regional-and Economic Sciences, e-mail: poreisz@sze.hu

ABSTRACT

The main goal of the study is to examine the connection between corporate and territorial competitiveness. Despite the competitiveness of companies and competitiveness of cities are widely investigated topics, the common aspects of them are less researched area. The current study is a small part of a bigger research project and focuses only on economic competitiveness, the connection between location and financial performance and the concentration of companies by labour and revenue. In the literature review, we take the main research directions of companies' and cities competitiveness. Most of the studies distinguish competitiveness into territorial (country, region, city) and economic (industry, corporate) levels. The starting point for corporate competitiveness research can be several, as detailed in the relevant literature chapter: management, financial, export-import, industrial level and company level approach. Territorial competitiveness is strongly connected to the model of territorial capital (Camagni 2008). Territorial competitiveness studies usually do not dispute the role of individual companies in the region, complex indexes and studies often have a separate economic (or even enterprise) dimension. In our study, we distinguished many approaches to spatial aspects of companies' research. A possible grouping criterion is the starting-point, the distribution according to the subject of the test (orientation). These research can be started from companies or a given area unit. The first main group (the starting point for companies) examines the location of companies. Another main group of orientation researches starts from the unit of territory, examines companies in the given region, sector or size category. The empirical part of the study focuses on Hungarian regional centres (eight cities) and investigates how the companies performance effects on their territorial competitiveness. Examining the spatial aspects of companies' competitiveness and the companies' role in urban success is important not only for the Hungarian level but also for international researchers due to the methodology. Using city level and company level data in order to analyse the connection between company performance and spatial location is a new aspect of our empirical research. The paper investigates the financial performance of companies, how it affects the competitiveness of the city and examines if the profitability has spatial patterns. Indexes of financial position, liquidity, profitability and performance (for example ROA, ROE, financial ratios) were calculated from company-level data. City level data were stood for describing the education dimensions of the labour market, demography, infrastructural and natural environment and the economic system. The research investigated the concentration of significant companies in given cities by revenue and labour and findings are displayed by Lorenz-curves. We distinguished two groups of them: one dominant company, which provides most of the employment and revenue and 5-6 dominant companies. Overall, there is a large inequality in companies' revenue and employment in all cities, the differences in revenues are more significant. In two cities the revenue and employment concentrate to one-one large automotive company (Audi and Mercedes) which determines the economy of the region and city. Findings indicate the obvious connection between companies' and cities' competitiveness but is hard to measure. In addition, we have analysed the effect of multinational manufacturing companies on the regional centres' economy.

The appearance of this publication is supported by the following projects: „Internationalization, initiatives to establish a new source of researchers and graduates, and development of knowledge and technology transfer as instruments of intelligent specializations at Szechenyi Istvan University EFOP-3.6.1-16-2016-00017” and EFOP-3.4.3-16-2016.

1 THE CONNECTION BETWEEN CORPORATE AND URBAN COMPETITIVENESS

1.1 Territorial competitiveness and territorial capital

Territorial competitiveness researches (at regional or city level) and the concept of territorial capital have a lot in common. Both topics investigates economic, social and environmental dimensions with complex indexes. The theory of competitiveness and the model of territorial capital based on regional growth and regional resources, but the territorial capital integrates the elements into a theoretical concept which involves not only classical capital and resources (for example labour or capital) but also immaterial assets too. The following dimensions are most often used for investigating competitiveness and territorial capital:

- economic
- environmental
- infrastructural
- cultural
- connections
- innovation
- social
- demographic

Regional competitiveness depends on developing immaterial resources, in particular, knowledge transfer. (Camagni 2009) Giffinger and Hamedinger (2009) associated the concept of territorial capital with the competitiveness of large cities and described how could be this concept the key element of competitiveness of metropolitan areas and regional cohesion. They determined the urban competitiveness not only with economic indicators, they extended it with the quality of life and socio-cultural dimensions. They highlighted that the most important competitive advantage based on creating immaterial assets like cooperation between economic actors. (Giffinger – Hamedinger, 2009)

It is often hard to distinguish territorial competitiveness and territorial capital. The differences beyond definitions are initial, the territorial capital is the sum of potentials of the given regions, while competitiveness is the ability for utilizing those potentials. Furthermore, territorial capital emphasizes immaterial assets, primarily social capital and relations, cooperation and innovations. The territorial competitiveness researches focus often on economic dimensions.

1.2 Competitiveness of cities

By measuring urban competitiveness, it is necessary to take into consideration the hierarchy of cities and the city-network, because only cities at the same level could be compared and ranked, for example, global cities, large cities, regional centres, small towns. The economic success of given cities can contribute to national competitiveness too. (Begg 1999.) The literature is extensive in urban competitiveness, there are studies determining competitiveness of cities in general (Kresl 1995, Jensen-Butler 1997, Kresl - Singh 1999, Lever 1999), while other studies focuses on cities of given region, for example developing Chinese cities (Shen, 2004, So - Shen 2004, Yu et. al. 2005) or industrial American metropolises (Markusen – Schrock 2006).

Kres (1995) determined six key elements of urban competitiveness: highly qualified labour, high wages, sustainability in operations, manufacturing attractive goods, economic growth, specialization and enhancing the position of city hierarchy. Urban competitiveness divides into two main components: economic (manufacturing and infrastructure) and strategic (policies, institutions).

The competitiveness of cities based on their rank in the national or international hierarchy, the infrastructure (transport and utilities), efficiency of government, the volume of R&D, the education system and human resources. (Jensen – Butler 1997)

The definition of urban competitiveness is more than national competitiveness (because of the inequalities and differences within countries) or corporate competitiveness (because multinational companies locate their operations to most cost-efficient sites). The competitiveness of cities can be measured by following indicators (Kresl – Singh 1999):

- enhancing the volume of retail: the indicator of growing population and wages
- the growth of added value by companies: investments, increase of employment, developing infrastructure
- increasing number of financial service providers

According to Lever (1999) the goals of urban competitiveness are investments, economic growth, increasing population, get subsidizations or permission for organizing events.

1.3 Competitiveness of companies

The studies of companies competitiveness are divided into four main topics:

- management aspects (company strategy, marketing, market share, culture)
- financial aspects (corporate finances indexes, profitability rates)
- export-import aspects
- industrial studies

The current study focuses on financial aspects of companies competitiveness.

According to Ballantine et. al (1988) companies compete in order to enhance profitability. Neoclassical economics determines that companies want to maximize their profit in a competitive environment. The profit or loss means the performance in competition for companies. There is a relationship between company size and profitability. Ballantine et. al (1988) measured the profitability with Return on equity (Roe) and Return on Sales (ROS) indexes in two different approaches:

- between industries: profitability and sales revenue correlate with the industrial correlation (or dominance of a large company).
- within industries: company size correlate with profit or loss

Chowdhury and Chowdhury (2010) investigated the effect of capital structure on companies' value in Bangladesh between 1996 and 2003. Their data based on financial reports, the dependent variable was the rate of shares, independent variables were company size, profitability, owners' structure, efficiency, growth rate and liquidity.

Grabowska (2014) investigated the added value and competitive ranking by corporations using the sales revenue, added value and rate of capital. Jasiniak and Pastusiak (2014) measured the effect of owners' structure on profitability. Katits and Szalka (2014) investigated the Hungarian TOP 100 companies' profitability, growing paths and effectiveness using profitability rates, profit and cash analyses, liquidity and other financial ratios of statements.

1.4. The companies approach of territorial competitiveness

The two different topics, territorial competitiveness and companies' competitiveness have a common section. Territorial – corporate literature can be distinguished, in one hand there are studies based on companies and investigate the spatial patterns of them, in the other hand, other studies are based on spatial units (national, regional or city level) and describe the characteristics of them by companies' performance. (Poreisz 2017)

Holl (2014) investigated the connection between location, accessibility and performance of Spanish companies. The study used spatial data (population, population density, infrastructure) and company level data from financial reports. The research found a significant correlation between companies' performance and spatial characteristics (for example transport accessibility). The market performance was correlated stronger to companies' efficiency than population data.

Floros et.al (2014) investigated the differences in economic performance of companies in Greece using company level data (size, export) and regional and industry level data.

Ketelhöhn and Quintanilla (2012) investigated the country effect on company performance by Central-American countries. The basis of their research was the resource-based theory, that the company performance is defined by the variety of resource. They used ROA (Return on Assets) for measuring profitability and found significant differences in companies performance between countries.

Kottaridi and Lioukas (2011) researched the location of companies in the approach of financial and corporate strategic approach with the following four group of indicators:

- corporate strategy: technology, functions (operation, marketing), relational capital
- corporate finances: liquidity, the ratio of debts, growth, profitability, export
- regional characteristics: R&D, higher education, regional GDP
- control variables: company size, industry

They found a significant correlation between regional characteristics, corporate relations and location (metropolitan region or periphery). Furthermore, empirical data indicated that strategy, financial strategy and growth rate effects also on location.

Stavropoulos and Skuras (2015) investigated 15 EU countries' 410 company in order to describe the effect of the location, the region on the company performance. Data were based on profitability indexes and employment data in 2005. Profitability was measured by indexes of ROA, profit, EBIT (earnings before interest and taxes), liquidity and solvency indexes, total assets, current assets, and the age and size of a company. The study ascertained that regional differences do not explain significantly the companies' performance. They concluded that regional characteristics do not or partly explain the companies' performance, furthermore, the regional industrial specialization was found as low impact determinant.

With regard to the subject of the research, it can be distinguished two main group of territorial – corporate studies (Poreisz 2017):

- Investigating the effect of the location (Kipnis 1982, Taylor 1993, O'Farrell – Hitchens – Moffat 1993, Bagchi-sen, – Macpherson 1999, Carlin et. al. 2001, Geishecker – Görg – Taglioni 2009, Mion - Naticchioni 2013)
- Measuring industry concentration, productivity and competitiveness (Costa-Campi – Viladecans-Marsal 1999, Hernandez-Sancho et. al. 2012, Taegeun – Kabsung – Hyejin 2012, Drucker 2011, Ducker – Feser 2012)

The used methods can be divided into two main groups: Descriptive statistics and relationship analysis (mainly when examining the impact of the location) as well as multivariable statistical analysis methods such as factor analysis or regression model. The most commonly used indicators are (Poreisz 2017):

- corporate operating data: site, size of the company, the number of employees, industry
- corporate financial data: revenue, wage costs, export sales, tangible assets/wage /operating income
- corporate strategy data: innovation, international relations, market strategy, R&D, export
- regional data: R&D, GDP, employment, unemployment, population density, industry concentration.

2. DATABASE AND METHODOLOGY

The main research question of the study was that how the location effects on the company performance. We investigated eight Hungarian large cities (regional centres) between 2010 – 2013.

The database consists of regional level data and company level data based on financial reports. Company level data were provided by Opten Kft. In the current study, we investigated the characteristics by revenue, employment, industrial concentration and performance of companies with more than 50 employees in the 8 cities in 2013.

Concentration in employment and revenue were measured by Lorenz – curve. The method is traditionally used for measuring the distribution of income or wealth but it is adaptable for measuring inequalities and concentration in other areas. The methodology indicates the ranking of the values (employment, revenue) and producing the cumulative relative percentage of the investigated values. The graphical representation (a square) of the cumulative percentage of employment/revenue (vertical axis) by cumulative percentage of companies (horizontal axis) shows the inequalities.

The diagonal of the square represents the total equality, and the curves below the diagonal indicate the degree of concentration.

Table 1: The number of companies over 50 employees in database

	2010	2011	2012	2013
<i>Debrecen</i>	131	134	136	136
<i>Szeged</i>	89	98	92	85
<i>Miskolc</i>	73	78	86	76
<i>Pécs</i>	80	70	68	64
<i>Győr</i>	106	121	123	117
<i>Nyíregyháza</i>	71	72	73	70
<i>Kecskemét</i>	75	75	79	78
<i>Székesfehérvár</i>	77	82	85	86

Source: own calculation, data: Opten

The connection between corporate profitability and location was measured by Variance-analysis. We researched the differences between cities by corporate performance, profitability, efficiency and finances and calculated for the four years of investigated period 2010 – 2013. Independent variable was the location, dependent variables were the financial indexes. Variance-analysis is a multidimensional method for investigating the differences between the means of independent variables. The calculated financial indexes were the followings:

- Amount of total assets and capital
- The ratio of export revenue
- Debts/equity ratio, the growth of capital, provision of fix assets
- Liquidity rates, debts ratio
- Profitability rates: ROS, ROE, ROA
- Added value, wage efficiency, assets efficiency, capital efficiency

3. EMPIRICAL FINDINGS

3.1. Measuring of concentration

We illustrated the Lorenz – curves for the investigated eight cities and distinguished two groups of them:

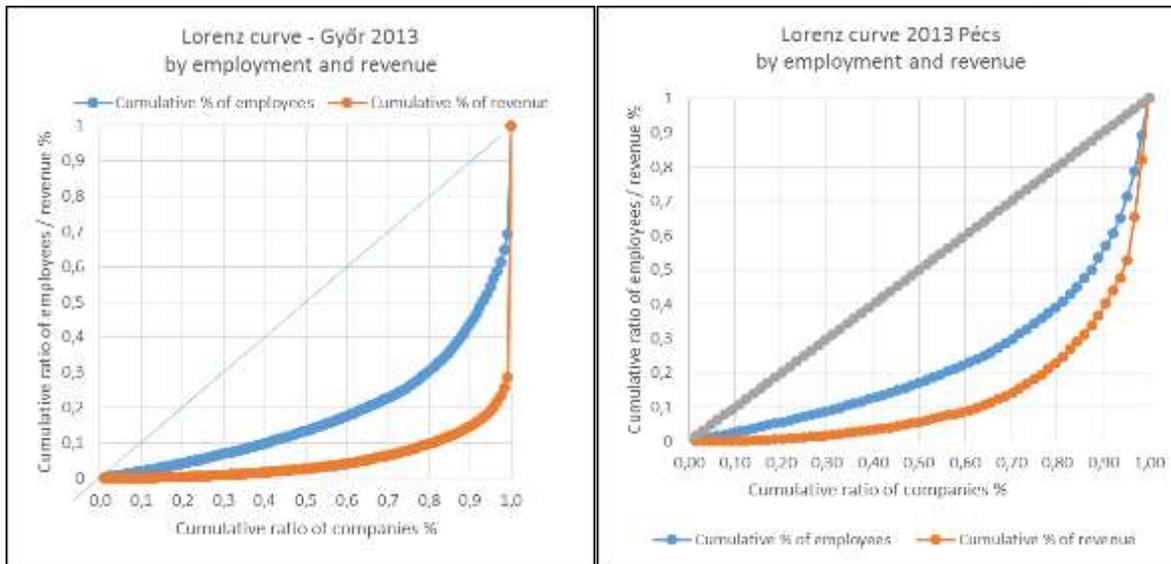

- cities with one dominant company, which provides most of the employment and revenue: Győr, Kecskemét (these cities have significant automotive industry)
- cities with 5-6 dominant companies.

Overall, there is a large inequality in companies' revenue and employment in all cities, the differences in revenues are more significant.

In Győr and Kecskemét the revenue and employment concentrate to one-one large automotive company (Audi and Mercedes) which determines the economy of the region and city. In Győr, Audi provides the 70% of total income and 30% of total employment. The half of the other, small companies give barely 5% of total revenue and 10% of employment. The 80% of companies give 10% of the total revenues and 30% of employment. This shows, how strongly concentrated the industry of Győr is. The structure of the companies in Kecskemét is similar to Győr, it is dominated by one automotive company, Mercedes, which gives the 60% of total revenue and 20% of employment. But in this city more than 80% of companies provide the 60% of employment, the dispersion of companies in the upper two deciles is favourable. Nyíregyháza has fewer inequalities by the upper 20% of companies, the half of the revenue is produced by the 5-6 company, but the 60% of total employment provides one large company.

The Lorenz – curves of the other cities with 5-6 dominant companies are similar to each other by revenue and employment too. The inequalities are higher by revenue in all cities. Only Szeged differs from the others, because concentration by employment is significantly lower, even so, it is extremely high by revenue. The industrial structure with smaller, mainly agricultural or food industry and energy industry companies explain the differences. (Figure 1)

Figure 1: Lorenz – curves of cities with one dominant company and 5-6 large companies

Source: own calculation, data: Opten Kft.

3.2. Variance – analysis

Data were most of the cases not applicable for Variance – analysis (the significance level of Levene statistics were lower than the expectable 0,05). By the cases, where the Levene statistics were acceptable, we found a significant connection with location and in 2010 for ROA and in 2012 for ROS. We can say that company location affected accidentally on companies' profitability on the investigated database.

4. CONCLUSION

The first part of the study reviewed the relevant literature of territorial competitiveness, the territorial capital, companies' competitiveness and the urban competitiveness. We focused on the common segment of them and described the most relevant studies on the topic of territorial and corporate competitiveness. Theoretically, it is proofed, that there is a connection between the companies' location and performance due to the territorial capital elements (immaterial assets like relations) and the vice-versa effect of companies and their region.

In the empirical part, we investigated the characteristics of Hungarian regional centres by economic competitiveness through the concentration of companies' employment and revenue. We distinguished two different groups of cities, one of them has a dominant company which rules the economic sphere of the city, the other group of cities have 5-6 large, significant companies. The cities with one dominant company are Győr and Kecskemét, the locations of two large multinational automotive company (Audi, Mercedes).

We investigated the correlation between company location and financial performance with Variance-analysis. We can say that the researched level of cities does not show significant differences by the financial performance of their companies. We can conclude that the Hungarian companies located in Hungarian regional centres are similar to each other by their profitability, liquidity and efficiency. Further researches are indicated, it is necessary to investigate, how the companies performance differ by automotive and non-automotive industry regions.

1735 FOREIGN DIRECT INVESTMENT AND INDUSTRIAL AGGLOMERATION: EVIDENCE FROM INDIA

ABSTRACT

Unevenness in the geographical distribution of economic activity is a persistent feature of all economies. The subject matter of economic geography since its inception tried to explain this unevenness. Differences in natural endowments and labour pool, scale economies are often cited by the previous studies to explain agglomeration of economic activity. More recently Foreign Direct Investment (FDI) is considered as a plausible factor to explain the concentration of industries (Ge, 2009; Gao, 2002; Zhang et al, 2014). It is evident from the empirical works that the unevenness persistent in the geographical distribution of economic activity is also observed in the distribution of Foreign Direct Investment (Guimaraes et al, 2000; Chung

RS06.5. Location of Economic Activity

1550 FOREST ACCOUNTING REGIONAL SUSTAINABILITY

Parashram Jakappa Patil, Debasis Patnaik

ABSTRACT

Forest accounting is having direct input to ecological ecosystem sustainability in various way such as (1) reducing loss of biodiversity. (2) Mitigate inflated economic production figures. (3) Enable value chain and supply chain accounting starting with net forest produce. (4) Enable Gross National Happiness –GNH calculation that is dependent on forest living and environmental standards. (5) Enable balanced economic growth keeping future economic concerns. (6) Enable balance in regional economic diversity. (7) Safeguard biodiversity (both plant and animal). (8) Assess tradeoff between agriculture and environment preservation exercises (9) assess nature of food safety networks based on area specific nutrition availability and bring economic measures for balanced nutrition in regions. (10) Cause rational international economic and diplomacy dialogues based on hard data. (11) Measure economic sustainability. However, following are the specific objectives of present research work: The present study is explorative study on sustainability through developing forest accounting system. Essential data has been collected to find out present nexus.

Key Word: Forest Accounting, Forest Ecosystem Services, Bio- Economics.

INTRODUCTION

Global concern about forest degradation and depletion is related to two main problems i.e. destruction of the carbon sinks affecting the global climate and extinction of species affecting the biodiversity.

STATEMENT OF THE PROBLEM

Forest accounting has dimension having various ecological classification and its invisible services of an ecosystem which is not valued in economic terms. Hence it is very difficult to establish scientific forest accounting system. Segregation and understanding of each forest accounting component are inevitable. Making an analysis of forest accounting cycle would provide a better understanding of forest accounting. Forest accounting is having direct input to ecological ecosystem sustainability in various way such as (1) reducing loss of biodiversity. (2) Mitigate inflated economic production figures. (3) Enable value chain and supply chain accounting starting with net forest produce. (4) Enable Gross National Happiness –GNH calculation that is dependent on forest living and environmental standards. (5) Enable balanced economic growth keeping future economic concerns. (6) Enable balance in regional economic diversity. (7) Safeguard biodiversity (both plant and animal). (8) Assess tradeoff between agriculture and environment preservation exercises (9) assess nature of food safety networks based on area specific nutrition availability and bring economic measures for balanced nutrition in regions. (10) Cause rational international economic and diplomacy dialogues based on hard data. (11) Measure economic sustainability. It has potential of regional sustainability which need to be assess scientifically.

REVIEW OF LITERATURE

Jianguo, Liu (2013) in his study explain the telecoupling process in chine's forest and its implication on forest sustainability. **Knut H. Alfsen (1993)** in his study he has been analyzed structure of natural resources accounting of Norway. **Elsa Varela and Jose Miguel Barrios (2014)** they have studied framework of forest accounts, general structure of forest accounts and assets flow accounts. **William N. Mkanta (2002)** in his research he has made valuation of non-marketed forest products.

OBJECTIVES OF THE STUDY

The specific objectives of the study are as follows;

1. To explore relationship between forest accounting and sustainability.
2. To develop theoretical modeling of sustainability and
3. To study case study of forest asset and regional sustainability.

PREPOSITION

1. Forest resources has potential to make regional sustainability.

RESEARCH METHODOLOGY

The present study is a theoretical analysis of various components of forest accounting. It has been done an extensive review of literature for making an analysis of a forest accounting system. Also, it has been taken into consideration of various concepts related to forest economics. It has examined earlier studies on forest accounting in order to explore various aspects of it, supports to understand inter-linkages between various factors while making a theoretical analysis of forest accounting and regional sustainability. Present study is based on secondary sources of data it has collected from various sources. The present research is a case study of one of the forest rich districts in India i.e. Kolhapur district forest. This district is situated in Western Ghaat which is one of the mega biodiversity hubs in the world.

ECOLOGICAL ANALYSIS OF FOREST ACCOUNTING

The value of the forest depends on its ecological characteristics and therefore, while making forest accounting ecological classification is significant. The Ecological land classification is a cartographical delineation or regionalization of

distinct ecological areas, identified by their geology, topography, soils, vegetation, climate conditions, living species, habitats, water resources, and sometimes also anthropic factors. However Forest Ecology is the scientific study of the interrelated patterns, processes, flora. Fauna and ecosystems in forests. The management of forests is known as forestry, silviculture, and forest management. A forest ecosystem is a natural woodland unit consisting of all plants, animals and micro-organisms (Biotic components) in that area functioning together with all of the non-living physical (abiotic) factors of the environment. The forest ecosystem is very important. Following is the forest ecological classification of Kolhapur district.

Trees: It has been in existence for 370 million years. In botany, a tree is a perennial plant with an elongated stem, or trunk, supporting branches and leaves in most species. In some usages, the definition of a tree may be narrower, including only woody plants with secondary growth, plants that are used as lumber or plants above a specified height. Trees are not a taxonomic group, but include a variety of plant species that have independently evolved a woody trunk and branches as a way to tower above other plants to compete for sunlight. In looser senses, the tall palms, the tree ferns, bananas and bamboos are also trees. Trees tend to be long-lived, some reaching several thousand years old.

Table 1 Trees in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Ain/Sadada	Terminalia tomentosa
	Alu	Vangueria spinosa
	Amba	Mangifera indica
	Ambada	Spondias mangifera
	Amberi	Nothopegia colebrookiana
	Ambat	Embelia basaal
	Anjani	edule
	Apta	Bauhinia racemosa
	Asana, Katak	Bridelia retusa
	Awala/Aonla	Emblica officinalis
	Arjun	Terminalia arjuna
	Akash neem	Millingtonia hortensis
	Bartondi	Morinda tinctoria
	Bakul	Mimusops elengi
	Bel	Aegle marmelos
	Bhendi	Thespesia populnea
	Bherli Mad	Caryota urens
	Bhokar	Cordia myxa
	Bhoma	Glochidion lanceolarium
	Bibla/Bija	Petrocarpus supium
	Biba/Bilva	Semecarpus anacardium
	Bibi/Ran/biba	Holigarna grahamii
	Bor	Zizyphus jujube
	Bulgi	Vitex altissima
	Babhul	Acacia Arabica

Source: Forest Department of Kolhapur District.

The table 1 shows that the Kolhapur district is reached by diversified trees at large number. There are various kinds of trees are available in forests in Kolhapur district. It increases prospects of forests. Therefore, it is important to protect them. Species of the tress are influenced forest monetary value that become basis for the forest accounting.

Shrubs: A shrub is an important component of forests. It is a small to medium-sized woody plant. It is distinguished from a tree by its multiple stems and short height. Plants of many species may grow either into shrubs or trees, depending on their growing conditions.

Table 2 Shrubs in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Adulsa	Adhatoda vasica
	Ankul/Ankol	Strobilanthes heyneanus
	Bedki/Gudmari	Alangium salvifolium
	Bhamani	Gymnema sylvestre
	Bhandira	Colebrookea oppositifolia
	Bhandira	Clerodendrum infortunatum
	Bharati/Hekal	Gymnosporia Montana
	Bohkada /Charbati/Kirmira	Casearia graveolens
	Bugdi	Ardisia humilis
	Bukra	Strobilanthes sessilis
	Dinda/Motha Dinda	Leea sambucina
	Dhaiti/Dhayati	Leea macrophylla
	Hesur	Woodfordia fruticosa

Source: Forest Department of Kolhapur District

The Table 2 shows that there are various species of shrubs are available in the Kolhapur district forest. It is providing very valuable input to society. These all shrubs has its contribution in forest economy. There is need to take that monetary contribution in forest accounting of the district.

Climbers: The climbing plant is vital in forest ecology. The Climbing plants are plants which climb up trees and other tall objects. Many of them are vines whose stems twine round trees and branches. There are quite a number of other methods of climbing.

Table 3 Climbers in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Alei	Dalbergia volubilis
	Amgul	Elaeagnus latifolia
	Bhui Kohola/Vidari Kand	Ipomaea digitata
	Cane	Calamus pseudotenuis
	Chambuli	Bauhinia vahlii
	Chickni	Bridelia stipularis
	Chillari	Caesalpinia mimosoides
	Garambi/Gardal	Entada scandens
	Ghotvel/Chopchini	Smilax zeylanica
	Gunj	Abrus precatorius
	Jungali miree	Piper hookeri
	Kajarvel	Strychnos colubrina
	Kanheri/Borati/Burgi	Zizyphus oenoplia
	Vilayati vakundi	Cryptolepis grandiflous
	Kali vel/Jungali Kajorne	Vitis auriculata
	Kavali	Cryptolepis buchanarous
	Khaj Kuhili	Mucuna pruriens

Source: Forest Department of Kolhapur District.

Table 3 shows that there are no of climbing plants available in Kolhapur district. Along with environmental there are commercial importance of such plants such as use in gardening and horticulture. It's a valuable addition in forest economics of the district.

Bamboos: The Bamboos are the significant crop of the agro forestry economy. It has notable economic and cultural significance in society being used for building material, as a food source, and as a versatile raw product. It has a higher specific compressive strength than wood, brick, or concrete and a specific tensile strength that rivals steel.

Table 4 Bamboos in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Chiwa/Huda/Chiwan	Oxytenanthera monostigma/ Pseudoxytenanthera ritcheyi
	Kalak/Padai/Mandgay/Velu/Kanak	Bambusa bambos
	Konda/Managa/Chiwari/Mes	Oxytenanthera stocksii/ Pseudoxytenanthera stocksii
	Shi/Udha/Medar	Dendrocalamus strictus

Source: Forest Department of Kolhapur District.

Table 4 indicates that there are total 4 kinds of Bamboos species available in the forest of Kolhapur district. The Bamboos have important commercial uses, such as culinary, medicine, constructions, weapons, food, textiles, and musical instruments etc. The commercial value of such inputs enriches the forest accounting at large extent.

Grasses: It means a low, green plant that grows naturally over a lot of the earth's surface having groups of very thin leaves that grow close together in large numbers (Oxford dictionary). It is a very common plant consisting of a large number of thin, spiky, green leaves that cover the surface of the ground.

Table 5 Grasses in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Anjan	Cenchrus ciliaris
	Bhalekusal	Andropogon triticicus
	Bhongrut	Themeda quadrivalvis
	Boru	Sorghum halepense
	Burghushi	Eragrostis tenella
	Chikra	Eragrostis tremula
	Chigan chara	Panicum prostratum
	Dongari gawat	Crysopogon Montana
	Gondal	Andropogon pumils
	Haryali/doob	Cynodon dactylon
	Kunda	Ischoemum pilosum
	Kusali	Heteropogon contortus
	Marvel	Dichanthium annulatum

	Natgras	Cyprus rotundus
	Nilgawat	Panicum antidotale
	Phuli/Kodmor	Apluda varia
	Phulera	Themeda ciliate
	Pandhari Kusal	Aristida paniculata
	Sheda	Sehima nervosum
	Pavana	Sehima sulcatum
	Rosha/Tokhadi	Cymbopogon martinl
	Shimpi	Panicum isachne
	Vala	Andropogon muricatus
	Wavashi	Saccharum procerum

Source: Forest Department of Kolhapur District.

Table 5 shows that there are total 24 different species of grass available in the district. It is very helpful to mankind, agriculturally, economically and ecologically. It is an important source of food for man and animals both. Thus its contribution needs to measure in monetary value and include in forest accounting.

Medical Plants: The medical plants have been identified and used through in human history. It's part of culture and tradition for centuries. Plants make many chemical compounds that are for biological functions including defense against insects, fungi and herbivorous mammals. The medical plants have huge commercial benefits, it generates business out of it. Kolhapur district has numerous medical plants in its forests as follows.

Abrus precatorius, Abutilon indicum, Acacia concinna, Achyranthes aspera var, aspera, Acorus calamus, Adansonia digitata, Aegle marmelos, Alangium salvifolium var, salvifolium, Alsaonia schloaris, Anacardium occidentale, Andrographis paniculata, Anogeissus latifolia, Artocarpus, heterophyllus, Asparagus racemosus var, javanica, Azadirachta indica, Bacopa monnieri, Balanites aegyptiaca, Baliospermum montanu, Biophytum sensitivum, Bixa Orellana, Boerhavia repens var diffusa, Bombax ceiba, Bombyx micranthus, Boswellia serrate, Bridelia retusa, Buchanania cochinchinensis, Butea monosperma, Caesalpinia bonduc, Calotropis gigantean, C. procera, Careya arborea, Cassia fistula, C. obtusifolia, C. tota, Catharanthus roseus, Celastrus paniculatus, Celosia argentea var, argentea, Centella asiatica, Colocasia esculenta, Convolvulus arvensis, Cordia dichotoma, C. gharaf, Costus speciosus, Crateva adansonii subsp, odora, Crossandra infudibuliformis, Cullen corylifolia, Cuminum cyminum, Curculigo orchioides, Cymbopogon citratus, Cynodon dactylon, Cyperus rotundus, subsp. Rotundus, Dendrophthoe falcate var, falcate, Dillenia indiaca, Dioscorea alata, D. bulbifera, Dodonea angustifolia, Dolichandrone falcate, Eclipata prostrate, Elaeagnus conferta, Embelia ribes, Emblica officinalis, Entada rheedei, Ficus amottiana, F. benghalensis, F. callosa, F. carica, F. racemosa, F. religiosa, Garcinia indiaca, Garuga pinnata, Gloriosa superba, Glossocardia bosvallea, Gmelina arborea, Gnidia glauca, Hedyotis herbacea, Helicteres isora, Heliotropium indicum, and others.

The identification and commercial valuation of medical plants provide the basis for forest accounting. The medical plants are a major component of forest economy. Its increase the monetary value of entire forest. In fact, there are certain forests are kept only for medical plants. Therefore collecting information of medical plants, analyzing it, interpreting it and recording it in monetary value is significant.

Mammals: The mammals include the largest animals on the planet, the great whales as well as some of the most intelligent such as elephants, primates and cetaceans.

Table 6 Mammals in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Bonnet Macaque	Macaca radiate
	Common Langur	Preshbytis entelhus
	Tiger	Panthera tigris
	Panther	Panthera pardus
	Leopard cat	Felis bengalensis
	Jungal cat	Felis chaus
	Desert cat	Felis libyca
	Small Indian Civet	Viverricula indica
	Common Plam civet	Paradoxurus hermaphroditus
	Common mongoose	Herpestes edwardsi
	Striped Hyena	Hyaena hyaena
	Wolf	Canis lupus
	Jackal	Canis aureus
	Indian Fox	Vulpes bengalensis
	Indian Wild Dog	Cuon alpinus
	Sloth bear	Melursus ursinus
	Common Otter	Lutra lutra
	Moles	Talpa micrura
	Indian Tree Shrew	Anathana ellioti
	Slender Loris	Loris tardigradus
	Flying Fox	Pteropus giganteus
	Fulvous Fruit-Bat	Rousettus leschenaulti

	Short-Nosed Fruit Bat	Cynopterus sphinx
	Indian Pipistrelle	Pipistellus coromandra
	Painted Bat	Krivoula picta

Source: Forest Department of Kolhapur District.

Table 6 shows that there are various species of mammals are available in the district. It has direct contribution in human society and economy. For instance domestic mammals form a large part of the livestock raised for meat across the world. It is commonly used in agriculture and allied activities. Forests is crucial component for existence of such mammals. The economic contribution of such mammals has linkages with forests.

Avifauna: The birds or the kinds of birds of a region, period or environment. In simple word birds of a specific region or period. Birds are essential elements of ecology.

Table 7 Avifauna in Kolhapur district

Sr. No.	Local Name	Botanical Name
	Little Grebe	Podiceps ruficollis
	Little Cormorant	Phalacrocoras niger
	Dater	Anhinga rufa
	Grey Heron	Ardea cinerea
	Purple Heron	Ardea purpurea
	Pond Heron	Ardea gravii
	Cattle Egret	Babulcus ibis
	Large Egret	Ardea alba
	Smaller Egret	Egretta intermedia
	Little Egret	Egretta garzetta
	Night Heron	Nycticoras nycticorax
	Little Bittern	Ixobrychus minutus
	Yellow Bittern	Ixobrychus sinensis
	Painted Stock	Mycteria leucocphala
	Openbill Stork	Anastomus oscitans
	Whitenecked Stock	Ciconia episcopus
	Lesser Adjutant	Leptptilos javanicus

Source: Forest Department of Kolhapur District.

Table 7 indicates that there are bird species available in the forest of Kolhapur district. Birds are providing very essential benefits to human beings such as food, business, pollination, fertility, pest control, rodent control, communication, company, and games, etc. Therefore the economic contribution of birds is vital and existence of birds depends on forests.

Crocodile: The Crocodiles (subfamily Crocodylinae) or true crocodiles are large aquatic reptiles that live throughout the tropics in Africa, Asia, the Americas and Australia.

Table 8 Crocodile in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Mugger	Crocodylus palustris

Source: Forest Department of Kolhapur District.

Table 8 shows that the crocodile is also found in forests in Kolhapur district. The Crocodiles play very important role in the river ecosystem to ensure that river. These invisible ecosystem services, in monetary value needs to be taken into consideration.

Herpetofauna: The reptiles and amphibians of a particular region, habitat, or geological period. The table 9 talks about Herepetoaua of Kolhur district.

Table 9 Herpetofauna in Kolhapur district

Sr. no	Local Name	Botical Name
1	Barhminy Wrom Snake	Ramphotyphlops braminus
2	Beaked Wrom Snake	Gryptotyphlops acutus
3	Large Scaled Shieldtail	Uropelepis macrolepis macrolepis
4	Indian Rock Python	Python molurus molurus
5	Common Sand Boa	Gongylophis conicus
6	Red Sand Boa	Eryx johnii
7	Common Trinket Snake	Coelusognath Helena Helena
8	Montane Trinket Snake	Coelusognath Helena monticollaris
9	Indian Rat Snake	Ptyas mucosa
10	Banded Racer	Argyrogena fasciolata

Source: Forest Department of Kolhapur District.

Table 9 reveals that there are different species available in the forest in Kolhapur district. It is an essential component of ecology and the food chain. They provide numerous invisible services to protection of the ecology.

Turtle: The Turtles are classified as amniotes, along with other reptiles, birds, and mammals. Like other amniotes, turtles breathe air and do not lay eggs underwater, although many species live in or around water.

Table 10 Turtle in Kolhapur district

Sr.No.	Local Name	Botanical Name
1	Black Turtle	Melanochelys trijuga
2	Indian Mud Turtle	Lissemys punctata
3	Brahminy River Turtle	Lissemys punctate punctata
4	Indian Flap-shell Turtle	Lissemys punctate granosa
5	Peninsular Flap-Shell Turtle	
6	Indian Soft Shell Turtle	Aspideretes ganeticus

Source: Forest Department of Kolhapur District.

Table 10 shows that there are total 6 species of turtle available in the Kolhapur district forest. Turtles play an important role in the ecology and well-being of coastal and open ocean environments. It is essential for a healthy ecosystem. It has biological, cultural and economic significance.

Gecko: The Geckos are lizards belonging to the infraorder Gekkota, found in warm climates throughout the world. Geckos are unique among lizards in their vocalizations.

Table 11 Gecko in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Northern House Gecko	Hemidactylus flaviviridis
2	Brook's Gecko	Hemidactylus brookii
3	Termite Hill Gecko	Hemidactylus triedrus
4	Rock Gecko	Hemidactylus maculatus

Source: Forest Department of Kolhapur District.

Table 11 shows that there are 4 species of Gecko available in the Kolhapur district forest. Geckos are reptiles with unique and interesting features and play an important role in maintaining a balanced ecosystem.

Agamids: The Agamidae is a family of over 300 species of iguanian lizards indigenous to Africa, Asia, Australia, and a few in Southern Europe. Many species are commonly called dragons or dragon lizards.

Table 12 Agamids in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Common Garden Lizard	Calotes versicolor
2	Forest Calotes	Calotes rouxi
3	Southern Green Calotes	Calotes calotes
4	Fan-throated Lizard	Sitana ponticeriana

Source: Forest Department of Kolhapur District.

Table 12 reveals that there are total 4 Agamids species found in Kolhapur forest. Agamids are important for ecosystem balance and its diversity.

Chameleons: Chameleons or chamaeleons (family Chamaeleonidae) are a distinctive and a highly specialized clade of old world lizards with 202 species described as of June 2015. These species come in a range of colors, and many species have the ability to change colors.

Table 13 Chameleons in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Indian Chameleon	Chamaeleon zeylanicus

Source: Forest Department of Kolhapur District.

In Kolhapur forest chameleons are also found. Chameleons are able to vary their coloration and pattern through combinations of pink, blue, red, orange, green, black, brown, light blue, yellow, turquoise, and purple. It is important features of nature's diversity.

Skinks: Skinks are lizards belonging to the family Scincidae and the infraorder scincomorpha. With more than 1,500 described species, the Scincidae is one of the most diverse families of lizards.

Table 14 Skinks in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Brahminy Skink	Mabuaya carinata
2	Little Skink	Mabuaya macularia
3	Snake Skink	Lygosoma punctatus

Source: Forest Department of Kolhapur District.

Table 14 shows that there skinks species also available in Kolhapur forest. Various species occur in ecosystems ranging from deserts and mountains to grasslands.

Monitor Lizard: Monitor lizard is the common name of several large lizard species, comprising the genus Varanus.

Table 15 Monitor Lizard in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Common Indian Monitor	Varanus bengalensis

Source: Forest Department of Kolhapur District.

Monitor lizards is useful. It is used for a variety of medical purposes. The flesh is eaten for the relief of rheumatic pain, abdominal fat is used as a salve for skin infections, oil and fat are used to treat hemorrhoids or chronic pain, and the oil is used as an aphrodesiac lubricant.

Toads: It is a common name applied to certain frogs, especially of the family Bufonidae that are characterized by dry, leathery skin, short legs, and parotoid glands.

Table 16 Toads in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Common Indian Toad	Bufo melanostictus
2	Marbled Toad	Bufo stomaticus

Source: Forest Department of Kolhapur District.

Toads are important to the ecology and to humans. Toads provide important values for ecosystems and for human beings ecologically, they are important in food chains. Toads also serve as indicators of environmental health.

Frogs: A frog is any member of a diverse and largely carnivorous group of short-bodied, tailless amphibians composing the order Anura.

Table 17 Frogs in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Bush Frog	Philautus sp
2	Common Tree Frog	Polypedates maculatus
3	Skittering Frog	Rana cyanophlyctis
4	Indian Pond Frog	Rarisna hexadactylus
5	Indian Bull Frog	Rana tigerina
6	Indian Cricket Frog	Rana limnocharis
7	Fungoid Frog	Rana malabarica
8	Bicoloured Frog	Rana curtipes
9	Golden Frog	Rana aurantiaca
10	Indian Burroowing Frog	Rana breviceps

Source: Forest Department of Kolhapur District.

Table 17 shows that there are total 10 species of Frogs available in Kolhapur district. The frogs provide essential benefit to human being such as medical advances, food, filter drinking water etc.

Butterflies: The butterfly is one of the most emblematic totem animals symbolizing personal transformation. Table 17 talks about different butterfly species in Kolhapur forest.

Table 17 Butterflies in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Twany Coaster	Acraea violae
2	Blue Tiger	Tirumal limniace exoticus
3	Common Crow	Eploea core core
4	Dark Blue Tiger	Tirumala septentrionis dravidarum
5	Glassy Blue Tiger	Parantica aglea aglea
6	Malabar Tree Nymph	Idea malabarica
7	Plain Tiger	Danaus chrisispsu chrisispsu
8	Banded Angle	Danaus genutia genutia
9	Brown Awi	Odontoptilum angulata angulata
10	Common Banded Awl	Badamia exclamationis
11	Common Spotted Flat	Hasora chromus chromus
12	Dark Palm Dart	Celaenorrhinus leucocera
13	Golden Angle	Telicota ancila bambusae
14	Indian Palm Bob	Caprona ransoneetta potiphera
15	Indian Skipper	Suastus gremius gremius
16	Malabar Flat	Spialia galba galba
17	Banded Blue Pierrot	Celaenorrhinus ambarreesa
18	Bright Bauul Blue	Discolampa ethion vavasanus

Source: Forest Department of Kolhapur District.

Table 18 reveals that there are total 75 various species of butterflies available in Kolhapur forest. Butterflies are indicators of a healthy environment and healthy ecosystems. Butterflies are an important element of the food chain and are prey for birds, bats and other insectivorous animals.

Moths: Moths comprise a group of insects, related to butterflies, belonging to the order Lepidoptera. Most lepidopteron are moths; and there are thought to be approximately 160,000 species of moth, many of which are yet to be described. Most species of moth are nocturnal, but there are also crepuscular and diurnal species. Table 18 belongs to the Moths of Kolhapur forest.

Table 18 Moths in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Moon Moth	-----
2	Owlet Moth	-----
3	Bee Hawk Moth	-----
4	Monkey Moth	-----
5	Atlas Moth	-----
6	Tussar Silk Moth	-----

Source: Forest Department of Kolhapur District.

Table 18 shows that 19 Kolhapur forest has 6 various species of moths. It is a major part of our biodiversity and play vital roles in the ecosystem, affecting many other types of wildlife.

Insects: Insects are a class of invertebrates within the arthropod phylum that have a chitinous exoskeleton, a three-part body (head, thorax and abdomen), three pairs of jointed legs, compound eyes and one pair of antennae. Table 19 related to Insects in Kolhapur district.

Table 20 Insects in Kolhapur district

11	Bombardial Bettle	-----
12	Long Horned Beetle	-----
13	Spittle Bug	-----

Source: Forest Department of Kolhapur District.

Table 20 shows that 13 species of insects are available in Kolhapur forest. Insects are very important as primary or secondary decomposers. Without insects to help break down and dispose of wastes, dead animals and plants would accumulate in our environment and it would be messy indeed. Insects are underappreciated for their role in the food web. Insects are important in nature to help keep pest populations (insects or weeds) at a tolerable level.

Arachnids: Arachnids are a class (Arachnida) of joint legged invertebrate animals (arthropods), in the subphylum Chelicerata. All arachnids have eight legs, although the front pair of legs in some species has converted to a sensory function, while in other species, different appendages can grow large enough to take on the appearance of extra pairs of legs. Table 20 belongs to Arachnids in Kolhapur district.

Table 21 Arachnids in Kolhapur district

Sr. No.	Local Name	Botanical Name
1	Scorpion	-----

8	Giant Wood Spider	-----
9	Black Wood Spider	-----

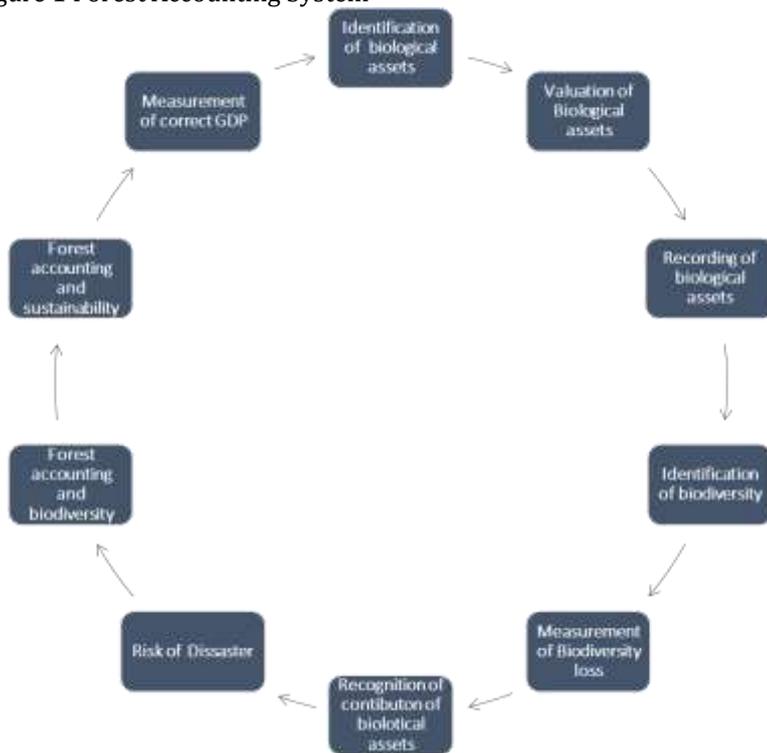

Source: Forest Department of Kolhapur District.

Table 22 reveals that there are totally 20 kind of species of Archinds are available in Kolhapur forest. The arachnids play an important role in limiting the size of other arthropod populations, especially insects. Some arachnids are pests, such as ticks and mites, but most are beneficial and should be protected.

FOREST ACCOUNTING SYSTEM

Forest Accounting provides a framework to capture the value of all economic contributions of forests and how they are linked to the economy (Making Waves, 2016). It does involve environmental accounting, physical accounting, monetary accounting and forest flow accounting of forest resources.

Figure 1 Forest Accounting System

Forest accounting cycle deal with forest capital (Forest capital refers to elements of forest that produce values directly and indirectly to people such as stock of trees, animals, goods and services etc). Forest accounting is given significant input in various ways, such as protecting biodiversity, sustainability, protection of ecosystems, livelihood, economic development, industry and trade, employment generation, reduction of biodiversity loss, a risk of disaster, the true measurement of economic development, and generating accurate data for policy makers etc.

Physical Resources Based Asset Accounts: Physical accounting refers to the natural resource and environmental accounting of stocks and changes in stocks in physical (non-monetary) units e.g. weight, area or number. Qualitative measures, expressed in terms of quality classes, types of uses or eco-system characteristics, may supplement quantitative measures (Statistic New Zealand, 2002). Forest resources based accounts accounted different forest resources individually. Forest has produce no of resources, it is significant to prepare accounting for it. In physical resources based forest accounting record all forest assets even if they are not currently expected to diliver benefits. And in monetary resources based asset accounting record economic value of such forest assets.

Forest Land Asset Accounts: Forest land asset account describe the area of forest land and changes in the area of forest land cover over an accounting period. Table presents a physical asset account for forest and other wooded land. It has given details of opening and closing stock by area, type and changes in forest stock. It has been accounted different additions and reductions in forest stock. Afforestation and natural expansion increases into forest stock. Deforestation or natural regression represents reduction in forest stock.

Table 22 Physical Asset Accounts for the area of Forest and other Wooded Land (Hectors)

Sr. No.	Particulars	Total
1	Opening stock of forest and other wooded land	13897100
2	Additions to stock: Afforestation Natural Expansions Total Addition to stock	5007
3	Reduction in stock Deforestation Natural regression Total reduction in stock	2276
4	Closing stock of forest and other wooded land	13899831

Source: Author calculations

Table 22 giving details about Physical Asset Accounts for the area of Forest and other Wooded Land of the Kolhapur district. There is total 13899831 hectare forest is available in district. Through afforestation (2495) and natural expansion (2512) there is addition in total forest. Similarly there is declined in stock (2276) due to deforestation. It

implies that there are constant efforts taken by forest department to keep forest intact. Deforestation is cover by continuous afforestation.

Timber Resources Asset Account: The timer resources accounts presents the volume of timber resources at both the beginning and end of an accounting period. It also records change in stock over the accounting period. The details of physical assets account of timber resources has been given in Table 22. Timber resources include volume of trees, living or dead, and include all trees regardless of diameter, tops of stems, large branches and dead trees lying on the ground that can be used fo timber or fuel. (SEEA Centrak Framework). The main additions to the stock of timber resources are annual growth and reclassifications. The main reductions in the stock due to removals, losses and reclassifications.

Table 22 Physical Asset Accounts for timber resources (No of Trees)

Sr. No.	Particulars	Total
1	Opening stock of Timber Resources	49952595
2	Addition in Stock Natural Growth Reclassification	91322 NA
3	Reduction in stock Removals Natural losses Catastrophic losses Reclassifications	NA 81521 NA NA
4	Closing stock of Timber Resources	49962396

Source: Author calculations

Table 22 giving details about Physical Asset Accounts for timber resources, entire forest cannot be treated as timber resources hence separate timber resources account is need to prepaid. There are total 49962396 tress are available as timber. Through natural growth (91322) there is addition in timber resources and there is declined in stock (81512) due to natural loss. Timber is the important resource of forest which is getting affected by various reasons such as natural growth, natural loss removals and catastrophic losses etc

Forest Products: Forest produces various non-wood product which has equally good demand in market. Non wood forest product has multiple uses hence they are constantly in demand. Non wood forest product market has good scope for further growth.

Table 23 Non Wood Forest Product

Table 23 shows various non-wood product of forest in which Cashew, Tamalpartha, Hirda, Honey, Shikakai and Amsole are the important products available in forest. Each product has its own market. Its raw material to various forest based industry such forest honey industry, cashew industry, pharmaceuticals, and food processing industry etc.

Live Stock Account: Livestock growth is largely depends on availability of forest. And livestock is essential component of rural economy. Based on forest resources only livestock resources build. Larges section of rural sector depend upon livestock and get their livelihood. It almost 16% income of small farm households come from livestock. Along with that also creates employment generation. In nutshell livestock influence rural economy at large.

Table 24 Live Stock Account

Sr.No	Tahshil	Cows and Bulls	Bufflows	Sheep	Goats	Total
1	Karveer	13318	85187	27729	14458	140992

Table 24 talks about livestock situation in Kolhapur district. Livestock only can be maintained if there is good forest in an around. Almost all Tahashils of Kolhapur district has very good livestock.

FOREST ASSETS AND REGIONAL SUSTAINABILITY

Case Study on Forest Honey Collection: This is the project where forest honey is collected scientifically. There are 100 traditional beekeepers from Malaiwada, Manoli and Barki in 3 villages of Shahuwadi taluka of Kolhapur district are involved. It is found that beekeeping is livelihood option offered to them is increasing social integration, responsibility and awareness about conservation of biodiversity. Important features of this project are as follows which has potential for regional sustainability.

- Organic honey collection in the Amba forests.
- Large potential for establishment and management of Honey clusters through state of art modern honey extraction and collection methods by training the traditional beekeepers.
- Protection and conservation of billions of bees, biology and diversity from becoming eminently endangered.
- It promotes regional sustainability.
- To improve the social status of these traditional beekeepers.

SUSTAINABLE MODEL: SCIENTIFIC METHOD OF HONEY COLLECTION

Smoking machines: Bees in the combs just fly away and do not die, thus not harming them. In the existing traditional method, fire is used wherein most of the bees die.

Sting protection suit: Beekeepers reach up to the comb wearing the suit with the help of ropes. In the traditional method there is a danger of bee stings and thus the beekeeper cannot reach up to the comb.

Tape Rope Ladder: The ladder is used to reach the branch of the tree or the stone in order to systematically slice the comb.

G.I.Cutter: The base of the comb is kept intact and the comb is cut above the base with the cutter and collected in a G.I.Bucket. About 20 % of honey is retained in the comb at the base for the growth of offspring's of bees and thereby sustaining of bee colony.

Rechargeable batteries: Honey is extracted in the evenings and early mornings in the dark.

Honey Extractor: The extractor uses centrifugal force to pour out honey in a pot and keeps the wax in the extractor itself and thus pure honey is extracted.

IMPACT OF THE PROJECT ON REGIONAL SUSTAINABILITY

- If honey is extracted without harming the bees, they revive the comb from the base of the comb in just one month.
- In this scientific method, honey can be extracted thrice a year.
- About 4 to 5 kg of honey can be extracted from a single honey comb through this method
- It helps to increase the population of bees as well as the honey production. This method is therefore useful to both beekeepers and eco-conservation.
- It curbs down deforestation as it is a source of income to the beekeepers.
- Beekeepers get the employment of about 50 to 60 days per year and improve the living standards.

THE TRADITIONAL DESTRUCTIVE METHODS OF HONEY COLLECTION OF FOREST BEEKEEPERS

THE MODERN AND SCIENTIFIC METHOD OF HONEY COLLECTION

CONCLUSION

In forest valuation ecological features of forest has significantly influenced forests monetary value. Hence it is inevitable that to make detailed ecological classification of particular forests. Kolhapur district forest has tremendous ecological inputs that increase value of forests. There are 20 ecological characteristics of Kolhapur forests such as Trees, Mammals, Arachnids, Insects, Moths, Butterflies, Frogs, Toads, Lizard, Skinks, Avifauna, Crocodile, Shrubs, Grasses, Bamboos,

Medical plants, Climber, Herepetauna, Agamids, Gecko, Turtle, Chameleons and its various species. These ecological elements enrich Kolhapur forest's value in greater extent. Ecological diversified forests have more monetary value because it provides diversification in output of forests. Therefore, in making of forest accounting analysis of ecological elements of forest is essential. Being a hilly region Kolhapur forests have scope for agro forestry practices such as cashew cultivation and mango cultivation. There is vast scope for Agro forestry practices in this region. Ecological classification does help in making scientific forest accounting system. Forest has tremendous potential for regional sustainability in which forest timber resources, livestock, forest non wood product and various forest assets are contributed. Forest regional sustainability brings biodiversity conservation, income generations, and improvement in food supply chain, and betterment in socio-economic status and sustainable economy.

1756 CONTRIBUTION AND CHALLENGES OF MSMEs IN INDIA

R. Jayarprakash Reddy, Babitha Vishwanath

Professor, AIMS Institute of Higher Education, Bangalore, Karnataka, renatilatha@gmail.com

Associate Professor, Sarojini Naidu Maha Vidyalaya, Secunderabad, Telangana, babithavin@yahoo.com

ABSTRACT

MSMEs have been playing dominant role in the growth of Indian economy since reforms period. As on today, they are contributing 33% of the total manufacturing output, 45% of exports and 6% of GDP²⁴⁰. Their contribution is valuable in terms of both manufacturing and services. They are complimentary to large enterprises and contribute significantly for the socio-economic development of the country. MSMEs not only play crucial role in providing large employment opportunities at comparatively lower capital cost than large industries but also help in industrialization of rural and backward areas, thereby, reducing regional imbalances, assuring more equitable distribution of national income and wealth. They are the centres for many unemployed and unskilled people; and giving birth to young entrepreneurs in starting their own enterprises. These young entrepreneurs with technological advancement are preferring MSMEs than to work for large corporate or multinational companies. Though MSMEs have progressed and evolved rapidly contributing significantly to the economy, are still facing several challenges.. They include - problems in getting adequate support from banks and other financial agencies., limited capital and knowledge, non-availability of suitable technology, ineffective marketing strategy, attrition of talented people with the tech-savvy background etc. Further, they are also facing challenges from overseas companies which are attracting the skilled manpower of MSMEs who were developed in these enterprises. In the light of this background, this conceptual paper aims at understanding the contribution of MSMEs to the Indian economy along with the role of government and the present challenges faced by them. For MSMEs in India challenges are not new. They are started with the inception of these enterprises and they are growing along with them. Some new challenges are emerging in place of the old as the time passes by. With the help of the secondary data, the authors try to analyse the contribution of MSMEs and their challenges to draw meaningful conclusions which show the way to eliminate some of the challenges which in turn help the MSMEs to contribute more to the economy.

Key words: MSMEs, Contribution, Challenges.

INTRODUCTION

All economies in the world, whether developed or developing, are directly depending on the contribution of MSMEs. Their contribution to employment, production, exports and GDP are considerable and in some economies, it is dominant. In India their contribution is significant. The growth of the economy cannot be imagined with out the contribution of MSMEs. They are complimentary to large enterprises and contribute significantly for the socio-economic development of the country. MSMEs not only play crucial role in providing large employment opportunities at comparatively lower capital cost than large industries but also help in industrialization of rural and backward areas, thereby, reducing regional imbalances, assuring more equitable distribution of national income and wealth. They are the centres for many unemployed and unskilled people; and giving birth to young entrepreneurs in starting their own enterprises. These young entrepreneurs with technological advancement are preferring MSMEs than to work for large corporate or multinational companies.

However, MSMEs have been facing some challenges. If the challenges are addressed, their support to the economy will increase drastically. Therefore, the importance of this paper lies in identifying the contribution and challenges of MSMEs in India and suggest suitable measures to overcome these challenges.

REVIEW OF LITERATURE

Urata and Jigyodan, (2000) in their policy recommendation for SME promotion of Jakarta found that MSMEs and potential entrepreneurs face supply and demand side challenges which can potentially impede their ability to establish, grow and ultimately survive. Overall, these challenges include both supply and demand side issues. Internally, challenges can be of financial nature (i.e. lack of access to financial markets and resources, business acumen), non-financial (i.e. lack of skills, lack of understanding of technology) and/or administrative (i.e. coordination, assessment and monitoring).

According to Ashok Kumar Panigrahi (2012), despite constituting more than 80% of the total number of industrial enterprises and supporting industrial development, many MSMEs in India have problems such as sub-optimal scale of operation, technological obsolescence, supply chain inefficiencies, increasing domestic and uncertain market scenario.

Lack of availability of adequate and timely credit from banks- Presently, high interest rates, high risk perception among the banks, unreasonable collateral demand, restrictive and conditional working capital limits and huge procedural transaction cost often creates problem for the MSMEs in availing easy credit from the banks as it does not have any alternative sources of finance (Pema lama, 2012 & 2013).

Uma, P (2013) observed that, lack of quality consciousness, lack of financial strength, and lack of industrial work culture are the major weaknesses of MSMEs in India.

Some major problems that approximately 80% MSME entrepreneurs face on a day-to-day basis while trying to obtain credit assistance for their business operations are as follows (Mishu Tripathi et al. 2016):

²⁴⁰ Annual Report of MSMEs 2016-17

Complex collaterals required to obtain term loans

1. High transaction costs in imports/exports
2. Private Equity Funding is difficult to obtain
3. Banks offer high rates for term loans
4. Private equity (PE) dilutes control in the company
5. Un-standardised project appraisal system for term loans
6. Cumbersome procedures and delay in fund disbursement

As found by Anshul Pachouri and Sankalp Sharma (2016), despite the numerous challenges, the SME sector in India has performed well. There are distinct barriers to innovation, the most important of which seems to be government policy. This leads to the adage that “entrepreneurs grow not due to the government in India, but despite the government.” However, a deeper analysis leads one to conclude that the government is trying to facilitate the growth of SMEs by promoting various schemes and programs to facilitate innovation in the sector through its distinct institutions. The Science, Technology and Innovation Policy 2013 has had an impact but the institutional functioning of the government, Council of Scientific and Industrial Research labs, and individual firms often does not match.

The OECD (2017) report enlightens that, in India, most concerns relating to general and business skills are a challenge primarily faced by potential entrepreneurs while growth companies primarily face challenges relating to a lack of individual financial literacy, financial exclusion and a lack of awareness/knowledge of financing options. Complexity of financing options was not considered to be a concern or priority to be addressed in India, though this may be due to a lack of data or less complex instruments.

Access to finance, market, people, infrastructure and technology are the major challenges of MSMEs in India (Sonu Garg, & Parul Agarwal, 2017).

Moloy Ghoshal (2017) identified that Indian MSMEs are lagging behind of China because of difference in outlook of government policies for development, more focus on public sector undertakings, late starting of reforms, and slow pace of infrastructure development.

The annual report of MSME (2016-17) reveals that the Indian economy thrives through the process of creation of enterprises. The MSMEs have been contributing to expansion of entrepreneurial culture through business innovations. The MSMEs are widely dispersed across sectors of the economy, producing diverse range of products and services to meet the demands of local as well as global markets. The contribution of MSMEs to GDP 6%, 33% in manufacturing sector and 45% in exports. It shows the valuable contribution that the MSME sector is making in the economy, both in terms of manufacturing and services.

Despite of the importance of the MSMEs in Indian economic growth, the sector is facing challenges and does not get the required support from the concerned Government Departments, Banks, Financial Institutions and Corporate which is proving to be a hurdle in the growth path of the MSMEs. The list of the problems that are faced by existing/new companies in SME sector are as under (Challenges to MSME, 2018):

1. Absence of adequate and timely banking finance
2. Limited capital and knowledge
3. Non-availability of suitable technology
4. Low production capacity
5. Ineffective marketing strategy
6. Constraints on modernisation & expansions
7. Non availability of skilled labour at affordable cost
8. Follow up with various government agencies to resolve problems due to lack of man power and knowledge etc.

METHODOLOGY

This conceptual paper is prepared based on secondary sources like, Annual Reports, Research Reports, Research Papers etc.

IMPORTANCE OF THE STUDY

All economies in the world are directly or indirectly depending on the contribution of MSMEs. India is not an exception. Though their contribution to the economy is significant, they have been facing challenges in different ways. Unless and until they are addressed, the expected contribution from them will remain a dream. In the light of this background, the present study focuses on the current contribution and challenges of MSMEs in India and probable solutions to address them.

LIMITATION

There many sources on MSMEs in India. While preparing this paper, the researchers consulted some of the prominent reports but not all. Some reports, which deserve to be looked into, might be missing. This might have some affect on the findings and conclusion.

OBJECTIVES

The following are the objectives of the study:

- to study the structure, growth and contribution of MSMEs in India; and
- to outline the challenges of MSMEs and suggest suitable measures for their improvement based on the findings of the study.

DEFINITION OF MSMEs IN INDIA

According to MSME Act, 2006, MSMEs in India are defined based on their investment in plant and machinery in manufacturing and equipment in service enterprises.

Category	Investment limit (in INR)
Micro - Manufacturing	< 25 ₹ lakh investment in plant and machinery
Micro -Services	< 10 ₹ lakh investment in equipment
Small - Manufacturing	< 5 ₹ crore investment in plant and machinery
Small - Services	< 2 ₹ crore investment in equipment
Medium - Manufacturing	< 10 ₹ crore investment in plant and machinery
Medium - Services	< 5 ₹ crore investment in equipment

GROWTH AND CONTRIBUTION

In India, MSMEs have been playing dominant role in the growth of Indian economy since reforms period (!991). As on today, they are contributing 33% of the total manufacturing output, 45% of exports and 6% of GDP(MSMEs Annual Report, 2016-17).

The Micro, Small and Medium Enterprises Development (MSMED) Act, 2006, provides for the filing of Memorandum for Enterprises. It empowers the Central Government to undertake programmes and issue guidelines and instructions to develop and enhance the competitiveness of MSMEs.

One of the critical indicators to access successful development of MSME sector in an economy is the data on opening of new MSMEs; it depicts the conducive environment for opening and growth of such units in an economy as well as show the high morale of entrepreneurs in the macro economics of the economy.

The data from the Entrepreneur Memorandum Part II(EM-II) filed at DICs (District Industries Centres) provides the information in the following paras about the growth and performance of MSMEs.

Number of EM-II filed during 2007-08 in the DICs across the country was 1.73 lakh. This has increased continuously during 2007-08 to 2014-15, the number of EM-II filings was 4.25 lakh.

The annual growth in the number of EM-II filings was 11 percent from 2007-08 to 2011-12. In 2014-15, the growth rate increased by 17 percent.

Since 2015, EM-II filings have been discontinued in favour of Udyog Aadhaar Memorandums - (UAMs). A total of 21,96,902 EM-II filings had taken place between 2007 and 2015. By contrast, 22,40,463 UAM filings have already taken place since 2015. An analysis of the EM-II filings is helpful in comparing overall trends within the sector. Since UAM filings have been introduced recently, their analysis is helpful in highlighting the current status of the sector.

An analysis of UAM filings also provides a break-up of manufacturing and services MSMEs. It must be noted that services MSMEs comprise a larger portion of UAM filings than those involved in manufacturing. It may therefore be noted that there is a progressive and healthy growth of the MSME sector that has resiliently withstood financial crisis and other shocks that have impacted the economy. The following table and figure followed by show the UAM-II filings during 2007-08 and 2014-15.

Table 1: UAM-II filings during 2007-08 and 2014-15

Year	No. of UAM-II filings (in lakhs)
2007-08	1.73
2008-09	1.93
2009-10	2.13
2010-11	2.38
2011-12	2.82
2012-13	3.23
2013-14	3.63
2014-15	4.25

Source: MSME Annual Report, 2016-17

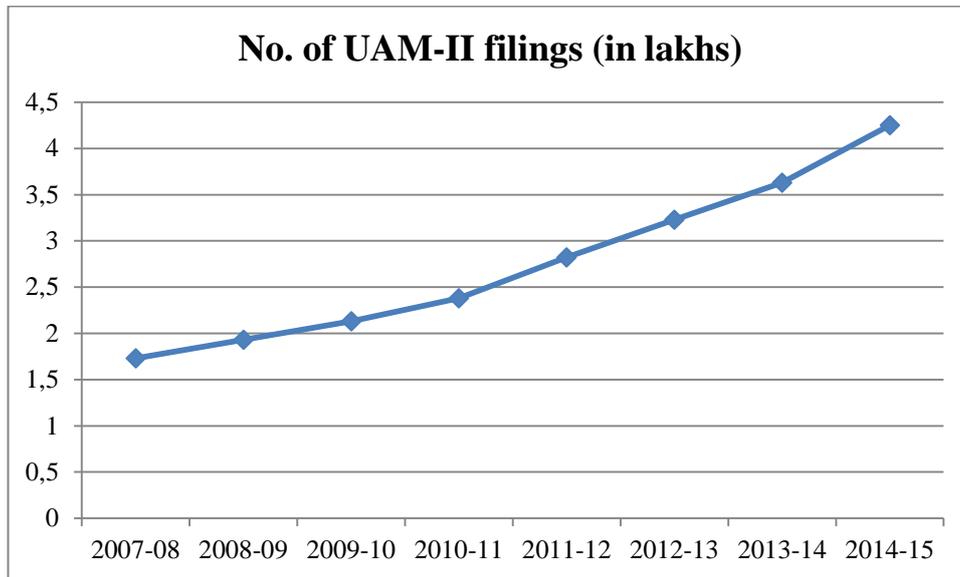

Fig 1: UAM-II filings

The growth rate of filings during this seven years period ranges from 10.45 to 17.18 per cent. The following table and figures display the facts.

Table 2: Rate of growth in UAM-II filings during 2007-08 and 2014-15

Year	Rate of growth in EM-II filings (in percentage)
2007-08 to 2008-09	11.77
2008-09 to 2009-10	10.45
2009-10 to 2010-11	11.83
2010-11 to 2011-12	18.45
2011-12 to 2012-13	14.3
2012-13 to 2013-14	12.44
2013-14 to 2014-15	17.18

Source: MSME Annual Report, 2016-17

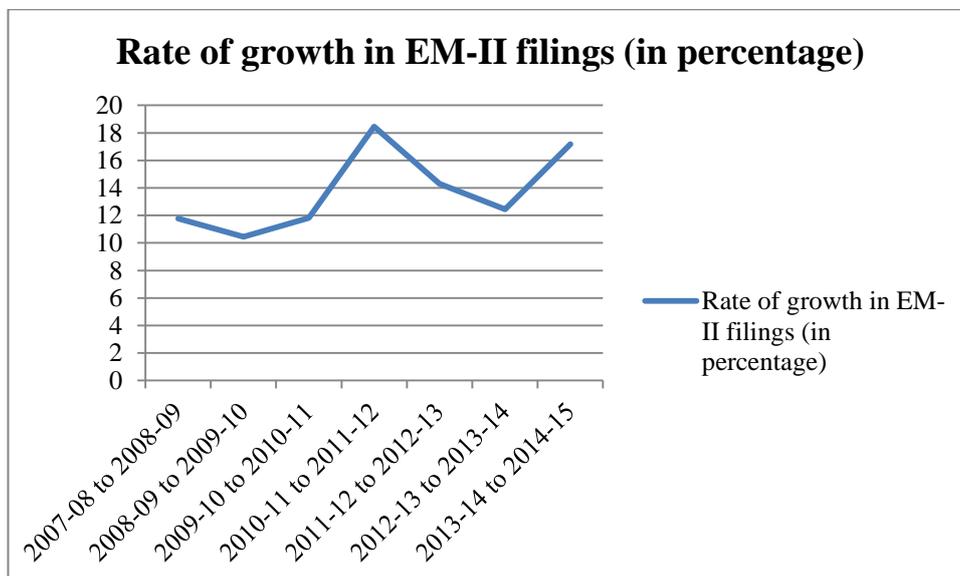

Fig 2: Rate of growth in EM-II filings

The Indian economy thrives through the process of creation of enterprises. The MSMEs have been contributing to expansion of entrepreneurial culture through business innovations. The MSMEs are widely dispersed across sectors of economy, producing diverse range of products and services to meet demands of local as well as global markets. The contribution of MSMEs in GDP is 6%, comprising of 33% in manufacturing sector, and 45% in exports. It shows the valuable contribution that the MSME sector is making in the economy, both in terms of manufacturing and services. The following table shows the share of MSME sector in GDP and total manufacturing output from 2011-12 to 2014-15.

Table 3: Share of MSME sector in GDP and total manufacturing output from 2011-12 to 2014-15

Share of MSME sector in GDP and total manufacturing output					
Manufacturing output at current price			Share of MSME GVA to GVA/GDP at constant price for the base year 2011-12(%)		
Year	MSME manufacturing	Share of MSME	MSME manufacturing sector	MSME services sector	Total

	output (₹ in crore)	output in the total Mfg. output (%)						
			In GVA	In GDP	In GVA	In GDP	In GVA	In GDP
2011-12	2167110	33.12	6.64	6.16	25.66	23.81	32.29	29.97
2012-13	2385248	33.22	6.77	6.27	26.05	24.13	32.89	30.40
2013-14	2653329	33.27	6.79	6.27	26.40	24.37	33.19	30.64
2014-15	2783343	33.40	6.63	6.11	26.72	24.63	33.34	30.74

Source: MSME Annual Report 2016-17.

The contribution of Gross Value Added (GVA)²⁴¹ of Manufacturing MSMEs to the economy at constant price with base year 2011-12 is 7 per cent (approx) of Gross Value Added (GVA) and 6 per cent (approx) of Gross Domestic Product (GDP)²⁴², amounting to more than 33 per cent of Manufacturing output²⁴³ at current price and also contributing to the tune of 45 per cent of exports of the country. This is as per the data available with Central Statistics Office (CSO). Ministry of Statistics & Programme implementation, Government of India, an approximation based on the results of Annual Survey of Industries (ASI) and survey on unorganised sector estimated contribution of the MSME sector to GVA, GDP and Manufacturing Output, during 2011-12 to 2014-15.

Source of data on MSMEs is taken from All India Census of MSMEs conducted by Ministry of Micro, Small and Medium Enterprises and Economic Census conducted by Central Statistics Office(CSO). Last All India Census of MSMEs was conducted for the year 2006 and results were published in 2011. Sixth Economic Census was conducted by CSO in 2013 and results were published in 2016. These Censuses being conducted with different methodology, criteria, definition and at different points of time give different results. The primary difference is that Economic Census collects data about all establishments including large, while Census of MSMEs collects data only for MSMEs. The percentage of large establishments in total is less than 1%. Therefore, the data on number of establishments in Economic Census could be used for total number of MSMEs. However, data on number of employees, production, etc cannot be used straight away for all MSMEs.

As per the Fourth All India Census of MSME covering both registered and unregistered sectors are shown in the table.

Table 4: Number of MSMEs as per Fourth All India Census

Sl. No.	Characteristics	Registered Sector	Unregistered Sector	Economic Census-2005	Total
1	No. of Enterprises (in lakh)	15.64	198.74	147.38	361.76
2	No. of rural Enterprises (in lakh)	7.07 (45.20%)	119.68 (60.22%)	73.43 (49.82%)	200.18 (55.34%)
3	No. of Enterprises owned by women (in lakh)	2.15 (13.72%)	18.06 (9.09%)	6.40 (4.34%)	26.61 (7.36%)
4	Employment (in lakh)	93.09	408.84	303.31	805.24
5	Per unit Employment	5.95	2.06	2.06	2.23

Source: MSME Annual Report 2016-17.

As per the estimates made using results of the sixth EC 2013 the results of which were published on the 31st March, 2016, the Fourth All India Census of MSME, 2006-07 and Fifth EC, 2005, the number of MSMEs and employment in MSME sector are 512.99 lakh and 1112.28 lakh respectively.

The volume of employment creation by the MSMEs is next only to that in agriculture. Thus the MSME sector has the potential of tapping individuals to associate with economic activities by way of self-employment. The All India Census of MSME was conducted with reference year 2006-07, wherein the data were collected till 2009 and results of the same were published in 2011-12. The results also made use of the Fifth Economic Census, 2005(EC,2005) conducted by CSO., for activities excluded from Fourth All India Census of MSMEs: 2006-07 for unregistered sector, namely wholesale/retail trade, legal, education & social services, hotel & restaurants, transports and storage& warehousing (except cold storage).

The primary difference between the Fourth All India Census of the MSME, 2006-07, and Sixth EC,2013, has enumerated all establishments engaged in various agricultural and non-agricultural activities excluding crop production, plantation, public administration, defence and compulsory social security, whereas the Fourth All India Census of the MSMEs, 2006-07, covered only MSME manufacturing and service sector establishments/enterprises which were defined as MSME under the MSME Act, 2006, thus, excluding large enterprises, retail and whole sale trading establishments amongst other.

As per the results of the Sixth Economic Census 2013, non-agricultural enterprises constitute 77.6 percent or more than three-fourths of all establishments (excluding crop production, plantation, public administration, compulsory social

²⁴¹ Gross Value Added (GVA): It may be noted that estimates of GVA had been prepared at factor cost in the earlier series (base year 2004-05), while these are being prepared at basic prices in the new series (2011-12). GVA estimated by production approach: (GVA= Output-Material Inputs) and GVA estimated by income approach: (GVA= Compensation of employees + operating surplus + CFC).

²⁴² Gross Domestic Product (GDP): GDP is derived by adding taxes on products, net of subsidies on products, to GVA at basic prices.

²⁴³ Manufacturing output: Manufacturing output is defined to include the ex-factory value, (i.e., exclusive of taxes, duties etc on sale and inclusive of subsidies etc., if any) of products and by-products manufactured during the accounting year, and the net value of semi-finished goods, work-in-progress, and also the receipts for industrial and non-industrial services rendered to others, value of semi-finished goods of last year sold in the current year, sale value of goods sold in the same condition as purchased and value of electricity generated and sold (Definitions above are from the CSO).

security) in the country. The non-agricultural sector that includes MSMEs and large establishments employed a total of 10,84,11,367 persons. This number is 82.6 percent of the total employment in agricultural and non-agricultural establishments (excluding crop production, plantation, public administration, and compulsory social security).

Most establishments were self-financed. A total of 35.48 million (78.2%) non-agricultural establishments were self-financed. In rural India 72.7% of the non-agricultural establishments were self-financed whereas this figure was 83.7% in urban India. This indicated the challenge of providing adequate financing to MSMEs in both rural and urban areas. It also highlights the challenge of providing other sources of financial credit and assistance for MSMEs, in order to enable greater capital investment within this sector. The following table shows the number of MSMEs, their employment generation and market value of fixed assets during 2006-07 and 2014-15.

Table 5: Total number of working MSMEs, Employment generation and Market Value of Fixed Assets during 2006-07 and 2014-15

	Total Working Enterprises (in Lakh)	Employment (in Lakh)	Market Value of Fixed Assets (in Crore)
2006-07	361.76	805.23	868543.79
2007-08	377.36	842	920459.84
2008-09	393.7	880.84	977114.72
2009-10	410.8	921.79	1038546.08
2010-11	428.73	965.15	1105934.09
2011-12	447.64	1011.69	1182757.64
2012-13	467.54	1061.4	1268763.67
2013-14	488.46	1114.29	1363700.54
2014-15	510.57	1171.32	1471912.94

Source: MSME Annual Report 2016-17

CHALLENGES

MSMEs in India, no doubt, are contributing to the economy a lot in the form of their number, employment, production and exports. It is also a fact that they are facing several challenges.

From the review of literature, it can easily be said that in India, MSMEs are struggling with many problems like finance, marketing, technology, human resources, infrastructure etc., despite of the efforts put in by the government through its policy measures, support and new initiatives. It is not exaggeration to say that if MSMEs are problem free, their contribution to the economy would be much better than what it is now.

The above challenges are the stumbling blocks for the growth of MSMEs in India. The growth of these enterprises has a direct effect on the GDP. Developed economies have always given specific policy thrusts for their development and yielded good results. For example, Taiwan, Italy, China, France, South Africa, Germany, UK, Singapore and US have contributed 85, 68, 60, 59, 57, 54, 50,50, and 48% respectively to their economies during 2013 (Maximilan ROBU, 2013). But in India the contribution of MSMEs to GDP is only 37.54%; where 7.28% is from manufacturing and the remaining from services in the same period. As on today, they are contributing still less i.e. 33% of the total manufacturing output, and 6% of GDP (MSMEs Annual Report, 2016-17). After economic reforms, when the Indian market was forced to open up, the real challenges began to MSMEs in India. Even after two and half decades since reforms, the Indian MSMEs could not face competition from countries like China because of the challenges they are facing..

FINDINGS

From the above secondary information, the following findings can be drawn:

1. The MSMEs are playing dominant role in the Indian economy contributing considerably for employment, production and exports.
2. The government of India has been supporting MSMEs through its policy measures and pronouncements.
3. Despite government support, MSMEs in India are still facing challenges like finance, marketing, technology, infrastructure etc.
4. Competition from countries like China makes Indian MSMEs more worried.

SUGGESTIONS

Based on the findings, the following suggestions can be made:

1. Government support for MSMEs should be continued, particularly for skill and infrastructural development; technological enhancement; marketing assistance; and timely finance.
2. MSME associations and the government should continuously find the ways for increase in the contribution of MSMEs to the economy without leaving any scope for weakening of these enterprises.

CONCLUSION

To survive and grow fast in the present competitive world, MSMEs in India should become strong in all fronts and face any challenge that comes from inside the country or outside. In addition to the government, the entrepreneurs should

also take active part in making these enterprises strong through finding other sources of finance, developing infrastructure, upgrading technologies and improving their marketing strategies.

1687 MAPPING CHINA'S FOREIGN DIRECT INVESTMENT IN THE GLOBAL ENERGY SECTOR

ABSTRACT

As China's current account surplus has grown and the nation has liberalized its capital account, Chinese overseas foreign direct investment has increased significantly. In 2016, Chinese overseas foreign investment flows were more than \$1.3 trillion and outward investment from Hong Kong was \$1.5 trillion, combining to \$2.8 trillion in total—up a factor of 10 since 2005 and second only second to the United States in total outbound foreign direct investment. This paper examines the extent to which Chinese overseas foreign investment is significantly different from the United States and other OECD foreign investors in general, and with a specific focus on electricity energy sector. After creating a unique spatial database, merging disparate datasets, that allows us to analyze both greenfield and merger

ABSTRACT

The input-output analysis has been used for many years as a tool to measure the economic effect when economic shocks occurred. However, editing of data is very difficult. In this study, it is assumed that changes in the industrial structure are stochastically performed on data difficulties related to the input-output table. Then, we conduct an input-output analysis under the stochastically estimated input-output table. Specifically, the input coefficient required for the input-output analysis fluctuates stochastically, and the spillover effect is estimated under the fluctuating input coefficient.

As a case study, we use an interregional input-output table consisting of two regions, Fukuoka prefecture and other prefectures (the rest of Japan). Based on the input coefficient of the most recent 2011 table, we generate random numbers with the standard deviation of input coefficients of 1995, 2000, 2005 and 2011 tables as the variation range, and carry out the Monte Carlo experiment.

Since the standard deviation of the input coefficient used for the experiment depends on the past input-output table, the fluctuation becomes relatively small. However, there were still differences between industry sectors and simulation patterns.

JEL classification: C15, C67, D57, O53, R15

Keywords: Interregional Input-Output Model, Regional Spillover Effects, Fukuoka Prefecture, Monte Carlo Experiment

1. INTRODUCTION

The input-output analysis has been used for many years as a tool to measure the economic effect when economic shocks occurred (Miller and Blair, 2009). The input-output table as its basic information has advantages in that the transaction structure between industries is shown in detail, but it takes a huge amount of time to edit the table. Therefore, the input-output table will be published at a frequency of once every several years. However, this cannot analyze with relatively new data. Therefore, sometimes trying to solve this problem by adding some new data based on the original data and estimating a table of a relatively new year.

The input-output table is usually edited in one country or one region. However, the economy will never be completed in one country, one region. Transaction information outside the country and outside the region is necessary. For this purpose, an interregional input-output table is created. This will reveal transactions from one industry in one area to another industry in another area. However, it is very difficult to obtain transaction information.

In any case, in order to conduct the input-output analysis, it is necessary to have an input-output table which requires huge amount of statistics. For the data difficulty in the input-output table, in this study, it is assumed that the change of the industrial structure is stochastically performed. Then, we conduct an input-output analysis under the stochastically estimated input-output table. Specifically, the input coefficient required for the input-output analysis fluctuates stochastically, and the spillover effect is estimated under the fluctuating input coefficient. Stochastic fluctuations in the industrial structure are made by Monte Carlo experiments. We use an interregional input-output table consisting of two regions, Fukuoka prefecture and other prefectures (the rest of Japan) as a case study. Moreover, the spillover effect also fluctuates, so the magnitude of the fluctuation range becomes the focus of study.

2. THE MODEL

As known well, input-output analysis consists of two basic models, quantity and price. The quantity model is $X=(I-A)^{-1}F$, where A is a matrix of direct-input coefficient,²⁴⁴ X and F are vectors of output and final demand in monetary values. The price model is $P=(I-A')^{-1}V$, where A' is a transposing of A , P and V are vectors of price and value-added. It can also be said the quantity model is featured the demand side and the price model is the supply side.²⁴⁵ Various analyses are developed by making one of these two models (those many being the quantity models) decompose intricately. In this study, we analyze changes in industrial structure in each of the two models. The inverse matrix in the input-output analysis can be easily calculated by Excel and others. However, since the objective of this study is in the Monte Carlo experiment, another software is used to organize the measurement results more easily.²⁴⁶ Therefore, return each model to its form before being expanded to the inverse matrix.

²⁴⁴ $A=Zx-1$, where Z is a matrix of inter-industry sales in monetary values and x is a diagonal matrix with the elements of the vector X along the main diagonal.

²⁴⁵ This argument is based on Leontief model (Leontief, 1936, 1941, and 1986). As a model which treats a supply side quantitatively, Ghosh (1958) suggests other model using direct-output coefficient ($B=x-1Z$).

²⁴⁶ This model is carried by GAMS (General Algebraic Modeling System) program. We use a solver to solve the optimization problem (CONOPT), but the equation written in the text is not an optimization problem, so we set up a fictitious optimization problem on the program code.

$$X_{r,i} \cdot x_{r,i} = \sum_s \sum_j \alpha_{s,r,i,j}^A \cdot X_{s,j} \cdot x_{s,j} + \sum_s \sum_d \alpha_{s,r,i,d}^F \cdot f_{s,d} + \alpha_{r,i}^E \cdot e - \alpha_{r,i}^M \cdot X_{r,i} \cdot x_{r,i} + ex_{r,i} \quad (1)$$

This is a so-called quantity model. The production-goods demand ($X \cdot x$) consists of the intermediate-goods demand $A \cdot X \cdot x$ ($\alpha \cdot X \cdot x$), the final demand f , export e , and import (function of production goods). ex is an adjustment term that exists in the table. α is a parameter to each demand and it is calibrated from the database. Needless to say, α^A is an input coefficient, and this coefficient varies according to the Monte Carlo experiment. As a point to note, the left side is ($X \cdot x$). X is an index and becomes an endogenous variable, and x is an exogenous variable with a number obtained from the data. More specifically, x is a fixed production quantity, and as X varies, the amount of production after simulation is calculated in the form of $X \cdot x$. Therefore, in the initial equilibrium solution, X is 1. Subscript at the lower right of each variable r and s are represented region, i and j are represented industry, d is represented demand item, and v is represented value-added item, respectively.

$$P_{r,i} = \sum_s \sum_j \alpha_{r,s,j,i}^A \cdot P_{s,j} + \sum_v \alpha_{r,v,i}^V \quad (2)$$

This is a so-called price model, which is a mathematical expression before it is expanded into an inverse matrix. As you can see from the equations, these two equations are independent and have common exogenous input coefficients α^A . Therefore, each can be regarded as a problem of independence. However, in this study, two separate equations were calculated by one program in order to save computational complexity.

3. DATA AND SIMULATION

Fukuoka prefecture (Fukuoka-ken) is a prefecture of Japan located on Kyushu Island. It faces the sea on three sides, bordering on Saga, Oita, and Kumamoto prefectures and facing Yamaguchi Prefecture across the Kanmon Straits. It is also located near the Korean peninsula. There are 60 municipalities (28 cities, 30 towns and two villages) including two government-designated major cities: the Fukuoka city, the capital and central city in Fukuoka Prefecture, and the Kitakyushu city, a big city with a population of about one million. It also has the largest economic scale in Kyushu region.

We use a data of inter-regional input-output table of Fukuoka prefecture. This table is constructed two regions of Fukuoka prefecture (hereinafter sometimes uses “*fp*”) and other prefectures (hereinafter sometimes uses “*op*”) in Japan. Currently, the tables of 1995, 2000, 2005 and 2011 are available, but the number of industrial sectors in each table is different (37, 37, 39, 42 industrial sectors respectively). On the other hand, tables of 13 industrial sectors where more industrial sectors were consolidated are also published at the same time, so we will use these 13 sectors tables in this study (see, Table 1).

Next, the variation of the industrial structure will be explained. It is assumed that the fluctuation of the industrial structure is caused by a change in input coefficient of the input-output table. Since the input coefficient is a key part of the input-output analysis, it is expected that the solution of the quantity model and the price model (that is, the spillover effect) will change by changing this coefficient.

By the way, in the case of interregional input-output tables between two regions, input coefficients can be divided into four according to regions (*fp* to *fp*, *fp* to *op*, *op* to *fp*, and *op* to *op*). Therefore, in this study, five Monte Carlo experiment patterns are set, centering on input coefficient in Fukuoka prefecture. In the Monte Carlo experiment, random numbers are generated in the input coefficients to give variations. Random numbers follow a normal distribution with an average of 1. The standard deviation is not necessarily the same. Here, we use the calculated standard deviation of the input coefficients in the tables of 1995, 2000, 2005, 2011 (only four data points). We use the latest 2011 table as the reference input coefficient. In other words, experiment is carried out by multiplying a part (whole) of input coefficient of 2011 table by a normal random number. Furthermore, in order to set more complicated random numbers, experiments were conducted by generating the normal random number twice and multiplying them by the input coefficient. Therefore, a total of 10 experimental patterns were set together with five regional patterns (see, Table 2).

4. RESULTS

Tables 3 to 6 show standard deviations used for Monte Carlo experiments. The calculation method is the standard deviation of the input coefficient between the four data points as described above. It is rounded off to the fourth digit after the decimal point and even if a result of the standard deviation which is considerably small in computation comes out, it is treated as 0 (0.0000). Needless to say, when the standard deviation is 0, the input coefficient does not fluctuate. In some places, it is indicated as 0.0000, and for these input-output combinations, the input coefficient does not change. Also, the standard deviation itself is not too large. Therefore, it seems that the change in industrial structure during the period (1995-2011) was not so big. At the same time, it is expected that there will be no extreme fluctuation in output amount and price even as a result of Monte Carlo experiments to be shown from now.

Before describing the details of the results, introduce the results of the overall Monte Carlo experiment. Table 7 summarizes the changes in production in all Monte Carlo experiments by region. Random numbers were generated 500 times each. The table lists the maximum, minimum, average, and standard deviation of output (x) in each region. Needless to say, since the input coefficient multiplies the random number of 1 on average, the average value of production is quite close to 1.000000. Therefore, the difference between the maximum value, the minimum value and the standard deviation in each simulation and region is compared.

In simulation 1, the fluctuation range of the output in Fukuoka prefecture is a very small difference of 0.6% to -0.6%. In other prefectures, the fluctuation was not so large from 1.4% to -1.3%, but it was found to be larger than Fukuoka prefecture. In Japan as a whole, the fluctuation range is slightly smaller than other prefectures. The standard deviation is

0.2362% for Fukuoka prefecture, 0.4960% for other prefectures, 0.4853% for Japan. Likewise, the fluctuation range is never large, and it is considered that the fluctuation of the industrial structure is not so large. In each of simulations 2 to 5, the input coefficients in other prefectures do not fluctuate. In this case, the fluctuation in the output of other prefectures becomes extremely small (0.0027% to 0.0141% with standard deviation). Also, because of the difference in economic scale between Fukuoka prefecture and other prefectures (46 prefectures), fluctuations in the output are extremely small in Japan (0.0073% to 0.0154% with standard deviation). Furthermore, due to the absence of changes in other prefectures, fluctuations in Fukuoka prefecture are also smaller than in simulation 1 (0.1347% to 0.1378% with standard deviation). However, the standard deviation in other prefectures and Japan in simulations 3 and 5 is larger than simulations 2 and 4. In simulations 3 and 5, input coefficients from other prefectures to Fukuoka prefecture fluctuate. It is understood that the production in other prefectures is slightly affected by the import demand from other prefectures in Fukuoka prefecture.

Simulations 6 to 10 make the random number generation method more complicated for simulations 1 to 5. This shows that the fluctuation range of the output is larger. For example, the standard deviations of simulation 6 were 0.3354%, 0.6824% and 0.6679%, respectively. The same applies to other simulations. By making the random number generation more complicated, we succeeded in creating possibilities of more complicated results.

Tables 8 to 17 are experimental results of Monte Carlo experiments with respective simulation patterns. The table also lists the maximum, minimum, average, and standard deviation of output (x) and price (p) in each industry in each region.

In simulation 1, in the case of Fukuoka prefecture, the industrial sector with large standard deviation was mining (fp-i002, output is 1.7945%, price is 1.5454%). In manufacturing, price fluctuations are relatively large (fp-i003, output is 0.5780, price is 1.2177%). The more extreme is electricity, water and gas supply (fp-i005, output is 0.1910, price is 1.0987%). On the other hand, communication is somewhat large (fp-s010, output is 0.7300%, price is 0.7737%). In the case of other prefectures, mining has large fluctuations in output and price fluctuation is small (op-i002, output is 2.8089%, price is 0.4665%). On the contrary, electricity, water and gas supply has large fluctuations in price and fluctuation in output is small (op-s005, output is 0.4432%, price is 2.6202%). In manufacturing, both output and price are relatively large (op-i003, output is 1.2250%, price is 1.6638%), the next is agriculture (op-a001, output is 0.7483%, price is 0.7581%) and communication (op-s010, output is 0.6426%, price is 0.7072%). In addition, although activities not elsewhere classified (fp-s013 and op-s013) has relatively large fluctuation, it is not taken up here.

Simulations 2 to 5 are almost the same as the trends of the results in Table 7. Changes in other prefectures are rather small. The fluctuation in Fukuoka prefecture is high in mining, but the next highest is communication. Regarding price fluctuations, electricity, water and gas supply is also large. Meanwhile, in manufacturing, price fluctuations of simulations 3 and 5 become large. This tendency was the same in the simulations 6 to 10 which made the random number generation more complicated.

In this way, we found that the fluctuations vary among industries. However, in the case of Japan, mining is not flourishing because it is not a resource-rich country. Therefore, even if the fluctuation of mining is large, the impact on the Japanese economy is small. The manufacturing industry also has a 20% to 25% share of importance. The relatively large price fluctuation of electricity, water and gas supply may affect consumption life. Although there is not much fluctuation compared with these industrial sectors, communication will be an important industry in the future. It is said that the ICT revolution was thriving, and it is expected to grow greatly in the future.

5. CONCLUDING REMARKS

In this study, in order to compensate for the difficulty of data editing in the input-output table and the input-output analysis, the input coefficients were varied by Monte Carlo experiments, and fluctuations in output and price were analyzed. As a case study, we use an interregional input-output table consisting of two regions, Fukuoka prefecture and other prefectures (the rest of Japan). Since the standard deviation of the input coefficient used for the experiment depends on the past input-output table, the fluctuation becomes relatively small. However, there were still differences between industry sectors and simulation patterns. And it turned out that fluctuations in mining, manufacturing, electricity, water and gas supply and communication are relatively large. In particular, since communication is a promising industrial sector, it is necessary to pay attention to future trends.

1196 SATELLITE AND WIRELESS INTERNET SERVICE IN LIEU OF WIRED RURAL INTERNET SERVICE

ABSTRACT

It has always been expensive to deliver telecommunication services to rural and isolated households, but as new broadband Internet technologies have been introduced that are both cheaper and more effective, the economic dynamics have changed. More rural areas have received the advanced broadband technologies, but many rural areas are still perceived as offering the least in economic returns for private investment and have not. Given the apparent benefits of the Internet, there are meaningful consequences for rural households remaining without, or with lesser, broadband service. Wireless Internet has improved a great deal over the last decade, but is it a solution to lack of universal rural service? Our research will be somewhat broad ranging at this point and constitute four questions: (1) the technical state of satellite and fixed and mobile wireless and how it fits into the rural broadband market, (2) how dependent are rural areas on the (various aspects of the) Internet? Or what is the relationship between rural economies and the Internet? (3) Are wireless broadband systems substitutes or complements to hardwired systems? What does substitute versus complement mean for rural households?

1767 A STUDY ON INTEGRATED WATERSHED MANAGEMENT BASED ON THE EXPANDED I-O ANALYSIS; A CASE OF PUBLIC WATER BODY IN KANTO REGION, JAPAN

ABSTRACT

In this study, we propose an optimal regional environmental policy to improve the environmental quality in and around the public water body, considering both - the total ecological system and periodical changes over a certain period of time. We specify three sub-models (water pollutants flow balance model, air pollutants flow balance model and socio-economic model) and one objective function based on expanded I-O analysis in order to analyze the policy to improve the water and air quality including reduction of GHG emission. The water pollutants flow balance model describes the amount of water pollutants generated in the municipalities of each sub-basin and the amount of water pollutants transported into the . The air pollutants flow balance model describes the amount of air pollutants and greenhouse effect gases generated and emitted into the air in each municipality. The socio- economic model describes the socio-economic activities in the sub-basins and the amount of air and water pollutants emitted by the activities. Also, the socio-economic model describes how the relation between the socio- economic activities and the emission of pollutants change dependent on the adopted watershed management policies in the region.

ABSTRACT

E3-India is a new state-level model of India, developed from the global E3ME macro-econometric model, linking the economic, energy and environmental emissions systems. The model is designed to assess policy through a highly empirical structure, whereby historical data is used to feed in to econometric estimations of model interactions, forming a consistent modelling framework. As a general model of the economy, E3-India can be used to assess a wide range of fiscal and general macroeconomic policies. However, it has been designed to have a particular focus on the energy sector. Policies can be introduced into this framework at a state level, allowing energy system and socio-economic impacts to be assessed both within that state and (through trade) spillovers into other states.

The model is macro-econometric in nature, based on a post-Keynesian framework within which optimisation is not assumed (i.e. it is not a general equilibrium model). Through accounting identities, demand must equal supply, but demand can be less than or equal to total potential supply; the implication of this framework is that, under the right conditions, it is possible for regulation to increase output and employment. E3-India combines the features of an annual short- and medium-term sectoral model estimated by formal econometric methods with the detail and some of the methods of CGE models, providing analysis of the movement of the long-term outcomes for key E3 indicators in response to policy changes. It is essentially a dynamic simulation model that is estimated by econometric methods. The data used represent the best available data sources relevant to India; the data used was largely sourced from official national and state sources, including the Reserve Bank of India and the Ministry of Statistics and Programme Implementation.

A key advantage of the E3-India model is its structure. The model disaggregates the economy by sector, which allows the representation of fairly complex scenarios at state level, especially those that are differentiated by sector. Similarly, the impact of any policy measure can be represented in a detailed way, for example showing the winners and losers from a particular policy. The full integration of separate energy, environment, & economy modules is an undoubted advantage over models that may either ignore these interactions completely or only assume a one-way causation.

E3-India also includes explicit treatment of technology, using the Future Technology Transformations (FTT) modelling framework for the power sector. This approach is qualitatively different from the optimisation tools that are used in other analyses and draws on theories from post-Keynesian and evolutionary economics. Instead of trying to find least-cost pathways, the model simulates the responses to policy inputs (including both regulation and market-based instruments) and is parameterized on real-world time-series data.

INTRODUCTION

E3-India model is a new macro-econometric E3 (energy-environment-economy) model of India that can be used to assess policy at the level of the 32 states and territories. It is built on the existing structure offered by the global E3ME model but accounts for more detailed data and issues that are specific to India. As the model operates at state level, policies in individual states can be addressed and the distribution of impacts across India can be considered for national policy.

- The E3-India model has the following dimensions:
- 32 Indian states and territories
- 20 economic sectors
- 8 users of 5 different energy carriers
- CO2 emissions from 8 sources
- annual projections out to 2035

E3-India is based on a series of econometric equations that are similar in design to those in the E3ME model (see www.e3me.com). Unlike the more common computable general equilibrium (CGE) approach to economic modelling, E3-India does not assume full employment or perfectly competitive markets; instead it estimates behaviour based on available historical data.

The E3-India model was constructed with the following aims:

- The model represents best practice for sectoral policy simulations.
- Its development is transparent. Designed through a collaborative process it aims to capture local knowledge and expertise in India.
- The data used represent the best available data sources relevant to India.
- The parameters in the model reflect the behavioural characteristics of the states of India.
- The outputs of model simulations can be readily identified and explained.
- Use of the model is accessible and affordable to a broad base of prospective users over time.

As a general model of the economy, E3-India can be used to assess a wide range of fiscal and general macroeconomic policies. However, it has been designed to have a particular focus on the energy sector. Policies that the model can assess include:

- changes in the power sector energy mix, including the share of renewables in the mix
- policies to promote renewable uptake, such as Feed-in-Tariffs or direct subsidies
- direct regulation on energy efficiency
- energy and carbon pricing instruments.

E3-India produces a wide range of socio-economic outputs at state and national level, for example:

- employment and unemployment
- GDP and sectoral output
- investment
- international trade and trade between states
- household income (by income group) and consumption
- public balances
- prices and inflation.

The model results also include a full set of energy balances (and prices), detailed power sector results by technologies, and energy-related emissions.

METHOD

The theoretical background

Economic activity undertaken by persons, households, firms and other groups in society has effects on other groups after a time lag, and the effects persist into future generations, although many of the effects soon become so small as to be negligible. But there are many actors and the effects, both beneficial and damaging, accumulate in economic and physical stocks. The effects are transmitted through the environment (for example through greenhouse gas emissions contributing to global warming), through the economy and the price and money system (via the markets for labour and commodities), and through transport and information networks. The markets transmit effects in three main ways: through the level of activity creating demand for inputs of materials, fuels and labour; through wages and prices affecting incomes; and through incomes leading in turn to further demands for goods and services. These interdependencies suggest that an E3 model should be comprehensive (i.e. covering the whole economy), and include a full set of linkages between different parts of the economic and energy systems.

The economic and energy systems have the following characteristics: economies and diseconomies of scale in both production and consumption; markets with different degrees of competition; the prevalence of institutional behaviour whose aim may be maximisation, but may also be the satisfaction of more restricted objectives; and rapid and uneven changes in technology and consumer preferences, certainly within the time scale of greenhouse gas mitigation policy. Labour markets in particular may be characterised by long-term unemployment. An E3 model capable of representing these features must therefore be flexible, capable of embodying a variety of behaviours and of simulating a dynamic system. This approach can be contrasted with that adopted by general equilibrium models: they typically assume constant returns to scale; perfect competition in all markets; maximisation of social welfare measured by total discounted private consumption; no involuntary unemployment; and exogenous technical progress following a constant time trend.

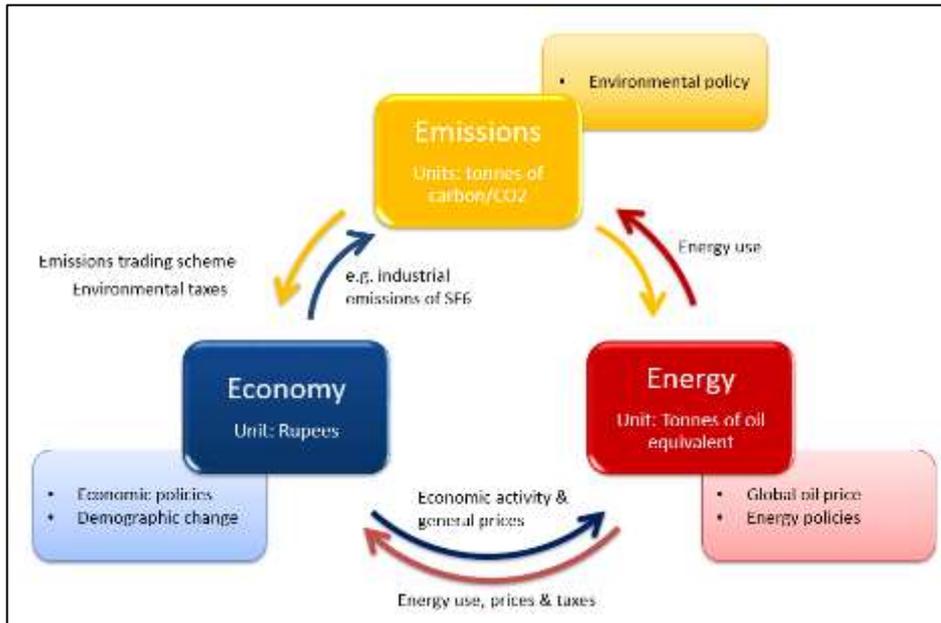

Model structure

The E3-India model comprises:

- the accounting framework of the economy, coupled with balances for energy demands and environmental emission flows
- detailed historical data sets, with time series covering the period since 1993, and sectoral disaggregation
- an econometric specification of behavioural relationships in which short-term deviations move towards long-term trends
- the software to hold together these other component parts

Figure 1 shows how the three components (modules) of the model (energy, environment and economy) fit together.

Figure 50 India-E3 as an E3 model

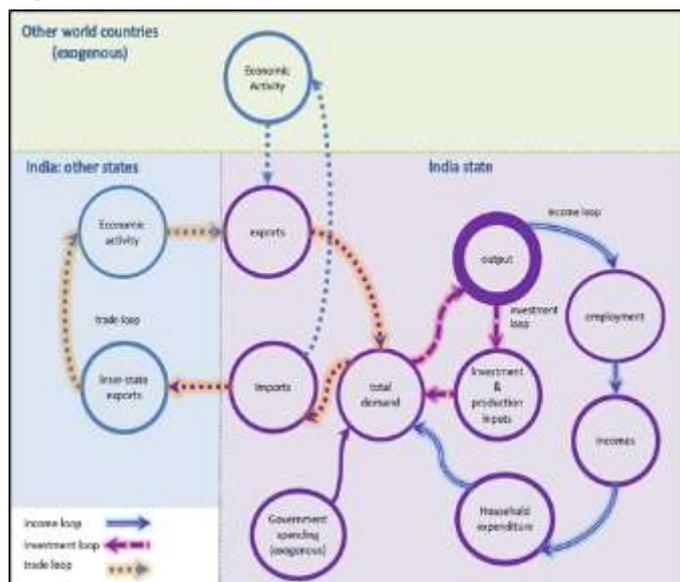

Each component is shown in its own box with its own units of account and sources of data. Each data set has been constructed by statistical offices to conform to accounting conventions. Exogenous factors coming from outside the modelling framework are shown on the outside edge of the chart as inputs into each component. For the economic module, these include demographic factors and economic policy (including tax rates, growth in government expenditures, interest rates and exchange rates). For the energy system, the outside factors are the world oil prices and energy policy (including regulation of energy industries). For the environment component, exogenous factors include policies such as carbon taxes. The linkages between the components of the model are shown explicitly by the arrows that indicate which values are transmitted between components.

The economy module provides measures of economic activity and general price levels to the energy module; the energy module then determines levels and prices of energy consumption, which is passed to the emissions module and is also fed back to the economic module.

E3-India's economic module

Figure 51 shows how E3-India's economic module is solved for each state. Most of the economic variables shown in the chart are solved at the sectoral level. The whole system is solved simultaneously for all industries and all states, although single-state solutions are also possible.

Figure 51 E3-India's basic economic structure

As the figure suggests, output and employment are determined by levels of demand, unless there are constraints on available supply. The figure shows three loops or circuits of economic interdependence, which are described below. In addition, there is an interdependency between the sectors that is not shown in the figure. The full set of loops comprises:

- Interdependency between sectors: If one sector increases output it will buy more inputs from its suppliers who will in turn purchase from their own suppliers. This is similar to a Type I multiplier.

- The income loop: If a sector increases output it may also increase employment, leading to higher incomes and additional consumer spending. This in turn feeds back into the economy, as given by a Type II multiplier.
- The investment loop: When firms increase output (and expect higher levels of future output) they will also increase production capacity by investing. This creates demand for the production of the sectors that produce investment goods (e.g. construction, engineering) and their supply chains.
- The trade loop: Some of the increase in demand described above will be met by imported goods and services (within India and outside India). This leads to higher demand and production levels in other states. Hence there is also a loop between states. Economic activities outside India are treated as exogenous in E3-India.

The components of demand

We now turn to how the model calculates results for each of the main components in the figure above. There is a mixture of accounting and behavioural relationships involved.

Intermediate demand (the sum of demand from other production sectors) is determined by the input-output relationships in the model. When one sector increases its production, it requires more inputs to do so. The sectors in its supply chain thus see an increase in demand for their products.

Estimating household consumption is a two-stage process. Total consumer spending by region is derived from functions estimated from time-series data. These equations relate consumption to regional personal disposable income, unemployment rates, inflation and interest rates. Share equations for each of the 16 consumption categories are then estimated. In the model solution, disaggregate consumption is always scaled to be consistent with the total.

Government consumption is given by assumption, split into the main different components of spending. It is therefore exogenous in the simulations and will not change unless explicitly requested by the modeller.

Gross Fixed Capital Formation is determined through econometric equations estimated on time-series data. Expectations of future output are a key determinant of investment, but investment is also affected by relative prices and interest rates.

Due to data limitations investment is not disaggregated by asset in E3-India. Stock building is treated as exogenous in the model.

In a sub-national model, trade represents a major issue in assessing regional economic impacts. Demand in each state can be met either by production within that state, production in another state in India, or production in another country. With no available data on trade between the states, it is necessary to impose assumptions on the rates of production in the states with relation to developments in neighbouring states.

The approach can be summarised as:

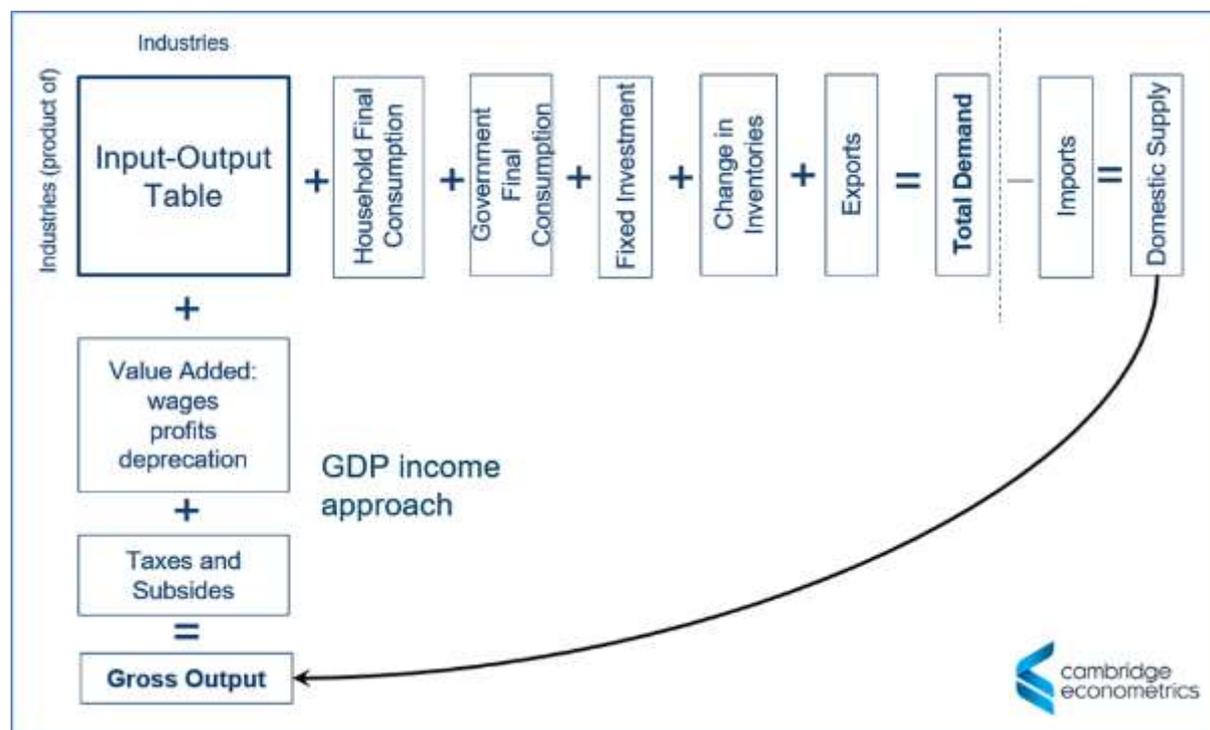

- International exports are estimated at state level, based on the production prices within each state.
- International imports are estimated at national level and applied to the states, based on estimates of current and baseline future state-level imports.
- Trade between states is estimated using production shares (export) and domestic demand shares (import).

Output and determination of supply

Total product output, in gross terms, is determined by summing intermediate demand and the components of final demand described above. This gives a measure of total demand for domestic production.

It is assumed that, subject to certain constraints, domestic supply increases to match demand (see Figure 3 for how this is implemented within the National Accounts structure). The most obvious constraint is the labour market; if there is not enough available labour then production levels cannot increase. However, full employment is an unusual position for the labour market to be in and thus the supply constraint is therefore unlikely to be an issue.

Figure 3 Determination of supply and demand

The labour market and incomes

Treatment of the labour market is another area that distinguishes E3-India from other macroeconomic models. E3-India includes econometric equation sets for employment (as a headcount), wage rates and participation rates. Employment and wage rates are disaggregated by economic sector while participation rates are disaggregated by gender.

The labour force is determined by multiplying labour market participation rates by population. Unemployment (including both voluntary and involuntary unemployment) is determined by taking the difference between the labour force and employment.

There are important interactions between the labour market equations. They are summarised below:

Employment = F (Economic output, Wage rates, ...)

Wage rates = F (Labour productivity, Unemployment, ...)

Participation rates = F (Economic output, Wage rates, Unemployment, ...)

Labour supply = Participation rate * Population

Unemployment = Labour supply – Employment

The full specification for the econometric equations is given in Chapter 5.

E3-India does not include measures of skills demand and supply explicitly, but the model results for sectoral employment and labour supply may be used to derive both of these. Nevertheless, it is important to be aware of the limitation in skills treatment within the main model structure. If a modelled scenario shows an increase in employment it is implicitly assumed that workers with the necessary skills are available. For studying large changes in employment, a supplementary bottom-up analysis is required to test feasibility of the model results.

Due to limitations in available time-series data, E3-India adopts a representative household for each region. Household income is determined as:

Income = Wages – Taxes + Benefits + Other income

The taxes currently distinguished are standard income taxes and employees' social security payments (employers' social security payments are not included in wages). A single benefit rate is used for each region.

'Other income' includes factors such as dividend payments, property rent and remittances. At present, it is not possible to derive data for these financial flows and so they are held constant in relation to wages.

Household income, once converted to real terms, is an important component in the model's consumption equations, with a one-to-one relationship assumed in the long run.

Due to data constraints, E3-India only includes a limited treatment of income distribution across different household groups.

Price formation

For each real variable there is an associated price, which influences quantities consumed. For example, each category of household expenditure has a price variable attached to it, which influences consumption patterns within the model.

Aside from wages, there are three econometric price equations in the model:

- domestic production prices
- import prices
- export prices

These are influenced by unit costs (derived by summing wage costs, material costs and taxes), competing prices and technology. Each one is estimated at the sectoral level.

One of the key price variables in the model is the price of domestic consumption. It is also determined by sector, by taking a weighted average of domestic and import prices, subtracting off the export component. This price is then used to determine the prices for final consumption goods; for example, if the car industry increases prices, this will be reflected in the price consumers pay for cars.

Aggregate deflators, including the Consumer Price Index, are derived by taking the average of prices across all products and sectors.

Social indicators

In quantitative modelling, the assessment of social impacts is often largely ignored. This is partly due to a lack of quantitative indicators but also that it often does not fit well into the basic structure of most macroeconomic models.

Like other models, E3-India can provide less coverage of social factors than economic factors and environmental impacts but social factors are not ignored completely. The main social indicators in the model are:

- sectoral employment and working hours
- sectoral wage rates
- unemployment
- an estimate of (real) income distribution when looking at issue of electricity price subsidies

The labour market indicators are discussed above, so the remainder of this section focuses on the estimates of distributional impacts.

There is no explicit modelling of the distribution of income in E3-India, except when looking at the issue of electricity price subsidies.

The model has an option to adjust electricity price subsidies by household group (five income quintiles and a rural/urban split), which enables users to adjust the subsidy rates and then assess the distributional impacts of electricity price policies (although without feedback to the rest of the model). The distributional impacts among households are calculated from state-level data on different electricity tariffs, average electricity consumption and income distribution by household group.

Demographic variables

Population projections are treated as exogenous in E3-India, apart from migration between Indian states. Aside from the endogenous treatment of migration, state population projections follow the overall population trends for India published by the UN (World Population Prospects).

Inter-state migration is modelled using a simplified concept of spatial transactions. The decision to migrate between states is determined by economic distance, i.e. pair-wise differences in GDP growth rates, weighted by physical distance between the states.

Energy-emissions modelling in E3-India

The energy module in E3-India is constructed, estimated and solved for each energy user, each energy carrier (termed fuels for convenience below) and each state.

Aggregate energy demand is determined by a set of econometric equations, with the main explanatory variables being:

- economic activity in each of the energy users
- average energy prices for each energy user in real terms
- technological variables, represented by investment and R&D expenditure

Price elasticities

Typically changes in energy prices in the historical data have been due to fluctuations in commodity prices and have been temporary in nature. However, the changes in energy prices that are modelled using E3-India tend to be based on permanent changes in policy and are therefore more likely to lead to behavioural change. Estimating elasticities based on the time-series data could thus lead to a downward bias.

Instead the long-run price elasticities used are taken from a combination of cross-section estimation and reviewed literature. For most sectors the values range from -0.2 to -0.3, meaning that a 1% increase in price leads to a 0.2-0.3% reduction in consumption. For road transport, a higher value of -0.7 is used, taken from Franzen and Sterner (1995) and Johansson and Schipper (1997, p.289) and confirmed by our own analysis. Short-run elasticities are based on the time-series data and are usually close to zero.

Fuel substitution

Fuel use equations are estimated for four energy carriers (coal, oils, gas and electricity) with four sets of equations estimated for the fuel users in each region. These equations are intended to allow substitution between the four energy carriers by users on the basis of relative prices, although overall fuel use and the technological variables can affect the choice.

Due to limitations in biomass prices, biomass consumption in E3-India is treated as a residual fuel demand and is modelled as a fixed ratio to aggregate energy use (final use only). Biomass used in power generation comes from FTT results.

One point to note is that the current version of E3-India includes only existing fuel types for road transport. The econometric equations are not able to consider electrification of the transport system as there is no historical precedent for this. These developments must therefore be entered by assumption by the model user.

Feedbacks to the economy

The economic feedbacks are based on the fact that the same transactions appear in the energy data and in the economic data, albeit in different units. For example, the iron and steel sector's purchases of coal appear as:

- coal consumption in the energy balances (as time series), measured in toe
- an input-output flow in the National Accounts (for the base year), measured in m rupees

The feedbacks from the energy module assume a one-to-one relationship between these two measures, once price changes are considered.

This places quite a strong reliance on consistency between the two data sets. Theoretically the energy balances multiplied by the fuel costs (excluding taxes) should match against the flows in the input-output table, once distribution costs are taken into account. However, this is often not the case (for example due to differences in definition and a lack of state-level input-output data) and the mismatch in data can lead to apparently non-important uses of fuel having large economic consequences.

The team at Cambridge Econometrics therefore works to ensure consistency in the data sets where reasonably possible. Adjustments are made to the base-year input-output tables to ensure accuracy in the modelling.

There are also feedbacks from the energy module to household final demand. In the same way that an input-output flow provides an economic representation of industry purchases of energy, consumer expenditure on energy in the national accounts is equivalent to the energy balances for household purchases. In E3-India, the approach is to set the economic variables so that they maintain consistency with physical energy flows. The same issues about consistency of data described above apply here.

Emissions

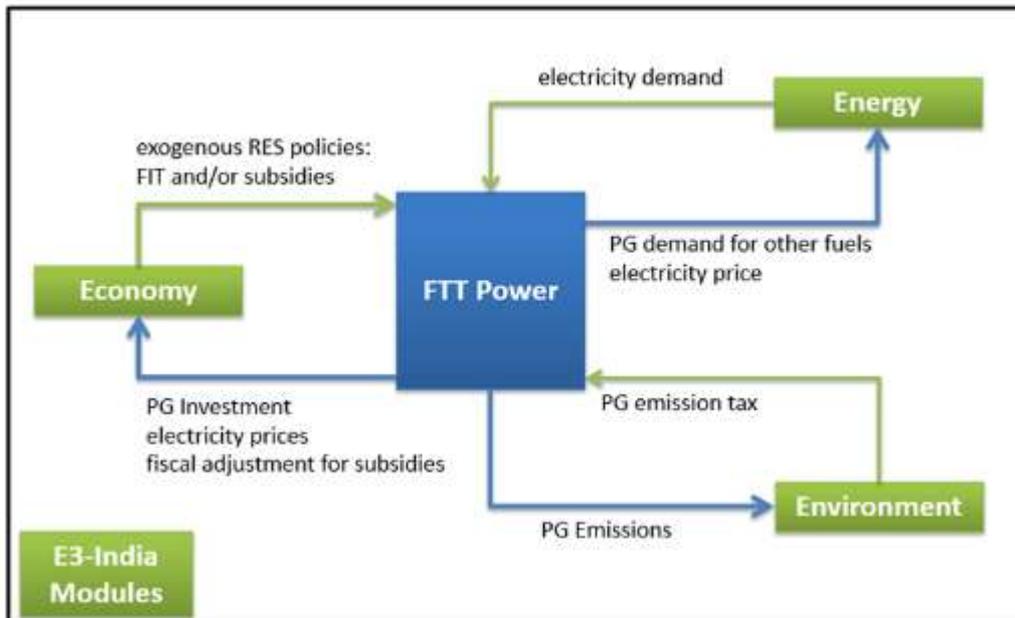

The emissions module calculates carbon dioxide emissions generated from end-use of different fuels and from primary use of fuels in the energy industries themselves, particularly electricity generation. The current E3-India version does not cover other non-CO₂ atmospheric emissions due to data limitations at state-level.

Emissions data for CO₂ from energy consumption are available for each of the energy users in the model. Coefficients (tonnes of carbon in CO₂ emitted per toe) are implicitly derived using historical data (and sometimes also baseline projections). This forms the relationship between energy consumption and emissions.

The power sector model

The power sector in E3-India is represented using a novel framework for the dynamic selection and diffusion of innovations, initially developed by J.-F. Mercure (Mercure, 2012), called FTT:Power (Future Technology Transformations for the Power sector). This is the first member of the FTT family of technology diffusion models. It uses a decision-making core for investors wanting to build new electrical capacity, facing several options. The resulting diffusion of competing technologies is constrained by a global database of renewable and non-renewable resources (Mercure & Salas, 2012, 2013; adapted for the states of India). The decision-making core takes place by pairwise levelised cost (LCOE) comparisons, conceptually equivalent to a binary logit model, parameterised by measured technology cost distributions. Costs include reductions originating from learning curves, as well as increasing marginal costs of renewable natural resources (for renewable technologies) using cost-supply curves. The diffusion of technology follows a set of coupled non-linear differential equations, sometimes called 'Lotka-Volterra' or 'replicator dynamics', which represent the better ability of larger or well established industries to capture the market, and the life expectancy of technologies. Due to learning-by-doing and increasing returns to adoption, it results in path-dependent technology scenarios that arise from electricity sector policies.

Figure 4 FTT basic structure

FTT:Power determines a technology mix by each state given a scenario of detailed electricity policy: carbon prices, subsidies, feed-in tariffs and regulations by technology. Changes in the power technology mix result in changes of production costs, reflected in the price of electricity. The model takes electricity demand from E3-India and feeds back a price, fuel use and investment for replacements and new generators.

Natural resource constraints

The representation of FTT:Power in the global E3ME model includes constraints on the supply of both renewable and non-renewable resources (Mercure & Salas, 2012, 2013, e.g. barrels of oil, or suitable sites for wind farms).

Non-renewable resources are treated as exogenous in E3-India since the rest of the world is not included. Due to data restrictions, it is only possible to introduced state-level constraints for some renewable technologies:

- for wind and solar, using information from MapRE , we introduce cost-curves to include diminishing capacity factors
- for hydro, state level maximum potentials are added using information from Energy Alternative India (EAI)
- landlocked states have zero potentials for wave, tidal and off-shore wind

Innovation and endogenous technological progress

In the past, technological progress has often been represented as exogenous in macroeconomic models (e.g. via a time trend) or as a residual in a neoclassical production function. Both methods have their drawbacks. The neoclassical approach is somewhat circular in its logic, i.e. to know a firm's production possibilities one needs to model technological progress, but in modelling technological progress one is already making an assumption about the production process. The time trend approach is also unappealing given its theoretical background.

Data availability for state-level investment is poor and there are no data for R&D. For this reason, R&D is set to zero in the technological progress indicator equation. In the future, R&D could be incorporated when data become available. Overall, the indicator is constructed using investment data of variable quality and users should exercise caution when using the indicator.

The measures of technological progress include both product and process innovation and this is represented in the various feedbacks to other parts of the model: a higher quality product could lead to higher levels of demand or command a higher price, so the technology indices feature in the model's trade and price equations. Additionally, the term is included in the model's energy demand equations to represent efficiencies.

The financial sector

E3-India features a specific treatment of financial balances in the economy. Equation specifications are included for each of the main institutional groups included in the model. Figure 5 presents a summary of the bilateral financial flows between groups. The crucial assumption in E3-India's financial block is that reserves provided by the central bank are not fixed: the money supply is endogenous. Pollitt & Mercure (2018) provides an analysis of the treatment of the financial sector in CGE and macro-econometric models, which are used to assess climate and energy policy.

Figure 52 Financial block basic structure

Sector Receiving

		Government	Households	Industry	Banking system	Other states	Other countries
Sector Paying	Government	x	Benefit payments	Government expenditure	Government saving and interest payments		
	Households	Taxes on income and expenditure	x	Household consumption net of tax	Household saving and interest payments	Expenditure in other states	Expenditure outside India
	Industry	Taxes on production	Wage payments, dividends	Inter-sectoral purchases	Retained profits, interest payments	Imports from other states	Imports
	Banking system	Government borrowing	Household borrowing	Industry borrowing	x		
	Other states			Exports, FDI (incl tourist expenditure)		x	
	Other countries			Exports, FDI (incl tourist expenditure)			x

COMPARING E3-INDIA TO ECONOMETRIC FORECASTING MODELS

E3-India could also be compared to short-term econometric forecasting models. These models, which are typically operational in government, describe short and medium-term economic consequences of policies but with a limited treatment of longer-term effects. This limits their ability to analyse long-term policies and they often lack a detailed sectoral disaggregation.

These models are usually used for short-term forecasting exercises, often with a quarterly or even monthly resolution.

E3-India combines the features of an annual short- and medium-term sectoral model estimated by formal econometric methods with the detail and some of the methods of CGE models, providing analysis of the movement of the long-term outcomes for key E3 indicators in response to policy changes. It is essentially a dynamic simulation model that is estimated by econometric methods.

E3-India has a complete specification of the long-term solution in the form of an estimated equation which has long-term restrictions imposed on its parameters. Economic theory informs the specification of the long-term equations and hence properties of the model; dynamic equations which embody these long-term properties are estimated by econometric methods to allow the model to provide forecasts. The method utilises developments in time-series econometrics, with the specification of dynamic relationships in terms of error correction models (ECM) which allow dynamic convergence to a long-term.

E3-India is therefore the result of an ambitious modelling project which expands the methodology of long-term modelling to incorporate developments both in economic theory and in applied econometrics, all applied at the state level in India.

Comparative advantages of E3-India

Compared to the other macroeconomic models in operation currently across the world (both CGE and otherwise), E3-India has advantages in the following four important areas:

- Geographical coverage
The current version of E3-India provides state-level coverage, with explicit representation of each state and territory in India.
- Sectoral disaggregation
The sectoral disaggregation of the model allows the representation of fairly complex scenarios at state level, especially those that are differentiated by sector. Similarly, the impact of any policy measure can be represented in a detailed way, for example showing the winners and losers from a particular policy.
- Econometric pedigree
The econometric and empirical grounding of the model makes it better able to represent performance in the short to medium terms, as well as providing long-term assessment. It also means that the model is not reliant on the rigid assumptions common to other modelling approaches.

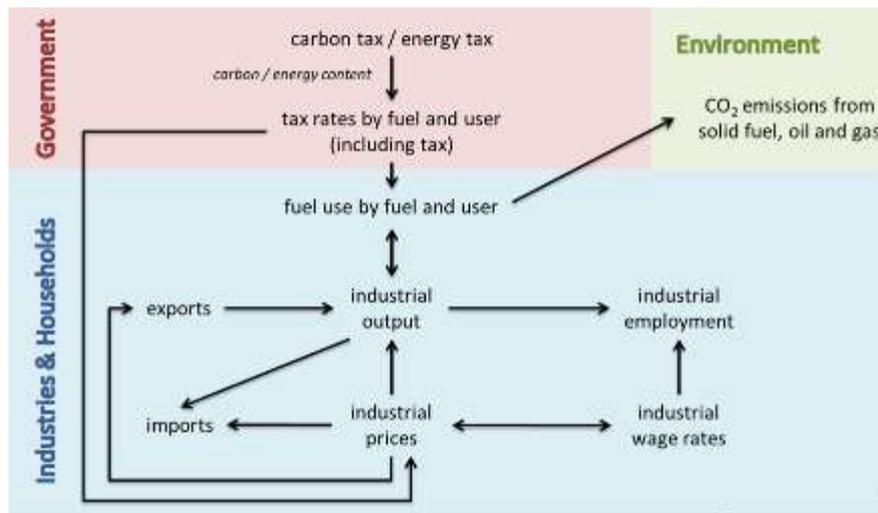

E3-India is a hybrid model. A non-linear interaction (two-way feedback) between the economy, energy demand/supply and environmental emissions is an undoubted advantage over models that may either ignore the interaction completely or only assume a one-way causation.

ILLUSTRATIVE EXAMPLE OF POLICY ANALYSIS USING E3-INDIA: CARBON TAX

Carbon pricing is a central pillar to the climate policy discussion globally. E3-India’s focus on energy and climate policy allow a detailed analysis of such a policy. Disaggregation by fuel types and fuel users enables users to assess targeted policy, such as future pathways of the Indian clean energy cess, introduced in 2010. Figure 6 details the key model interactions of introducing a carbon or energy tax. It illustrates the socioeconomic, energy, and environmental implications of policy which can be assessed.

The financial specification in E3-India allows users to develop the fiscal side of a carbon tax. Users can decide if carbon revenues are used to reduce government deficit or to reduce other taxes. Alternatively, the user can develop a more comprehensive climate and energy policy, such as directing carbon tax revenues to subsidising renewable technologies in power generation.

Figure 53 Modelling a carbon tax: E3-India interactions

1625 ENERGY, EMISSIONS AND ECONOMY WIDE IMPACTS OF COUPLED ENERGY EFFICIENCY AND RENEWABLE ENERGY MEASURES

ABSTRACT

This paper is being proposed as part of "E3-India Special Session". As India moves towards meeting its Intended Nationally Determined Contributions (INDCs) to emissions, policy makers have to choose among alternative policy options. The investment in renewable energy continues to be the primary choice. Energy efficiency is relegated to the second place as savings are not visible and its economy wide impacts are difficult to estimate. The debate on the choice between energy efficiency and renewable energy is far from settled and decisions continue to be made void of empirical evidence. In this paper, we estimate the (a) reduction in energy consumption and emissions, (b) economy wide impacts on GDP, employment and income over time due to promotion of efficient household appliances in the India. We find that this leads to reduction in electricity demand and avoided investments in construction of new power plants. In the next step, we allocate the money saved in construction of new power plants to promotion of renewable energy. We then re-estimate on emissions and economy as a result of two pronged approach. This method helps to quantify the complete monetary and environmental benefits of efficiency improvement programs dovetailed with renewable energy policy. The impacts of these scenarios are estimated based on their economy wide impacts using a coupled input-output econometric framework of the newly developed E3-India model. The model captures the relationship between Economy, Energy and Emissions, covering 20 economic sectors and five income quintiles for India's 27 states.

1769 THE IMPACT CREDIT, PUBLIC SUPPORT AND EXPORTS ON REGIONAL GROWTH. THE CASE OF THE AZORES

ABSTRACT

According to the Base Model, regional growth depends on the growth of the basic activities. Nevertheless, these basic activities involves not only exports but also all the inflows of money associated with public and private transferences and credit. The aim of this paper is to analyze the factors of growth in the economy of the Azores. To achieve that we estimate an econometric model with data from 2000 until 2016 that relates total employment with the main exports, credit and external support for the Azores Economy. We conclude that in a period of crises the dynamic of credit plays a crucial role in the economy and that the change in policies related to the exports activity do have a major impact on the economic system.

RS07.3. Methods in Regional Science and Urban Economics

1022 THE ROOTS OF A DUAL EQUILIBRIUM: GDP, PRODUCTIVITY AND STRUCTURAL CHANGE IN THE ITALIAN REGIONS IN THE LONG-RUN (1871-2011)

ABSTRACT

The article presents and discusses up-to-date estimates of GDP per capita, GDP per worker (productivity) and employment for Italy's regions, spanning 140 years in ten-year benchmarks (1871-2011), at the NUTS II level and at current borders, for the whole economy and its three branches - agriculture, industry, services. Sigma and beta convergence are tested for GDP per capita, productivity (GDP/employment) and workers per capita (employment/population). Four phases in the history of regional inequality in post-unification Italy are identified, roughly coinciding with the different political eras of the country: mild divergence (the liberal age), strong divergence (the two world wars and Fascism), general convergence (the golden age) and the "two-Italies" tale (1971-2011). Over the long-run, we document an increasing North-South polarization, with differences in employment becoming more important than those in productivity. This result is in line with a socio-institutional interpretation of the North-South divide.

1036 A STUDY ON ENVIRONMENTAL VIOLATIONS FOR BRAZILIAN MUNICIPALITIES: A LIMITED INFORMATION MAXIMUM LIKELIHOOD APPROACH TO SPATIAL DYNAMIC PANEL

ABSTRACT

This paper presents novel evidence for environmental offenses in Brazil. IBAMA's strategy to deter violations is based on large operations and on decapitalizing offenders to signal it's will to monitor and enforce the law. We want to answer the following questions: Do the sanctions applied by IBAMA, especially sanction charges, deter actual and potential offenders? Are there any spatial or temporal patterns affecting violations? We use data on offenses against flora and applied fines for Brazilian municipalities between 1998 and 2015. We contribute to the existing research by providing evidence for Brazil and by incorporating spatial controls in a dynamic panel approach to explain infractions against the environment. We develop and apply a Spatial LIML estimator that accounts for the endogeneity of sanction charges to estimate our panel models. Results show that there is a pedagogic deterrent effect associated with applied fine values. Sanction charges are important to discourage new offenses.

1048 CAREER PATHS AND WAGES IN DIFFERENT CITY SIZES

ABSTRACT

We assess how career paths are influenced by the size of the cities. We follow a group of 2 million Brazilian workers for 14 years and assess their wage history, as well their mobility in terms of occupations, firms and cities. We estimate the wage premium for staying in the same job or changing jobs in the same city or in another city. We are able to determine the role of city size on career success.

RS08.1. Migration and Labor Markets

1186 HETEROGENEOUS BENEFITS OF DENSE LABOUR MARKETS - EVIDENCE FROM TRANSITIONS TO EMPLOYMENT IN GERMANY

ABSTRACT

We investigate whether the size of the local labour market impacts on the wage of new employment relationships and whether the benefits of large urban labor markets significantly differ across distinct types of transitions to employment. The analysis is based on a large data set providing detailed micro-level information on transitions to employment in Germany. Our results suggest rather small static urbanisation benefits. Doubling employment density increases the productivity of new employment relationships by 0.9% up to 2.2%. Moreover, the findings indicate that the benefits accrue only to persons experiencing job-to-job transitions and short-term unemployed. We detect no important impact of urbanisation on transitions from long-term non-employed. We suppose that these differences point to matching advantages in large urban labour markets from which only some job seekers benefit.

1253 EMERGING KOLKATA WITH ITS MIGRATING POPULATION MAKING CHANGE IN LABOR MARKET

ABSTRACT

Migration means movement of people from one place to another place. It plays an important role on labor market. Migration is affected by pull and push factors, which transfers labor from areas of surplus to areas of deficit. It helps to raise productivity of the labor force and minimizing imperfections in the labor market. This paper is an attempt to discuss the relationships between migration and labor market. The main objective of this paper to analyze the impact of migration on labor market. For this purpose Kolkata Metropolitan area has been chosen as study area. Kolkata is located in 22.5726°N to 88.3639°E. It is the capital of the Indian state West Bengal, situated on the east bank of river Hooghly. Kolkata is the third most populous metropolitan area in India after Delhi and Mumbai but now days, Kolkata is suffering from high migrated population. Migration is one of the common trends in these days. In rural Bengal, people are facing so many problems which pull them to Kolkata. In search of employment people are migrating from rural areas as daily workers. They are migrating from mainly South 24 Pargana, North 24 Pargana and Howrah. This continuous influx of migrated labor is creating pressure on labor market which results the stagnation of employment. The study is based on primary and secondary data. Primary data are collected through random, stratified and purposive sampling process. The secondary data are collected from different data sources such as Census Report 2011, professional magazines, reference book, newspapers, journals etc. various quantitative techniques are applied to establish the relation between migration and labor market. Gravity Model, based on Newton's law of gravitation has been used here to analyze the relationship between distance and migration. Relative Deprivation theory of migration by Oded Stark, applied here to create link between social mobility and migration. Lastly, the main pull factors of the rural to urban migration are identified with the help of Dual Labor Market theory. Perception study of laborers is also done here. The study reveals that migration has both positive and negative impacts on labor market. It creates labor availability but also reduces wage rate of the labors. Due to excessive labor, skilled labors are getting more priority than unskilled labors and a huge wage difference has been created between skilled and unskilled labors which results inequality in society. There is a need for balanced development across all regions of West Bengal. More focus is needed on the employment opportunities of rural areas and better schemes should be designed to overcome this condition. Key words: Migration, labor market, pull and push factors, impact of migration, gravity model, dual labor market theory, relative deprivation theory.

1482 INTERNATIONAL COMMUTING BETWEEN NEIGHBOURING EU-COUNTRIES

ABSTRACT

This paper will investigate annual international commuting between neighbouring EU-countries during the period 2011-2014. International commuting from one EU-country to a neighbouring EU-country will be explained by differences between the two countries in (i) hourly (net) wage costs; (ii) kilometres of expressways; (iii) unemployment rates. See also Mathä and Wintr (2009). A common language between neighbouring countries will also be taken into account when explaining international commuting. Apart from overall commuting, we also distinguish between commuting by different types, like gender, education level, working time, contract type, age- group, firm size of the working firm and nationality of the commuter. These different types may lead to different levels of commuting and thus may have different effects of our explanatory variables. These different estimation results will be presented and discussed. Finally, we will also make recommendations based on our analysis that will help to stimulate cross-border commuting in the EU.

1518 DETERMINANTS OF RURAL TO URBAN MIGRATION IN LARGE AGGLOMERATIONS IN INDIA: AN EMPIRICAL ANALYSIS

Sabyasachi Tripathi

Assistant Professor, Department of Economics, Lovely Professional University, Email; sabya.tripathi@gmail.com; Phagwara, Punjab 144411.

ABSTRACT

The paper investigates the relevant determinants of rural to urban migration in large agglomerations in India. The OLS regression results based on data from 51 cities, show that city-wise employment and unemployment situation (measured by male self employed, not in labour force male, male casual labourer) have a negative impact on city level rural to urban migration. The level of poverty (measured by poverty head count ratio) and inequality level of a city also has a negative impact. However, infrastructure condition (availability of total number of electricity connection) of a city has a positive impact on city-wise rural to urban migration. Economic conditions also matters higher level of rural to urban migration. Finally, it suggests that cities need to equip themselves with better infrastructural facilities along with higher job opportunities to encourage urbanization through rural-urban migration for higher and sustainable economic growth in India.

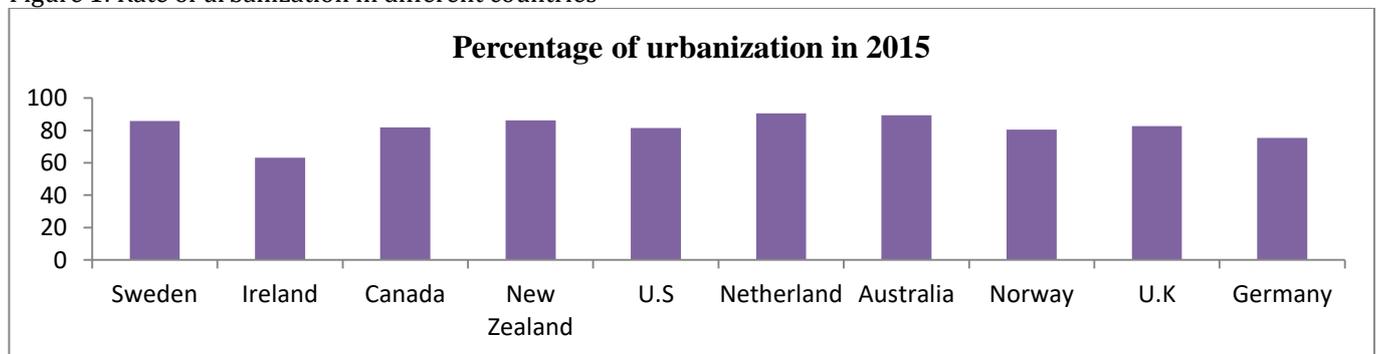

Key Words: Urbanization, rural to urban migration, urban economic growth, India.

JEL Classification: R12, O10, O15

1. INTRODUCTION

In the wake of the rapid urbanization in recent years, Indian economy is witnessing a transformation from an agro-based rural economy to an urbanized modern economy. After independence, urbanization rate has increased continuously; in urban population in India was 28.53 percent in 2001 which increased to 31.16 per cent in 2011. The growth of urbanization has led to higher economic growth (Tripathi, 2013; Tripathi and Mahey, forthcoming) i.e., urbanization is the engine of economic growth in India. Currently 31.16% urban population is contributing about 63% of India’s GDP (GOI, 2011). However, the percentage of population residing in urban areas in developed countries is far greater than in India. As shown in Figure 1, per the data given by World Urbanization Prospects (WUP) (UN, 2014) 85.8 % (or 75.3 % or 63% or 81% or 90.5 % or 89.4 % or 80.5 % or 82.6 %) urban population live in Sweden (or Germany or Ireland or Canada or New Zealand or U.S.A. or Netherlands or Australia or Norway or U.K.) as of 2015. This clearly indicates that India's urbanization rate is lower than in the developed countries.²⁴⁷ It is also predicted that India’s future development process ought to be lead by high urbanization rate.

Figure 1: Rate of urbanization in different countries

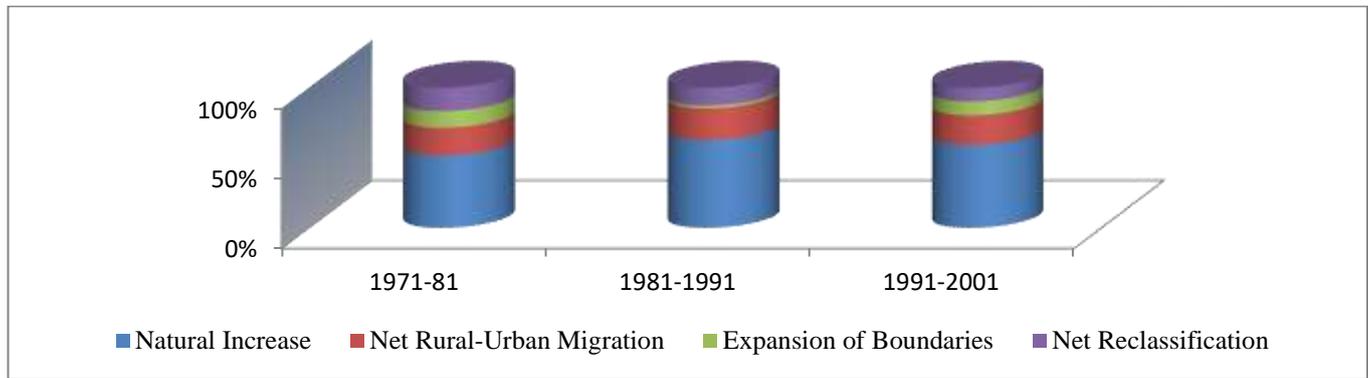

Source: WUP (2014)

The urban growth occurs due to the natural growth of population, expansion of city boundaries, net rural to urban migration, and reclassification of rural areas into urban. Figure 2 shows that net migration from rural to urban areas contributed to about 21 per cent to the increase in urban population in the 1990s, a little smaller than its contribution of 22.6 per cent in the 1980s. Natural increase has been by far the largest source of increase in urban population (62.7 per cent in the 1980s and 59.2 per cent in the 1990s).

Figure 2: Sources of Increase in Urban Population

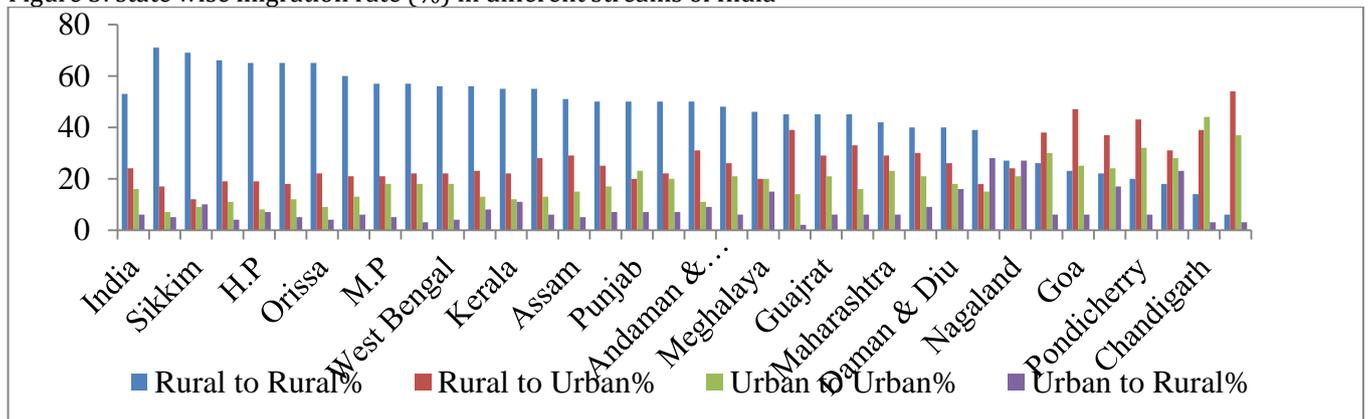

²⁴⁷ Though different countries follow different definitions to measure urbanization still we can say India’s urbanization rate is much lower than other developed countries.

Source: GOI (2011)

Migration is the transfer of population from one area to another. Labour migration from agricultural sector to non-agriculture sector in 2007-08 was 66% in which 63% of migrants were men in India. The migration of male population is greater than female. Migration leads to higher growth in urban population, but the migration rate has been very low in India. To increase the growth rate of urbanization, it is essential to promote rural to urban migration. Migration depends upon many factors like job opportunities in urban areas, urban poverty, and higher urban wage rate. Thus, migration positively impacts, the growth of economy, albeit indirectly. Rural to urban migration leads to the growth of economy through the growth of urbanization. Migration could be voluntary or coercive. Voluntary migration occurs due to the promise of job opportunities, education, better medical care, securing family links, industrial job, higher income etc. in the host city. On the other hand, forced migration occurs due to drought, political war, poor medical care, loss of wealth, forced labour, etc.

Figure 3: state wise migration rate (%) in different streams of India

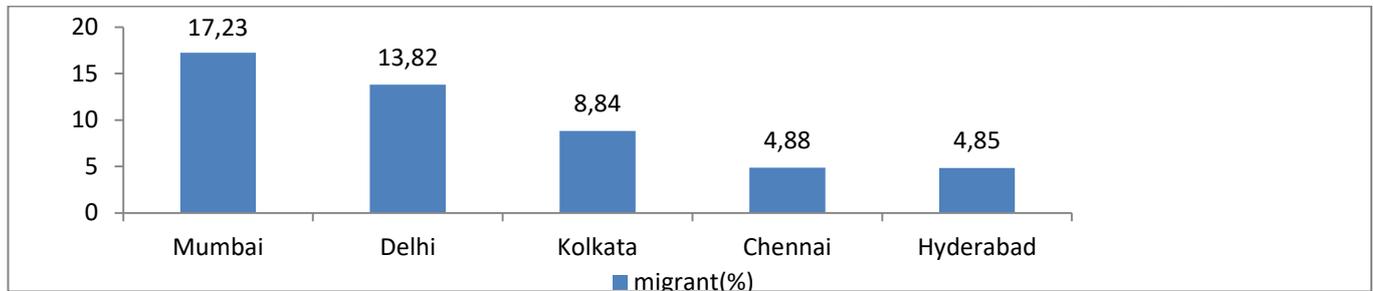

Source of data: NSSO 64th round National Sample Survey of India

The 64th round of Indian National Sample Survey Office (NSSO) on “Employment & Unemployment and Migration Particulars” during July 7 to June 8 2007-08, covered a sample of 1,25,578 households and 5,72,254 persons. The survey, taking into account the entire mobility including within - and between states, estimates the mobility of the Indian population as about 30 percent. However, within this 30% the share of migrants within the state was 85% and across state, 15%. In other words, migration was by and large rural to rural. Figure 3 provides figure of state- wise migration between rural to rural, rural to urban, urban to urban, and urban to rural. As can be seen from the table, in internal migration, the maximum percentage of migration was rural to rural. Rural to urban migration was the highest in Delhi at 54%. In the rural to urban migration stream, Sikkim had the lowest percentage value of 12%. The percentage of urban to urban migration was quite in Chandigarh at 44%. The percentage value of urban to urban migration was quite for Manipur also. The figure shows that the percentage of rural to urban migration is less than that of rural to rural migration in India. On the other hand, developed or economically advanced Indian states have a higher level of rural to urban migration rate than the less developed states. It becomes clear from the above analysis that in order to have higher development, rural-urban migration needs to be promoted.

Given the present focus on smart cities/million plus cities, it is necessary to consider India-specific data on migration, particularly rural-urban migration arrive at any meaningful conclusion. The diagram below (Figure 4) shows the trends of migration in top five million plus cities on the basis of census of India in 2001 on a time-scale of ten years and more than 10 years. Mumbai reported 17.32% its population as migrants, which is quite higher than in other million plus cities. The second-ranking city, Delhi, reported 13.82% as its migration of population.

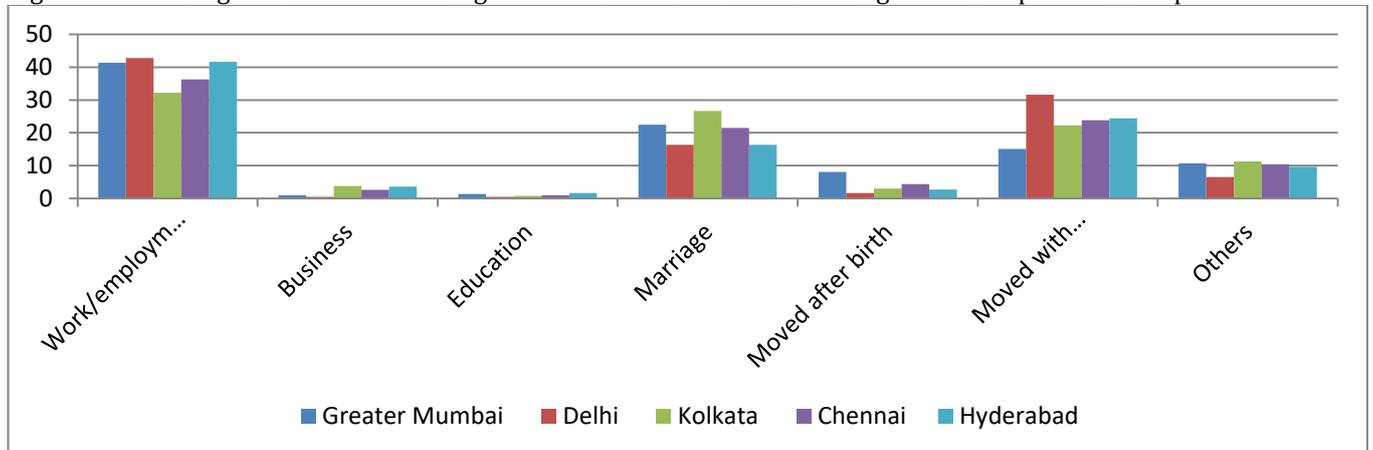

Figure 4: Percentage of rural to urban migration in top five (as per population size) million plus cities

Source: Census of India 2001

The Census data also provides enough clues about the reasons for rural to urban migration in these cities. Figure 5 shows the percentage of rural to urban migrants on the basis of reasons of migration in top five million plus cities with the time duration of ten years and more than ten years. The figure indicates that the main reasons behind the migration of population are work and employment. A large part of migrants move from backward to modern areas due to lure of job opportunities. It is observed that the largest rural-urban migration was to Mumbai (28,47,510 persons), of which 41% people cited work and employment as reasons for migration; 22% people migrated due to marriage in which the percentage of women was higher than that of men. Migration to Delhi, Chennai and Hyderabad also show the same pattern; higher rural to urban migration was dominated by work and employment reasons in these cities. Marriage and consequent re location of households is also cited as causes for rural to urban migration.

Figure 5: Percentage of rural to urban migrants on the basis of reasons of migration in top five million plus cities

Source: Census of India (2001)

Recently, government of India has launched several policies and programmes to promote urbanisation-led development in India as urban areas have traditionally contributed higher level of GDP than rural areas. Among the various policies, 100 Smart Cities Programme, AMRUT (Atal Mission for Rejuvenation and Urban Transformation), JNNURM (Jawaharlal Nehru National Urban Renewal Mission), UIDSSMT (Urban Infrastructure Development Scheme for Small and Medium Towns), NERUDP (North Eastern Region Urban Development Programme), NUIS (National Urban Information System), Capacity Building for Urban Local Bodies, Lump Sum Provision Scheme for the benefit of North East Region (NER) including Sikkim, Brihan Mumbai Storm Water Drainage (BRIMSTOWAD) project at Mumbai, PPP (Public Private Partnership), Clean India Mission are the major programme and policies introduced by governments in recent years to promote urbanization in India.

The above discussion clearly indicates that India is experiencing a higher level of urbanization and its contribution to national income is also high. This in turn indicates that Indian economy is going through a transformation from an agricultural based rural economy to an industry and service lead urban economy. In fact, recent years government has initiated and implemented various urban related policies and programs to promote urbanization in India. However, the country needs still better policies in the days to come to promote planned urbanization in India and to absorb the maximum economic potential that urban areas can provide for sustainable economic growth in India. Given the importance of knowing the factors which contribute to rural to urban migration in India, it is imperative to systematically study the determinants of rural to urban migration in India. It is only fair to that rural to urban migration will lead to future rapid urbanization in India which in turn will lead to higher and sustainable economic growth. It is hoped that the findings of this paper will help policy makers to formulate effective policies in India to promote urbanization through rural to urban migration. It is also surmised from a review of existing studies on this topic is that this is first study in India which considers city specific factors to identify the reasons behind city level rural to urban migration.

In this study, urban agglomeration is defined as a geographic concentration of urban population and related economic activities. This implies that urban agglomeration includes, but is not equal to, urbanization. Here, cities with 750,000 or more inhabitants as of 2015 are defined as large urban agglomerations. There are several reasons behind the selection of such large agglomerations as the units of analysis. First, World Urbanization Prospects provide updated data for the

cities with 750,000 or more inhabitants for the years 1950 to 2025 with five year intervals, whereas Indian census data only provides data up to the 2001 census (as latest 2011 census data is yet to be published) with a 10 year interval. Second, because of the unavailability of city specific data for a large number of variables used in this study (e.g. city income data), city district (where the sample city is located) is used as a proxy of a city. Larger cities are a good proxy for a city district as they cover a larger portion of a district than the smaller cities. Third, as India's urbanization (i.e. share of urban population) is mainly centred around Class I cities, these cities by definition belong to Class I cities. On the other hand, urban economic growth is defined by growth rate of city domestic income (i.e. non - primary district domestic product [DDP])

2. BRIEF REVIEW OF LITERATURES

To understand the movement of people occurring within the country, it is important to study the migration pattern initially. Arzaghi and Rupasingha (2013) argued that the migration of rural to urban occurs due to diversification. The migrants get opportunities to migrate due to correlation of income between origin and destination as measure of diversification, as in the case of United States. Iversen (2006) argues that the rural to urban migration is a dynamic migration model. The reasons of migration are social network, multipliers, spillovers, and caste affinities and the job opportunities in urban areas. According to McCatty (2004) who examined the need of rural to urban migration in developing countries, migration takes place in these countries due to both the push-pull migration forces these forces are of two types -- voluntary forces and involuntary forces. Voluntary forces are job opportunities; education, medical facilities, high per capita income, transport facilities, high living standard etc., and the involuntary forces are political disputes, strike, fighting with neighbors, lack of transport facility, illiteracy, natural disaster, bullying etc.

In the context of India, Mitra and Murayama (2009) found that intra state migration is much higher in magnitude than inter-state migration rate in India. Male and female migration rates are closely inter connected irrespective of whether they migrate from rural areas within the states and outside the states. The social and cultural diversity in India stands as a major hindrance to population mobility. Bhagat (2014) argued that migrants with low education and skills, given with the seasonal and temporary nature of their employment, are more vulnerable and subject to various kinds of exclusions in urban areas. Migration is treated more as an issue of governance rather than one of development in developing countries like India. Akram (2015) analyzed the push factors of rural to urban labour migration in India. His empirical analysis shows that increase in per capita Net State Domestic Product tends to decrease the number of out-migrants from the rural areas of that state whereas increase in the proportion of population living below poverty line, higher proportion of Scheduled Castes in the population and illiteracy rate in the rural area of the state, etc. tend to decrease rural to urban labour migration from that state to other states. Agasty and Patra (2013) who examined the determinants of rural to urban migration in the Indian states of Orissa states that there are two types of variables that influence the migration rural to urban: micro variables and macro variables. These are the two variables that influence people to move from one place to another. Micro variables are individual variables and macro variables refer to the factors that influence the whole population of a particular place or area to move.

However, there only a few studies that have tried to investigate the economic factors that contributes to rural to urban migration in India. Therefore, it is hoped that the present study will be useful not only to measure the effect of migration on urbanization but also its effect on economic growth and development.

3. EMPIRICAL FRAMEWORK AND RESULTS OF THE ESTIMATION OF DETERMINANTS

To empirically investigate the determinants of rural to urban migration in large agglomeration in India, the following OLS regression model is used for estimation.

$$\text{Migrant} = \alpha_0 + \sum_{i=1}^9 \alpha_i X_i + \epsilon \tag{1}$$

Here, the dependent variable 'Migrant' in equation 1 has two different forms; first it is measured by percentage of rural to urban migration in large agglomeration in India and secondly, it is measured in terms of the total number of rural to urban migrants. The X_is are independent variables i.e. city wise total self employed male, city-wise self employed female, level of inequality, railway station- distance from the city, total number of electricity connections, not in male labour force, city-wise total number of universities, casual worker male, city output, city-wise poverty headcount ratio, city-wise poverty gap ratio, city-wise total no. of medical facilities, city wise average rain fall, city-wise total receipts and city-wise total number of colleges.

Appendix table AI lists out the all the cities which are considered for the study. Summarized in Appendix table AII are the descriptions, measurements, and data sources of all of the variables used in estimation of OLS regression of Equation 1. Table 1 explains the means, standard deviations, minimum, maximum, and coefficient of variation (CV) values for the variables used for the regression analysis. Most importantly, the CV aims to describe the dispersion of the variables in a way that does not depend on the variable's measurement unit. The higher values of CV for railway station distance from the city in and total number of electricity connections indicate a greater dispersion in these variables. On the other hand, city output, city wise average rain fall and city wise total number of self employed male show a lower dispersion in these variables. On the other hand, Table 2 presents the row correlation coefficients.

Table 1: Description of data used in the regression equation

Variables	Mean	Std. Dev.	Min.	Max.	C.V.
Percentage of rural to urban migration in 2001 (prum)	18.6	12.2	2.7	47.4	65.7

Total number of rural to urban migrants (trum) (in thousands)	383.1	794.9	25.7	4651.5	0.21
City wise total Self employed male in 2004-05 (selfm)	328.4	94.6	188.8	615.8	28.8
City-wise self employed female in 2004-05 (self)	91.0	71.8	7.4	348.2	79.0
Level of inequality in 2004-05 (Gini)	0.3	0.1	0.1	0.6	28.7
Railway Station distance from the city in 2001 (rail dist)	0.4	1.4	0.0	8.0	383.6
Total no. of electricity connection in 2001 (elect) (in thousands)	461.4	1222.2	0.0	8560.3	0.26
Not in male labour force in 2004-05 (nlfm)	215.1	64.2	72.3	439.2	29.8
City-wise total number of universities in 2001 (univ)	1.1	1.2	0.0	5.0	105.0
Casual worker male in 2004-05 (casualm)	104.3	60.4	9.3	300.9	57.9
City output in 2001 (ddp)	16597.8	7614.6	797.2	38412.6	45.9
City-wise poverty headcount ration in 2004-05 (fgt0)	12.2	12.5	0.2	57.8	102.4
City-wise poverty headcount ration in 2004-05 (fgt1)	2.3	3.1	0.0	16.1	132.7
City-wise total no. of medical facilities in 2001 (medi)	187.4	213.8	2.0	781.0	114.1
City wise average rain fall in 2001 (rain)	1075.3	570.2	266.0	3053.0	53.0
City-wise total receipt through taxes and revenue derived from municipal properties (trmp) (in lakh) in 2001	14.9	53.2	0.0	380	0.004
City-wise total no. of colleges (ctc) in 2001	41.5	49.0	1.0	195.0	118.2

Note: Figures in parentheses represent robust standard errors. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% level, respectively. Source: Estimated using equation 1.

Table 3 presents the estimated regression results from Equation (1). Regression 1 reports the full model where all the independent variables for OLS estimation are considered. On the other hand, regression models 2-4 represent the parsimonious model by excluding the explanatory variables that did not show statistically significant results or match with the expected sign conditions. Regression models 1-5 consider the robust standard errors (to control for heteroskedasticity). The significant values of F statistics for Regressions 1-4 indicate that the overall model is statistically significant. The higher values of R² indicate that Regression 1 explains a good percentage of total variation in the dependent variable. The study has also calculated the adjusted R², as it adjusts for the number of explanatory terms in a model, i.e., it incorporates the model's degrees of freedom. The multicollinearity problem does not seem to be troublesome, as the mean VIF values do not exceed 10 for Regression model 1-5.

Regression 1 shows that city-wise total self employed male has a negative impact on the percentage of rural to urban migration. In particular, a 100 percent increase of city-wise total self employed males decreases rural to urban migration by 8 percentage points. However, percentage of city-wise total self employed female has a positive impact on the percentage of rural to urban migration. This indicates that cities having higher percentage self employed female attract higher rural to urban migration whereas cities having higher percentage self employed male discourage to urban migration. This may be the case that if women have the chance to make them self employed in the city; more rural women from rural households will migrate to urban areas to earn more provided that their male partners also find jobs in the same city. The possible increases in income of the households make rural to urban migration easier and also attractive. On the other hand, city-wise availability of higher number of electricity connections has a positive impact on rural to urban migration. The estimated result shows that a 10 percent increase of total number of electricity connection in the host city increases rural to urban migration by about 65 percent. It is important to indicate here that availability of electricity connections stand as a proxy of availability of infrastructure facility. The result indicates that infrastructure facility has a positive impact on rural to urban migration. Finally, regression 1 shows that city wise per capita income also has a negative impact on percentage of rural to urban migration. This means that if a city has higher per capita income (i.e., richer city), it discourages rural to urban migration. It therefore indicates that a richer city may be more expensive for a person to migrate from rural to urban areas. City-wise total number of colleges also has a negative impact on percentage of rural to urban migration. This indicates that the educational facilities do not attract higher percentage of rural to urban migration. The other independent variables i.e., city-wise level of inequality, road distance from a city to nearest railway station, poverty ratios, medical facilities, number of universities, average rain fall, and total receipt through taxes and revenue derived from municipal properties do not show any statistically significant effect on the percentage of rural to urban migration.

Regression 2 shows very important results; it shows that level of inequality in a city has a negative impact on the percentage of rural to urban migration. On the other hand, road distance from the nearest railway station to a city exerts a positive impact. In particular, a one percent increase in level of inequality (or road distance from nearest railway station to a city) decreases (or increases) 32 (or 2) percentage of the rural to urban migration. The result indicates that if a city has higher level of inequality, it discourages rural to urban migration. On the other hand, if a city has higher road distance from the nearest railway station, naturally indicates the lower economic potential and therefore it encourages rural to urban migration. This means that cities having lower economic potential attract higher rural to urban migration. Similarly, cities having lower percentage (number) of the higher number of persons those are not in labour force attract lower percentage of rural to urban migrations. This shows that employment potential in the host city is one of the main factors behind rural to urban migration. People move from rural areas with the expectation of getting absorbed in the urban areas. City wise total number of self employed male or females, and total number of electricity connections of the host city has a similar impact on percentage of rural to urban migration as explained in regression 1. However, city-wise total number of universities, number of male casual worker, poverty head count ratio, medical facilities, and average rain

fall again do not show any statistically significant effect on percentage of rural to urban migration. Most importantly, city wise per capita income lost its significant level in regression 2 compared to regression 1.

Regression 3 shows that city-wise total number of male casual worker has a negative impact on rural to urban migration. A 100 percent increase in total number of casual workers decreases rural to urban migration by about 5 percent. This clearly indicates that cities need to provide formal regular jobs than making the migrants casual workers to attract higher level of rural to urban migration. City-wise total number of self employed males or females, level of inequality, road distance from nearest railway station to a city, availability of electricity connections and number of persons not in labour force show a similar impact on percentage of rural to urban migration. However, city-wise poverty situation does not have any significant impact on rural to urban migration.

Regression 4 shows that city-wise higher poverty ratio (measured by poverty head count) has a negative impact on city-wise rural to urban migration. A 10 percent increase in poverty head count ratio decreases city-wise rural to urban migration by about 5.5 percent. This indicates that poorer cities discourage rural to urban migration. On the other hand, city-wise higher total receipt received through taxes and revenue derived from municipal properties, also have a positive impact on rural to urban migration. This indicates that strong economic conditions encourage higher rural to urban migration. The availability of electricity connection in a city shows a positive impact on rural to urban migration as explained in regression 3. However, city wise total number of universities and squared poverty gap ratio again do not show any statistically significant affect on city-wise rural to urban migration.

Finally regression 5 considers the total numbers of rural to urban migrants as the dependent variables. The estimated results show that city-wise total number of self employed males has a negative impact, and city-wise total number of self employed female has a positive impact on city-wise rural to urban migration. These results are identical to the results obtained in regression models 1-3. However, other independent variables do not show any statistically significant effect on city-wise rural to urban migration. It also indicates that the data considered in this study does not fit properly when the total number of rural to urban migrants is considered as a dependent variable.

4. CONCLUSION AND POLICY IMPLICATION

This paper tries to investigate the determinants of rural to urban migration in large cities of India based on 2001 data. For this analysis, data from various sources such as Census of India and unit/individual level data of National Sample Survey data on employment and unemployment and consumption expenditure data have been used for analysis. Due to lack of city-wise data district level data is used by considering urban sample located in that particular district as a proxy of the city. OLS regression method is used to analysis data in this study. City wise rural to urban migration rate and total number of rural to urban migrants are considered as dependent variables.

The descriptive analysis shows that India's urbanization rate is much lower than other developed countries. Natural increase in population is one of the main sources of increase in urban population in India. The net rural to urban migration from 1991 to 2001 is about 21 percent. Economically developed states have been witnessing higher rural to urban migration than economically underdeveloped states. Among the large cities, Mumbai has recorded the highest (i.e., 17.32%) rural to urban migration rate in the time span of ten years and more, among all other large agglomerations. City-wise analysis shows that reasons for rural to urban migration are predominantly work/employment and marriage.

The OLS regression results show that city-wise total number of male self-employed, level of city level inequality, males not in labour force, male casual labour, city-wise per capita income, city level poverty measured by poverty head count ratio, and city wise total number of colleges have a negative effect on city-wise percentage of rural to urban migration. On the other hand, city wise total number of self employed female, road distance to nearest railway station from a city, total of number of electricity connections and city-wise total receipts through taxes and revenue derived from municipal properties have a positive impact on city-wise rural to urban migration. On the other hand, city-wise total number of self employed male has a negative and city wise total number of self employed female has a positive impact on city-wise total number of rural to urban migrants. This results indicate that city level employment situations, city level inequality level, city level poverty and infrastructure facilities play an important role in rural to urban migration.

It is quite obvious that the country needs more rural to urban migration for economic development in India. In rural areas, more population depend upon agriculture, and the higher dependence on agriculture leads to disguised unemployment in rural area. If the disguised unemployed population is relocated in urban areas, then the supply of labour and demand of consumer goods in urban areas will increase. This will in turn lead to more production, higher level of economic activity and also higher per capita income. The level of job opportunities in the cities will also increase in this process. And this increase will promote investment which will in turn lead to further economic growth. So, the economic growth in India can be catalyzed through the growth of urbanization resulting from rural to urban migration.

In this perspective we suggest the following policies; first, we need to increase the job opportunities in the urban area for higher rural to urban migration. Second, level of urban poverty and urban inequality has to control for this purpose. Third, basic urban infrastructure facilities such as road, electricity, education etc has to increase not only to make investment friendly but also to promote rural to urban migration. Finally, living cost such as urban housing prices has to control for making Indian cities migrant friendly for higher and sustainable economic growth.

APPENDIX

Table A1. Names of Cities Used in Regression Analysis

Agra (Agra), Aligarh (Aligarh), Allahabad (Allahabad), Amritsar (Amritsar), Asansol (Bardhaman), Aurangabad (Aurangabad), Bangalore (Bangalore Urban), Bareilly (Bareilly), Bhiwandi (Thane), Bhopal (Bhopal), Bhubaneswar (Khordha), Chennai (Chennai), Coimbatore (Coimbatore), Delhi@, Dhanbad (Dhanbad), Durg-Bhilainagar (Durg), Guwahati (Kamrup), Gwalior (Gwalior), Hubli-Dharwad (Dharwad), Hyderabad (Hyderabad), Indore (Indore), Jabalpur (Jabalpur), Jaipur (Jaipur), Jalandhar (Jalandhar), Jamshedpur (Purbi- Singhbhum), Jodhpur (Jodhpur), Kanpur (Kanpur Nagar), Kochi (Ernakulam), Kolkata (Kolkata), Kota (Kota), Kozhikode (Kozhikode), Lucknow (Lucknow), Ludhiana (Ludhiana), Madurai (Madurai), Meerut (Meerut), Moradabad (Moradabad), Mumbai (Mumbai), Mysore (Mysore), Nagpur (Nagpur), Nashik (Nashik), Patna (Patna), Pune (Pune), Raipur (Raipur), Ranchi (Ranchi), Salem (Salem), Solapur (Solapur), Thiruvananthapuram (Thiruvananthapuram), Tiruchirappalli (Tiruchirappalli), Varanasi (Varanasi), Vijayawada (Krishna), Visakhapatnam (Visakhapatnam).

Note: City district (where the sample city is located) is used as a proxy of a city to measure all the variables (except population data) used in estimation of OLS regression of Equation 1 by considering urban sample persons (if data available for rural and urban separately) of that district. Name in parentheses indicates the name of the district in which the city is located. @ Delhi are considered as a whole proxy of a city district.

Appendix A2: Variable sources and definitions

Work-force participation rate (WPR) (As given in NSSO: The number of persons employed in *usual status* (ps+ss) per 1000 persons is referred to as work force participation rate (WFPR) or worker population ratio (WPR) in *usual status* (ps+ss). **Usual principal activity status:** The usual activity status relates to the activity status of a person during the reference period of 365 days preceding the date of survey. **Usual subsidiary economic activity status:** A person whose usual principal status was determined on the basis of the major time criterion could have pursued some economic activity for a shorter time throughout the reference year of 365 days preceding the date of survey or for a minor period, which is not less than 30 days, during the reference year. **Usual activity status considering principal and subsidiary status taken together:** The usual status, determined on the basis of the usual principal activity and usual subsidiary economic activity of a person taken together, is considered as the usual activity status of the person and is written as usual status (ps+ss). According to the usual status (ps+ss), workers are those who perform some work activity either in the principal status or in the subsidiary status. Thus, a person who is not a worker in the usual principal status is considered as worker according to the usual status (ps+ss), if the person pursues some subsidiary economic activity for 30 days or more during 365 days preceding the date of survey.

City output: Per capita non-primary District Domestic Product (DDP) over the period 2000-01 to 2004-05 at 1999-2000 constant prices is taken as a measure of urban economic growth. Source: Directorate of Economics and Statistics (DES), various State Governments, GoI.

City inequality level: Gini coefficient of the large city districts by considering urban sample persons of that district. Source: Unit level data of NSS 2011-12 on consumer expenditure.

Rain fall: City wise average rainfall.

Medical facilities (Numbers): City- wise Total Number of Hospital + Number of Dispensary + Number of Health Centre + Number of Family Welfare Centre + Number of TB Clinics + Number of Nursing Home + Number of Other Medical Institutions.

Total university (Numbers): City-wise total number of universities.

Electrification (Number of Connections): City- wise Total number of connection by Domestic + Industrial + Commercial + Road Lighting (Points) + Others

Railway Station distance: Railway Station Road Distance (in kms)

RS08.2. Migration and Labor Markets

1126 AN ISTANBUL CASE STUDY OF RECIPROCAL RELATIONSHIP BETWEEN EDUCATION AND EMPLOYMENT IN CREATIVE INDUSTRIES

Büşra Güven Güney¹, Ebru Kerimoğlu²

1 Büşra Güven Güney (Res. Asst.), ITU, Department of Urban and Regional Planning, Istanbul, Turkey, buguv297@gmail.com

2 Ebru Kerimoğlu (Assoc. Prof. Dr.), ITU, Department of Urban and Regional Planning, Istanbul, Turkey, kerimoglu@itu.edu.tr

ABSTRACT

In the 21st century, parallel with the knowledge economy, knowledge, innovation and creativity are the most important products, and the universities, which are the main knowledge production and transfer places of these phenomena, are in an important position. The new economic geography brings with it new considerations and requirements for labour motivation. Relevant departments of universities in creative fields are increasingly facing the challenge of developing curriculum for more employable creative people. In Turkey, as an emerging economy, creative industries have not yet argued in urban and regional economy in relation to the political axis and higher education. The main purpose of the study is investigate reciprocal relationship between creative employment and education in creative industries in terms of education-industry relations in Istanbul, having highest share of creative industries and higher education institutes both in quality and quantity, as a reflection of Turkey. In this paper, creative capital theory regarding to urban and regional development and industry-education relationship in relation with the theory are discussed. Interviews with selected educational institutions and professional organizations were conducted for deeply understanding of current situation of education in creativity fields and its contribution to the development of creative industries with respect to urban economy in particular creative economy. As a result, quality of education in related industries is not able to meet to the needs of industry, but this is due to reciprocal situation and problems too. Co-operations are not clear and institutional enough because of the financial and administrative problems and inefficiency of academic staff is another problem for collaborations between industry and higher education institutes. This study will shed light on future researches for the development of creative industries, are very important for urban and regional economic development today, by discussing to gain educated employment to these industries.

INTRODUCTION

Creative economies are emerging from the concept in the agenda of the countries and regions since the year 2000. The competitive environment that emerged as a result of globalization has made new, different, original and specific things valuable. Therefore, the importance of a creative economy is increasing in ensuring the economic sustainability of cities and regions.

By the end of the 1990s, the manufacturing industry, which had been influential but largely lost its significance, had to leave its place to the service sectors with the developing technological climate and the postmodern economic approaches in an effort of articulate to the global world. Since the industrial changing labour force structure, services and sociological interactions in cities, where many different models have been tried to be idealized, have also been drawn towards post-fordist production standards. In this process, the economic and labour force structure of cities has shifted to a more powerful service and knowledge-based economy (Hamnett and Shoval, 2003).

Countries that developed creative industries have begun to realize higher education quality in creative fields. In general, education in creative fields has to cope with certain challenges in terms of employment and its sustainability (Bennett, 2009, Bridgstock and Carr, 2013, Collis, 2010, Menger, 1999, Towse, 2006). According to Zelenko and Bridgstock (2014), graduates are experiencing increasingly dynamic, unknown and ontologically unfamiliar work life. For this reason, graduates in creative industries need to have equipment that will respond to this rapidly changing and complex working environment (Daniel and Daniel, 2014).

Within the context of this study, creative industries that are important for modern city economies have been addressed with in the context of the development of cities. Istanbul is the city in which the locomotive of creative industries in Turkey was discussed through education and labour relations in relation to creative industries, theoretical framework, data of the industry and interviews made with university-professors.

CREATIVE CLASS, INDUSTRIES AND EDUCATION

Changing production and lifestyles have changed the urban land use and consumption structure. Creative and cultural industries directly contribute to economic growth through creative output, while at the same time increase the innovative potential of the rest of the economy with creative products offered by other industries (Chapain et al., 2010; Lazzeretti et al., 2014).

The concept of creative class emerged from Richard Florida who is an American social science expert, as a labour force in America's post-industrial cities to guide economic development. Florida (2002) divided the labour force into three main classes using the professional analysis approach: Creative Class, Employee Class, and Service Class (see Table 1). Creative class is divided into two sub-groups. Super creative class; occupations related to computer and mathematics, architecture, engineering, social and physical sciences, education, librarianship, art and design studies, entertainment,

sports and media. Creative professions are occupations about management, financial operations, legal positions, health, and technical professions.

Table 1. Labour force classification

		
Creative Class - Super Creative Class - Creative Professions	Service Class Occupations related daily services	Employee Class Works based on physical strength

Source: Florida (2002)

In order to systematically analyse the structural characteristics of creative industries, many different classifications have been made up to now. UNCTAD's (2010) this paper is based on the creative class classification (see Table 2).

Table 2. Creative class classification

THE RELATIONSHIP BETWEEN INDUSTRY AND EDUCATION: SITUATION IN CREATIVE INDUSTRIES

With the emergence of post-industrial economies, concepts such as knowledge, talent and human capital appear to be at the forefront in the literature. The theory of human capital was revealed by Becker (1964); assumes that fees will rise with the level of knowledge or ability. According to Florida, in recognizing regional economic development, creativity is important, not education. But Florida did not fully support his theory with empirical analyses (Marlet and Woerkens, 2007). At the same time, it was argued in the academic community that Florida's creative class theory would be too broad and uncertain to evaluate the regional performance empirically (Marrocu and Paci, 2012). Glaeser et al. (2004) indicated that; if Florida argues that creativity has superior effects on economy than human capital, he had to prove it. The creative class and widely accepted human capital theories have strongly correlated and coincided (Glaeser (2004). As a result, the lack of a clear definition of creativity and education components in empirical analyses creates a measurement problem involving deviation caused by multiple linearity or neglected variables (Marrocu and Paci, 2012).

CHANGING CONTENT OF HIGHER EDUCATION IN CREATIVE INDUSTRIES AND EMPLOYMENT

A consequence of this transition has been the transformation of the workforce, from labour intensive into flexible, decentralized, networked and multi-skilled. This transition requires new cross public sector strategies, systems and policies for educational innovation. (Wright et al., 2013). It has become imperative for individuals and organisations to continuously evolve, learn, create and apply knowledge to participate in "lifelong learning" (Bentley, 1998). To this end, Bentley (1998) argues that education systems should strive for three things (1) autonomy, (2) responsibility and (3) creativity. Bentley (1998); a new "landscape of learning" that understands the business climate and extends beyond teacher responsibility in the classroom, to address the pressing challenges of promoting active citizenship, developing employability and tackling under achievement and social exclusion, is required. As universities are seen as the central actors in this networked knowledge economy, it is critical that their role and contribution as a key stakeholder is

understood and clarified to ensure future policy is directed to generating conditions in which they best perform (Dodgson, 2012).

Harvey and Blackwell, (1999) and Ball, Pollard, and Stanley (2010) revealed that the equipment and skills of creative industry workers did not match the characteristics of working environment. The Council of Higher Education Funds in the UK (in 2003) reported that as a result of the research on employability in higher education, the skills of creative graduates were very different from those needed to be employed in business life. Likewise, in the UK Lambert Review of Business-University Collaboration Report (2003), it is emphasized that creative industry employers have not been able to fully develop the skills necessary for successful career development in the business world, because of recent expansion of creative industry-related departments. Creative Skillset (2009) reported that despite the excessive supply of alumni in creative industries, universities failed to achieve the skills needed in the industry.

Knight and Yorke (2003) in the UK higher education institutions are now charged with promoting graduate employability -contributing directly to the stock of human capital- and their performances are monitored. As a consequence of the educational policy bases, there is an assumption that the inclusion of university management, curriculum development and teaching transferable employment skills is the main concern of the teaching staff (Thornham and O'Sullivan, 2004).

Rapid change in labour force requirements (particularly in digital skills and knowledge) means that skill forecasting will always be inaccurate. In addition, given the fluidity of the creative industries labour market, it is impossible to identify the exact destinations of graduates ahead of time, and thus know what their various skill needs are going to be. Finally, the process of renovating course content can be unwieldy, time-consuming, and expensive, and by the time the process is completed, courses are often once again out of date (Bridgstock, 2011).

Ball, Pollard, and Stanley (2010) emphasized that "Creative Graduates Creative Futures" contributes to the longest continuous study of occupational choices and working patterns, offering comparable data to the pioneering Destinations and Reflections (Harvey and Blackwell, 1999) which followed more than 1,800 graduates from art and design disciplines into their early careers and was one of the first studies to provide evidence of synergy between higher education and growth in the creative industries. These reports, in addition to the role of education in the formation of next-generation ability also include the following trends. These are;

- Increasing number of lessons that provide applied learning at universities as a way to increase graduate employment
- The educational process in many creative disciplines are project-oriented, collaborative, and empirical, which improves the skills and attitudes of successful entrepreneurs and innovators that creative economies need,
- Entrepreneurship education is increasingly prevalent and it is stated that universities are actively supporting business co-operation and entrepreneurship projects.

Pollard (2013) indicated that strategies for increasing employability;

- Placement and implementation of simulations,
- Research collaborations with the industry,
- Curriculum design with industry practitioners.

Employment literature often emphasizes the importance of post-graduate employment security and internships in terms of placement and ideas in the workplace. These are part of a modern and flexible economy and are useful to both trainees and employers (Pollard 2013).

Universities UK (2010) have made suggestions for the education of the creative class according to the results of their work. These suggestions, which may be guiding in the scope of the study, are listed in two chapters; 'addressing the barriers to successful engagement' and 'investing in opportunity'.

The approaches taken from the results of the extensive studies mentioned above are summarized. In the conclusion part of the paper, these approaches have been evaluated together with case study findings.

CREATIVE CLASS/INDUSTRIES IN ISTANBUL

The first analytical work on creative industries in Istanbul is the Environmental Plan (2006) by the IMP. In this plan study, some detailed analyzes were made by the cultural industry working group within the IMP (Kerimoğlu, 2012). With the election of Istanbul as the European Capital of Culture in 2010, the Ministry of Culture and Tourism announced the support of local governments, non- governmental organizations, renewal projects that will cooperate with education, culture and art institutions (Kerimoğlu, 2012). Based on the distribution by employment and employee data, basic indicators according to local unit activities and population and demographic statistics, Seçilmiş (2015) revealed that, Istanbul has the highest clustering rate in creative industries in Turkey. Aksoy and Enlil (2010) provided some information about Istanbul's cultural activity possibilities and the economic percentages of creative and cultural industries in Istanbul and Turkey on Istanbul Cultural Economy Inventory study (see Table 3-4).

Table 3. Share of the creative industries in 2008

Creative Industries	share of creative industries in Istanbul	share of creative industries of Istanbul in Turkey
Software	33.25	51.35

Publishing	1.15	45.35
Cinema	7.63	77.33
Programming and publishing	0.99	64.34

Library	0,05

Source: (Aksoy and Enlil, 2010)

According to YEKON (2014) the number of individuals working in creative industries in Istanbul constitutes 52.4% of the individuals working in creative industries in Turkey, and the share of total endorsement in creative industries in Istanbul is 74.5%, while total employment in creative industries was 1,09%, the total number of individuals working in creative industries in Istanbul was 3,28% in 2011 (TUIK, 2001; YEKON, 2014).

It is quite obvious that there is a need for a comprehensive case area research and knowledge base in Istanbul that will serve as a basis for making policies that will guide the future of the industry.

AN EVALUATION OF RELATIONSHIP BETWEEN EDUCATION AND EMPLOYMENT IN CREATIVE INDUSTRIES IN ISTANBUL

In the scope of the study, in-depth expert opinions within the descriptive methodological framework were obtained from the open-ended questions generated from the literature and the answers obtained were evaluated comparatively.

Methodology

Within the scope of the study, the conceptual framework and various classifications of creative industries were examined and the analysis of economic development and educational situation in Turkey and Istanbul and the relationship between industry and education was examined through the contribution of urban development and creative class theory and education-industry relations were revealed. The contributions of education-industry relations have been identified through world examples. Accordingly, in the determination of the creative industries to be worked on, priority was given to the creative industry classifications determined by UNCTAD (2010) (see Table 2), and then, taking into consideration the economic shares and the development potentials of the industries in Istanbul, universities and professional organizations were selected within the determined criteria.

While industry choices are made, multiple variables are treated separately. The following steps have been taken in the selection of creative industries:

1. First of all, the software (33.25%), architecture (23.00%) and advertising (19.76%) industries, which have the greatest proportions, were selected by considering the economic shares of creative industries in Istanbul (see Table 3),
2. The cinema industry was included in the study because of the fact that the Istanbul cinema industry has the largest share in Turkey (77.33%),

3. It has been decided to go through the creative services, which is one of the four main titles of UNCTAD (2010) classification, with the fact that the biggest economic shareholders in Istanbul are in the categories of creative services and the interior architecture, graphic design, industrial design and fashion departments have undergraduate programs at universities,
4. It has been researched that certain industries whether there are four-year undergraduate departments and professional organizations in Istanbul,
5. Interior design was not included in the design which is one of the three sub-titles of the creative services of the four main titles of UNCTAD (2010) classification because of architecture department, graphic design, industrial design and fashion design were included. It has been found that the advertising and architecture industries under the sub-title of creative services also provide the 4th criterion. The software industry that is under the title of new media was not included in study because of the difficulties in the division of labor in the industry on a departmental basis and the absence of a specific professional organization.

Thus, architecture, industrial design, graphic design, fashion design, advertising and television-cinema industries have been selected. Graphic design, industrial design, architecture and advertising industries can work when all the criteria are taken into account and when access is provided with departments and professional organizations. Thus, in total four different departments, six different universities, twelve teaching members and seven professional associations were interviewed.

Table 5. Interviewed universities, departments and professional organizations.

Industries/ Departments	Universities	Professional Organizations

	Istanbul Bilgi University	
Graphic Design	Mimar Sinan University of Fine Arts	Graphic Designers Professional Organization
	Marmara University	

Findings/discussion

The following are highlights from the literature research and also topics discussed in the interviews :

Topics discussed with universities;

- Training programs and industry expectations
- Industry collaborations
- Relationships with professional associations
- Alumni networks
- Future objectives within the context of education and industry relations

Topics discussed with professional organizations;

- The place of creative industries in urban economy
- Evaluation of creative class
- Education of creative class
- University collaborations
- The importance of industry and educational cooperation
- Recommendations to universities.

The study could be used in the context of policy making in the future, but the government agencies were not included in this study because it is aimed at defining university-industry relations.

The problems that emerged as a result of interviews between education and industry in creative industries, summarized in terms of university and industry (see Table 6).

Table 6. Problems in university and industry collaborations

University	Industry
<ul style="list-style-type: none"> • No updating education programs • Inability to have a flexible structure • To be able to establish industry and education balance • Lack of state funds • The lack of graduate follow-up systems is due to the 	<ul style="list-style-type: none"> • A market environment in which interests are dominant impedes the development of cooperation • The fact that the current industry structure is not able to transfer the desired ones or the approach to university collaborations with very defined and limited demands • University partnership is used as an advertising tool and therefore

<p>methodological inadequacies in collaborations</p> <ul style="list-style-type: none"> • The fact that market dynamics can not be taught in universities and subjects such as accounting and law are weak, information about the legal infrastructures of the industry is not given • The current educational approach could not respond to industry expectations and there is even a big gap between education and industry • Need for instructors who can collaborate. 	<p>can not progress in a way that is appropriate for the purposes of industry and educational relationships.</p>
--	--

The departments stated that benefits of industrial cooperation as;

- Industry try to attract talented students who meet in industrial partnerships,
- The development of master-apprentice relations,
- Students have the opportunity to create networks.

As a result of the interviews, the work of the universities and professional organizations on education- industry integration and cooperation are summarized (see Table 7).

Table 7. Practices in the context of university and industry integration and cooperation

University	Professional organizations
<ul style="list-style-type: none"> • The introduction of outside professionals in elective courses and compulsory courses, • Internships, • Mentoring courses, • Master-apprentice relationships • Common training models 	<ul style="list-style-type: none"> • To cooperate with the university, • To support the education system, • Seminars, conferences, etc. related to vocational education. • To help students find a job before graduation and after graduation, • In order to facilitate job alignment, activities such as internship, job placement, • To work on copyright and patent rights issues

Suggestions made for industry collaborations itemized (see Table 8). When problem areas of two different groups are overlapped; the fact that the perspectives for cooperation are not clear from both the universities and the industries, the financial impossibilities of developing the university-industry interaction and the lack of the flow of state funds have emerged as barriers to cooperation and hence to the industry.

Table 8. Proposals for the development of university and industry collaborations

<ul style="list-style-type: none"> •The development of education to contribute to the society and the relations with the industry,, •In terms of being able to show how education works in real life, it is important to be in touch with the industry, to be open to mutual development and to be able to blend current topics in educational programs in a rapidly changing industry climate, •The fact that education is a structure that adopts the differences of the students in the flexible structure means that if all the students are taught the same thing, this work is taken away from the logic and the necessity of leaving the students free, •The development of awareness that could be a guide to the way many learners want to be directed rather than challenging, •The emphasis on the ideological dimension of the work done in education, •Instructors' involvement in industry, •The academicians are expected to gain industry experience and constantly improve themselves, •Academicians should be aware of the difference of generation and educate in this direction, •Ensuring that project production processes are dominant, •More responsibility is given to students, •Providing students to think about projects they do •Beyond traditional lessons, •In addition to academic knowledge, one develops himself / herself •Commercialization of universities and demonstration of how they are done •The need for universities to raise awareness in decision making •When you graduate from university you do not know what to do, •Ownership of the projects to be realized and endeavoring to achieve, •Failure to be passive in industrial relations, •The realization of the collaborations, both intellectual and creative dimension, •Preventing the approach of the industry as an advertising tool for university collaborations •The state should regulate education and industry relations •Experience of master-apprentice relationship •Gaining experience while studying •Giving all equipment required in the industry, •Establishment of collaborative environments with different disciplines, •Giving flexible and diversified projects.
--

IN BRIEF

The studies (Wright et al., (2013), Bentley, (1998), Dodgson, (2012), Harvey and Blackwell, (1999), Ball, Pollard, and Stanley, 2010) on the employment of creative industries and the creative class have focused on the characteristics of the changing employment structure of the industry. The properties of this changing structure are flexible, part-time, decentralized, free or short-term jobs, small or medium sized business.

It appears that the discussion of education on the basis of human capital has recently been dealt with in a professionally specific way on the axis of creative capital. It has been shown that Florida does not treat education as a fundamental element in the development of a creative industry in a city, and that it cannot be empirically proven that it is unhealthy to evaluate education and creative class-work independently.

The socio-economic transformations emphasize the necessity of accommodating industrial concerns in universities, but the fact that faculty members are lagging behind the creative industry market in Istanbul has distracted them from educating students for industry needs. To make this distinction in terms of universities and to be able to provide the education industry balance, it has become a problem area that must be realized.

One of the reasons for the failure of university and industry relations, which is often emphasized in the development of creative industries, is the lack of methodological approaches. For the development of collaborative methodologies by universities and professional bodies it has become clear that it is important for universities to identify their roles in industrial cooperation and to ensure that they have a certain quality in approaching university collaborations, avoiding advertising projects, and determining the frameworks of collaboration processes.

It is seen that the expectations of the creative class educator meet the needs of the universities in the literature to develop creative class employment.

The most fundamental issues raised by universities regarding the development of education and industry relations are; the existence of administrative obstacles and therefore financial impossibilities, the rapid movements in bureaucracy and the inability to access the appropriate infrastructure and methodological deficiencies in cooperation. This seems to constitute a disadvantage for the employment of the creative class. Prioritized areas of education for creative class, which are at the center of creative industries that play a key role in urban economic development are the recapitalization of universities, the liberalization of the university from traditions and the making of public-private investments.

The most serious problems concerning the industry are; no analytical analysis of the economic value of creative industries that can be expressed in numbers, and an industry that is not recognized in the politically.

In the framework of the recommendation of the Universities UK (2010) study discussed in the previous chapters, when the problems and suggestions arising from the case area are summarized and evaluated:

Under the subheading of addressing the barriers to successful engagement;

- It is observed that in Istanbul there are methodological problems in the process of working universities with the creative industry and that the speed of interaction of traditional education and management approach is obstructed. In the face of a proposal to emphasize industrial relations in evaluating academic performances, the necessity of academicians to gain industry experience in Istanbul has proven to be an advantage of having strong relationships with industrial associations. In this context, the existence of policy supports that the increase in weight of industry interaction in academic performance will encourage academicians to engage with the industry.
- The demonstration of university and industry influences as priority targets for development agencies is consistent with the objectives of the Istanbul Development Agency to increase education and industry interaction in the development of creative industries.
- With the overlap of the job descriptions of professional organizations with the literature, it has become necessary to take place more effectively between universities and industry.
- The need for universities to develop policies and work on their ownership of intellectual property rights has also been voiced in Istanbul, and in this context it is crucial that studies on intellectual property rights are passed on.

Under the subheading of investment in opportunities;

- It is stated that the importance of the mentioned third wave funds is increasingly emphasized on the interface mechanisms that will enable the transfer of information and technology between universities and industry and their commercialization in the Istanbul regional plans. It was also emphasized that these contacts would be beneficial for both sides. In this context, it is necessary for the state to develop third wave funds to develop the industry.
- The necessity of the training given in universities with different disciplines was also challenged in Istanbul regarding the expectations of creative class education. In this context, education in creative industries is required to offer diversity.
- The proposal of professional associations to contribute to the education arrangements related to the curriculum could not be more than stated in the professional organizations in Istanbul. Occupational organizations as well as public institutions must be involved in the process of training programs.
- It is also seen that there is a profound dilemma in Istanbul, as universities continue to raise talent to challenge the world and argue that industry expectations should be increasingly focused on employability and entrepreneurship. Nevertheless, it appears that there are no major concerns about employability and

entrepreneurship at the universities in Istanbul. In this context, the contents of the university education program need to be re-examined on the axis of industry expectations, employability and entrepreneurship.

- Activities such as collaborations between the university and industry to develop opportunities such as real business reports and practical learning are being implemented at universities in Istanbul, but the industry emphasizes that these applications are inadequate. In this context, developments towards applications are required.

In this context, considering the suggestions from the literature and the problems and suggestions from the policies and interviews investigated within the scope of the study, it is possible to see the existence of the universities in Istanbul concerned about responding to the industry expectations that are based on the recommendations in the literature, but the problems brought about by the inadequacy of the creative industry market in Istanbul, lack of policy and funding.

For the identification of current educational and industrial relations and problems in Istanbul it is crucial to include strategies for resolving these problems in future policies on creative industries. In this context, it is necessary first to systematize the data related to the industry in Istanbul, to treat creative industries as a separate industry field and to create policies around the country. The role of the government in providing policy makers and funding in educational and industrial relations may be possible with the existence of national decisions and policies.

As a result, creative economies have become one of the most important sources of economic development for cities and regions. In addition to having this source and employment, the role of creative class education and approaches developed to keep the creative class in line with changing condition. This role has been an important axis in ensuring the sustainability of creative industries in cities. In a rapidly changing economic environment, the education of the creative class must be able to adapt to these processes and even be far ahead. In this context, the consideration of education as a key component in the creation of labor and employment for creative industries and raising awareness in this regard will contribute to industrial development and consequently, urban economic development.

1132 THE ELECTORAL MIGRATION CYCLE

ABSTRACT

This paper proposes a new test of Tiebout sorting that relies on the exogenous time structure of recurrent local elections. The test is based on the idea that the uncertainty that is associated with periodic competitive elections should be expected to induce procrastination of costly migration decisions until political uncertainty is resolved, thus projecting the calendar of local elections onto the timing of sorting processes. Conversely, interjurisdictional migration flows that have nothing to do with the demand for public goods and policies over which localities vote recurrently ought to be orthogonal to the timing of elections in a reduced-form migration equation. I exploit the staggered schedule of mayoral elections in Italy to analyze migration, election, and budget data across several thousands of municipalities, and find evidence of a systematic influence of the electoral calendar on the timing of migration decisions, with the political budget cycles induced by the electoral schedule rather than the recurrence of uncertainty per se turning out to be the most likely cause of the observed time pattern of sorting.

1516 URBAN INFORMAL HOUSEHOLD FORMATION IN SOUTH AFRICA: A LIFE COURSE TRANSITIONS PERSPECTIVE

ABSTRACT

This study uses the South African National Income Dynamics Survey (NIDS), collected biennially between 2008 and 2015, to examine how individuals select into urban informal settlements in South Africa. The advantage of using this panel data set is that it allows for the inclusion of individual retrospective (lagged) variables that are not readily available using cross-sectional data sets. This work is unique in that it uses longitudinal data to shape a dynamic perspective on new urban informal household formation in the South African context. The sample is restricted to black and coloured individuals between the ages of 20 and 64 years old who report being the household head or partner to a household head in the current wave. Probit regression analysis reveals that new household formation in urban informal areas is highly age-selective. Young individuals are most likely to form new households in urban informal areas. However, age may be a proxy for life stage transitions, with young adulthood in South Africa coinciding with labour market entry, partnership formation and migration. These critical life course transitions are conceivably associated with the transition from the teenage years to adulthood, a hypothesis that is lent some credence by the declining significance of age as a predictor of urban informal household formation when marital status changes between periods are added to the regression. An explanation for this finding is that newly married adults may find the relatively low cost of urban informal household formation attractive, while newly divorced adults may also be incentivised by the financial hardship associated with divorce to settle in urban informal settlements. While area of origin does not predict urban informal household formation, being a migrant and the destination area type are significant predictors of new household formation in urban informal areas. Migrating across district council (DC) borders increases the probability of forming an urban informal household (relative to staying within DC boundaries). Moving to a metro municipality from a non-metro municipality also increases the probability of forming a new urban informal household. The findings from the regression analysis seem to support the widely-held view that urban informal settlements offer low-cost labour market entry points for young and migrating individuals. Additionally, informal settlements also offer low-cost accommodation for both recently married individuals looking to form new households and recently divorced individuals who may be faced with economic hardship.

1716 WHAT DRIVES MIGRATION MOVES ACROSS URBAN AREAS IN SPAIN? EVIDENCE FROM THE GREAT RECESSION

ABSTRACT

In Spain, economic disparities between regions have traditionally played a relevant role in migration. Nevertheless, during the previous high-instability period, analyses provided conflicting results about the effect of these variables. In this work, we aim to determine the role that labour market factors play in internal migration during the Great Recession, paying special attention to the migration response of the heterogeneous population groups. To do so, we resort to an extended gravity model and we consider as a territorial unit the 45 Spanish Functional Urban Areas. Our results point to real wages as having a significant influence on migration motivations.

ABSTRACT

This paper investigates the welfare effects of an income transfer from urban manufacturing workers to rural agricultural workers in an open dual economy where the urban manufacturing wage is fixed under the minimum wage legislation. Then we show that the utility of a rural worker may reduce by the transfer if capital is specific but such a transfer paradox never appears if capital is mobile between industries. We also derive the result that the transfer makes the urban unemployment decrease in the specific capital case but possibly increase in the mobile capital case.

1. INTRODUCTION

Most developing countries are experiencing a wide income gap among regions. It is recognized in particular that the wage of urban areas is much higher than that of rural areas. This is one of the strong engines for a large scale inflow of rural labor force into an urban area in those countries. In order to improve the living standard of the national people, the government adopts the minimum wage legislation. But it tends to be executed mainly for the urban workers from a practical point of view. Therefore the legislation seems to enhance a regional income gap. The direct method to resolve this deficiency is the income transfer from urban workers to rural workers. In the present paper, we examine how this transfer works for rural workers as well as urban workers under the existence of the minimum wage legislation.

There exist vast literature concerning the modern treatment of the international transfers appears after the Keynes and Ohlin dispute in 1929 and the penetrating comment by Samuelson (1947). Among others, a rigorous and comprehensive treatment was explored by Kemp (1995) and a survey in this field was proposed by Brakman and Marrewijk (1998). On the contrary, there are few studies concerning the theoretical treatment of the domestic transfers, particularly focusing developing countries. One exceptional work is Ravallion(1984). He analyzed the domestic transfer in a dual economy of the Harris and Todaro type but assumed that labor is the only primary factor in his model. Therefore the role of capital is disregarded in the analysis. In our present paper we show that the role of capital is crucial in the welfare of the regional workers.

In order to deal with this topic we consider an open dual economy based on Harris and Todaro (1970). So there are two sectors which are a manufacturing sector located in an urban region and an agricultural sector located in a rural region. The minimum wage legislation is applied to the urban manufacturing sector. The production of each sector is operated by the use of labor and capital. We consider two cases. One is where capital is sector-specific and the other where capital is mobile between sectors. Then we examine the effect of the domestic income transfer from the urban manufacturing workers to the rural agricultural workers. The analysis is simple but the derived result seems to be interesting. In the specific capital case, there possibly appears the transfer paradox that the rural workers become worse off by the transfer. In the mobile capital case, however, such a paradox never appears. In this sense capital mobility between sectors plays a crucial role to the emergence of a transfer paradox. Based on these discussions we also show that the labor income disparity between these two sectors necessarily contracts in any cases. Finally we investigate the effect of the income transfer to urban unemployment and reveal that urban unemployment necessarily reduces by the transfer in the specific capital case, while the transfer possibly enlarges the urban unemployment in the mobile factor case.

Our paper is organized as follows: Our basic model is presented in Section 2. Sections 3 and 4 deal with the specific capital case and the mobile capital case, respectively. The effect of the transfer to urban unemployment is analyzed in Section 5 and our conclusion is placed in the last section.

2. MODEL

We consider a dual open economy of the Harris and Todaro type. There are two industries which are rural agricultural and urban manufacturing industries. In the production of each industry, labor and capital are used as production primary inputs.

Let the production functions of the manufacturing and agricultural industries be, respectively,

$$M = F(L_M, K_M), \tag{1}$$

and

$$A = G(L_A, K_A) \tag{2}$$

where M and A are, respectively, the outputs of the manufacturing and agricultural goods, L_M and L_A are, respectively, the labor inputs in the manufacturing and agricultural industries, and K_M and K_A are, respectively, the

²⁴⁸ We are grateful to Professors Xiaochun Li and Dongpeng Liu of Nanjing University, Professor Binh Tran Nam of University of New South Wales and, in particular, an anonymous reviewer for their valuable comments. We also appreciate Professors Kojun Hamada of Niigata University and Mitsuyoshi Yanagihara of Nagoya University for useful discussions.

capital inputs to the manufacturing and agricultural industries. The production functions $F(\cdot)$ and $G(\cdot)$ are assumed to be linearly homogenous, concave and twice continuously differentiable with positive first derivatives.

Perfect competition prevails in all industries. The minimum wage legislation is, however, introduced into the urban manufacturing industry, so that the wage is fixed at \bar{w} in the manufacturing industry. Labor is assumed to be mobile between the rural and urban regions according to the difference in the expected wage between two regions.

There are four different income groups which are

- (i) Manufacturing worker group,
- (ii) Agricultural worker group,
- (iii) Manufacturing capitalist group,
- (iv) Agricultural capitalist group.

In each group, every individual owns one unit of the respective primary factor, provides it in production inelastically to all prices and consumes the manufacturing and agricultural goods.

Each individual's demands for the manufacturing and agricultural goods are determined by the individual's utility maximization behavior. The utility function of each individual is assumed to be identical within the same group. We assume that the economy is small and open and the manufacturing and agricultural goods are tradable.

The profit maximization conditions for each industry are described as

$$F_L = \bar{w}, \tag{3}$$

$$F_K = r^M, \tag{4}$$

$$pG_L = w^A, \tag{5}$$

$$pG_K = r^A, \tag{6}$$

where $F_L \equiv \partial F / \partial L_M$, $G_L \equiv \partial G / \partial L_A$, $F_K \equiv \partial F / \partial K_M$, $G_K \equiv \partial G / \partial K_A$, P is the price ratio of the agricultural good to the manufacturing good, w^A is the wage of the agricultural industry, r^M and r^A are, respectively, the rental prices of capitals to the manufacturing and agricultural industries.

The labor market equilibrium condition is

$$L_M + L_A + L_U = L, \tag{7}$$

where L_U is urban unemployment and L is the labor endowment of this economy and supposed to be given and constant.

Let t^{ML} , t^{AL} , t^{MK} and t^{AK} be, respectively, the per capita income transfer to the manufacturing workers, agricultural workers, manufacturing capitalists and agricultural capitalists. Then the per capita income of each group (i) to (iv) becomes $\bar{w} + t^{ML} \equiv i^{ML}$, $w^A + t^{AL} \equiv i^{AL}$, $r^M + t^{MK} \equiv i^{MK}$ and $r^A + t^{AK} \equiv i^{AK}$, respectively. Here we assume each worker to be risk neutral, so that all workers move from the lower expected income region to the higher expected region. Then the arbitrage condition for the labor movement between urban and rural areas is described as

$$w^A + t^{AL} = \frac{L_M}{L_M + L_U} (\bar{w} + t^{ML}) \tag{8}$$

Throughout of this paper, we basically consider the transfer scheme from the manufacturing worker group to the agricultural worker group. Let T^{ML} and T^{AL} be, respectively, the total income transfer received by the manufacturing worker group and agricultural worker group. Now we suppose the case where $T^{AL} = -T^{ML} \geq 0$ and initially $T^{AL} = T^{ML} = 0$. T^{ML} and T^{AL} should be $t^{ML}L_M$ and $t^{AL}L_A$, respectively. Then, by the use of (7), (8) can be rewritten as

$$w^A + \frac{T^{AL}}{L^A} = \frac{L_M}{L - L_A} \bar{w} + \frac{T^{ML}}{L - L_A} \tag{9}$$

3. SPECIFIC CAPITAL CASE

In this section we consider the case where capital is specific to the industry and cannot move between industries. So K_M and K_A are given and fixed. Then, once T^{ML} and T^{AL} are given, the equilibrium is described by the set of equations

(3) to (7) and (9), which determine L_M , L_A , L_U , w^A , r^M and r^A .

In particular, equations (3), (4) and (9) determine L_M , L_A and w^A . Total differentiation of these equations gives

$$F_{LL}dL_M = 0, \tag{10}$$

$$pG_{LL}dL_A = dw^A, \tag{11}$$

$$dw^A - \frac{\bar{w}}{L-L_A}dL_M - \left(\frac{T^{AL}}{L_A^2} + \frac{L_M\bar{w} + T^{LM}}{(L-L_A)^2}\right)dL_A = -\frac{1}{L_A}dT^{AL} + \frac{1}{L-L_A}dT^{ML}, \tag{12}$$

where $F_{LL} \equiv \partial^2 F / \partial^2 L_M < 0$ and $G_{LL} \equiv \partial^2 G / \partial^2 L_A < 0$.

Equation (10) implies $dL_M = 0$. Moreover, $dT^{AL} = -dT^{ML} > 0$ and $T^{AL} = T^{ML} = 0$ by assumption. Thus (12) becomes

$$dw^A - \frac{L_M\bar{w}}{(L-L_A)^2}dL_A = -\frac{L}{L_A(L-L_A)}dT^{AL},$$

which is further expressed as

$$\left[pG_{LL} - \frac{L_M\bar{w}}{(L-L_A)^2}\right]dL_A = -\frac{L}{L_A(L-L_A)}dT^{AL},$$

from (15).

So we have

$$\frac{dL_A}{dT^{AL}} = -\frac{\frac{L}{L_A(L-L_A)}}{pG_{LL} - \frac{L_M\bar{w}}{(L-L_A)^2}} > 0, \tag{13}$$

and

$$\frac{dw^A}{dT^{AL}} = -\frac{\frac{pG_{LL}L}{L_A(L-L_A)}}{pG_{LL} - \frac{L_M\bar{w}}{(L-L_A)^2}} < 0. \tag{14}$$

The transfer effect to the per capita income of a typical agricultural worker is calculated as

$$\begin{aligned} \frac{di^{AL}}{dT^{AL}} &= \frac{dw^A}{dT^{AL}} + \frac{1}{L_A} - T^{AL} \frac{1}{L_A^2} \frac{dL_A}{dT^{AL}} \\ &= \frac{-\frac{pG_{LL}L}{L_A(L-L_A)}}{pG_{LL} - \frac{L_M\bar{w}}{(L-L_A)^2}} + \frac{1}{L_A} \\ &= \frac{-pG_{LL}L_A - w_A}{L_A(L-L_A)(pG_{LL} - \frac{L_M\bar{w}}{(L-L_A)^2})}, \end{aligned} \tag{15}$$

from (18) and the assumption that initial T^{AL} is nil. This yields

$$\frac{di^{AL}}{dT^{AL}} > 0 \Leftrightarrow \varepsilon^{AL} < 1$$

$$\varepsilon^{AL} \equiv -\frac{L_A}{G_L} \frac{dG_L}{dL_A}$$

where ε^{AL} is the labor elasticity of the marginal labor productivity of the agricultural industry.

Concerning the transfer effect to the per capita income of the manufacturing worker group, it works as a negative impact, implying that the transfer lessens the income of each manufacturing worker. This is because \bar{w} is not affected by the transfer and the present transfer works negatively to the income of this group.

As for the per capita income of the manufacturing capitalist group, (9) and (14) assume

$$F_{KL} \frac{dL_M}{dT^{AL}} = \frac{dr^M}{dT^{AL}} = 0$$

So the transfer does not affect the income of any manufacturing capitalist. On the other hand, the transfer raises the income of any agricultural capitalist since

$$pG_{KL} \frac{dL_A}{dT^{AL}} = \frac{dr^A}{dT^{AL}} > 0$$

by (10).

Under the assumption that the prices of all goods are given and constant, any consumer's utility rises if and only if the consumer's income goes up.

Finally, in view of (13), (7) and the fact that $dL_M / dT^{AL} = 0$, we can easily see $dL_U / dT^{AL} < 0$. Now we can establish

Theorem 1

Suppose a small open country where capital is immobile between industries. And consider the introduction of the income transfer from manufacturing workers to agricultural workers. Then,

- (i) *the level of unemployment decreases,*
- (ii) *any manufacturing worker's utility falls,*
- (iii) *any agricultural worker's utility rises if and only if the labor elasticity of the labor marginal productivity in the agricultural industry is less than one,*
- (iv) *any manufacturing capitalist's utility is unchanged,*
- (v) *any agricultural capitalist's utility rises.*

In the above theorem, the most important result is (iii), which was shown by Ravallion (1984) and states that, if the labor elasticity of the marginal labor productivity in the agricultural good is large enough, the income transfer from manufacturing workers to agricultural workers lowers the utility of agricultural workers. This transfer paradox appears even if there is no price effect.²⁴⁹ The direct effect of the income transfer necessarily raises the agricultural wage. This wage increase, however, attracts the urban workers to the agricultural industry, so that the agricultural wage falls. If this indirect effect is greater than the direct effect, the transfer paradox occurs.

Even though there is a possibility of the transfer paradox, we can prove that the labor income disparity between two sectors always contracts. In order to see this, it is sufficient to consider the case where the income of an agricultural worker decreases by the transfer, since the income of a manufacturing worker necessarily decreases by the transfer. On

the one hand, since $i^{ML} = \bar{w} - (T^{AL} / L_M)$, we have

$$\frac{di^{ML}}{dT^{AL}} / i^{ML} = -\frac{1}{L_M} \frac{1}{\bar{w}}$$

for $T^{AL} = 0$ initially. On the other hand, since di^{AL} / dT^{AL} is expressed by (15), we have

$$\frac{di^{AL}}{dT^{AL}} / i^{AL} = \frac{-pG_{LL}L_A - pG_L}{L_M \bar{w} (pG_{LL}L_A - L_A pG_L / (L - L_A))} < 0$$

by the assumption that $di^{AL} / dT^{AL} < 0$. The it is obvious that

²⁴⁹ If the agricultural production function is the Cobb-Douglas type, $\varepsilon^{AL} < 1$. Hence the paradox never occurs.

$$\left| \frac{di^{AL}}{dT^{AL}} / i^{AL} \right| - \left| \frac{di^{ML}}{dT^{AL}} / i^{ML} \right| = \frac{1}{L_M \bar{w}} \left[\frac{-pG_{LL}L_A - pG_L}{-(pG_{LL}L_A - L_A pG_L / (L - L_A))} - 1 \right] < 0, \quad (16)$$

because

$$-(pG_{LL}L_A - L_A pG_L / (L - L_A)) > -pG_{LL}L_A > -pG_{LL}L_A - pG_L > 0.$$

The inequality (16) means that the labor income disparity between sectors contracts even when the agricultural income decrease by the transfer.

Now we can state

Theorem 2

Suppose a small open country where capital is immobile between industries. And consider the introduction of the labor income transfer from manufacturing to agricultural workers. Then the labor income disparity between these two sectors necessarily contracts.

The possibility of this transfer paradox has nothing to do with the stability of the Walrasian price adjustment since all good prices are given and constant. If labor moves sluggishly between two regions according to the difference of the expected wages of two industries, the labor movement process is expressed as

$$\dot{L}_A = a \left(w^A + \frac{T^{AL}}{L_A} - \frac{L_M}{L - L_A} (\bar{w} + \frac{T^{ML}}{L_M}) \right),$$

where a is an adjustment speed and assumed to be a positive parameter. Then the equilibrium is shown to be globally stable, for

$$\begin{aligned} \frac{d\dot{L}_A}{dL_A} &= a \left[\frac{dw^A}{dL_A} - \frac{\bar{w}}{L - L_A} \frac{dL_M}{dL_A} - \left(\frac{T^{AL}}{L_A^2} + \frac{L_A \bar{w} + T^{ML}}{(L - L_A)^2} \right) \right] \\ &= a \left[pG_{LL} - \left(\frac{T^{AL}}{L_A^2} + \frac{L_A \bar{w} + T^{ML}}{(L - L_A)^2} \right) \right] < 0 \end{aligned}$$

The paradox possibly appears under these circumstances.

Although we have considered the case where the transfer is from manufacturing workers to agricultural workers, we can extend the scheme to the case where the transfer is from capitalists as well as manufacturing workers to agricultural workers. Even in this extended case the primal results such as (i), (ii) and (iii) carry over because the income transfer of the capitalists does not have any influence in the equation system described by (3) to (7) and (9).

4. MOBILE CAPITAL CASE

In this section we examine the case where capital can move freely between industries. Then the equilibrium system can be described by the following set of equations:

$$F_L = \bar{w}, \quad (3)$$

$$F_K = r, \quad (4')$$

$$pG_L = w^A, \quad (5)$$

$$pG_K = r, \quad (6')$$

$$L_M + L_A + L_U = L, \quad (7)$$

$$w^A + \frac{T^{AL}}{L_A} = \frac{L_M}{L_M + L_U} \left(\bar{w} + \frac{T^{ML}}{L_M} \right), \quad (9)$$

$$K_M + K_A = K, \quad (17)$$

where K is capital endowment and assumed to be given and constant.

By (2') and (4') we have

$$F_K = pG_K, \quad (18)$$

The endogenous variables L_M, L_A, K_A, K_M and w^A are determined by (3), (5), (17), (18) and (9) once T^{AL} and T^{ML} are given.

Now we examine how the individual utility of each income group is influenced by the introduction of the transfer, where the capitalist income groups are now combined together as one capitalist income group and each capitalist receives income r .

Let $F(L_M, K_A) = L_M f(k_M)$, where $k_M \equiv K_M / L_M$. Then (3) can be expressed as $f(k_M) - k_M f'(k_M) = \bar{w}$, where $f' \equiv df / dk_M$, so that the transfer has no impact on k_M . Since $f'(k_M) = r$, r does not change by the transfer.

Therefore, $k_A \equiv K_A / L_A$ does not change because of (6') and neither does w^A by (5). Thus the transfer raises the per capita income of the agricultural worker group and reduces that of the manufacturing worker group necessarily, implying that the individual utility of the agricultural worker group rises and that of the manufacturing worker group falls. Since r stays constant to a change in the level of transfer, the individual utility of the capitalist income group does not change. Obviously these results hold without the condition that the initial level of the transfer is zero.

Now we can assert

Theorem 3

Suppose a small open country where capital is mobile between domestic industries and there is an income transfer from manufacturing workers to agricultural workers. If the level of the transfer is raised, then

- (i) any agricultural worker's utility rises,
- (ii) any manufacturing worker's utility falls,
- (iii) any capitalist's utility does not change.

The results (i) and (ii) of Theorem 3 immediately bring forth of

Theorem 4

Suppose a small open country where capital is mobile between domestic industries and there is an income transfer from manufacturing workers to agricultural workers. Then labor income disparity between these two sectors necessarily contracts.

Since neither w^A nor r is affected by a change in the level of any transfer, we can extend the above theorem. We show it as the following remark:

Remark

Suppose a small open country where capital is mobile between domestic industries. For any transfer scheme that income is transferred from some income groups to some other income groups, the individual utility of the donor group falls, that of the recipient groups rises and that of the outside group does not change by an increase in the level of the transfer,

All these results have nothing to do with the stability of any dynamic adjustment process. The key equation to produce these results is (3) which characterizes the dual economy of the Harris and Todaro type. Because of (3), none of factor prices receive any impact from any sort of income transfer.

5. TRANSFER EFFECT TO URBAN UNEMPLOYMENT

In a dual economy much attention is centered to urban unemployment. We focus it in this section. In the analysis of Section 3, it was already revealed that, if capital is industry specific, the agricultural employment increases and the urban unemployment decreases by a rise in the income transfer from manufacturing workers to rural workers.

So we deal with the mobile capital case. In view of the analysis of the previous section we know that the capital-labor ratio of any industry on the agricultural wage never varies for a change in the income transfer. Keep these in mind, we differentiate (8') totally. Then we have

$$\frac{L_M \bar{w}}{K_M (L - L_A)} \left(\frac{K_A}{L_A} - \frac{K_M}{L - L_A} \right) dL_A = - \frac{L}{L_A (L - L_A)} dT^{AL}, \tag{19}$$

by the use of (7), (17) and the assumption that $T^{AL} = T^{ML} = 0$ initially and $dT^{AL} + dT^{ML} = 0$.

Therefore we find

$$\frac{dL_A}{dT^{AL}} > 0 \Leftrightarrow \frac{K_A}{L_A} < \frac{K_M}{L_M + L_U},$$

implying that, if and only if the capital-labor ratio of the urban area is greater (smaller) than that of the rural area, the labor employment of the agricultural industry increases by the introduction of the transfer. Since $k_M \equiv K_M / L_M$ and

$k_A \equiv K_A / L_A$ are constant to the introduction of the transfer and $dK_M = -dK_A$, we easily show that an increase in L_A implies an increase in K_A and decrease in L_M and K_M , and vice versa.

Based on these facts, we investigate the sign of dL_U / dT^{AL} . By (19) and the fact that $L_A K_M dL_M + L_M K_A dL_A = 0$, we obtain

$$\begin{aligned} \frac{dL_U}{dT^{AL}} &= -\left(\frac{dL_M}{dT^{AL}} + \frac{dL_A}{dT^{AL}}\right) \\ &= \left(1 - \frac{L_M K_A}{L_A K_M}\right) \frac{\frac{L}{L_A(L-L_A)}}{\frac{L_M \bar{w}}{K_M(L-L_A)} \left(\frac{K_A}{L_A} - \frac{K_M}{L-L_A}\right)} \\ &= \frac{L_M L}{L_A \bar{w}} \frac{\frac{K_M}{L_A} - \frac{K_A}{L-L_A}}{\frac{K_A}{L_A} - \frac{K_M}{L-L_A}} < 0, \end{aligned}$$

if

$$\frac{K_A}{L_A} < \frac{K_M}{L_M + L_U}. \quad (20)$$

Thus, if the capital-labor ratio of the urban areas is greater than that of the rural area, the introduction of the transfer reduces the urban unemployment. The condition (20) is a global stability condition of the following dynamical factor movement process:

$$(D) \quad \begin{cases} \dot{L}_A = \alpha_L \left(w_A - \frac{\bar{w} L_M}{L - L_A} \right), \\ \dot{K}_A = \alpha_K (pG_K - F_K), \end{cases}$$

where α_L and α_K are positive and constant parameters implying adjustment speeds. The proof of the stability is provided in Appendix²⁵⁰.

Now we can summarize results derived in this section as

Theorem 5

Consider the income transfer from manufacturing workers to agricultural workers. Then,

- (i) *in the specific capital case, a rise in the level of transfer always increases the labor employment in the agricultural industry and decreases the urban unemployment,*
- (ii) *in the mobile capital case, the introduction of the transfer increases (decreases) the labor employment as well as capital employment in the agricultural industry and decreases (increases) the labor employment as well as capital employment in the manufacturing industry if and only if the capital-labor ratio of the urban region is greater (smaller) than that of the rural region,*
- (iii) *in the mobile capital case, the introduction of the transfer reduces the urban unemployment if the capital-labor ratio of the urban area is greater than that of the rural area.*

6. CONCLUSION

We investigated the welfare effect of a domestic income transfer from urban workers to rural workers in a dual open economy and showed that the transfer possibly lowers the welfare of the rural workers in the case where capital is sector-specific but such a transfer paradox never occurs in the case where capital is perfectly mobile between sections. This is, because, in the specific-capital case, the rural income goes up by the transfer and thus labor flows into the rural area and reduces the rural wage. If this latter effect overwhelms the former, the rural workers will be worse off. This paradoxical phenomenon appears when the wage reduction is very sensitive to the labor inflow. In the mobile capital case, labor should move together with capital since the capital-labor ratio of each sector is constant by the fixed urban wage. Thus, the transfer does not influence the rural wage, so that the paradox cannot occur. All these results has nothing to do with

²⁵⁰In the mobile capital case the stability was first investigated by Neary(1981).

the dynamic stability condition of which is often made use. The reason is the open economy assumption which enables the good prices to be constant.

Based on these two distinct outcomes, one policy implication could be proposed that the effect of a domestic transfer to raise the welfare of the rural worker depends on the capital mobility. If only labor flows into the rural region by the transfer, the policy may not be effective. If capital also together with labor flows into the rural region, however, the policy becomes necessarily effective. For the purpose to shrink the wage disparity, however, this transfer policy is effective in both cases. We also inspected the effect of the transfer to the urban unemployment and derived the result that the transfer always reduces the urban unemployment in the specific capital case but it does not so in the mobile capital case. The sufficient condition to reduce the urban unemployment is the urban region is more capital-intensive than the rural region.

Finally we should notice that our transfer scheme is slightly different from that of Ravallion(1984). Ravallion considers the source of income transfer to agricultural workers comes from manufacturing firms, so that the labor cost in production goes up while the labor income in the manufacturing sector stay constant. In our supposition, however, the source of income transfer relies on the income of manufacturing workers, which implies that the labor income of manufacturing workers necessarily goes down but the labor cost in manufacturing production is not affected. This difference does not influence our results much but a little. Suppose Ravallion's transfer scheme. Then, in the specific capital case, the income disparity expands if and only if the agricultural wage decreases. In the mobile capital case, we can see easily that the agricultural wage necessarily increases and the rental of capital decreases.

Our present analysis is simple enough to derive clear results, since we assume the economy to be small and open. If the economy is closed, the analysis becomes complicate by the disturbance of the endogenous good prices. Although most developing countries are small and open, the close economy case is more interesting from a theoretical point of view and it is a future topic to tackle.

APPENDIX

In this appendix we prove that, if $T^{AL} = T^{ML} = 0$, the equilibrium is globally stable under factor movement dynamic process (D). Total differentiation of (D) with respect to the endogenous variables yields

$$dL_A \equiv dw^A - \frac{\bar{w}(L-L_A)dL_M + \bar{w}L_M dL_A}{(L-L_A)^2},$$

$$d\dot{K}_A = pG_{KK}dK_A + pG_{KL}dL_A - F_{KK}dK_M - F_{KL}dL_M.$$

Therefore Jacobian matrix of (D) is exhibited as

$$J \equiv \begin{bmatrix} pG_{LL} - \frac{\bar{w}L_M}{L-L_A} & pG_{LK} - \frac{\bar{w}F_{LK}}{(L-L_A)F_{LL}} \\ pG_{KL} & pG_{KK} + F_{KK} - \frac{F_{KL}^2}{F_{LL}} \end{bmatrix},$$

since $pG_{LL}dL_A + pG_{KK}dK_A = dw^A$, $F_{LL}dL_M + F_{LK}dK_M = 0$ and $dK_M + dK_L = 0$.

Every diagonal element of J is negative. The determinant of J is derived as

$$|J| = (pG_{LL} - \frac{\bar{w}L_M}{(L-L_A)^2})(pG_{KK} + F_{KK} - \frac{F_{KL}^2}{F_{LL}}) - pG_{KL}(pG_{KL} - \frac{\bar{w}F_{LK}}{(L-L_A)F_{LL}})$$

$$= (\frac{F_{KL}^2}{F_{LL}} - pG_{KK} - F_{KK}) \frac{\bar{w}L_M}{(L-L_A)} + pG_{KL} \frac{\bar{w}F_{LK}}{(L-L_A)F_{LL}}$$

$$= \frac{p\bar{w}G_{KL}}{L-L_A} \frac{L_A L_M}{K_A K_M} (\frac{K_M}{L-L_A} - \frac{K_A}{L_A}),$$

implying that $|J|$ is positive in sign if the urban area is more capital intensive than the rural area.

Applying the stability theorem in Oleck(1963) to these results, we can assert that the equilibrium is globally stable in the case where $T^{AL} = T^{ML} = 0$.

1160 STUDY ON THE DETERMINANTS OF CREATIVE CLASSES AND ITS IMPACTS ON REGIONAL ECONOMIC GROWTH: CASE STUDY FROM MAJOR CITIES IN JAPAN

Shinichi Furuzawa¹, Lily Kiminami¹, Akira Kiminami

¹Niigata University

²The University of Tokyo

ABSTRACT

Understanding the mechanism and impact of creative classes (CCs) on regional economic growth is important not only for academia but also for the policy makers, practitioners and so on. In recent years, various number of empirical studies based on the theory of creative class has been conducted. However, the research of the CCs in Japan focusing on its major cities is scarce, especially on cultural diversity. The purpose of this study is to clarify the determinants of CCs and its impacts on the economic growth of the cities by using the official statistical data in Japan. Specifically, it will construct the indicators of amenity, tolerance, job opportunity and openness to clarify the determinants of CCs and its impacts on regional economic growth and innovation by using structural equation modeling (SEM) analysis. Finally, policy implication for a sustainable development of cities will be derived from the analytical results.

Keywords: Creative Class(CC), Cultural Diversity, Japan

JEL codes: R1, J1

1. INTRODUCTION

Creativity and diversity are fundamental elements in promoting innovation which is the source of economic development. Empirical analyses on creative classes (CCs) conceptualized by Richard Florida (e.g. Florida 2005) and creative capital theories have been mainly conducted in North America and Europe, and both from intra-national and international comparative perspectives. In recent years, the accumulation of empirical analysis on Asian countries has also getting progresses.

In the meantime, according to the results of a representative international comparison (MPI 2015), the creative index of Japan is the 24th among 139 countries high in its overall rank. Although the domain of Technology (2nd) is high, Talent (58th) and Tolerance (39th) are comparatively low. In addition, Westlund and Calidoni (2010) clarified that tolerance and social capital had no effect on regional development at the prefecture level of Japan in the first half of the 2000s

However, according to the results of theoretical and empirical studies about the mechanism of the diversity of human beings and cultures contributing to innovation, benefits can be drawn successfully from cultural diversity when it overcomes the obstacle of cross-cultural communication which contributes to the reduction in transaction cost. In other words, the region where it can derive the benefits of cultural diversity is the region where people can live with coexisting of heterogeneous and/or different values and is a society with a high degree of tolerance.

Therefore, in order to consider a desirable urban policy for the sustainable development of regional economy, this research attempts to clarify the determinants of the CCs and its impacts on regional economic development in Japanese cities based on the theories of CC and cultural diversity by using the structural equation modeling.

2. SURVEY OF PREVIOUS RESEARCH

2.1 Creative classes and creative cities in Japan

There have been a few empirical analyses on creative classes in Japan (Westlund and Calidoni 2010, Ishizaka 2014, Yoshimura 2009, Yoshimura 2010, Kiminami et al. 2018). Among them, Westlund and Calidoni (2010) found that human capital and population density had a significant influence on the regional development at the prefecture level in Japan (population growth, corporate growth rate, high-tech employment rate) in the early 2000s. In addition, the reason that the effects of tolerance and trust were not confirmed was considered as the immaturity of Japanese civil society. However, due to the focus of their analysis was on which fitness is high between the types of Florida's CC and Putnam's SC, the analysis about basic factors such as amenity, employment, openness and tolerance were insufficient.

Yoshimura (2009) argued that the direction of urban policy is required as to promote two coexisting characteristic functions of the agglomeration of enterprises and research institutes, and the enhancement of housing, medical care and education in order to attract creative classes through the investigation targeted the CCs in Fukuoka city and Kitakyushu city. In addition, Yoshimura (2010) conducted surveys on employment and housing orientation for technology-based employees in seven major cities across the country. The results clarified that the CCs did not have an extremely heterogeneous orientation with respect to employment or residence, but their desire for 'self-esteem' and 'self-actualization' were strong and their evaluation on the functions of cities depends on if such desire can be pursued through work. Furthermore, it clarified that the CC's evaluation on the residential environment from urban functions were put in the aspects of medical, educational and cultural facilities.

2.2 Cultural diversity and tolerance

In recent years, theoretical and empirical researches clarified that cultural diversity (Cultural Diversity) plays an important role in knowledge creation for innovation. Jacobs (1969) had early pointed out that cultural diversity was a source to encourage development in the qualitative sense of the economy. Berliant and Fujita (2011) clarified that,

although knowledge creation and innovation are promoted through communication among people in difference while having a certain extent of common knowledge, the cost of interaction will increase and make it impossible to generate positive influences if diversity progresses too much.

In these empirical analyses, the cultural diversity was measured in the meaning of the place of origin and ethnicity of immigrants, and the effects of cultural diversity on income, innovation, and entrepreneurship etc. were quantitatively clarified in general in the cases of positive (Niebuhr 2009; Ozgen et al. 2011) or in the cases of non-positive effect. In other words, there is an optimum level for cultural diversity, and “tolerance” that promotes cross-cultural communication plays an important role in knowledge creation for innovation.

Concerning tolerance, some interesting results are reported in a project called “World Values Survey” which investigates and compares values of countries around the world. The cultural values of the world are classified into two axes of the (traditional versus) secular-rational value and the (survival versus) self-expression value (called the Inglehart-Velzel diagram). As for Japan, it is reported that the secular-rational value index is high, but self-expression value index is low (Inglehart and Baker 2000, WVS homepage²⁵¹). In other words, secularization has progressed in Japan which is neither bound by tradition and religion, nor is based on individual rights²⁵². In a comparative survey among each country Inglehart and Baker (2000) found that economic growth did not necessarily accompany a rise both in secular-rational and self-expression value indexes which was thought as the processes of modernization did not always converge in one direction deterministically followed by a nonlinear path with its path dependence.

Issues of tolerance and cultural diversity can become represent the issues of suicides in societies. For example, issues of the suicide which is considered as one of the most serious social problems in Japan shall be caused by the such kind of social environment. Chen et al. (2009) clarified that suicides in high rate of suicide (generally ratio of suicide is almost 2.0-2.5 timers higher in male compared to female) in Japan can be explained by economic factors by investigating among OECD countries. Andrés et al. (2011) clarified that female suicides was positively associated with sociological factors (divorce and fertility rates) rather than economic factors (GDP per capita and unemployment). Furthermore, the existing study (Heirigs et al. 2017) clarified that ratio of suicides is positively correlated with ratio of CCs by using the cross-country analysis. It can be interpreted that low(high) ratio of suicide represents that people can(not) choice their way of life in one’s own way in the society. Thus, we also focus on the relationship between suicide and CCs in the empirical analysis.

In spite of the importance of the cultural diversity, researches on the relationship between cultural diversity and regional economic development for Japan has not been done so far (See also Kemeny 2017; Hagiwara and Nakajima 2014), although empirical economic analyses of foreign workers in Japan has been conducted in recent years (Nakamura et al. 2009; Machikita 2015; Hashimoto 2015)²⁵³. We would like to make an empirical analysis to add some new consideration on this issue.

3. ANALYTICAL FRAMEWORK AND METHODOLOGY

3.1 Analytical framework and hypothesis

Based on the literature review in the previous section, we constructed the conceptual framework for this research as shown in Figure 1. We also set hypotheses of H1-a, H1-b and H 2 as working hypotheses for the analysis.

That is, when hypothesis 1 is satisfied, it means that the regional development based on the creative class theory is realized in the region. Furthermore, when hypothesis 2 is satisfied, it means that regional development has been realized in line with diversity theory.

Hypothesis 1 - a. Determining factors for the residence of creative classes are amenity, employment, and tolerance.

Hypothesis 1 - b. The residence of creative classes positively influence the sustainable development of the region.

Hypothesis 2. A high tolerance linking with a high cultural diversity will promote sustainable development of the region.

251 See World Value Survey (<http://www.worldvaluessurvey.org/wvs.jsp>) for more details.

252 In addition, Florida (2005, Ch.5) also introduced the results of the survey, and pointed out that Japan and Germany are in a similar situation. However, Japan has a higher secular-rational value index and a lower self-expression index than Germany.

253 As for the empirical economic analysis on the labor market of immigrant in Japan, please see Nakamura et al. (2009). and as for the recent trend of labor market situation, please see Machikita (2015) for example. As for the technology transfer policy and institutional problems in the agriculture and construction sectors, please also see Hashimoto (2015).

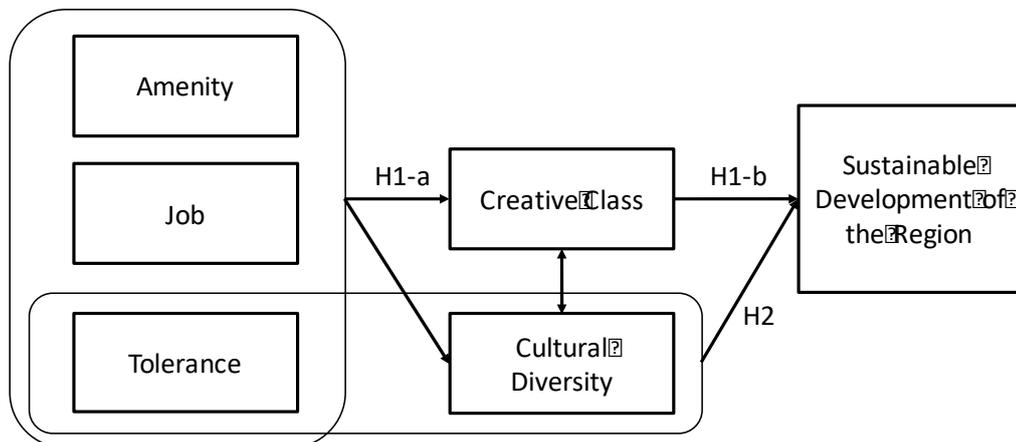

Figure 1. Conceptual Framework and Hypotheses

3.2 Data and analytical method

We introduced the method of covariance structure analysis (Structural Equation Modeling). The framework of path diagram for the SEM analysis is shown in Figure 2. The summary of the variables used for the analysis is shown in Table 1. For the third layer, we will use population growth rate, growth rate of income per capital and growth rate of patent growth as proxy indicators for sustainability, economic performance and innovation respectively.

Next, as for the CCs, we use the ratio of the total of professional, technical and artistic jobs in socio-economic classification divided by total number of employment in the region. As for the index of cultural diversity, we use two type of indexes: the Shannon index of nationality of foreigner and foreigner ratio in total population. Regarding the diversity of nationality, although the diversity of the area of origin should be used in precisely, such kind of statistical data is unavailable in Japan, the Shannon index of the number of foreign nationals by nationality is used as a proxy index²⁵⁴. We also use the ratio of suicide based on the literature review in the above section (low ratio of suicides indicates high level of cultural diversity in general sense).

Finally, for amenity, employment and tolerance, the number of urban parks, unemployment rate and tolerance are used as proxy variables. Population density is used as a control variable as the degree of urbanization. The tolerance index is calculated as a subjective indicator (see Appendix 1).

The data of the first hierarchical is in the year of 2000 and the second hierarchy is the data in 2005-06. For the third layer, growth rate of the variables for the period from 2005 to 2010 (for patents 2014 to 2016) is used.

The number of cities to be analyzed is 109 and they are major cities in Japan: core cities, special cities (at the time of enforcement) and prefectural government cities including Tokyo special wards (see Appendix 2).

Note: Covariance between variables is assumed in the first hierarchy and covariance of error terms is assumed in layer 2.

4. RESULTS OF THE ANALYSIS

The results of covariance structure analysis are shown in Figure 3, Figure 4, Figure 5 and Table 2²⁵⁵. The results showed that employment and degree of urbanization had influences on the CCs, but tolerance and amenity didn't have. Thus, about for the Hypothesis 1-a, it was verified that only the job factor is determinants of CCs. On the other hand, there was a positive correlation between unemployment rate and urbanization; tolerance and urbanization; tolerance and urbanization, but the correlation between amenity and other indicators could not be confirmed. This indicated that urbanization in Japan had been generally undertaken in the employment-driven way and the supply of amenity was relatively weak. Furthermore, such kind of employment-driven urbanization would further promote population concentration in specific areas (OECD 2016).

Regarding the impacts of the CCs on the sustainable development of regions, the higher the CCs ratio, the higher rate of population growth and per capita income was confirmed. This means that the CCs contributes to the economic performance and population growth. However, their effect on promoting innovation could not be confirmed since no significant results were obtained with respect to the patent growth rate. Therefore, the Hypothesis 1 - b. "The residence of creative classes positively influence the sustainable development of the region" was only limitedly verified.

Regarding the influence of diversity on the sustainable development of the region, it was confirmed that the immigrant diversity was negative with respect to the economic growth rate, and the ratio of foreigner was positive to the population growth rate. In addition, the ratio of suicide was negative with respect to population growth. It was positive with respect to economic performance. The one of the possible explanation of the high ratio suicides with high economic growth is that income growth might positively correlates with longer working hours²⁵⁶. Therefore, Hypothesis 2 "The higher the cultural diversity, the more sustainable development of the region" was also limitedly verified in Japan, because the foreigners contributed to the population growth rate in the Japanese Cities but their capability for the economic growth could not be sufficiently drawn out due to the employment-driven urbanization mentioned above. Such kind of situation can be explained by the concentration of foreign workers from specific countries in the cities in Japan.

255 In order to test whether our results hold or not in the case where largest cities excluded from the sample, we conducted additional SEM analysis. We conducted SEM analysis by using sub sample which the 4 largest cities (Tokyo 23 wards, Yokohama, Osaka, Nagaya city > 2 million of population) are excluded from the sample. The result show the almost same result of the full sample model (109 cities) and signs of the coefficients and level of significant is stable except for the relationship between "Foreigner and CC (become not significant)" and "Foreigner and GIPC (become significant)". Thus, our hypotheses verification and conclusion also holds in this case.

256 In general sense, it can be considered that low level of tolerance leads to low level of cultural diversity, and it can not promote the regional economic growth because of the exclusion problems. This contradictory (high rate of suicides with high growth rate of income per capita) result might show the characteristics and distortion of labor markets of Japanese society.

5. CONCLUSIONS

The conclusions derived from the above-mentioned results are as follows. First, the direction of urbanization shifting from the employment-driven to a sustainable development linked with a sufficient supply of amenity is required. For example, it is confirmed that supply of amenity through the multi-functionality of urban agriculture brings positive utility to residents and enhances the sustainability of cities (Kiminami and Kiminami 2007; Kiminnami et al. 2018).

Secondly, the acceptance of foreign workers, as well as the acceptance of foreign labor force in Japan has been focused on the technology transfer and labor shortage which has made great contribution to the regional economic growth (especially to the population growth) in policy. However, in order to promote the sustainable and inclusive development of regions in the long-term, policy on the innovation that includes social innovation²⁵⁷ (OECD 2011; Nicholls and Murdock 2012) through enhancement of tolerance including the acceptance of cultural diversity is called for. These kinds of policy innovation can also contribute to solve social problems such suicide in Japan because it will lead high level of cultural diversity with tolerance for all people of the society.

Finally, because economic development of cities has multiple aspects, analyses by considering the institutional environment and structure of cities, and from the perspectives of international comparison based on the understanding each country’s context will be necessary. These will be our future research challenges.

ACKNOWLEDGEMENTS

This study was supported by JSPS KAKENHI Grant Number 15K18750 (study on the entrepreneurship of social business in rural and agricultural sector), and 17K07989 (study on the creativity of cities through improving agriculture amenity: comparative analysis between Japan and China). We wish to express our gratitude for the support.

<FOR JGSS DATASET>

The Japanese General Social Surveys (JGSS) are designed and carried out at the Institute of Regional Studies at Osaka University of Commerce in collaboration with the Institute of Social Science at the University of Tokyo under the direction of Ichiro TANIOKA, Michio NITTA, Hiroki SATO and Noriko IWAI with Project Manager, Minae OSAWA. The project is financially assisted by Gakujutsu Frontier Grant from the Japanese Ministry of Education, Culture, Sports, Science and

257 Social Innovation can be defined as the innovation and its process that can contribute to solve the social problems (e.g. addressing social needs and market and government failures) for the sustainable development of the region through the innovation at incremental, institutional and disruptive levels. It becomes effective by using the multi-sector collaboration approach based on the social entrepreneurship. As for the definitional arguments, please see Nicholls and Murdock (2012) for example.

Technology for 1999-2003 academic years, and the datasets are compiled and distributed by SSJ Data Archive, Information Center for Social Science Research on Japan, Institute of Social Science, the University of Tokyo.

APPENDIX 1. HOW TO CREATE A TOLERANCE INDEX

With respect to the tolerance index, referring to the method used in Westlund and Calidoni (2010), based on the answers of the following nine questions, the latitude ($1 = \text{tolerance}$, $0 = \text{not tolerance}$) Was calculated.

Specifically, after calculating the response rate (Tir , $0 \leq Tir \leq 1$) for each region ($r = 1, \dots, 58$), the total value of nine items ($i = 1, 2 \dots 9$) is calculated, The tolerance index ($\sum Tir$, $0 \leq \sum Tir \leq 9$). In some areas, since there were cases where it was a small number of samples, in order to reduce the sample bias, the average value of data for three years was calculated. Specifically, after calculating the same index for each year of JGSS - 2000, JGSS - 2001 and JGSS - 2002, average values were calculated.

<JGSS-2000 and JGSS 2001> (Note)

<Foreigner1>

Are you for or against an increase in the number of foreigners in your community?

Yes=1, No and Others=0

<Foreigner 2>

Have you had any contact with foreigners in Japan?

Yes=1, No=0

<Marriage and Family View>

When a marriage is troubled and unhappy is it generally better if the couple gets divorce for wife?

Yes=1, No and Others=0

<Gender View 1>

If a husband has sufficient income, is it better for his wife not to have a job?

Yes=0, No and Others=1

<Gender View 2>

Can a working mother establish just as warm and secure a relationship with her children as a mother who does not work?

Yes=1, No and Others=0

<Gender View 3>

A husband's job is to earn money; a wife's job is to look after the home and family. Do you agree?

Yes=0, No and Others=1

<Gender View 4>

Is having a job the best way for a woman to be an independent person?

Yes=1, No and Others=0

<View of Life and Death>

When a person has a fatal disease, do you think doctors should be allowed by law to end the patient's life by some painless means if the patient and his/her family request it?

Yes=1, No and Others=0

<LGBT View>

Do you think that sexual relations between two adults of the same sex are wrong?

Wrong and Others=0, Not wrong=1

Note: With regard to JGSS-2002, there is a change in the question items (foreigner 2, marriage / family view, gender view 2 & 4) with JGSS-2001 and JGSS-2002, so do not strictly connect. Also, regarding LGBT view, there is no question item, so it is not taken as the target of summarization of the index calculation.

In addition, in the same survey, information on city size ("13 large cities", "other cities", "other districts") is investigated in addition to information on prefectures as residential areas. Therefore, for Yokohama City and Kawasaki City, among the 13 major cities, Fukuoka City and Kitakyushu City, the aggregated values of "13 large cities" categories in Kanagawa Prefecture and Fukuoka Prefecture, respectively, are used for other large cities, we use the aggregate value of "13 large cities" category of prefecture (total 11 areas).

For core city, special case city and prefectural government cities, aggregate values of "other cities" category of each prefecture are used (total 47 areas).

APPENDIX 2. LIST OF TARGET CITIES

No.	Prefectures	City
1	Hokkaido	Sapporo-shi
2		Hakodate-shi
3		Asahikawa-shi
4	Aomori-ken	Aomori-shi
5		Hachinohe-shi
6	Iwate-ken	Morioka-shi
7	Miyagi-ken	Sendai-shi
8	Akita-ken	Akita-shi
9	Yamagata-ken	Yamagata-shi
10	Fukushima-ken	Fukushima-shi
11		Koriyama-shi
12		Iwaki-shi

INTRODUCTION

Construction sector is an important source of employment in India also leads to sizeable amount of migration. The largely labour intensive production process in construction industry depends on cheap and flexible migrant labour in order to reduce the cost of production (Krogh, 2014) .Construction labour consists of diverse labour arranged in a hierarchical order. At the top of the hierarchy is the builder or main-contractor followed by subcontractors, supervisors of main contractor, maistry, masons and leaves unskilled labour at the lowest edge. The system of contracting in construction sector is a response to the flexible production demands derived from the “need to respond to short-term project objectives, fluctuating demand, changes and uncertainties in the worksite” (Bresen, 1985). Migrants are recruited mostly by labour only contractors (agent or dalal), middle man or through maistry. The current study is based on primary survey conducted in Northern Kerala in 2017. Construction in general and private construction in particular is noticed significantly in this region. Major chunk of the construction labour is constituted by migrants hailed from distant corners of the country. Broadly, this study is an attempt analyse the firm’s strategies to access cheap labour pool. Firstly study the process of migration with particular focus on migrant’s place of origin, channels and patterns of migration. Remaining session deals with the working condition of migrant labour in informal construction sector.

Migrant Construction Labour: Place of Origin

The flow of migration from various parts of India to Northern Kerala reveals that out of total migrants surveyed (figure 1), 45% are from West Bengal followed by Odisha (24%), Bihar (9.3%), Tamil Nadu(9.3%) , Madhya Pradesh (6.25%), Uttar Pradesh, Jharkhand etc. Majority of the migrants are hailed from eastern part of the country.

Figure 1: Flow of Migrants from Different States to Kerala: 2011

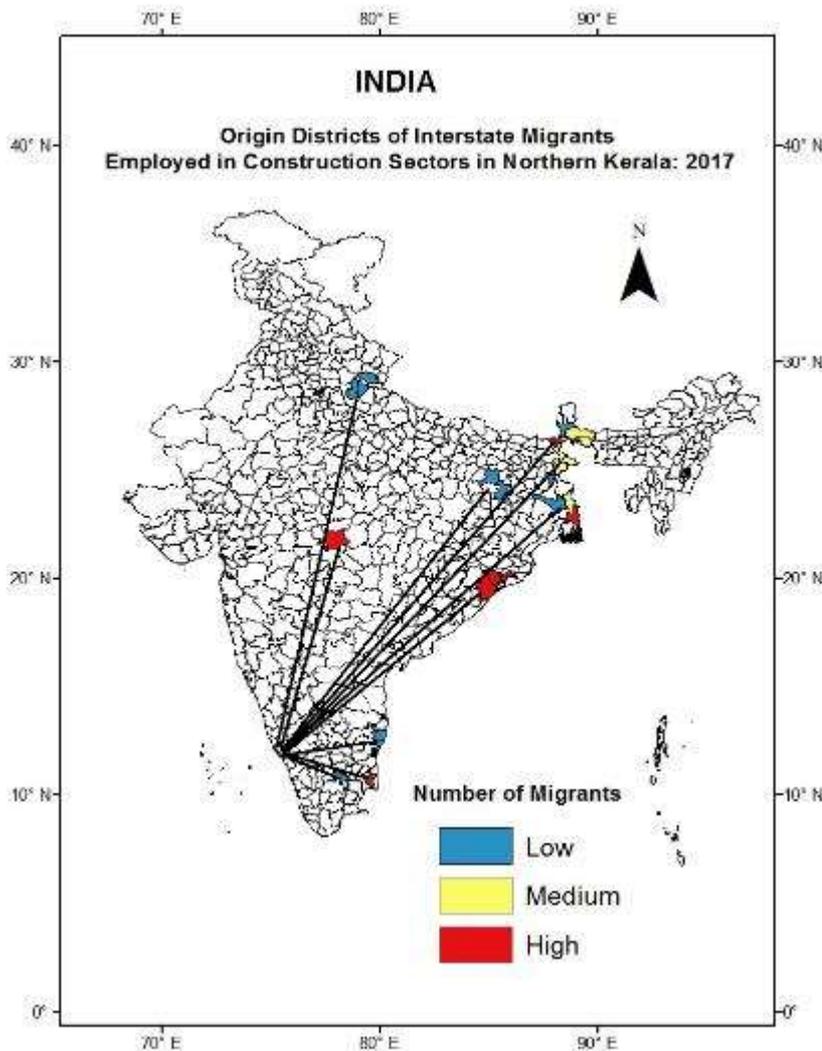

Source: ISMSK (2011)

West Bengal and Odisha together constitutes about 69% of the migrant population. These are the states from where the first flock of migrants came to Kerala. Other states from where migrants are coming very recently to Kerala are Uttar Pradesh, Bihar, Jharkhand and Uttarakhand etc.

The choropleth map of districts of migrant origin (figure 2) shows the district wise location of interstate migrants in Kerala. The categories of low, medium and high show the intensity of flow in terms of number of migrants.

Figure 2: Origin Districts of Interstate Migrants Employed in Construction Sectors in Northern Kerala: 2017

Source: Primary Survey (2017)

Migrants are coming from different spatially disjunctive centers. Generally major origin districts surrounded by medium and minor origin districts. A definite spatial contiguity is seen in the place of origin facilitated by chain migration. The 'location specific capital' at the destination encourages the probability of chain migration (Haug, 2008). "Being embedded in social networks thus has a significant influence on migration decisions" (Haug, 2008). The most developed migrant originating centre is West Bengal, especially the Bangladesh bordering and northern districts followed by districts located north of Chilka lake in Odisha; Rampur, Nainital and Moradabad districts in Uttarakhand and Uttar Pradesh boarder; Gaya and Hazaribagh districts of Bihar and Jharkhand. Betul is the only district in Madhya Pradesh from where migrants are coming. Migrant sending states in Tamil Nadu are showing a discrete pattern. Except Madhya Pradesh and Tamil Nadu, all migrant origin places show a spatial contiguity. The two major centers of migrant origin ie. Odisha and West Bengal are enlarged to see the locational characteristics in detail (figure 4 and 5).

Odisha shows a shear spatial contiguity of out migration (figure 3). Unlike others, all the migrants from Odisha were exclusively belong to traditional fishing community have been engaged in fishing for generations. All of them are settled in the banks of Mahanadi river or Rushikulya river or on the banks of Chilka lake. Negligible or very narrow margin of profitability of fishing also the ever decreasing fish resources compelled them to shift to other reliable economic activities. Odisha migrants are largely comprises of young male cohorts.

Figures 3 and 4 the Spatial Contiguity of Migrants' Place of Origin Northern Kerala, 2017

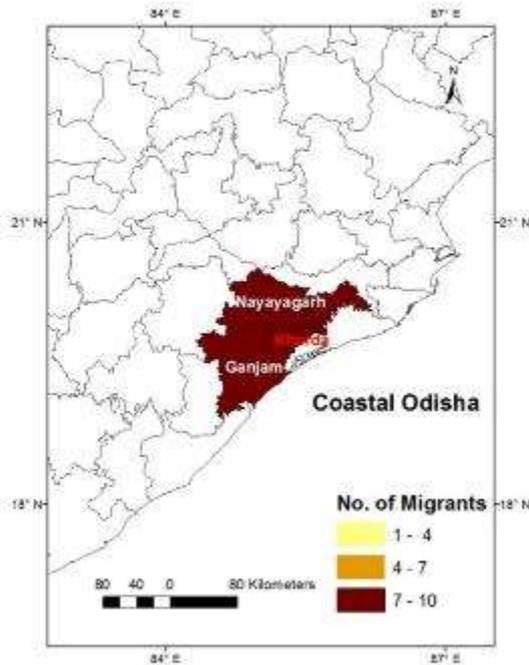

Figure 3

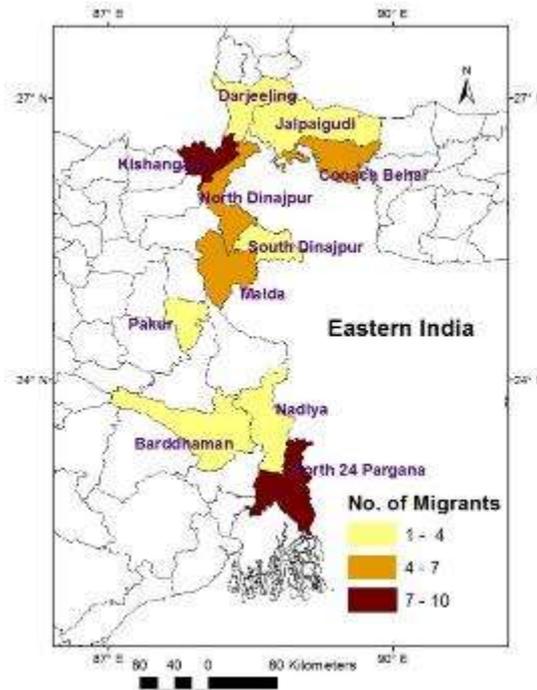

Figure 4

West Bengal is also showing a spatial contiguity of out migration in which major sending districts are surrounded by medium and minor sending districts (figure 4). There are two cores in this out migration region i.e. Kishanganj (Bihar) in the north and North 24 Parganas in southern West Bengal. Kishanganj district is located in the West Bengal-Bihar border surrounded by the northern districts such as Uttar Dinajpur, Darjeeling, Jaipalguri, Cooch Behar, South Dinajpur, Malda and Pakur. The southern core is surrounded by Burdhaman and Nadia.

The migration from Madhya Pradesh is seasonal in nature. The activities of construction and repair of roads usually carried out from January to May, which is basically agricultural off season in the place of origin. The highly remunerative road construction work is an option extended for the migrants to diversify their usual economic activity. All these seasonal migrants have a better socio economic background than other temporary migrants.

Scarcity of water for agriculture forced migration from Tamil Nadu to supplement their household income. They are also engaged in farming along with the construction work in Kerala with the help of other family members, as the distance from village is not so far. Though better economic opportunities are the driving force behind most migration, securing a decent job is one of the major initial confrontations of migrants.

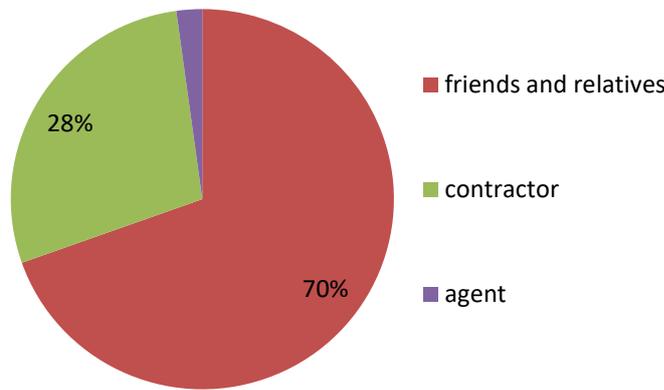

Migration channels:

The rural labour migration to construction sectors of Kerala is constituted by diverse and distinctive informal channels. The migration channel refers to the means through which migrants have been informed of the job and then recruited. The channels of migration refer to friends and relatives, contractors, agents and other sources. Figure 5 explains the percentage share of migrants recruited through different channels.

Informal networks (friends and relatives: 70%) play an important role in the recruitment of migrants followed by contractors (28%), agents (2%). Most of the migrants who were recruited by the informal channels are also paying a fixed amount regularly to their friends who brought them. Migrants prefer their friends than strange agent/contractor due to their anxiety of working in a distant place with no familiar faces. Such intermediaries in collaboration with contractors ensure a constant supply of labour to the construction sites when demanded.

The friends and relatives constitute a sizeable share of maistry informal sector. A fixed amount is given to maistry by the migrants as service charges for the necessary social capital provided at the destination.

Figure 5: Source Channels of Migration in Northern Kerala, 2017

Source: Primary Survey (2017)

Migration Pattern

Migration pattern refers to how labourers are migrating, whether in group or single. Mostly migrants prefer group migration (68.8%) than single migration (31.3%) as these social ties could provide useful resources to reduce risk and high cost and it would also help them to establish their base in the destination.

WORK CONDITION OF MIGRANTS IN THE INFORMAL CONSTRUCTION SECTOR

Task Assignment

Table 1: Task Assignment among Migrant Labour in Informal Construction Sector, Northern Kerala: 2017

Status	Persons by Type of Task Assigned (Figures in Brackets are in %)			Supervisor	Total
	Helper	Mason			
Migrant	25 (54)	21 (46)		00 (00)	46

Source: Primary Survey (2017)

Task assignment in a work site encapsulates the pattern of distribution of tasks within that worksite. Table 3 shows the task assignment within the construction work site. More than half of the migrants in construction sector are employed as helpers (54%) and the remaining (46%) are employed exclusively as masons. Mostly, migrants are employed as less remunerative helpers.

Daily Wage Rate

The following table (table 2 shows the daily wage rate across tasks classification. About 72 % of migrants employed as helpers are receiving daily wages less than Rs. 500. Reja et. al (2016) pointed out the migrant daily wages as Rs 400-500 per day, rightly emphasized that it is lower than the wages for local labour by about Rs100-150.

About 4.76% of the masons are receiving a very low daily wage rate even less than Rs. 500. There is no significant relation between job experience and type of task assigned. There is no significant relation between job experience and type of task assigned. However the highest daily wage rate received by migrant mason is about Rs.1200.

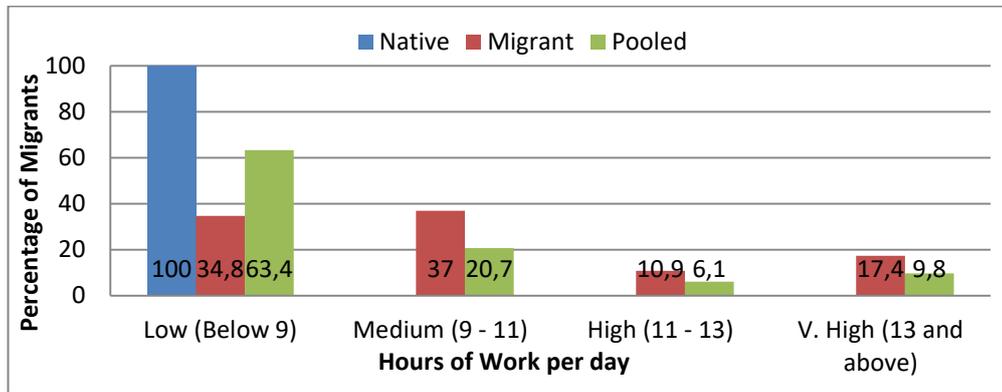

Table 2: Distribution of Migrants across Wage Levels in Informal Construction Sector, Northern Kerala: 2017

Daily Wage Rate (Rs.)	Migrants		
	Helper	Mason	Total
Below 500	72	4.8	41.3
500-600	24	38.1	30.4
600-700	4	38.1	19.6
Above 700	0	19.0	8.7
Total %	100	100	100

Source: Primary Survey (2017)

Hours of Work and Weekly Work Days

Figure 6: Hours of Work among Construction Labour in Informal Construction Sector, Northern Kerala: 2017

Source: Primary Survey (2017)

The number of hours of work is an important issue of concern when it comes to the long term health impacts, equally important is the weekly workdays. Figure 6 shows the percentage distribution of construction labour across hours of work. In case of natives 8 hours of work has strictly been taken care of. But migrant labour is seen as an instrument to complete the task shortly at low cost. Most of the migrants (65.2%) are working more than 9 hours (hours is taken because one hour overtime is quite reasonable during concrete and road tarring work due to the wrong estimate of concrete mixture or melted tar). In order to avoid the wastage, workers do overtime but anyways not more than one to maximum two hours. Alarmingly, 17.4% of the migrants take up more than 13 hours of work is a serious issue requires immediate attention.

Table 3 shows the percentage of migrants with reference to work days. About 13% of migrants are working 6 days with a break in Sundays. Around half of the migrants (58.7%) have break only in Sunday afternoons. But 28.3% of the migrants have no weekly break from routine work. They are free to take leaves in any day but. This way a minimum work can be carried out each day, also an easy way to earn money shortly for migrants.

Table 3: Weekly Work Days of Migrant Construction Workers in Informal Sector, Northern Kerala: 2017

Weekly work Days	Percentage
Whole week (break is up to the worker)	28.3%
Whole week except Sunday afternoon	58.7%
Six days work and Sunday holiday	13%
Total	100%

Source: Primary Survey (2017)

As far as regularity is concerned, there is seldom exist ant formal contracts between the contractor and labour (Wells, 2007). The stability of employment depends on the nature of relationship between labour and the contractor leads to feudal dependency of labour (Kumar; 1991). Migrants are more deprived in terms of regularity of employment.

Worksite Accidents and Treatment

Work site accidents are not rarely reported among the migrants depending upon the type of task they are assigned with. Though building and road construction works are risky and prone to accidents, the type of task determines the degree of vulnerability. Besides the incidents of workers being hit by vehicles during their work in a crowded road, the other important source of vulnerability is road tarring in construction. Nonetheless the incidents of workers fell from high storied buildings are also common in the worksites.

Health and Medical Benefits

Table 4: Health and Medical Benefits of Migrant Labour in Informal Construction Sector, Northern Kerala: 2017

	Migrants
Only Medical expenditure	82.6%
Only Health insurance	00
Medical expenditure and health insurance	6.5%
Paid sick leave and medical expenditure	8.7%
Paid sick leave, medical expenditure & health insurance	2.2%
Total (N)	100%

Source: Primary Survey (2017)

Construction work is prone to accidents and other health related risks. Table 4 shows the percentage of labourers receiving various medical benefits. Only 2.2% of the migrants have access to health insurance. In case of natives, Kerala Building Workers Union (KBWU) plays a crucial role in universalizing health insurance. Payment of medical expenses is only rendered to 82.5% of the migrants. Payment of medical expenses doesn't cover all medical expenses due to worksite accident or any occupational disease. The amount of money provided is often the mercy of the employer.

Status of Unskilled Migrants in Informal Construction Sector

The construction in unorganized sector is marked with casual nature of employment, cycles of excessive seasonality of job or lack of stability and durability of job, low wages, uncertain working hours, unhygienic and unsafe working

conditions, vulnerability to occupational diseases and serious injuries, absence of social security provisions, lack of attention of labour unions, no formal employer employee relations. Every worker surveyed for this study face some or other kind of injuries and occupational diseases due the high risk associated to their work.

Thampan Thomas, a lawyer and trade union leader said, "Death of migrant workers at workplace cannot be construed as accidents but culpable homicide since in majority of cases there is an element of criminal negligence on the part of the employer" while commenting on the refusal of compensation after the death of four migrants labourers of a plywood factory in Kochi (The Hindu; Kochi; 04/03/2014). In another incident in Thiruvananthapuram, two road construction worker from Bihar were dead in 2004 (The Hindu, Thiruvananthapuram, Dated 13th March, 2007). Incidents of occupational hazards are reporting quite often by the regional news papers.

The provision of basic needs of workers is the obligation of the contractor who employ them. Construction workers are compelled to work on poor working and living conditions by taking benefit of their 'poor bargaining' and socio-economic conditions. They are not only discriminated but also exploited by the contractors also because of ignorance of working conditions. Apart from poor bargaining power and ignorance of working conditions, another issue of concern is the 'improper channels of recruitment' to construction sites more relevant in case of migrants. These three factors can be seen as the major causes of migrants' deprivation.

The recruitment channels of migrant construction workers receive substantial attention as the root cause of migrant deprivation. Depending on the value of contract, the number of migrants who are directly recruited by the employer is decreasing. Multiple levels of subcontracting produces significant gap in between the employer and the labour. The proportion of directly recruited labour by a subcontractor in a large scale construction is significantly low. In one of the large scale construction site the ratio between migrant masons and unskilled labour remained 1:4. Every contractor maintains a small number of migrant masons, always functions as maistry but not necessarily, depending on their social capital and preference. Maistry employ fresh migrants for the construction work also functions as a bridge between the subcontractor and labourers with definite economic prospects. Such 'Fragmentation of economic relations' within the worksite allow the contractors to not take the burden of labour welfare (Shivakumar, 1991). Such practices of direct and subcontracted indirect labour are seen only in large scale construction. Medium scale contractors surveyed has arranged accommodation for the migrants and also ensured regular work.

In times of exploitation, labour department and other formal legal bodies assure justice to the labour. But the time consuming legal procedures is many a time not convenient for the construction workers due to their unawareness and frequently changing location of the job especially for the migrant adding to their lack of accessibility to formal channels. The role of trade unions are marginal in the construction sector. Those existing unions are not aware of organizing the migrants to end labour market stratification. It is interesting to note here the first state conference of the Kerala Migrant Workers Union²⁵⁸ was held in Kerala in April 2017. The unionization of migrant labour is a response to the exploitative contractors and agents also a protection from police as explained by one of the coordinator of the conference. Apart from bonus contractors are also very generous at times of financial support such as marriage or work site accidents or any diseases. However a few native workers are the only beneficiaries of it. Kettida Nirmmana Thozhilali Union is the major formal institution extends services at the time of emergencies to construction workers in Kerala which is not convenient for migrants due to the transient nature of their stay in Kerala.

On that account, nature of relationship between the contractor, maistry and labour plays a vital role during emergencies compel the labour to maintain loyalty with their maistry. Migrants attempt to build a good relation with the maistry for the existence of a secure employment, also enkindles a feeling of clemency in the superior maistry and contractors to give more than he would otherwise consider to be his minimum responsibility. This hierarchical patronage like relationships in order to secure job and income resembles a feudal relationship in an agrarian society. Dependency introduces insecurity via hierarchy undermines the working and living conditions of labour. Unlike the natives, migrants are entangled in the web of restrictive paternalistic practices of wage benefits which he receives but also for the minimum social capital sustaining him in the destination. The institution of maistry allowed sufficient chances for exploitation and leave the labourers on the borderline of subsistence. Kinship and caste norms proved functional in the profit maximization of labour recruitment in construction.

CONCLUSION

The typical production process along with the capitalist monopoly over production led to the system of subcontracting in construction industry. The 'fragmentation of economic relations within the firm' fostered a hierarchical arrangement in which contractors remained at the top and migrant labour at the bottom. The system of subcontracting and institution of maistry enhance the profitability of contractor and maistry. Because of the flexible labour requirements of varying skill levels at different levels of production direct employment of labour reduce the profitability from the contractors perspective. The institution of maistry allowed the contractor to access cheap and reliable unskilled labour force at lowest cost by utilizing the employee referral system. Young individual mostly male forms a chain migration to Kerala is overwhelmingly unskilled or semiskilled. The migrant labour accounts a sizeable share of total unskilled construction workforce in Kerala. Maistry arrange all necessary services needed for a labour in the destination includes both work and accommodation in return of some monetary gains. Migration cut the labour from his traditional sources of social security and limits it to maistry as his godfather in the new destination. The long hours of work, lower hourly wages and

²⁵⁸ Kerala Migrant Workers Union, affiliated to the All India Trade Union Congress (AITUC) was constituted by 20 members.

limited bargaining power make migrants the most economic option of a contractor whereas migrants also prefer overtime work to earn maximum amount in short while. The socio-spatial isolation, spatial dispersion of worksites and temporary to transient nature of construction work intensify migrant vulnerability.

ABSTRACT

India witnessed a good number of art in different fields. Our ancestors were trend in doing number of arts by their own methods. An art which originated from the eastern Indians 'Patachitra' an integral part of intangible heritage. This art is more than 2500 years old and the style of painting is similar to the cave paintings of Mhenjodaro, Harappa and Ajanta. Patashilpa may be an art of tribal (Santal of West Bengal). Although its essence had not been spread in other parts of India but still this folk and traditional art is alive. The basic concept of the 'Patachitra' was to communicate the message visually. These drawing include the story and facts related to the religion and culture and when these are shown, are supported by lucid dialogue. Especially in last 50 years scenario of the society has changed very fast and India has also changed to adapt the global technological transformations. Telephone, Television, Cameras, Mobile and web has become strong media for fast convincing communication for all. Patuas display the painted scrolls in the houses and explains the stories related to the paintings. They are invited also in some occasions by rich and wealthy people to entertain their guests and invites. They make colours to make these paintings by their own sources and technology, e.g. yellow is made from turmeric or soil; green is from leaves of hyacinth bean plant or the leaves of wood apple. After completion of the drawing songs are created. Earlier only song was sang with the display but later on very simple musical instruments were introduced, e.g. dugdugi, flute, harmonium etc. The basic concept of the 'Patachitra' include various socio-cultural and religions incidents of social significance across the nature. Economic development of Patuas is not viable because still more to be done. Most of them do not have house and they were earlier earning Rs. 600.00(six hundred) per month only and now they earn Rs. 7000.00(Seven thousand) per month. Their children's are not getting higher education but after school education they also involve themselves in this parental business. They move other places of India there do the decoration by their art as per requirements. Modern facilities still lack such as Gas, AC, Refrigerator, Gyzer etc. No pakka road is available in Patua para. Health insurance has been lodged for the artists and their families. The art of Bengal 'Patachitra' is a typical representation of oral tradition which had been kept alive by our old generations which narrates the minute weaving of various cultures that were present in the region. Demand of the 'Patachitra' has increased in the world market. It is a manifest that the art has lost its original ethos but it shows a passive trend to the market. The rising demand in the market has attracted the newer generation to return back to the business. Now several NGO's have come forward to support this business and popularization, e.g. Daricha, banglanatak dot com etc. A good number of ancient art that existed in the world are dying due to overlap of modern technology. This art 'Patachitra' must be saved and also to be popularized so that the business must grow globally. In 2004 52 families were present now this has increased to 85 family in which 20 person living as son-in-law (Migrant person) having mixed religion. When there will be more inflow of money more family members will be attracted towards this traditional art which is the proud of India. They made picture, various decorative items such as hand-held fans, pen stands, dining table, napkin holders, dress materials etc. There is a huge scope in this business which may need slight modification as per the demand of the market. The Eastern Zonal Cultural Centre along with other bodies supported capacity building and promotional activities. All modern marketing technology including web is required to give suitable flourishing world market to these products which will not only protect the heritage patua and patachitra but also these artist will get proper recognition along with economic upliftment.

Key words: Patua, Patachitra, Naya Village.

INTRODUCTION

India has a long history of tradition of art. Although different parts of India has various trends that flourish in historical periods but south India has magnificent examples to represent this tradition (Sivaramamurti, 1994). In India it is commonly seen that painter or sculpture usually dedicated himself to his art in such a way that what he creates in the form of a painting, is almost an offering to the Divine Spirit and subordinated himself and this is the main reason most of the artists are not known or had been obscured with the time. The painter had always a delight in fashioning the pictures with his own hand and tried to complete the same as good as possible. Various steps exist in the preparation of a painting which include (rekhapradana or chitrasutradana), covering the board, and filling of the colours and achievement of modeling and so on. In the final process of making the picture, line is the Chitranmilana, and infusion of life in the picture is done. Art has a softening influence on the mind and senses of men. It is felt in China that art represents what eye's sees in the Indian art. It is not only the total view but it also gives the feelings of touch because always there is a perfectness which gives the feelings in the figure. Paintings in India make an attempt at modeling. Although several creations had been lost due to one or the other reasons but the earliest reference to a painter in an inscription in India is in the 2nd century B.C., in the Ramgarh (Jogimara) cave, in early characters, mentioning a rupadakha and his sweet heart, an adept in dance. Permeated life had given rise seedling of art, dance and music in the every young man and women of India. In later days these items becomes essential factors in literary and aesthetic education. Art was a vinodasthana, and painting, being an easier medium than modeling and sculpture, was probably more readily practiced. Indian culture and art is the reflection of the Indian way of life.

West Bengal is a confluence of a rich past, diverse Geography, architectural grandeur and culture. The cultural repertoire of W.B. is large because good numbers of festivals are celebrated in their own way. It is not limited to Durga Puja or Chhau dance of Purulia only. It is a matter of pride in hosting the world's renowned Kolkata Book Fair as well as the spring festival of Santiniketan; craft display of the Bankura, terracotta of the wooden mask of Dakshin Dianjpur.

Mystic sounds have been grooved for Boulds and Fakirs as well as the subtle points of Rabindra Nath Tagore's songs which not only explain the nature's beauty but also it touches the heart. West Bengal exhibits a unique amalgamation of number of diverse cultures and natural beauty of myriad play of colours. It is unique to note that about 1.35 billion travelers worldwide and in which 35% are interested in visiting the places of cultural significance. One should not miss the opportunity to showcase the cultural heritage of west Bengal. Patachitra and Pater Gaan (songs for Patachitra) are unique cultural traditions of Bengal. There are around 400 Patua living in Naya village in Pingla, W.B.

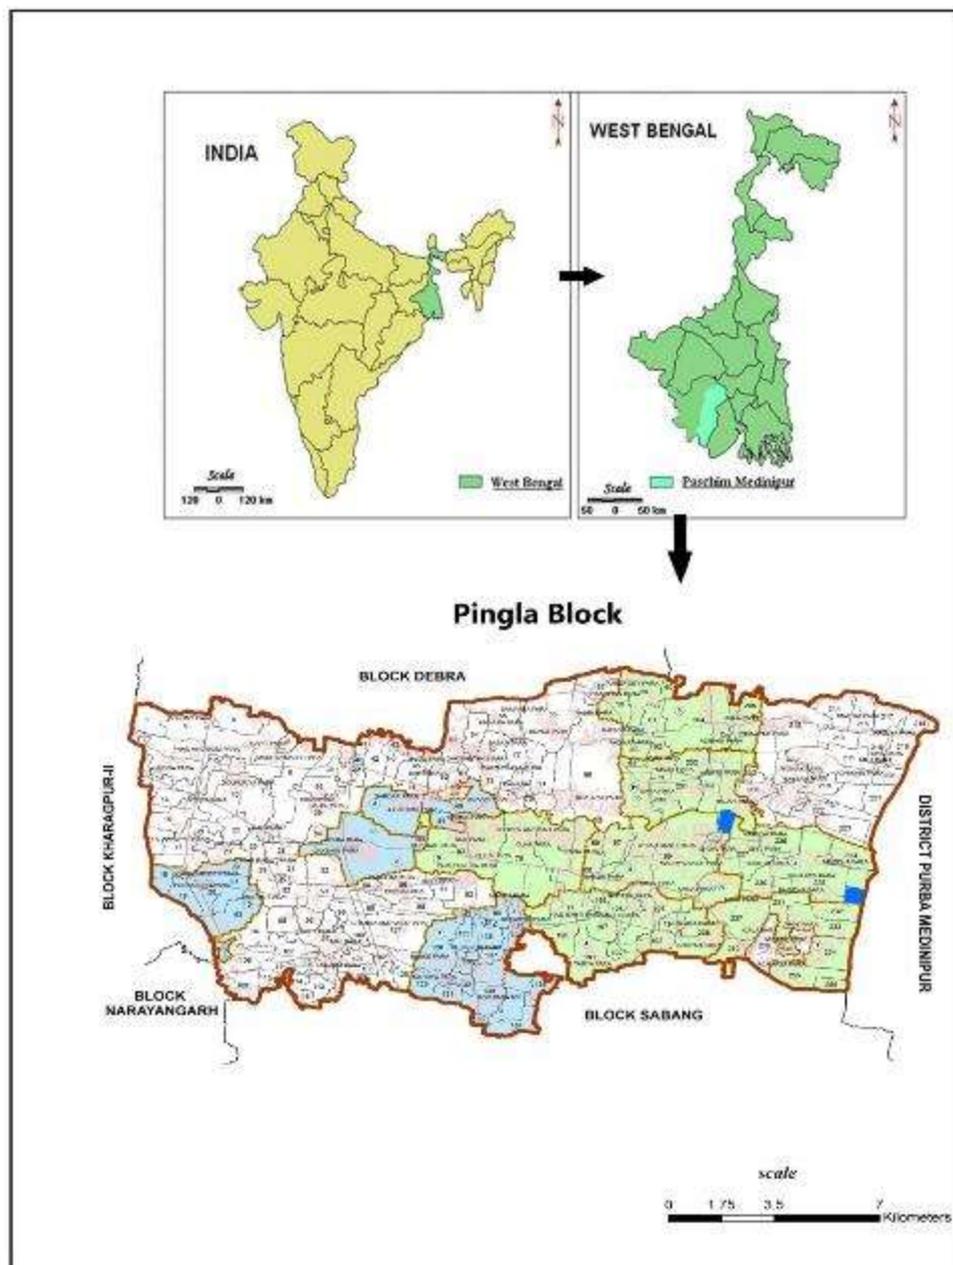

Fig. 1 LOCATION MAP

LOCATION AND APPROACH TO THE AREA

West Bengal is located in the eastern side of India which is extended in N-S direction. The widest part is Bay of Bengal side. Paschim Medinipur is situated on the south-west part. In Paschim Medinipur Pingla block is bounded in North by Debra, in west by Kharagpur -1 and in the west by Sabang block. Pingla Block is more extended in E-W direction. Chondi River flows N-S direction and almost forming the border of this block. Khirai canal (Khal) is also present in the area. Pingla (Paschim Medinipur district) can be reached from Kolkata by car about 3 hours drive only. The nearest railway station is Balichak (after panaskura) can be reached by local train. From Balichak about 30 minutes drive to reach the Naya Village, Pingla. The Pingla area is also well connected by road with neighboring places. For stay furnished rooms

with basic amenities are available in community resource centre. There are staying facilities also available at guest house in Pingla, hotels in Balichak or at artist's houses at Pingla. This is a small newly growing village with small cemented houses with a flavour of hut. Complete village look like a museum because one can see all around paintings. Although they are not financially very sound but their hospitality and behavior is very good.

PREVIOUS WORKS

Limited published literature with sufficient information related to heritage and culture of Bengal is available. There is complete paucity of published literature about the Naya village as well as about the migration of Patuas. "banglanatak dot com" stated in 2000 with a aim to develop the culture of Bengal and it's office at 58/114, Prince Anwar Shah Road, Kolkata-45. This organization accreted in 2010 with the advice of UNESCO ICH committee. UNESCO signed a partnership to promote "Art For Life" AFL across India in April 2013 and in July 2013 banglanatak dot com got special consultative status to UNESCOSOC. This organization started working for the development of 10 Rural Craft Hubs in West Bengal, supported by UNESCO and Department of Micro, Small & Medium Enterprises & Textiles (MSME&T), Government of West Bengal.

In Puranas, Epics, Ancient literatures and historical descriptions of "Patachitra" is present. The style of painting is similar to the cave paintings of Mahenjodaro, Harappa and Ajanta. The works of "Patuas" and Chitrakars has been dated back to more than 2,500 years. Some researchers believe that "Patashilpa" has come from the art of the tribal community "Santhals" (Dutta Gupta, 2011).

METHODS AND MATERIALS USED FOR THE PREPARATION OF "PATACHITRA"

It is generally felt that the mental and physical state (feelings) of painters are always reflected in their paintings. They use all natural colours. For the preparation of colours they use various vegetables. Patuas do not use synthetic colours. Generally they do not use synthetic colours. Generally they do not purchase the colours from the market but few required ingredients are purchased. Traditionally they prepare the colours eco-friendly from the leaves, fruits, flowers, plants, trees and other natural elements. For example muroom and non-boiled rice is used for the preparation of white colour. Earlier with the help of betel leaf, lime and catechu red colour were prepared but later on as per the research carried out at IIT Kharagpur, seeds of the fruit "Latkan" is used for red colour. To give natural glow to the colours bale gum is added. Saffron is extracted from Latkan leaves. Blue is from Aparajita flowers, brown from Segun tree, yellow from turmeric, black form charcoal, green form seem or babul tree, white from Ghusum mati, etc. Bright colours are used for making the "Pata" for giving the aesthetic sense meaningfully.

The paintings are made on Pata or canvas, so these are called "Patachitra". The phalaka or board is covered with the cloth/dress materials on which it is to be made. Bhatti or wall and murals were the most popular surface for painting. After completion of the colouring it takes 1 to 2 hours only for drying and then the painting is rolled and preserved in silken covers.

Patuas were mainly men even 3 to 4 decades back. They prepare these patachitra and move place to place, door to door to collect the food, clothes and other materials for their survival. Early days the women were assisting the men but last decade it is noticed that the women had come forward and prepare good number of patachitras, e.g. Patua artist Moyna Chitrakar, Rani Chitrakar, Karuna Chitrakar, Madhu Chitrakar and so on. In early days the theme of pata were centralized mainly around the religious (Ramayana, Mahabharat, Historical Stories, etc.) stories and these were circulated orally and also some comments written on the pata. They explain these "pata" either by dialogue or songs, e.g. Conflict between "Manasa and "Chand Saudagar" marriage of fish (for entertainment). With the changing time and development so many recent and significant events which occurred have influenced the pata painting. These patuas were actually educating the people indirectly. The work on the Patuas" done by Frank J. Korom is remarkable. The Patuas (West Bengal) prepare printed narrative scrolls (Patachitra) on cloth and it is shown with songs related to that by unrolling it. Now numbers of current events are also included in the theme of "Patachitra".

EVOLUTION OF THE PATACHITRA FAMILY IN NAYA VILALAGE PINGLA

As per the literature available the first Late Abdul Chitrakar and his Mrs. Late Subhodi Chitrakar came in this profession. They had 3 sons and 2 daughters, names are Subham, Mantu, Jhuntu, Arjun and Jyotsna. Family started expanding and they got married, and their names are Arati (W), Jilgun (W), Sumitra (W), Khudi (Son in law) & Akbar (son in law). In later periods it is seen that they were marrying in their own known persons generally living in this village. So "Chitrakar" surname in their significant for their recognition and also used for quick identification. Family is growing gradually and smoothly.

They live in a very simple way. Except few people most of them are financially weak. Their children are also learning all aspects of this art of painting. They run classes for this. Parents are not much interested towards the learning so they do not encourage their kids to go to school, although the school is not very far from the place where they live. Even up to few years back Rabin Chitrakar was the only graduate in this village. Government has made a museum and guest house so that visitors can see their works and also if they need can stay. These people are very homely and have an affectionate behaviour. Although they do not know English but they speak Hindi & Bengali fluently. In 2011 there were 53 families but in the present time more than 90 families are living here.

LABOUR MARKET AND MIGRATION

Almost all the members of the family do the work or help in the work except small kids. They take classes also for the people to trend them in this profession. First names of the ladies in general indicates one caste where the first names of the male indicates the other casts. Records shows that the people of one caste got marry to the girl of the area and settled here and involved themselves in this art. In this way gradually with the increase of the population the business has also got expanded. Every year they celebrate their village festival “Pat Maya” generally in the month of November. This Naya Village is surrounded by agricultural lands mainly producing rice, three times in a year. In this place people do manually as well as use modern machinery in the agriculture. The people of this area “Chitrakar” do not do the agricultural works. May be they do not have the agricultural lands. They grow the plants mainly for the preparation of natural colours for their paintings. To minimize the financial constraints state Government is giving stipend to about 300 persons in this village Rs. 1,000 p.m. All the persons having age above 18 years are eligible to get this stipend.

LIFE STYLE AND SOCIAL PROBLEMS

In the West Bengal a good number of places exists, has preserved the ancient Indian Arts. Some places can be named e.g. Bamnia, Chelyama, Nimdih & Charida (Purulia district), Gorbhanga (Nadia district), Kushmandi (Dakshin Darjpur district), Natungram & Tepantar (Bardhaman district), Panchmura (Bankura district), Ghughumari (Coach Behar district), Nanoo (Birbhum district) and Naya, Pingla block(Paschim Medinipur district).The people of Naya area live in a very simple way but their coordination in between themselves is remarkable. Although some of the “Patachitra” has been sold as costly as Rs.80,000 and this was made by Mr. Anwar Chitrakar. He got President’s award in 2006.His painting not only purchased by Delhi Metro Rail Corporation (Rs. 80,000) also got space in the Harley Gallery, United Kingdom. Smaller paintings (8” x 12” size) costs about Rs. 800 to 1,000 in general. Prices increases with the size of the paintings (Datta Gupta, 2011). Because two casts had mixed in an inseparable way so probably due to non-responds of the society they are marrying in between themselves. Male who has come from outside in this area after marrying they started living here only.

CONCLUSION

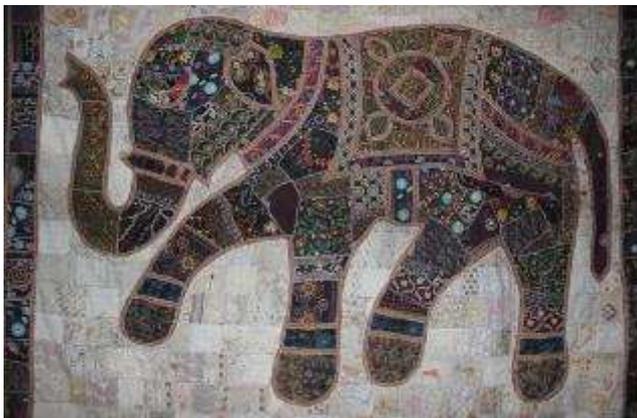

India exhibits a confluence of a good number of traditions & cultures and its impact can be seen in their festivals and also in paintings. The ancient culture and tradition are struggling for their survivals. Government and semi-government organizations have come forward to save this dyeing ancient art. The “Patachitra” is an ancient art of Bengal and this is more than 2,500 years old. The “Patachitra” might not be originated at the place where now it is blooming but not only their numbers has increased but they got the national and international recognition. Because of one or other reason original caste has mingled and now all write their surname as “Chitrakar”. They organize annual mela in November training to their children and other interested persons. These also have migrated from outside have settled here and involved themselves in this art whole heartedly. Advertisement and popularity of the art in the International market will definitely generate more export and this will finally enhance the export amount. This increase will not only help to take a forward step for the development of the Naya village along with the art but this will also provide food and shelter to the other people.

Mamani Chitrakar showing the photos of her visit to foreign countries.

Discussing with Bahadur Chitrakar, Naya village, Pingla, W.B.

1217 MIGRATION SIGNIFICANCE IN THE DIFFERENTIAL URBANISATION MODEL

ABSTRACT

The differential urbanization model was introduced in the early 1990s and has since become widely used in different parts of the world to trace evolutionary changes in national urban systems over time. It uses changing main and substream migration trends between large, intermediate-sized and small cities as an instrument to track urban systems development over time. While migration studies have always tended to focus on mainstream migration as the only significant indicator of demographic and urban change, this model has demonstrated that substream migration could be equally significant in predicting change in urban systems. Distinctions between what could be regarded as main and substream migration at different levels of spatial aggregation has highlighted the fundamental problem in all migration analyses: The question of significance. Significance is context dependent and migration can be viewed in a number of different contexts, each leading to very different conclusions. Foreexample, migration can be viewed in gross numbers, proportional to targeted populations, proportional to target population growth rates, proportional to prior migration rates, proportional to total migration volumes, etc. Each alternative produces its own specific interpretation of the results, and different interpretations of the same results can vary diametrically based on the chosen context. This issue is of special importance when examining migration substreams, which is of growing importance internationally as the science proceeds from general to particular questions. Significance is also relative to size. Unfortunately, not every instance of migration can be afforded equal consideration, and large changes to large populations are generally more significant than small changes to minor populations. But this forces the difficult question of at what point does size start to matter, and when does it cease to. This paper examines this issue in light of general migration theory, and proposes that while different approaches will each have their own occasions of relevance, in general all theories agree that the most crucial issue is the question of how migration affects sedentary populations ability to compensate for the greater or smaller than anticipated growth rates resulting from migration. Migration significance, both for the migrants themselves, and the sending and receiving populations, is in general then relative to the amount of population stress placed on a population by population influx or departure. This presentation applies this hypothesis to the analysis of substream counterurbanisation in South Africa between 2001 and 2011.

1265 POPULATION GROWTH IN INDIA: DOES PROXIMITY TO URBAN HIERARCHY MATTERS***Durba Chakrabarty***

Oklahoma State University, Department of Economics and Legal Studies in Business, Stillwater, OK, 74078-4011

N.L. Dalmia Institute of Management Studies and Research, Mumbai, India, 401104

Corresponding author; email: durba.chakrabarty@okstate.edu**ABSTRACT**

This paper examines how proximity to higher-tiered centers in the urban hierarchy affects the population growth in Indian towns from 2001 to 2011 and the role of amenities in spatial distribution of population across India. There are similar trends of urban centric growth like Canada, China. The massive population growth in India is not driven by amenities. I find a negative and statistically significant effect of the nearest city distance variable on the growth rates of towns. In terms of distance penalty for towns, it is approximately 6.1% less population growth given the mean distance to its nearest city averaged at 53.57 km. Thus, my findings lend support to the hypothesis of urban hierarchical effects as evident in other countries like United States, Canada and China.

JEL classification: R11, R12, R23**Keywords:** Population Growth, Urban Hierarchy, India**1 INTRODUCTION**

There is a need to study the increasing role of distance in the urban hierarchy for India. The Urban India is rapidly growing and expanding in terms of boundaries with the level of urbanization increasing from 27.81% in the 2001 Census to 31.16% in the 2011 Census. Studies find that the trajectory of the urban hierarchy in India is stable, as most of the growth in urban India has mainly occurred in large metropolitan areas compared to small and medium size cities (Schaffar & Dimou, 2012). There exists a large regional literature in the US on proximity to urban agglomerations (Partridge et al., 2008a; Partridge et al., 2008b; Partridge et al., 2009; Partridge et al., 2010). In addition, there are studies done in Canada (Partridge et al., 2007) and China (Chen & Partridge; 2013). Until now, no such study has been carried out in India. Thus, this paper aims to study the proximity of higher-tiered urban centers in explaining the population growth across towns from 2001 to 2011 and the role of amenities in spatial distribution of population across India.

The spatial studies in India have focused on agglomerations economies for formal and informal sectors (Lall et al., 2004; Ghani et al., 2012; Ghani et al., 2014; Mukim, 2015). Even various studies have been carried out in determining the growth rates based on initial population sizes and also on the relationship between ranks and size of cities (Soo, 2014; Luckstead & Devadoss, 2014 a; Luckstead & Devadoss, 2014 b; Chauvin et al., 2017). The growth in India among different states have been tested based on economic indicators like per-capita income and well-being (Chikte, 2011; Mallick, 2014; Arora & Ratnasiri; 2015). Recent study in India looks at the distance effect on urban transformation in the national capital region of India (Jain, 2017).

Another important aspect is the role of geography and amenities (weather, man-made amenities) in shaping up the spatial distribution of population. The importance of geography holds true for the US, as there is amenity-driven migration. Though most of the growth in the US and China took place along the coastal areas, no such conclusion can be made for China (Chen & Partridge, 2013). There exists a mixed literature on the contribution of weather to the growth of European cities. While Cheshire & Magrini (2006) find amenities matter only on a national scale for the European countries, Rodriguez-Pose & Ketterer (2012) observe amenities play an important role in explaining population patterns across Europe. In the case of Canada, the growth is urban centric and weather hardly plays any role as there is little variation in climate across Canada (Partridge et al., 2007).

The population growth in India has been urban centric like Canada and China. The development trajectory for most of the countries in the world including the US and even China has been a shift from agriculture to industries and then to the services sector. However, India's growth path has been unique because of its transition from the agriculture to the service sector. In addition, the growth driven by the services and to a lesser extent by the manufacturing has taken place in high-density clusters unlike the US and China where the medium density locations are the major drivers of growth (Desmet et al., 2015).

I employ a cross-sectional population growth equation to estimate the percentage change in population growth rate of Indian towns from 2001 to 2011. A key feature of this reduced form empirical model are all the initial period values of the explanatory variables are considered and additionally, the distance to different man-made amenities (railway station, hospital, college and school) have been reported rather than the actual number of amenities, which lessens the problems of endogeneity. There is also advantage in terms of the Indian census data being used. The disaggregated level of data on towns helps to capture a large degree of heterogeneity. Further, the distance variables are measured in terms of road distance in kilometers rather than straight-line distance. This reduces to some extent the measurement error created by using straight-line distances.

One can easily conclude that the massive population growth in Indian towns is not driven by natural amenities. The weather has an insignificant role to play in explaining the growth patterns of towns, as these low-income developing countries do not have the means to pay for nice weather. They care about other necessities in life. Even for man-made

amenities, the distance to some of these infrastructure like railways, hospitals, colleges and schools have a negative but not statistically significant effect on population growth. Thus, no clear definite conclusion can be inferred that the growth is driven by amenities.

The geographical position of an area with respect to its urban hierarchy has an influence on population. The farther a town is away from the higher tiered urban centers, the lower is the growth rate of population. I find a negative and statistically significant effect of the nearest city²⁵⁹ distance variable on the growth rates of towns. Every kilometer farther away from the city is associated with approximately 0.113% less population growth in towns for 2001-2011. In terms of distance penalty for towns, it is approximately 6.1% less population growth given the mean distance to its nearest city averaged at 53.57 km (Table 1). There is a cost for remoteness in terms of lower population growth. Each of the higher ordered urban tier offers access to additional amenities and services, and thus there is an incremental distance penalty. There is the growth penalty of approximately 0.05% per incremental kilometer to reach a large city²⁶⁰, which are higher ordered city. As expected, the quadratic terms associated with the distance variables have a declining marginal effect. Thus, the penalty varies across different tiers in urban hierarchy.

Irrespective of the size of the urban center, the agglomeration effects will be greatest in the highest tiered center. The results are robust using different specifications which proves the initial hypothesis that one must incur costs for remoteness in terms of lower population growth. The agglomeration effects have much wider reach in terms of geography. The findings indicate that the proximity to cities and higher tiered cities are important in explaining the urban hierarchical effects for towns in India. Thus, the results lend support to the hypothesis of urban hierarchical effects as evident in other countries like the US, Canada and China (Partridge et al., 2007; Partridge et al., 2008a; Partridge et al., 2008b; Chen & Partridge, 2013).

The remainder of the paper is organized as follows. Section 2 discusses the geography and the population patterns of India followed by the conceptual framework and the related literature in section 3. Section 4 discusses the data and the definitions used. Section 5 specifies the empirical approach used and section 6 presents the main empirical findings. Finally, section 7 describes different robustness checks followed by conclusion in section 8.

2 GEOGRAPHY AND POPULATION PATTERNS OF INDIA

India lies in the northern hemisphere, has a long coastline, extending to about 7,500 km. The entire nation is divided into twenty-eight states and seven union territories²⁶¹ based on the recent Census of 2011. There are mainly six broad regions in India, the North, the South, the East, the West, the Central and the Northeast. At the next level, are the districts²⁶², which are the second level of administrative division of the country after states and union territories. The lowest administrative unit is town in urban areas.

There is a wide variation of topography in India, as it comprises mountains, plateaus, plains, deserts and coasts. However, there is no such tendency to concentrate along coasts such as the US and China despite having a long coastline. Most of the concentrations in India are along the major rivers of Ganges and Godavari, and hence more inward-oriented. These places were home to ancient civilizations, because of fertile soils and easy availability of water for agriculture. Initially, the migration took place from the lagging states of Bihar, Orissa, Rajasthan, and Uttar Pradesh to agriculturally prosperous northwest states of Gujarat, Maharashtra and Punjab. There have been shifts in migration from these backward states to cities in search of jobs following the Second Five-Year Plan (1956-1961), whose focus was on rapid industrial development of the country. Even after economic reforms in 1990, there have been incentives for rural people to migrate to urban areas for work. Most of the migration is inter-district rather than inter-state. The highest level of migration is observed within the same district. (World Bank, 2009).

The current growth in India is geographically scattered but concentrated along few urban areas. Desmet et al. (2015) finds the large mega cities of India that are driving the spatial development unlike the US and China where medium density locations are the major drivers. The spatial concentration of industries depends on the age of the industry. The services industries (considered as young) are located in medium-sized locations like California's Silicon Valley, Boston's Route 128, and the North Carolina Research Triangle and others in US. However, in India, it is the "young" services industry (driven by strong agglomeration forces) and to a lesser extent the "less mature" manufacturing industry that are located in high-density locations. There is no clear explanation for the obstacles faced by these medium-density locations in their growth but find evidence of low levels of highly educated persons and the inadequate local infrastructure, in terms of poor access to telecommunication services.

In addition, given the geographical size, most of the densely populated cities in the interior are not as far away from coasts as in the cases of China and the US and thus have an added advantage. Other reasons for less concentration along the coasts can be attributed to the growth in the services sector. For its operation, one needs to have good access to the internet and telephones, rather than being close to a coast for exporting manufactured goods as in China (Sachs et al., 2002; World Bank, 2009; Soo, 2014; World Bank, 2013b).

259 Towns with a population of 100,000 and more.

260 A large city is a town with a population of 500,000 and above.

261 The difference between the states and union territories is that states have their own elected governments but union territories are ruled directly by the Central Government.

262 These districts are equivalent to counties in the US and China.

The spatial aspect is an important feature especially for developing countries like India where economic geography is still shaping up. In explaining the growth in regions, both Gibrat's and Zipf's law have been tested for different sets of countries. While Gibrat's law states that growth rates of cities should be independent of initial population sizes, on the other hand, the sizes of cities are inversely proportional to ranks according to Zipf's law. Chauvin et al. (2017) observes that both these laws hold for the US and Brazil but the situation is different in case of India and China. However, Gibrat's law holds for the large cities in India. Zipf's Law does not hold for India, but holds for China and Brazil (Luckstead & Devadoss, 2014b). Initially, China had restrictive mobility of people from rural to urban areas imposed by hukou system. In recent decades, there has been relaxation of hukou requirements for China and thus the distribution of population in large cities are close to Zipf's Law. Although there exists no such restrictions in India but there are mobility restrictions in terms of variations in ethnic groups, languages, culture and traditions all across India (Luckstead & Devadoss, 2014a; Soo 2014).

3 LITERATURE REVIEW AND CONCEPTUAL FRAMEWORK

3.1 Role of Amenities

The geography determines largely the spatial distribution of population. The US is such an example as the people are highly mobile compared to other parts of the world. Despite having abundant interior land, it is mostly a coastal nation as most of the population is in counties within eighty kilometers of an ocean or Great Lake (Rappaport & Sachs, 2003). The historical conditions drove the initial concentration of human settlements in coastal places. In recent times, coastal proximity has present day contributions to both productivity and quality of life.

Nice weather is valued as a consumption amenity contributing to quality of life due to rising income levels. According to the Rosen-Roback compensating differential methodology, weather is valued as the sum of the wages that a person is willing to forgo and the increased housing prices that she/he is willing to pay to enjoy it. A significant part of the migration in the twentieth century took place due to nice weather (Rappaport, 2007). Further, in some metropolitan areas with increasing numbers of high-income households combined with inelastic supply of land, rapid housing price appreciation occurred (Gyourko et al., 2013). Here, factors like inherent local productivity, amenities, or fiscal policies alone did not lead to the high value of house prices in these superstar cities as described by the standard compensating differential models in urban economics. However, the weather did not contribute to growth of Sunbelt areas since 1950s. The Sunbelt areas are places with warm winters and hot summers and so before the introduction of air conditioning, these places were unpleasant to live. Even after the introduction of air conditioning, it has not grown because of household amenity attractiveness. Glaeser & Tobio (2008) have attributed the stronger population growth to the elastic growth in housing supply. In the US, the growth is amenity-driven leading to migration away from historically-created urban areas that is from Frostbelt to amenity-attractive areas, many in non-humid Sunbelt areas.

There exists a great deal of skepticism of amenity-related migration in Europe. Cheshire & Magrini (2006) find the importance of weather in explaining population growth but only within European Union countries. Besides economic factors, amenities play an important role in migration patterns across Europe according to Rodriguez-Pose & Ketterer (2012). The Canadian population growth was driven by the metropolitan areas from 1981-2001 supporting the hypothesis of cities being engines of growth. The role of amenities in explaining population growth in Canada is not important due to less climactic variation (Partridge et al., 2007). China too has urban centric growth patterns like Canada. In addition, the scale is much larger in China. Most of the growth in China is driven by megacities on coast (Chen & Partridge, 2013), but it is not clear whether the growth is amenity driven or not.

3.2 Urban Hierarchy and Distance

Urban places differ in size and in terms of characteristics. There are different tiers in the urban hierarchy that vary in terms of economic activity and range of services provided. For example, the higher tiered centers offer a higher end of goods and services, such as legal, accounting, and management services, operas, nice restaurants and higher order entertainment services compared to the lower tiered centers. It follows from Central Place theory (CPT) developed in 1933 by a German geographer, Walter Christaller, who studied the settlement patterns in southern Germany. He showed where and how the central places in the urban hierarchy would be functionally and spatially distributed.

According to the theory, the market town having a central location will provide goods and services to neighboring areas. Thus, a hierarchy forms based on provision of goods and services. The high-ordered central places are settlements, which provide a higher range of goods and services than other places. The number of such higher-order places are fewer and more widely distributed than lower-order places. Further, the settlements having the same hierarchical level will have the same types of business and all higher-order central places must contain all the business types already contained in lower-order places. However, Lösch modified CPT in 1954 to capture the real world. The settlements of the similar size may not have the same arrangement of business types, and the higher-order central places do not need to possess all the functions available in lower-order places (King, 1985).

The trajectory of the urban hierarchy in India is quite different from that of other countries, including China. Schaffar & Dimou (2012) finds that India urban hierarchies are more stable than Chinese urban hierarchies. Most of the growth in urban India have taken place in large metropolitan areas compared to small and medium size cities. In China, with the relaxation of hukou restrictions, there has been increase in the number of medium and small size cities. Also, there has been control over mega cities due to anti-megacities policies followed by China (Desmet et al., 2015).

With the innovations of technology, it is expected that the role of distance has diminished over time. Though there has been debate regarding the role of distance in regional economic growth and development, one cannot deny the importance of distance in accessing different tiers in urban hierarchy. Several regional studies look at the proximity to urban agglomeration as measured by distance to higher tiered areas. The proximity effects in terms of employment growth on the US counties holds for rural and nonmetropolitan samples in addition to the metropolitan sample between 1970 and 2000, particularly for the 1990s (Partridge et al., 2008a). Fallah et al. (2013) even finds the role of distance affecting specific sector employment like high-technology sector. As the distance to large cities in urban hierarchy increases, there is negative impact on high technology sector employment. Partridge et al. (2009) studies capitalized penalties for remoteness into factor prices. They observe significant distance penalties on median earnings and housing costs both for rural and urban counties across the US urban hierarchy. Further, Partridge et al. (2010) assess the relative importance of proximity to urban consumer amenities and production spillovers in explaining the changing factor price penalties for remoteness.

Chen & Partridge (2013) uses both the CPT and NEG framework to study spread and backwash effects of cities on GDP and employment growth in counties of China. The NEG models explains regional development in terms of market potential differences and hence is suitable to Chinese economy due to its large markets on the coast. However, the heterogeneous effects across the Chinese urban hierarchy supports the CPT framework. Thus to explain the differential urban hierarchical effects in India, it will be suitable to employ the CPT to study the population growth in Indian towns.

3.3 Penalty Distance to Urban Hierarchy

The urban hierarchy in India will be different from the developed countries of the world. Instead of offering higher end services and amenities, the urban places will differ in terms of basic amenities such as hospital, schools, college and infrastructure like transportation facilities. I am looking at three tiers of urban hierarchy in India. For the urban sample, at the lowest tier are the towns. The next higher level of hierarchy are the cities, one whose population is 100,000 and more. At the top level, are the large cities, those with population 500,000 and above. As stated earlier, there exists considerable differences across these tiers in terms of quality of amenities and services being provided. Both the households and firms from a lower tiered town have to travel to the nearest urban center, which is a city to access amenities, services, jobs etc. There is an incremental distance penalty for travelling to a large city as each high tier city offers additional or high quality amenities.

I measure the distance penalty in the same manner as Partridge et al. (2009). It is referred as a penalty as one is incurring a cost in terms of less population growth due to increasing distance. Here penalty is defined as the sum of added penalties on population growth for a given town i in the j th tier of the urban hierarchy.

$$Penalty_{ij} = \sum_t d^t \varphi^t$$

Suppose an area is at the lowest tier in urban hierarchy, a town, then people have to travel distance d_1 to access the nearest urban center (city) and d_2 for travelling furthest to a higher ordered city (large city with a population of 500,000 and more), and thus an incremental distance of $(d_2 - d_1)$. At the same time, being farther away from a city and a higher tiered city will incur a penalty captured by φ . For example, Murud is a town (population of 12,552²⁶³) in the state of Maharashtra. The nearest city is Panvel (population of 104,058), which is at a distance of 102 kilometers (d_1) from Murud. The topmost large city is Mumbai (population of 11,978,450) and the incremental distance from Panvel to Mumbai is 16 kilometers ($d_2 - d_1$). Thus, Mumbai is 118 kilometers away from the town of Murud. The location of tier in urban hierarchy will give different values of φ i.e., marginal penalties. Thus, the distance impacts are not the same and will have nonlinear distance effects in the urban hierarchy.

4 DATA

The data come from the District Census Hand Book (DCHB), which forms part of the Indian Census data. The Office of the Registrar General and Census Commissioner of India under the Ministry of Home Affairs, Government of India conducts the decennial Census. The first population Census started in 1872 when India was under the British rule. The first Census of independent India began in 1951. The latest one is the 2011 census. The Census of India is the largest statistical database in providing information on demographic and other socio-economic variables of India.

The DCHB contains both the Census data and the non-Census data on various civic amenities and infrastructural facilities. I am using part-A of DCHB as it has data at the town level of the district, which constitute the town directory. The town directory consists of different natural amenities and infrastructural facilities. The natural amenities include information on rainfall in millimeters, maximum and minimum temperature in centigrade. These physical aspects have been recorded by taking the average for the last ten years, i.e., from the years 1990 to 1999 for the 2001 census. The infrastructural facilities include education, medical, drinking water, communication and transport, post and telegraph, electricity, recreational, banking, and other miscellaneous facilities. The incremental distance to a large city is computed as the distance from the city (population of 100,000 and more) to the nearest large city (population of 500,000 and above). The following information has been collected from Maps of India²⁶⁴. Each of this city corresponds to the nearest city

²⁶³ All the population figures are from 2001 Census data of India.

²⁶⁴ <https://www.mapsofindia.com/aboutus.html>

associated with each of towns in the sample. I pick up the year 2001 and 2011 as the town directory for these years contain detailed information on distance variables, that is the distance to the nearest city and also the amenity distance variables.

One of the biggest advantages is the disaggregated data at town level. Most of the earlier literature considered states or districts as units of analysis as the data are of better quality and reliable at the state and district level. However, for detailed spatial analysis, it is better to have disaggregated level of data, which will capture a greater degree of spatial dimension. Further, the districts are wider geographic areas that include the rural population. Since our focus of analysis is on urban areas, it is better to have separate and demarcated data on towns. Further, it captures a larger degree of heterogeneity in terms of demographic and economic nature of variables.

A town is defined by the Census of India as areas where population is 5,000 and above; the density of population is 400 per square kilometer (i.e. 1000 per sq. mile); and at least 75 per cent of the male main working population engaged in non-agricultural pursuits. There exist different categories of towns based on population size. These are as follows: (i) Class I towns are those with population of 100,000 and above (ii) Class II towns have population between 50,000 to 99,999;

(iii) Class III towns are those with population of 20,000 to 49,999 (iv) Class IV towns have population between 10,000 to 19,999; and finally (v) Class V towns have population between 5,000 to 9,999. Class I towns are also known as cities. These cities and towns form the sample of urban areas. Another type of town are the district headquarters. These are home to administrative offices and serves as the seat of the state government. There are more than one headquarter town for each of the states.

I matched 2001 with 2011 Census data by town names resulting in 5,177 towns as some of the new towns are not part of 2001 Census data. Thus, the omitted observations is due to matching the data of 2001 with 2011²⁶⁵. One needs to keep in mind while considering the figures for urban population is the statistics suffers from downward bias. As stated by experts in India and internationally, the definition of urban areas misses the population growth occurring in urban areas just outside of the official city boundary, and hence is restrictive. Despite these problems, the Census definition of urban population is at best, just an approximation of reality (Cohen, 2004; McKinsey Report, 2010; World Bank, 2013b).

5 EMPIRICAL SPECIFICATION

This paper examines the proximity to a nearest high-ordered urban center and incremental distances to higher ordered cities affects the population growth models for urban areas. The proximity to a major center (such as city) for urban areas matters, as the cities are centers of jobs, education and household amenities. Additionally, the incremental distance to a higher ordered city means better access to potential markets, services and amenities.

The base specification is a cross-sectional growth equation given below which captures the total population growth for town i , located in state, s , for the time interval from 2001 to 2011. The dependent variable is the percentage change in population between periods 0, the initial period, and t , the end period.

$$\% \Delta \text{POP}_{is(t-0)} = \alpha + \beta \text{DEMOG}_{iso} + \lambda \text{AMENITY}_{iso} + \gamma \text{GEOG}_{is} + \theta \text{DIST}_{is} + \delta_s + \varepsilon_{is(t-0)} \quad (1)$$

DEMOG includes the initial period population density to account for the initial agglomeration including market potential and localization effects. **AMENITY** takes into account the natural amenities, like the rainfall, the maximum and the minimum temperature variables. One concern regarding the measurement of these variables is these have been recorded as averages for the last ten years. Hence, it might not be a good representation like the mean July and mean January temperatures which account for the summers and winters in the US. One of the reasons for recording in such a manner could be that India's variety of climate ranging from the tropical monsoon in south to the temperate in north and thus making overall generalization difficult.

DIST includes the man-made amenity distance variables. These are distance to the nearest rail station, distance to the nearest hospital, distance to a nearest college and distance to nearest school. These infrastructure facilities are important in determining concentrations of people. For example, the location of railways is important, as there are concentrations of people close to those networks (World Bank, 2013a). The initial development of railways was done by the British colonial India, connecting the interior to three main port cities of Kolkata, Mumbai, and Chennai, to transport raw materials from interior to coasts. After Independence, the Indian government expanded their railway networks and connected cities with other cities and suburbs. According to the Guinness Book of World Records, the Indian Railways are biggest in the world in terms of size (World Bank, 2009).

GEOG is a vector of spatial distance variables reflecting proximity to urban areas and its location in urban hierarchy. The first one measures the distance to the nearest city. The second includes the incremental distance to a higher ordered city to account for added benefits such as spillovers and agglomeration effects for being closer to large cities. Further, the quadratic terms of the distance to the nearest city variable and incremental distance to a large city are considered to capture the non-linearity in distance. δ_s are the state dummy variables capturing the fixed effects.

These account for time-invariant state-related growth factors such as migration flows, geographic location, regulatory policies in a state, etc., and ε is the residual. The standard errors are clustered

²⁶⁵ Overall, the omission of data was by 0.3% in urban sample.

by districts to address issues of spatial autocorrelation and heteroscedasticity.

All the distance variables report the road distance in kilometers. Most of the spatial literature considers straight-line distance due to its ease of interpretation and use. However, it ignores roads, rails and other forms of transportation and their travel times. Further, the straight-line distance faces the classic measurement error which would bias the distance regression coefficients towards zero (Lall et al., 2004; Partridge et al., 2008b; Partridge et al., 2014).

6 EMPIRICAL RESULTS

6.1 Summary Statistics

Table 1 reports the descriptive statistics for the urban sample consisting of towns and cities. Column 1 and Column 2 display the means and standard deviations and Column 3 and Column 4 represents the minimum and the maximum values of the variable. The mean population levels of 2011 are higher than 2001 implying there has been growth of towns. However, the mean growth rates of urban areas is approximately 20%, which is much lower compared to earlier growth rates in previous years. The nearest urban center is a city and the second closest higher tier urban center is a large city. Thus, the nearest city distance variable averaged 54 km while the incremental distance to a large city stands at an average of 81 km. Thus, one has to travel more to access a higher ordered city.

For the man-made amenity distance variables, the mean distances to hospitals and schools are approximately 4 km and 2 km respectively. These are much lower compared to other distance amenity variables. It implies that the basic amenities like hospitals and schools are present in almost all towns and people do not have to travel much to access these health and school amenities. However, to avail higher education like colleges and to access railway infrastructure, one has to travel further.

6.2 Regression Analysis for Towns

Table 2 shows the regression results for the 2001-2011 period town sample. One of the concerns for these cross-sectional regressions is the problem of endogeneity, which is taken care by considering the initial period value of the explanatory variables. Besides, the natural amenity variables and density, all the other variables are distance variables. Even for man-made amenities, the distance to different amenities is taken into account rather than the actual number of amenities, which might be endogenous. All these distance variables measure the road distance in kilometers.

Another way to is to add the different category of variables at each stage to identify the causal effects of those added variables. The stepwise regression includes five models. Model 1 includes only the natural amenity variables as shown in column (1). Model 2 adds to the initial model the distance to the nearest city along with its square term²⁶⁶ as represented in column (2). In Model 3, the incremental distance to a large higher ordered city is further added to model 2 in column (3). In column (4), model 4, which is the base model, adds further the demographic variable and the state fixed effects, and finally model 5 includes the amenity distance variables as shown in column (5).

Population density has a negative impact on the growth rates but is statically significant at 10% level implying that denser towns have lower population growth rates. The nearest city distance variable is negative and statistically significant across all models implying that proximity does matter for population growth. Thus, the further a town is located away from the city, the lower is the population growth. An increase in nearest city distance variable by one kilometer *ceteris paribus* reduces the population growth of towns by 0.113 percentage points as shown in the base model. In terms of distance penalty for towns, it is approximately 6.1% less population growth given the mean distance to its nearest city averaged at 53.57 km (Table 1). The distance penalty to reach the nearest city becomes less important at greater distances as evident by the positive coefficient for quadratic terms. The results suggest that positive marginal effects from proximity to nearest city extend out about 333 km for towns.

The next closest higher ordered urban center is a large city. All the coefficients for the incremental distance to a large city are negative and statistically significant again. Thus, one will be penalized even more if the current town is not only far away from a city but also farther away from a large city. There is an added penalty of 0.049% per incremental kilometer to reach a higher ordered large city. Also, the positive coefficient for quadratic terms points that the incremental distance penalty to reach a large city becomes less important at greater distances. Given the mean incremental distance to reach a large city from a city is 80.74 km (Table 1), the incremental distance penalty results in approximately 4% lesser population growth of towns. Adding up, the total distance penalty for a town to be farther away from a higher ordered city is approximately 10% less population growth.

The natural amenity variables do not have much impact on growth of towns. The only significant result holds for model 1 (in column 1) when only the natural amenities are included and it is the negative effect of the average rainfall variable, which is significant at the 10% level. However, there exists mixed results for these variables on population growth as these are measured as averages for the last ten years, which does not give a clear picture about natural amenity and topographic variables as in the related US literature. All of the man-made amenity distance variables have a negative impact on the population growth of towns. The only significant result holds for the nearest school distance at 10% level.

²⁶⁶ I also checked the model fit comparing models with logarithmic distances and the one with cubic and quartic distance effects added. Based on AIC/BIC, the smaller values are observed for the logarithmic distance model. However, based on R2 and Adjusted R2, there are slight differences between the two models, though the model with cubic and quartic distances have slightly higher R2 and adjusted R2.

The nearest city distance variable might actually contain these effects, as most of these amenities are present in cities. The nearest distance for these amenities might coincide with distance to nearest city for some of them.

A consistent pattern is observed for both the distance to the nearest city and incremental distance to a large city and its respective quadratic terms across all the five models. It implies strong evidence for urban hierarchical effects. Thus, the proximity to a nearest high-ordered urban center and incremental distances to higher ordered cities affect the population growth of towns in India. Moreover, one can conclude that the given findings are not driven by one particular specification or by one single model as the results holds across all specifications.

Two things need to be noted. One could argue that the model is not able to capture the large variations in town population growth as given by low R2. Despite having low R2, the model can be a good fit given the cross sectional level of data which produces large variation across individual units of observation. Thus, R2 alone cannot fully explain the suitability of the model. Another is the different number of observation being reported for different specifications. Most of it is due to the missing data on the amenity distance variables. However, I ran all the five models with the same set of observations. The resulting significance levels are the same with slight difference in magnitudes but exhibit a similar pattern.

7 SENSITIVITY ANALYSIS

Though our empirical model is in general exogenous due to the predetermined nature of the explanatory variables, several other specifications are estimated to check for robustness. Table 3 re-estimates the town level regression analysis considering the initial population levels of 2001 instead of the initial population density. The resulting coefficients and t-statistics on the distance to nearest city and incremental distance to a large city are approximately the same as for the population density model, indicating that the conclusions would be essentially unchanged regardless of using population density or initial population to measure the urban hierarchy effects.

Table 4 looks at the town level population growth considering the distance to nearest district headquarter. In this urban hierarchy, the nearest urban center is the district headquarters, and the second next urban center is the proximity to a nearest city and at the topmost level urban center is the distance to a large city. All the distance variables (related to agglomeration) are negative and statistically significant lending support to urban hierarchy claims. The distance penalty is much higher when a town is located farther away from a district headquarter than farther away from a city. However, the incremental distance to nearest city from the district headquarters is still negative and statistically significant. Even the incremental distance to a large city exhibits a similar pattern.

Jawaharlal Nehru National Urban Renewal Mission (JNNURM) is a huge mission undertaken by Government of India meant for urban development focusing on the Indian cities. It was launched in 2005 for a seven-year period (up to March 2012) to encourage cities to initiate steps for bringing phased improvements in their civic service levels. The government had extended the tenure of the mission for two years, i.e., from April 2012 to March 31 2014 for lagging projects. Given the period of my sample, this large-scale program might have an effect on the population growth of the town. Table 5 presents the regression results where I exclude from my sample the JNNURM cities and towns. The negative and significant impact of distance to the nearest city and the incremental distance to a higher ordered city on town population growth holds even for this specification. Thus, one can easily conclude that the urban hierarchy effect holds and is not driven by the massive urbanization program.

As already mentioned above, a large part of GDP growth in India is driven by the Information Technology (IT) services sector and is the second largest generation of employment after agriculture. The IT cities are Bangalore, Gurgaon, Noida, Mumbai, Hyderabad, Pune, Ahmedabad, Gandhinagar, Chennai, Trivandrum and Delhi. Therefore, Table 6 reports the regression results for the non-IT sample, which excludes the 26 IT cities mentioned above. Here again, the negative and statistically significant results for the nearest city distance and incremental distance to a large city variables point to the urban hierarchical effect and is not driven by these IT cities.

Finally, Table 7 incorporates deeper lags by taking into consideration the 1991 population level. The urban hierarchical effects holds across most of the specifications. The base model which includes the natural amenity variables, vector of spatial variables, population of 1991 and the state fixed effects points out to urban hierarchical effects as evident by distance to the nearest city and incremental distance to a large city. Thus, all sensitivity analyses supports the claim that the proximity to a nearest and higher ordered urban center matters and the distance impacts on population growth differs by its status in urban hierarchy.

8 SUMMARY AND CONCLUSIONS

Although India is a part of the South East Asian countries, it possesses distinctive traits. It is the second most populated country in the world and is the world's largest democracy. The large population caters to the world market as consumer, producer and investor. It is projected that the population of India is expected to surpass that of China within a decade or two (Mckinsey Report, 2010). It is a point of concern given that such a large population will use resources for food, clothing, housing, medical care etc. However, India will have young and working population unlike other countries like China, which will face a burden of older population.

The uniqueness is seen in the population growth patterns of India. Regional population growth in India is quite different from other countries as it has been in the interior rather than along the coasts. One could argue that the interior places in India have an added advantage compared to interior places in the US and China in that these are not far away from the coasts. Another reason is that the current growth in India is mostly driven by the high-tech services, such as Information

Technology (IT), financial, and telecommunications. This led to the development of high tech cities like Bangalore, Gurgaon, Noida, Mumbai, Hyderabad, Pune and Chennai, which are located in the interior of India, except Mumbai, because exporting these services does not require access to a coast.

However, India has experienced similar trends of urban centric growth like Canada and China. There was only one city Kolkata (then Calcutta) having a population of one million in the beginning of the twentieth century. By 1991, the number of cities had increased and also the share of urban population. There are six megacities (Kolkata, Mumbai, Delhi, Chennai, Bangalore, and Hyderabad) with population of 5 million and above in 2001. The policy reforms in the 1980s and 1990s favored the coastal provinces due to export-driven growth in China leading to a divergence between the coastal and interior regions. However, India had no such preferential policies. The economic reforms in 1991 set up the path for a market-oriented economy in India. Thus, the urban agglomerations in India are market-oriented and policy-driven by schemes like Jawaharlal Nehru National Urban Renewal Mission (Sridhar, 2010).

Based on a set of countries, World Bank (2013a) finds that China, India, Indonesia, and Vietnam are in the intermediate stage of urbanization. Thus, it is expected that cities will matter, as this will generate 70 percent of new jobs given the recent trends of urbanization. People will settle for locations close to cities to enjoy improved access to jobs, markets, and urban infrastructure or amenities (McKinsey Report, 2010; Bloom 2011). The findings also provide such insights to these projections. A strong inverse relationship exists between town population growth and the two important distance variables; the distance to the nearest city and incremental distance to a large city. Further, the positive quadratic term implies these adverse effects weaken at greater distances. In other words, a town is penalized for being located away from nearest urban center that is a city. In addition, an incremental penalty is incurred from being farther away from large cities. Thus, people have to pay a price for remoteness in terms of lower growth rate of population in town. There is insignificant impact of weather on urban growth and no clear definite conclusion can be inferred about the man-made amenities. Hence, one can conclude that the growth is not driven by amenities unlike the US, where growth is amenity-driven leading to migration away from historically created urban areas in the Frostbelt to Sunbelt areas.

Thus, the Indian policymakers need to keep in mind the role of urban centers and its differential effects due to its position in urban hierarchy. The adverse distance impacts on population growth is evident and thus policies need to be framed keeping in mind the importance of distance penalty. Thus, one should encourage public investment to reduce transportation time and costs. The place-based policies like JNNURM has been successful in terms of inputs and processes but not much can be concluded regarding the impacts (World bank, 2013b). One should focus more on the broad based policy bringing improvement in economic indicators and quality of life considerations such as environment, health, and infrastructure. Policies should target the cities given these will be highest generator of jobs in future.

Recently, India's metropolitan cities have been stagnant and have not shown any improvement in economic indicators (World Bank, 2013a). The urbanization pattern of India is following a different path. Although urban India is rapidly growing and expanding in terms of boundaries, it is not significant. The level of urbanization in recent years (2001-2011) was lesser in extent compared to the last twenty years (Sridhar, 2010 ; Sharma, 2013; Tripathi, 2013; Das et al., 2015; Mukim, 2015). Most of the concentrations have been taking place in suburbs rather than metropolitan areas, which is termed as suburbanization. It can be attributable to poor land management practices, insufficient modes of transport etc. (World Bank, 2013b). This could also be driven by restrictive definitions of urban areas whereby there exists grey zones of large villages which have urban traits (Cohen, 2004; Urban India, 2011). The towns should be given more importance as this could reduce the load from the cities that are already dense and congested. Policies such as investment in infrastructure, like schools, colleges, hospitals etc. should be taken for towns. Given the growth differences across the urban hierarchy exist and will continue to attract the attention of researchers and policymakers, future research can be carried out to decompose these growth differentials into productivity and amenity effects through wages and housing prices.

Nearest college distance	63.17	71.41	0	1232
Nearest school distance	1.78	6.56	0	150

Notes: The sample consists of towns and cities. Cities are often referred as Class I towns, population of 100,000 and above. Temperatures are measured in centigrade and rainfall is recorded in millimeters. All the distance variables are measured in terms of road distance in kilometers. Nearest city distance captures the road distance in kilometers from a town to the nearest city (population of 100,000 and more) and is equal to zero if the town itself is a city. Nearest district headquarter distance considers the distance from a town to the nearest district. Incremental distance to a large city measures the additional distance from a district headquarters to a city with population of 100,000 and more. Incremental distance to a large city measures the additional distance from a city with population of 100,000 and more to a higher ordered city with population of 500,000 and more. Amenity distance variables are zero if that amenity is present in that town. There are 5,177 towns according to 2001 Census of India. In 2011 Census, there were additional towns, which were not part of our 2001 Census data set. Thus, due to missing data, definitional problems and matching data of 2001 with 2011 resulted in 5,161 towns. Overall, the omission of data was by 0.3% in town sample.

Notes: The sample consist of towns and cities which are not IT (information technology) driven. Temperatures are measured in centigrade and rainfall is recorded in millimeters. All the distance variables are measured in terms of road distance in kilometers. Nearest city distance captures the road distance in kilometers from a town to the nearest city and is equal to zero if the town itself is a city. Incremental distance to a large city measures the additional distance from a city with population of 100,000 and more to a higher ordered city with population of 500,000 and more. All the distance square terms are expressed as hundreds of square kilometers. Population Density is also reported as hundreds of square kilometers. Amenity distance variables are zero if that amenity is present in that town. Standard Errors are clustered by districts.

*Significant at 10% level; **Significant at 5% level; ***Significant at 1% level.

1523 DOES UNEMPLOYMENT CAUSE MIGRATION: THE EVIDENCE FROM SRI LANKA**T. Vinayagathan**Department of Economics and Statistics, Faculty of Arts, University of Peradeniya, Sri Lanka. email: vinayagamkili@yahoo.com, Phone No: +94779353302**ABSTRACT**

This study attempts to investigate whether the unemployment causes to migration. For this aim, we use the annual data from Sri Lanka over the period of 1990 – 2016. KPSS unit root test confirmed that none of the variables are I(2), which allows us to examine long run relationship between the variables using Autoregressive Distributed Lag (ARDL) bound testing method. AIC is suggested to adapt ARDL (1, 2, 2, 2, 0) model among the top 20 models. The bound testing results detected the cointegrating relationship between the variables. The result of ARDL bounds test and Error Correction version of ARDL model reveal that unemployment and per capita GDP have positive and significant impact on net migration in the long run and the short run while other variables do not have significant impact on net migration in both periods. The results of CUSUM test of both model discloses that the estimated model is stable. The negative and significant coefficient of error correction term reveals that net migration moves backward towards steady state line with the speed of 57% in each period one period after the exogenous shocks. Both ARDL model passes the all the diagnostic test. Moreover, Granger causality test identified a causal relationship that stemming from unemployment to net migration, GDP per capita to net migration and consumer price index to net migration. These findings could be useful to policy makers when they formulating and implementing the monetary policy.

Key words: Migration, Unemployment, Bound Test, Auto Regressive Distributive Lag Model

1. INTRODUCTION

Improving the allocation of human resources is called as migration. People living in area where they are not fully employed or partially employed are expected to move to termini that having brighter futures. However, both migration analysts and policymakers seem to have mixed views as to whether private market forces are only adequate to encourage them to do so. On the one hand, there has been substantial discussion regarding policies designed to affect migration directly by permitting or tempting the unemployed to move for more hopeful labor markets. But, the implication is that the unemployed are not themselves sufficiently responsive to economic conditions. On the other hand, investment policies of in depressed places are based largely on the premise that expanded local economic chances will shrink economically forced outmigration (Julie DaVanzo, 1978).

There are many arguments about the benefits and costs of migration for both host country and countries of origin. It is clear that immigration can be beneficial for migrants, but only if their rights are protected properly. It can also be economically beneficial for both countries of origin and host countries; however, with present economic and trading structures it is the rich and powerful countries that benefit most. Migration brings social and cultural pressures that need to be taken into account in planning for future services. Migration also has the potential for bringing peoples together culturally but friction occurs if efforts are not made to dispel the myths held by local people. It is also essential to provide good information about the local way of life to newcomers and ensure opportunities for people to mix and integrate. Where the economic preconditions exist, migration is inevitable. When people try to prevent immigration it just goes underground.

When the economic environment declines, the host country population tends to fear the impact of immigration on employment or on wages (European Social Survey (2002). For instance, following the 1974 oil crisis, European governments implemented selective or restrictive migration policy in order to slow down the entry of immigrants whose assimilation into the host country labor market was not certain and to satisfy national public opinion. Nevertheless, in Sri Lanka, from 1980s to 2009, people migrated not only for finding the job and education but also for security purposes due to unstable political environment whereas after 2009, they migrate especially by targeting the labor markets.

The relationship between unemployment rate and migration is not obvious. On the one hand, many studies using survey data (e.g., Fromentin, 2013; Lansing and Mueller, 1967; Saben, 1964) found that certain unemployed workers are more likely to migrate than employed workers, but, Saben, and Lansing and Mueller studies do not use ample controls for other characteristics that may have affect migration. Lansing and Mueller (1967, p. 91) further explain that people are faintly less likely to leave depressed areas than non-depressed areas. On the other hand, some of the literatures (e.g., Lowry, 1966) have obtained mixed results using aggregate data, but Lowery explain that since unemployment is often measured at the end of the period of migration and thus may have been affected by the intervening migration. Further, Lowry confirmed that outmigration to be insensitive to conditions of local labor market. Thus, the direct contribution of unemployment to migration cannot be determined (Julie DaVanzo, 1978).

The studies of Harris and Todaro (1970) and Todaro (1969) are considered to be founding works for the investigation of migration flows in a context of underemployment, with the presence of real wages rigidities. They explain that migrations are likely to have a negative impact on the general level of employment, since workers are encouraged to migrate to certain regions, due to higher wages, even if the rate of unemployment is higher.

Some authors (e.g., Fields, 1976; Olvey, 1970; Blanco, 1964) have discussed that unemployment "push" at origin is operative but that its role is masked by improper measures of true unemployment conditions. Blanco, and Olvey suggest

and employ synthetic measures such as "potential" or "prospective" rate of unemployment, which examine what unemployment rates would be if there were no out- migration (net), and find them positively correlated to (net) outmigration.

Therefore, the query of the economic impact of migration has been broadly addressed by literature of economics, notably taking into deliberation the characteristics of the migrants and the labor market of the country, the degree of substitutability and complementarity between the workers, the elasticity of work demand and supply, the mobility of workers', the protagonists' negotiating power, global demand, etc. Although if there is a quasi-consensus appears from literature of economics regarding economic impact (e.g., Longhi et al., 2010; Okkerse 2008), the conclusions can be diverge. Nevertheless, according to the context of geographical, methodological and temporal analysis, Borjas (1994) demonstrate that "the most important lesson is that the economic impact of immigration varies by time and place and can be beneficial or harmful".

Having these mixed results, an individual characteristic can be seen in the Sri Lankan economy during the last five decades until 1997 was the experience of two-digit rate of unemployment and then it became one digit, which implies that the rate of unemployment has gradually decreased in the last five decades. However, data regarding net migration shows a high negative value in early 1990s and gradually decreased until 2001 then there is high fluctuation until 2010 and again net migration started to increase dramatically. Therefore, we could not see the clear pattern regarding the net migration. In this respect, it seems vital to ask questions about the link between migration and the labor market in Sri Lanka and to wonder about the existence of cointegration and/or of a causal relationship (unidirectional or bidirectional) between migration and economic growth, migration and unemployment.

In addition, several studies examine the relationship between immigration and unemployment instead of link between migration and unemployment by considering American (e.g., Ottaviano and Peri, 2012; Card, 2009; Borjas, 2003; Friedberg, 2001; Borjas, Freeman and Katz, 1997; Borjas, Friedberg and Hunt, 1995; Card, 1990; Grossman, 1982) and European (e.g., Galloway and Josewicz, 2008; Dustman, Fabbri and Preston, 2005; Gross, 2002; Winter-Ebmer and Zeimuller, 1999; Pischke and Velling 1997) countries since these countries have positive net migration. Among these studies, there is no consensus on whether the link between immigrant and wages or unemployment is negative, positive or null (e.g. Ottaviano and Peri, 2012; Card, 2009; Galloway and Josewicz, 2008; Fabbri and Preston, 2005; Borjas, 2003). For instance, Using the data of France, Gross (2002) found some detrimental effects in the short run perspective, but in the long run, he revealed negative relationship between immigration and unemployment rate. Nevertheless, his general result shows that the inflow of immigration on the labour market indicators was not significant and temporary. Dustman, Fabbri and Preston (2005) used the data from the British Labour Force Survey aggregated into the 17 regions and have not identified any significant effects of immigration on the employment, participation and rate of unemployment. Employing the pooled cross-sections data collected from Austria, Winter-Ebmer and Zeimuller (1999) obtained only slight effect of immigration on native employees and more significant on time labour and already employed immigrants. Pischke and Velling (1997) used 328 regions data from German and concluded that no detrimental effect of the immigration on employment. In contrast, data of Sri Lanka revealed that net migration is negative, indicating that emigrants are higher than the immigrants. And, to best of our knowledge, there is no study that investigates the relationship between unemployment and migration using Sri Lankans data. Taking this in to account, we attempt do it. In this manner also our study differs from existing literatures.

Thus, the aim of this study is to examine whether the unemployment causes to migration and the impact of unemployment on the migration using data of Sri Lanka between 1990 and 2015 with a long-term and short-term distinction, since the conclusions may diverge in particular owing to the adjustment time of the labor market (Damette and Fromentin 2013, Dustmann, Glitz and Frattini 2008, Gross 2004, Cohen-Goldner and Paserman 2004).

2. DATA, VARIABLES AND METHODOLOGY

In this study, we use annual time series data from Sri Lanka over the period of 1990-2016²⁶⁷ to examine whether the unemployment causes to migration and impact of unemployment on net migration of Sri Lanka. Net migration, unemployment rate, Gross domestic product per capita, consumer price index and wage are used as variables. All the variables data were extracted from World Development Indicator of the World Bank data base. Table 1 below shows the variables that are used in our growth regression, definition, and abbreviation.

Table 1: variables, description and abbreviation

Variables	Description	Abbreviation
Net migration (Dependent Variable)	The number of immigrants minus the number of emigrants over a period, divided by the person-years lived by the population of the receiving country over that period. It is expressed as net number of migrants per 1,000 population.	netmig
Gross domestic product per Capita	gross domestic product divided by midyear population (current LCU)	gdppc
Consumer price index	changes in the cost to the average consumer of acquiring a basket of goods and services that may be fixed or changed at specified intervals, such as yearly (2010 = 100)	cpi
unemployment rate	% of total labor force (national estimate)	unemp

²⁶⁷ Due to the availability of the data of selected variables, we considered this period in our sample.

wage	Wage and salaried workers, (% of total employment)	wage
------	--	------

Following the empirical literature in related to unemployment and migration, we develop the long-run relationship between the variable as below:

$$netmig_t = \alpha_0 + \alpha_1 unemp_t + \alpha_2 gdppc_t + \alpha_3 cpi_t + \alpha_4 wage_t + \varepsilon_t \quad (1)$$

where, variables name are as explained in Table 1, ε_t is the white noise error term with zero mean and constant variance and t illustrate the time period.

The estimation of equation (1) begins with the identification of the order of integration of each variable using Augmented Dickey Fuller (ADF) and Philips-Perron (PP) unit root test for this analysis. Therefore, we can compare the results of ADF test with PP test to see whether we have obtained the same conclusion or not. The AR (p) model with intercept of the ADF test can be described as below:

$$Y_t = \alpha + \sum_{i=1}^p \beta_i Y_{t-i} + \varepsilon_t \quad (2)$$

The null hypothesis of equation (2) is that the variable Y_t is non-stationary ($\beta_i = 1$) and the alternative hypothesis is that the variable Y_t is stationary ($\beta_i < 1$). If the test statistics less than the critical value we will reject the null hypothesis and conclude that the variable Y_t is stationary. Then we can use the variable Y_t in its original form. In contrast, if the test statistics greater than the critical value we will failed to reject the null hypothesis and conclude that the variable Y_t is non-stationary. In this situation, we can include linear trend in equation (2) or we can exclude both intercept and linear trend from the equation. Even in these two situations also, if we failed to reject null hypothesis then the ADF is suggested to take difference for the series. After taking the first difference, the equation (2) can be written as below:

$$\Delta Y_t = \alpha + \rho^* Y_{t-1} + \sum_{i=1}^{p-1} \beta_i \Delta Y_{t-i} + \varepsilon_t \quad (3)$$

The null hypothesis of equation (3) is that the series ΔY_t is non-stationary ($\rho^* = 0$) and the alternative hypothesis is that the series ΔY_t is stationary ($\rho^* \neq 0$). If the absolute value of test statistics is greater than the absolute value of critical value, then we will reject null hypothesis and conclude that the variable ΔY_t is stationary. Then we can use the variable Y_t in first difference form in our model. In contrast, if the absolute value of test statistics is less than the absolute value of critical value, then we will failed to reject null hypothesis and conclude that the variable ΔY_t is non-stationary. In this situation, we can include linear trend in equation (3) or we will exclude linear trend and intercept from the equation. Suppose, if we failed to reject null hypothesis in these two cases as well, then the ADF is suggested to take further difference until it became a stationary. Alternative to test statistics and the critical value, we also can compare the probability value and the alpha (significance level) value to test the hypothesis. If probability value is less than the alpha value we will reject null hypothesis and vice versa. The PP unit root test method also has the same procedure as ADF test.

In the second step of the estimation procedure, we have to identify the optimal lag length that can be used in the model. Because, the underlying theory and any hypothesized structure indicate to the economist which variable to include in the model and how many lags would be appropriate. Therefore, the method of determining the appropriate lag length is still an important issue in the time series literature since longer lag lengths increase the number of estimated parameters, reduce degrees of freedom and increase data requirements. There have been several methods proposed to deal with the problem of correctly determining the proper lag length for time series model like Vector Autoregressive (VAR), Vector Error Correction Model (VECM) and Autoregressive Distributed Lag (ARDL) etc. There are several criterions such as sequentially modified Likelihood Ratio (LR) statistics, Akaike Information Criterion (AIC), Swartz Information Criterion (SC), Hannan-Quin Information Criterion (HQIC) and Final Prediction Error (FPE) to select the optimal lag length that can be included in a time series model. However, we will adopt either one or more of these criterions in our analysis according to our results and the requirements.

In the third step, To empirically analyze the dynamic relationship between the variables, the model specified in equation (1) can be estimated by the ARDL co-integration procedure developed by Pesaran et al. (2001). Firstly, this method can be a valid amendment when endogenous variables are included in the explanatory variables. Secondly, the bound testing is applicable for a small sample size unlike Johansen cointegration, which requires a large sample size to ensure the reliability of the results. Third, with the ARDL it is possible that different variables have differing optimal number of lags. Fifth, the bound testing can be employed irrespective of whether the variables are purely I(0), I(1), or mixed integrated. However, this procedure will crash in the presence of I(2) series. Finally, the long-run and short-run effects can be estimated simultaneously in bound testing. The model includes lagged value of the dependent variables, current and lagged value of explanatory regressors. An ARDL representation of equation (1) is formulated as follows:

$$\Delta netmig_t = \delta_0 + \delta_1 netmig_{t-1} + \delta_2 unemp_{t-1} + \delta_3 gdppc_{t-1} + \delta_4 cpi_{t-1} + \delta_5 wage_{t-1} + \sum_{i=1}^{q_1} \beta_{1i} \Delta netmig_{t-i} + \sum_{i=0}^{q_2} \beta_{2i} \Delta unemp_{t-i} + \sum_{i=0}^{q_3} \beta_{3i} \Delta gdppc_{t-i} + \sum_{i=0}^{q_4} \beta_{4i} \Delta cpi_{t-i} + \sum_{i=0}^{q_5} \beta_{5i} \Delta wage_{t-i} + e_t \quad (4)$$

Where, Δ denotes the first difference operator, δ_0 is the drift component, e_t is the usual white noise error term, $\delta_1 \rightarrow \delta_5$: correspond to the long-run relationship, the remaining expressions with the summation sign ($\beta_{1i} \rightarrow \beta_{5i}$) represent the short-run dynamics of the model.

To investigate the presence of long-run relationships among the variables, bound testing procedure is used. The bound testing procedure is based on the F-test. The F-test is actually a test of the hypothesis of no co-integration among the variables against the existence of cointegration among the variables, denoted as:

$$H_0: \delta_1 = \delta_2 = \delta_3 = \delta_4 = \delta_5 = 0 \text{ (there is no cointegration among the variables)}$$

$H_1: \delta_1 \neq \delta_2 \neq \delta_3 \neq \delta_4 \neq \delta_5 \neq 0$ (there is cointegration among the variables)

The ARDL bound test is based on the Wald-test (F-statistic). The asymptotic distribution of the Wald-test is non-standard under the null hypothesis of no cointegration among the variables. Two critical values are given by Pesaran et al. (2001) for the cointegration test. The lower critical bound assumes all the variables are $I(0)$ meaning that there is no cointegration relationship between the examined variables. The upper critical bound assumes that all the variables are $I(1)$ meaning that there is cointegration among the variables. When the computed F-statistic is greater than the upper bound critical value, then the H_0 is rejected (thus, the variables are cointegrated). If the F-statistic is below the lower bound critical value, then the H_0 cannot be rejected (thus, there is no cointegration among the variables). When the computed F-statistics falls between the lower and upper bound, then the results are inconclusive.

In the next step of the estimation procedure we obtain the short run dynamics of parameters and long run adjustment of the model by estimating the error correction version of ARDL model pertaining to the variables in equation (4) is as follows:

$$\Delta netmig_t = \pi_0 + \sum_{i=1}^{q_1} \pi_{1i} \Delta netmig_{t-i} + \sum_{i=0}^{q_2} \pi_{2i} \Delta unemp_{t-i} + \sum_{i=0}^{q_3} \pi_{3i} \Delta gdppc_{t-i} + \sum_{i=0}^{q_4} \pi_{4i} \Delta cpi_{t-i} + \sum_{i=0}^{q_5} \pi_{5i} \Delta wage_{t-i} + \gamma ECT_{t-1} + \mu_t \tag{5}$$

where, γ : speed of adjustment, which should have statistically significant and negative sign to support the cointegration between the variables, μ_t : pure random error term.

Finally, once we confirmed the presence of co-integrating relationship among the variables, we adapted Vector Error Correction Model (VECM) based granger causality approach to identify the direction of causality between unemployment rate and net migration. Granger (1969) argued that VECM is more appropriate to examine the causality between $I(1)$ series. VECM is restricted form of unrestricted VAR and restriction is levied on the presence of the long - run relationship between the series. The system of error correction model (ECM) uses all the series endogenously. This system allows the predicted values to explain itself both by its own lags and lags of forcing variables as well as the lags of the error correction term and by residual term. The VECM equation is modeled as follows:

$$\Delta Z_t = C + \sum_{j=1}^q \Phi_{ij} \Delta Z_{t-j} + \Psi ECT_{t-1} + \varepsilon_t \tag{6}$$

where, Δ is the first difference operator, Z_t is the 5×1 vector of dependent variables C is the 5×1 vector of constant, Φ is the 5×5 matrix of coefficients, Z_{t-j} is the lagged value of Z_t , $\Psi = \alpha\beta'$, where, α is the 5×1 vector of adjustment coefficients, β' is the 1×5 vector of cointegrating coefficients, ECT_{t-1} represents the one period lagged error-term derived from the co-integration vector and the ε_t is the 5×1 vector of white noise error term. In the above equation, all variables are treated as endogenous variables. We used F test to examine the direction of any causal relationship between the variables.

3. RESULTS AND DISCUSSIONS

In this section we discuss both results of descriptive analysis and econometric analysis. First, we discuss the descriptive results and then results from econometric analysis are discussed.

3.1 Descriptive Analysis

We employed scatter plot with confidence ellipse to observe the relationship between the variables considered in this study. The Fig 1 and 2 below shows the relationship between unemployment rate (unemp) and net migration (netmig) and unemp and GDPPC respectively.

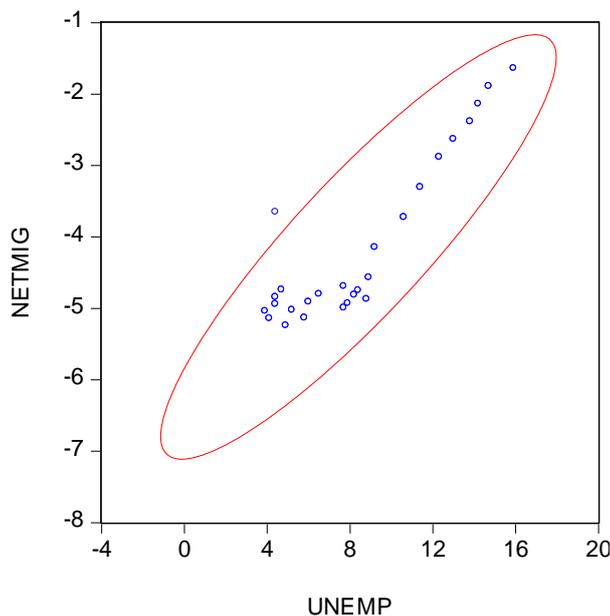

Fig 1: Relationship between netmig & unemp

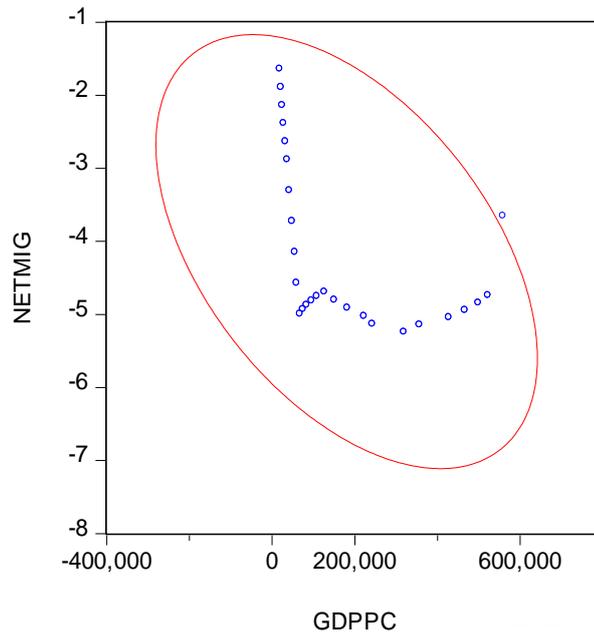

Fig 2: Relationship between netmig & gdppc

The confidence ellipse of the Fig 1 depict that a positive link between rate of unemployment and net migration. It implies that when the rate of unemployment increases in native country, then the net migration also increases in negative term, i.e. emigrants are higher than the immigrants in native country. Fig 2 shows that there is no clear association between net migration and per capita GDP. The Fig 3 and 4 below shows the relationship between net migration and consumer price index (cpi) and net migration and wage respectively.

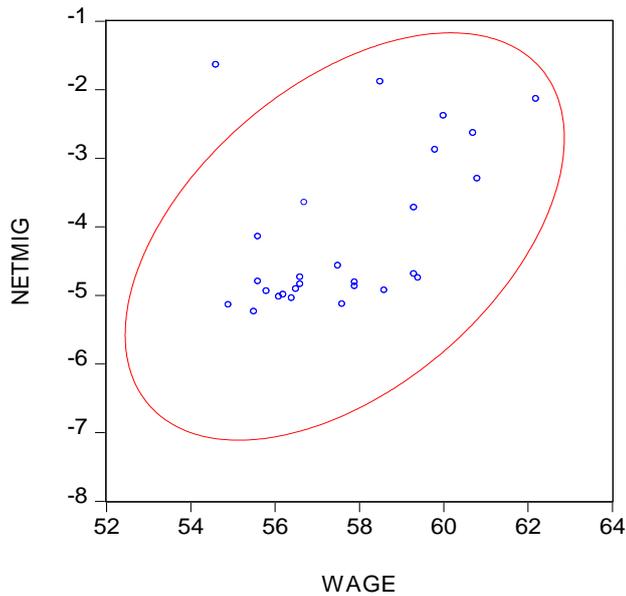

Fig 3: Relationship between netmig & cpi

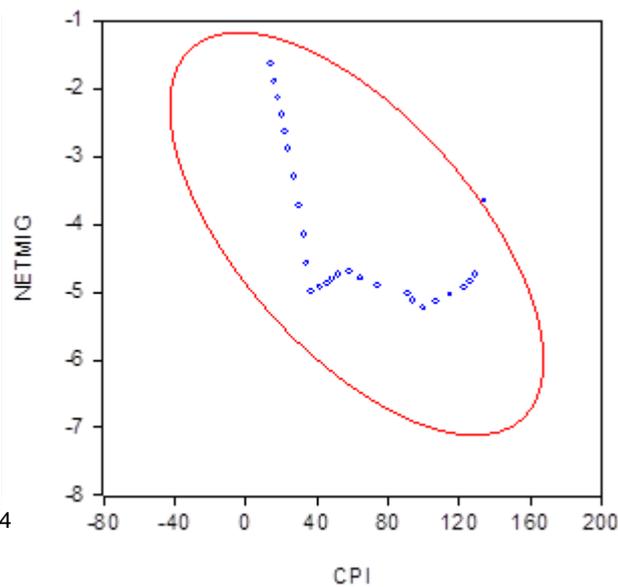

Fig 4: Relationship between netmig & wage

The confidence ellipse of the Fig 3 and Fig 4 illustrate that there is no clear association between net migration and cpi and net migration and wage. Therefore, it is crucial to examine the relationship by econometrically.

3.2 Econometric Analysis

We now used ordinary least squared (OLS) estimation technique to investigate the relationship between the variables. The results are given in Table 2.

Table 2: Results of OLS

Variable	Coefficient	Std. Error	t-Statistic	Prob.
UNEMP	0.456922	0.046092	9.913282	0.0000
GDPPC	3.82E-06	1.92E-06	1.989170	0.0593
CPI	0.002863	0.011219	0.255169	0.8010
WAGE	-0.005356	0.032900	-0.162780	0.8722
C	-8.540647	1.992996	-4.285330	0.0003

Note: R-squared=0.951820, Prob(F-statistic)= 0.000000

Source: Authors' Calculation

The results reveal that there is a positive and statistically significant relationship between rate of unemployment and net migration, which the expected since the Sri Lanka experienced as negative net migration country. This indicates that, when the unemployment rate increase by 1 percentage which tend to increase the net migration in negative term by 457 person. That is emigrants are higher than the immigrant by 457 person. Some of the existing studies (e.g., Fromentin, 2013; Lansing and Mueller, 1967; Saben, 1964) also supports to our finding. In addition, GDP per capita affect the net migration positively at 10% level of significance. In contrast, wage and cpi do not have statistically significant impact on emigration. This required us to use different estimation method instead of OLS in order to compare the consistency of the relationship. Thus, we employed ARDL bound testing approach in this regard.

According to the results of ADF unit root test, wage is I(0) while net migration is I(1) at 10% level of significance at the same time, other all variables such that unemployment rate, cpi and GDP per capita are I(1) at 5% level of significance when we included intercept only in the model. But, PP unit root test shows that net migration and GDP per capita are neither I(0) nor I(1) in this case. Both ADF and PP unit root approaches detected that net migration is neither I(0) or I(1) when the equation contain trend and intercept in the model (see Table 3 below).

Table 3: Results of ADF and PP Unit Root Test

Form	Variables	ADF		PP	
		Intercept	Trend & Intercept	Intercept	Trend & Intercept
Level	NETMIG	0.747	0.999	0.142	0.999
	UNEMP	0.120	0.832	0.120	0.819
	GDPPC	0.838	0.563	1.000	0.980
	CPI	0.999	0.736	0.999	0.742
	WAGE	0.055*	0.002**	0.041**	0.002***
1 st Difference	NETMIG	0.074*	0.112	0.109	0.142

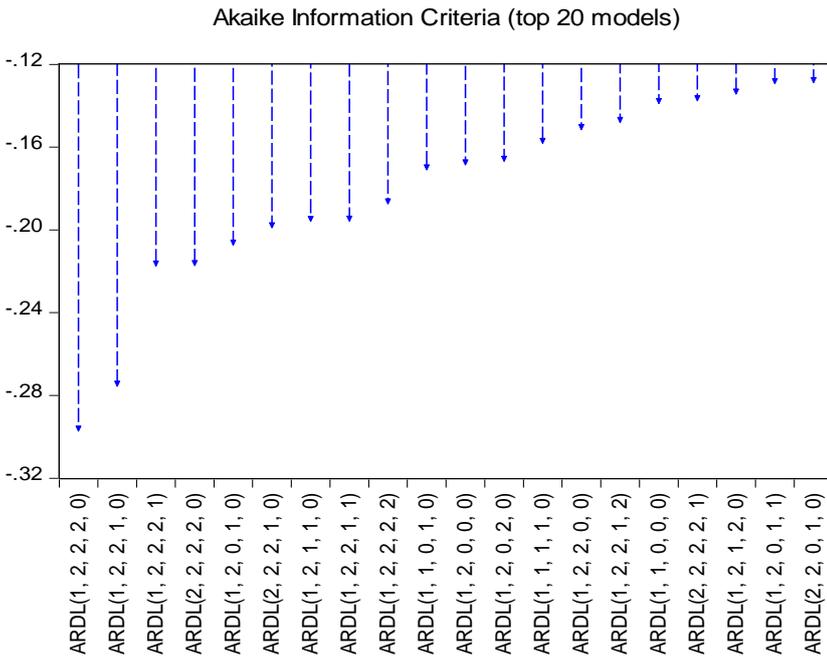

UNEMP	0.001***	0.003***	0.001***	0.003***
GDPPC	0.029**	0.012**	0.166	0.008***
CPI	0.045**	0.058*	0.047**	0.056*
WAGE	0.003***	0.013**	0.000***	0.000***

Note: Probability values are given in the Table. ***, **, * represents variables are stationary at 1%, 5% and 10% level of significance respectively.

Source: Authors' calculation

Now, we check the order of integration using other unit root test called KPSS in order to compare the consistency of the results. This unit root test procedure also confirm that there is no I(2) variables, i.e. wage is I(0) and others are I(1)²⁶⁸. Thus, taking in to consideration of ADF and KPSS procedure, which are confirmed that none of the variables are I(2) when the model include intercept only, we adopt Autoregressive Distributed Lag (ARDL) bound testing method to examine the relationship between the variables.

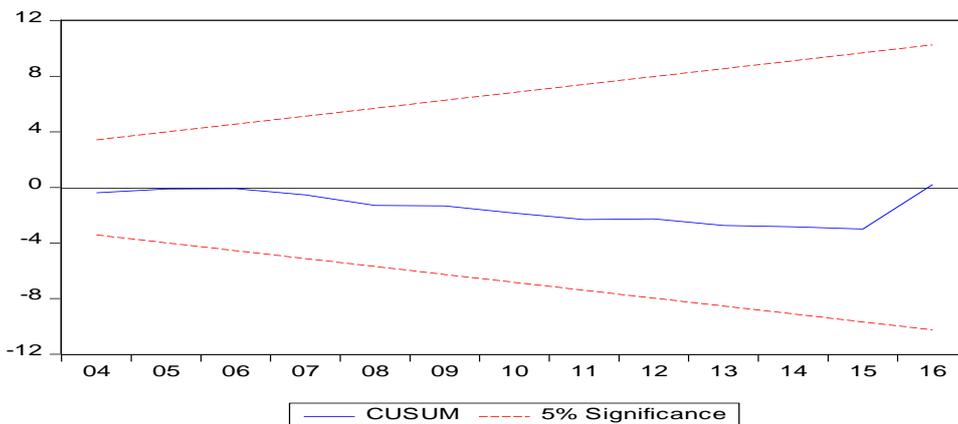

Next we employed AIC to select the optimum number of lag for each variables that can be included in the model. Since the lowest value is better, the results suggest that to employ ARDL (1, 2, 2, 2, 0) model among the top 20 models (see Fig 5 below).

Source: Authors' calculation

Fig 5: Results of Optimum Lag Length of Each Variable (AIC)

The CUSUM test plots lie between the lower and upper critical bounds at the 5% level of significance, which confirms the stability of the model (see the Fig 6 below).

Source: Authors' calculation

Figure 6: The Results of CUSUM Test for ARDL (1, 2, 2, 2, 0) model

The **ARDL (1, 2, 2, 2, 0)** model passed all the diagnostics tests (see Table 4, Panel B below). That is, firstly, Lagrange Multiplier (LM) test of autocorrelation advocates that the residuals are not serially correlated since we failed to reject the null hypothesis of no serial correlation in the residual as probability value is greater than the 5% level of significance. Second, according to the Jarque-Bera (JB) test, the null hypothesis of normally distributed residuals cannot be rejected as probability value is higher than 5% significance level, which indicates that error is normally distributed. Thirdly,

²⁶⁸ Results are not presented here but available upon request.

Breusch-Pagan-Godfrey (BPG) test of heteroscedasticity suggests that the disturbance term in the equation is homoscedastic as we failed to reject the null hypothesis since the probability value exceeded the 5% significance level. Finally, the Ramsey RESET test result confirms that there is no specification error in the estimated model since we accept the null hypothesis of no omitted variable in the model as probability value is greater than 5% level of significance.

Table 4: The Results of Diagnostics Test of ARDL (1, 2, 2, 2, 0)

Test	Probability value (F or Chi-square)
Serial Correlation [LM Test: $\chi^2_{(df)}$]	0.062
Normality Test (Jarque-Bera)	0.177
Heteroscedasticity (BPG Test)	0.251
Omitted Variable (Ramsey's RESET)	0.625

Source: Authors' calculation

The result of Wald test confirms that there is a long run relationship between the variables under considered in this study since we reject the null hypothesis of no cointegration among the variables due to the computed F-statistics (4.025) greater than the upper bound critical value (3.49) at 5% level of significance (see Table 5 below).

Table 5: The Results of ARDL Bounds Test

F-Bounds Test		Null Hypothesis: No levels relationship		
Test Statistic	Value	Signif.	I(0)	I(1)
F-statistic	4.025577	10%	2.2	3.09
k	4	5%	2.56	3.49
		1%	3.29	4.37

Source: Authors' calculation

Therefore, now we can estimate the model further in order to identify the long run relationship between the variables, which are given in the Table 6 below:

Table 6: The Results of ARDL Long run Form

Dependent Variable: D(netmig)					
Panel A: The Results of Long run Coefficients					
Cons	unemp	gdppc	cpi	wage	R ²
-14.86851 (-3.376)	0.8372*** (3.103)	8.08E-06* (2.099)	0.0044 (0.268)	-0.0228 (-0.461)	0.980

Note: Test statistics are given in the parenthesis. ***, **, * represents the variables are significant at 1%, 5% and 10% level of significance respectively.

The long run form of ARDL results reveals that unemployment and GDP per capita has positive and significant impact on net migration in the long-run while other variables, CPI and wage, do not have significant impact on it. Nevertheless, former variable affects at 1% level of significance whereas later affects at 10% significance level. The finding of this study regarding the impact of unemployment on net migration is similar to some of the existing studies (e.g., Fromentin, 2013; Lansing and Mueller, 1967; Saben, 1964) and as the expectation. Because, Sri Lanka's data of immigration and emigration shows that the net migration (that is, immigrants minus emigrants) is negative and it increases continuously in absolute term. The reason is since the people living in area where they are facing difficulties to find the job are expected to move to places that having brighter futures. In addition, unstable political situation in the country until middle of 2009 also another reason for emigrants are higher than immigrants in Sri Lanka. But, after 2009 also net migration increases in absolute term due to increase in skilled labor emigrants. The results of OLS also found the same conclusion as in this form.

Finally we estimated the error correction representation of ARDL model in order to identify the short run relationship and long run adjustment between the variables. The results are given below:

Table 7: Results of Error Correction Representation of ARDL Model

Dependent Variable: Δ NETMIG			
Variables	Lag order		
	0	1	2
Δ NETMIG		-0.5854 (-1.73)	
Δ UNEMP	0.1935** (2.62)	0.3366*** (4.39)	0.2488*** (3.56)
Δ GDPPC	1.59E-05*** (3.73)	-3.96E-06 (-1.71)	-1.20E-06 (-0.41)
Δ CPI	0.0219 (1.54)	0.0179 (1.26)	-0.0682*** (-4.09)
Δ WAGE	0.0122 (0.52)		
ECT(-1)	-0.5736 (-5.45)		
R ²	0.924		
F - Stat	11.18246		

Note: Test statistics are given in the parenthesis. ***, **, * represents the variables are statistically significant at 1%, 5% and 10% level of significance respectively.

Source: Authors' calculation

The above table explains that as in the long run results and some of the existing studies that earlier we have discussed current and one and two year lagged value of rate of unemployment have positive and significant impact on net migration in the short run. The reason could be as we explained in under the long term situation. There is positive and significant relationship between current value of GDP per capita and net migration whereas CPI and wages do not affect net migration significantly in the short run. Further, coefficient of error correction term (ECT) is significant and negative implies that the model can get back to long run steady state line (or equilibrium) at the speed of 57.36% in each year one period after the exogenous shocks.

Finally we discuss the direction of causality between the variables via error correction representation of ARDL model. The results are presented below:

Table 8: The Results of Granger Causality Test

Null Hypothesis	Probability Value	Decision
Unemployment → Net migration	0.0042	Reject
Net migration → Unemployment	0.2312	Failed to Reject
GDPPC → Net migration	0.0089	Reject
Net migration → GDPPC	0.4123	Failed to Reject
CPI → Net migration	0.0039	Reject
Net migration → CPI	0.6213	Failed to Reject
Wage → Net migration	0.6144	Failed to Reject
Net migration → Wage	0.3452	Failed to Reject

Source: Authors' calculation

The results reveal that there is a unidirectional causality relationship between unemployment and net migration, GDP per capita and net migration and CPI and net migration in the long run at 5% level of significance. This causality relationship is running from unemployment to net migration, GDP per capita to net migration and CPI to net migration.. Further there is no causality relationship between other variables.

4. CONCLUSION AND POLICY RECOMMENDATIONS

ADF and KPSS unit root test confirmed that none of the variables are I(2), which allows us to examine long run relationship between the variables using Autoregressive Distributed Lag (ARDL) bound testing method. AIC is suggested to adapt ARDL (1, 2, 2, 2, 0) model among the top 20 models. This model passes the all the diagnostic test. The bound testing results detected the cointegrating relationship between the variables. The result of ARDL bounds test and Error Correction version of ARDL model reveal that unemployment and per capita GDP have positive and significant impact on net migration in the long run and the short run while other variables do not have significant impact on net migration in both periods. The result of CUSUM test discloses that the estimated model is stable. The negative and significant coefficient of error correction term reveals that net migration moves backward towards steady state line with the speed of 57.63 % in each period one period after the exogenous shocks. Both ARDL model passes the all the diagnostic test. Moreover, Granger causality test identified a causal relationship that stemming from unemployment to net migration, GDP per capita to net migration and consumer price index to net migration. Since the unemployment causes to emigration, the government of Sri Lanka should take necessary action to reduce the rate unemployment by providing relevant job for youth and should implement restrictive or selective migration policy in order to prevent the emigration of skilled people.

RS09.1. Real Estate and Housing

1144 DEVELOPMENT PREMIUMS AND PROPERTY MARKETS IN INDONESIA

ABSTRACT

This paper investigates the Indonesian property market with a particular emphasis on understanding development patterns in rural and low population density regions. We use implicit price estimates from property markets using a technique which yields robust results in areas with sparse data to analyze spatial trends in the development premium for residential and commercial properties in Indonesia. Our findings elaborate how market incentives to invest in residential and commercial development vary by region, level of development, population density, and political context. Our research fills an empirical void on development patterns in developing countries, particularly related to residential and commercial land development. We use a uniquely compiled dataset of over 80,000 residential, commercial, and undeveloped land prices extracted from an Indonesian online classifieds website, which we join to local census level data. We then estimate a geographically weighted regression and a multilevel regression with poststratification. The geographically weighted regression provides a descriptive analysis of the spatial patterns, while the multilevel regression with poststratification provides robust estimates in rural and low population density regions with fewer observations by linking property characteristics with census level data. This approach is particularly advantageous for datasets with regions of sparse data, a common problem in property market research in developing countries. The spatial extent of our data allows us to examine the spatial distribution of implicit property prices in a developing country, and the multilevel regression with poststratification enables us to further describe aspects of the property market in less populated areas with relatively scarce available data on property prices. We use the estimation results to construct a spatial index evaluating the premium for residential and commercial properties by extracting regency specific price levels for undeveloped land, residential properties, and commercial properties. This index yields a series of maps examining the geographic distribution of development premiums. In addition, we test multiple hypotheses to explain differences in the development premiums, including urban vs rural, proximity to Jakarta, the central economic hub of Indonesia, and local political differences. Overall, this research makes three significant contributions to the literature: (1) the multilevel regression with poststratification allows for robust estimates in rural and low population density regions, which to date have greatly understudied property markets in developing countries, (2) we provide a descriptive analysis of the spatial variation in relative premiums for commercial and residential development across the country, and (3) we link development premiums with regional characteristics which provide descriptive explanations for differences in the premiums. This is the first research paper to our knowledge to utilize such a large dataset of property prices in a developing country to examine development patterns and provides critical insights into understanding development trends in these areas of the world.

1228 EQUITY IN JOB ACCESSIBILITY AND ENVIRONMENTAL QUALITY IN A SEGMENTED HOUSING MARKET: THE CASE OF GREATER LONDON*Like Jiang, Alex Hagen-Zanker*, Prashant Kumar*

Department of Civil and Environmental Engineering, University of Surrey

*Corresponding author at: Department of Civil and Environmental Engineering, University of Surrey Guildford, GU2 7XH, UK. Email: a.hagen-zanker@surrey.ac.uk**ABSTRACT**

Public services and resources such as job accessibility and environmental quality are often not equally distributed in spatial and/or social dimensions within metropolitan regions. Availabilities of these public services and resources affect the quality of residential locations, and can be expected to be capitalised into house prices. For prospective house owners, selections of properties will be based on their preferences and appreciations of different attributes of the properties, but also be constrained by their housing budgets. Such a constraint may lead to segmentation of local housing markets into submarkets by price bands, and availabilities of public services and resources, as well as prices of them, might be different between the resulted submarkets. In such a case, distribution of public services and resources might be highly dependent on the public's abilities to pay for housing, rather than based on their needs for, consumptions of, or expenses on each specific service or resource. Using Greater London as the case metropolitan region, this study examined the existence of housing submarkets by price bands, and explored the differences in availabilities, prices and trade-offs of job accessibility and environmental quality between the submarkets. Results of this study show that submarkets by price bands did exist in Greater London, and indicate that households with lower housing budgets were more likely to have lower job accessibility but enjoy higher environmental quality. They were also more likely to pay less, in relative to the total house price, for both job accessibility and environmental quality.

Keywords: social equity, job accessibility, environmental quality, submarket, hedonic price model

1. INTRODUCTION

Public services and resources such as schools, hospitals, transport infrastructure, green space, clean air, clean water, etc. are often not equally distributed in spatial and/or social dimensions within metropolitan regions, as the distributions can be affected by various factors such as ecological and physical constraints, predefined standards in the planning systems, political activism, and market process (Lucy, 1981; Mitchell, 2005; Talen, 1998). Regardless of varied conceptions of fairness, numerous studies have demonstrated the unequal distributions of various public services and resources, for example, healthcare facilities among different residing locations (Jin et al., 2015; Matsumoto et al., 2012), public transport service among different age, income and car-ownership groups (Riccardi et al., 2015), job accessibility among different racial and income groups (Grengs, 2012), green space among different racial and income groups (Sister et al., 2010; Talen, 1997), air quality among different income and education groups (Crouse et al., 2009; Padilla et al., 2014).

Availabilities of these public services and resources affect the quality of residential locations, and can be expected to be capitalised into house prices. Based on hedonic price modelling (Rosen, 1974), great amounts of research has been made to study the values or implicit prices of individual housing attributes, including specific public services and resources available to the properties. For example, for job accessibility, Ottensmann et al. (2008) shows every 10 km increase in mean distance to employment centres leads to decreases in house price by around 9% in Indianapolis, US, while every 10 minutes increase in mean travel time by car leads to price decreases by around 12.5%. With multiple measures tested, Osland & Thorsen (2008) concluded that job accessibility can explain variations of up to 0.8 million NOK in house price in the southern Rogaland region of Norway, compared to variations of up to 0.7 million explained by CBD accessibility. For green space, McLeod (1984) investigated the demand in Perth, Australia, and found that decrease in distance to parks by one street block increases house prices by 3%. In a recent study in Leipzig, Germany, Liebelt et al. (2018) found €1.15/m² to €1.52/m² increases in house price depending on property type for every 1% increase in area of green space within 300m from the properties. For air quality, a meta-analysis made by Smith & Huang (1995) reports an interquartile range of house price increase from 0 to \$98.52 for 1 mg/m³ reduction in total suspended particulates in US cities, when the annual incomes were around \$15,000. More recently, Kim et al. (2010) found increases in house price by from 5.23% to 11.32% for 1 ton/km³ decrease in total suspended particulates in four regions in the US. For sound environment, Lake et al. (1998) shows that each dB(A) increase in road traffic noise calculated in L_{10,18h} decreases property prices by 1.07% in Glasgow, Scotland, whereas in Baranzini et al. (2010) it shows that each dB(A) increase in daytime road traffic noise reduces the rent of residential properties by around 0.23% in Geneva, Switzerland. Other examples can be found for transport service (Debrezion et al., 2007; So et al., 1997), schools (Haurin & Brasington, 1996; Sah & Conroy, 2016), shopping centres (Colwell et al., 1985; Des Rosiers et al., 1996), etc.

For prospective house owners, selections of properties will be based on their preferences and appreciations of different attributes of the properties, but also be constrained by their housing budgets (Hausman & Wise, 1980; McMillan, 1979). As for many households the housing budget makes up a very large share of their total household budget, there would be little flexibility in increasing housing budget for more desired options (Stone, 2006). Thus, their options will be limited to properties within certain price bands depending on their housing budgets. Such a constraint may lead to segmentation of local housing markets into submarkets by price bands, as a result of differences in housing supply and demand between price bands.

The existence and significance of housing submarkets have long been debated (Watkins, 2001). It is argued that a market cannot be characterised by a single price model where submarkets exist, due to differences in capitalisations of housing attributes between submarkets (Watkins, 2001). However, interests have more often been found in submarkets defined in spatial and/or structural dimensions (e.g. Allen et al., 1995; Bourassa et al., 1999; Maclennan & Tu, 1996; Wu & Sharma, 2012), few studies have been made to examine submarkets defined by price bands. While there are studies on submarkets by income groups (e.g., Munro, 1986; Schnare & Struyk, 1976), or studies where income and/or other indicators of wealth are included in cluster analysis to empirically identify submarkets (e.g., Day, 2003, Keskin & Watkins, 2017), they do not directly examine whether households are allocated to different submarkets depending on the amount of money they are able to pay, i.e., their housing budgets.

If submarkets by price bands do exist, availabilities of public services and resources might be different between the submarkets depending on their spatial distributions, and prices of these services and resources would also vary between the submarkets due to different capitalisations. In such a case, distribution of public services and resources might be highly dependent on the public’s abilities to pay for housing, rather than based on their needs for, consumptions of, or expenses on each specific service or resource.

Therefore, this study aims to examine the existence of housing submarkets by price bands, and consequently, explore the potential differences in the availabilities, prices and trade-offs of public services and resources, in particular, job accessibility and environmental quality, between the submarkets. Greater London was used as the case metropolitan region, and a database of structural, neighbourhood, environmental and accessibility attributes of the sample properties was built for spatial analysis and hedonic price modelling. While this study does not debate on equity judgements, i.e., who should get what, findings of this study will shed light on the role of the housing market in equity and/or inequity in distributions of public services and resources in metropolitan regions.

The paper is structured as follows: Section 2 describes the dataset and variables used in this study; Section 3 details the steps of defining submarkets by price bands and examining their existence; Section 4 gives the final hedonic price models accounting for spatial autocorrelation; Section 5 compares the submarkets; and Section 6 concludes the paper.

2. DATASET

2.1. Case city and sample properties

Greater London was used as the case metropolitan region for this study, and house price data was collected from the Price Paid Data (HM Land Registry, 2017), which contains sales prices of properties in England and Wales submitted to Her Majesty’s Land Registry for registration. In total, 85732 sale prices were registered in Greater London during the year 2011 and they were used for this study. The year 2011 was chosen since most of the available data for socio-economic information of London were based on the UK 2011 Census (see Section 2.3).

2.2. Structural attributes

Due to the unavailability of Ordnance Survey’s AddressBase data through Edina DigiMap for academic research during the time of this study, it was not possible to link each property sale price to building features on map to estimate the floor area and height of the property or the size of the plot. Thus, only property type, tenure type and whether new build, which were provided in the Price Paid Data, were used as structural attributes (Appendix 1).

2.3. Neighbourhood attributes

Neighbourhood attributes were constructed based on the UK 2011 Census data (Office for National Statistics, 2017a). A list of the used attributes can be found in Appendix 1. All the attributes were on Lower Layer Super Output Area (LSOA) level except the secondary school Ofsted rating which was on ward level. Values of these neighbourhood attributes were attached to the house price data according to the LOSAs and wards that the properties were located in.

As would be expected, many of the neighbourhood attributes were highly correlated with each other. To reduce collinearity between independent variables to be entered into the hedonic price models, principal component analysis was used to identify major dimensions of associations between these neighbourhood attributes, and eight principal components were produced to replace the variables. Table 1 lists the components with interpretation.

Table 1. The principal components of neighbourhood attributes.

Component	Variation explained	Cumulative variation explained	Attributes with high positive loading	Attributes with high negative loading	Interpretation
Component 1	25.2%	25.2%	car ownership, home ownership, % couple households, % detached and semi-detached houses, % aged 45-64,	% household without cars, % flats, % one person household, population density, % aged 16-44, % property rented	Neighbourhoods with higher car and home ownerships, more couple households and in less populated areas
Component 2	18.6%	43.8%	% people with day-to-day activities limited, % people with fair or bad health, % people with no or low qualifications, unemployment	% people with day-to-day activities not limited, % people with good health, % people with high qualifications, employment	Neighbourhoods where residents are less healthy, less educated, and less employed

			rate	rate	
Component 3	8.5%	52.3%	% black people and people of mixed ethnic groups, % lone parent household, % aged 0-15, unemployed rate		Neighbourhoods with more black and mixed-ethnic residents, and more children
Component 4	7.9%	60.2%	% white people, % UK born people,	% Asian, % people with other qualifications	Neighbourhoods with more white and native residents
Component 5	5.6%	65.9%	Ofsted primary school rating, Ofsted secondary school rating	KS2 Assessment score, Level 3 score	Neighbourhoods with schools of lower performances
Component 6	5.0%	70.9%	% people with Level 3 qualifications, % school children and full-time students	employment rate	Neighbourhoods with more university students
Component 7	4.0%	74.9%	% terraced house, % household with one car		Neighbourhoods with more typical mid-class households
Component 8	3.2%	78.1%	% household spaces with no usual resident, crime rate		Neighbourhoods that are less safe

2.4. Accessibility attributes

Accessibility attribute used in this studies focused on accessibility to jobs, which is of main interest to this study. A list of the attribute can be found in Appendix 1. All attributes were on LSOA level. Apart from travel time, destination and origin indicators to employment centres by public transport/walk, by cycle and by car obtained from Department for Transport (2017a), we also calculated accessibility to jobs of the seven NS-SeC categories (Office for National Statistics, 2017b) by car based on Hansen’s original formula (Hansen, 1959), taking into account travel time and number of jobs.

We also included attributes that describe the Public Transport Accessibility Level (PTAL) in Greater London, which is a measure of the accessibility of a point to the public transport network, taking into account walk access time and service reliability, number and frequency (Transport for London, 2017).

2.5. Environmental attributes

Environmental attributes used in this studies include air quality, noise, land cover and accessibility to parks. A list of the attribute can be found in Appendix 1. Values of air quality and noise attributes were assigned to each property by overlaying air quality and noise maps (Department for Environment, Food and Rural Affairs, 2017; Greater London Authority, 2017; Department for Transport, 2017b) onto location points of properties in GIS. Since we did not have exact property location data, centroids of post code units where the properties were located were used as their location points.

Land cover ratios within each LSOA were calculated in GIS based on Ordnance Survey MasterMap (Ordnance Survey, 2017) and Greenspace Information for Greater London’s open space data (Greenspace Information for Greater London, 2017a). Data on accessibility to parks by four park categories and to nature were obtained from Greenspace Information for Greater London (2017b), and the measures were on ward level.

3. EXAMINING THE EXISTENCE OF SUBMARKETS BY PRICE BAND

The examination followed the procedure introduced by Schnare & Struyk (1976) which has been commonly used in subsequent studies for testing submarket existence. We first defined a number of potential submarkets by price bands, and then defined the specification of the hedonic models to be developed. Finally, we tested for significant differences in model parameters between the submarkets, which indicate differences in monetarisation of housing attributes between the submarkets, and thus the existence of the submarkets.

3.1. Defining the potential submarkets

To define the submarkets in an a priori manner by price bands, the number of submarkets needed to be determined first. According to the 2011 Great British Class Survey (Savage et al., 2013), households in the UK can be divided into seven social classes, among which four housing groups can be identified, as shown in Table 2. Without more relevant stratification schemes available, assuming four submarkets were thought to be appropriate for the purpose of this study. Nevertheless, it should be noted that the housing market in London is distinct from the rest of the UK, and the average house prices could be expected to be much higher than those reported in Savage et al. (2013).

Table 2: The four housing groups based on results of the Great British Class Survey (Savage et al., 2013).

Housing group	Average house price	Social class
1	£325k	Elite
2	£163k - £177k	Established middle class, Technical middle class
3	£127k - £129k	New affluent workers, Traditional working class
4	N/A (likely to rent)	Emergent service workers, Precariat

To determine the range of each price band that demarcates the submarkets, optimal locations of the three price breakpoints were estimated, by minimising the sums of squared errors of the four resulted hedonic price models (one for each resulted submarket) over all possible alternatives, to achieve the best fit to the data. The calculation was run in R and the package 'strucchange' was used (Zeileis et al., 2002). To reduce calculation load, smaller datasets, each

containing 10000 house sales randomly selected from the full sample with a limited number of key attributes, were used for the calculation. Five random samples each with two different sets of key attributes were tested and their results compares. The ten sets of estimated breakpoints have similar locations. Based on these locations, we defined the four submarkets to be tested: Submarket 1: below £190,000, 14610 properties; Submarket 2: £190,000 - £320,000, 33770 properties; Submarket 3: £320,000 - £595,000, 24471 properties; Submarket 4: above £595,000, 12881 properties (Figure 1).

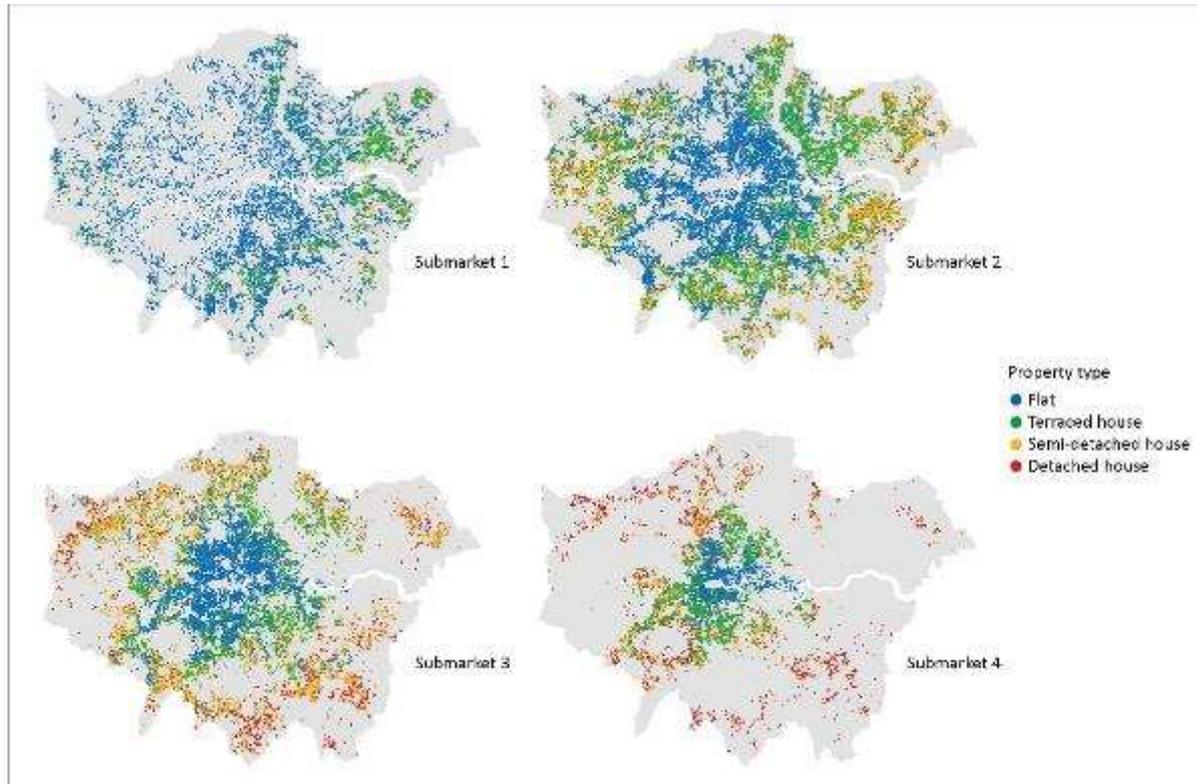

Figure 1. The four submarkets by price band: Submarket 1: below £190,000, 14610 properties; Submarket 2: £190,000 - £320,000, 33770 properties; Submarket 3: £320,000 - £595,000, 24471 properties; Submarket 4: above £595,000, 12881 properties.

3.2. Defining the model specification

We used the natural logarithm of house price as the dependent variable and kept the independent variables untransformed. For one reason, we were interested in comparing marginal prices of housing attributes in relative to the house prices (e.g., per unit increase in air quality costs a certain percentages of the house price) between submarkets, for the other, this is a usual assumption of functional form in the absence of indications from the literature (Day, 2003).

With the existence of submarkets, it would be expected that model specifications that best describe the characters of the submarkets would differ from each other. However, to be able to compare the marginal prices of housing attributes between submarkets, consistency in model specifications across the submarkets was needed. For this purpose, we first ran an ordinary least square (OLS) regression with backward stepwise variable selection for each submarket, to get model specifications that fit the individual datasets. Then we adjusted variable selections in each model, controlling multicollinearity and significance, as well as taking into account research interests, to achieve the same model specification for the four submarkets. Table 3 shows the achieved model specification and the resulted models details. It should be noted that R²s of the submarket models are very low. This is probably due to the relatively narrow range of price in each submarket, which means even small variations in price due to error could lead to a low R².

Table 3. Hedonic price models for the full sample and the four submarkets, using ordinary least square regression.

Variable	Full sample	Submarket 1	Submarket 2	Submarket 3	Submarket 4
Constant	Coefficient	Coefficient	Coefficient	Coefficient	Coefficient
Whether detached house (1 = yes, 0 = no)	11.504	11.929	12.341	12.536	11.027

3.3. Testing differences in model parameters between the submarkets

Differences in model parameters between the four submarkets were tested using Chow test. The test statistic is given by: RSS_c

$$F = \frac{RSS_c - RSS_i - RSS_j}{k} \times \frac{N_i + N_j - 2k}{RSS_i + RSS_j} \quad (1)$$

where RSS_i , RSS_j and RSS_c are the residual sum of squares of the models of Submarket i , Submarket j and the combined model respectively, N_i is the number of observations in Submarket i and N_j is the number of observations in Submarket j , and k is the number of model parameters.

Table 4 shows the Chow test results. All the F values are larger than the critical values, suggesting that significant differences in model parameters exist between all the four submarket.

The Chow test results were further confirmed by comparing the sum of the weighted standard errors of the submarket models to the standard error of the full-sample model. The sum of the weighted standard errors of the submarket models is calculated by:

$$SE_{sw} = \frac{N_1 - k}{\sum(N_j - k)} SE_1 + \frac{N_2 - k}{\sum(N_j - k)} SE_2 + \dots + \frac{N_j - k}{\sum(N_j - k)} SE_j \quad (2)$$

where N_j is the number of observations in Submarket j and there are j submarkets, and k is the number of model parameters.

The result shows a large reduction in standard error from 0.38 of the full-sample model to 0.19 with the four submarkets. Thus, there is clear evidence of the existence of submarkets defined by the four price bands, and that marginal prices of housing attributes are not constant between the four submarkets.

4. SPATIAL REGRESSION

Since spatial autocorrelation would normally be expected in house prices (Dubin, 1992; Pace & Gilley, 1997), diagnostics for spatial autocorrelation was conducted for each of the four submarket OLS regression models, as well as for the full-sample model. The Diagnostics was conducted in GeoDa (Anselin et al., 2006), and a distance-based spatial weight with a threshold distance of 200m was used.

The results show that for all the models, both the Lagrange multiplier tests for spatial error dependence and for spatial lag dependence were highly significant, suggesting existence of spatial autocorrelation. Since in our study, spatial autocorrelation was considered a nuisance, spatial error models were used as the alternative to OLS models to address the issue. Table 5 shows the spatial error models for the four submarkets and the full sample. As expected, the parameters do not differ remarkably from those of the counterpart OLS models in Table 3. However, the increased values of R² and log likelihood and the decreased values of Akaike info criterion and Schwarz criterion of the spatial error models indicate improvements in general model fit.

Table 5. Hedonic price models for the full sample and the four submarkets, accounting for spatial autocorrelation using spatial error regression.

5. COMPARING SUBMARKETS

5.1. Availabilities of job accessibility and environmental quality

Table 6 shows the means and standard deviations of the variables for the full sample and the four submarkets. For job accessibility, Public Transport Accessibility Level, number of employment centres with at least 500 jobs available by public transport/walk, number of employment centres with at least 500 jobs available by cycle, and index of job accessibility by car considering travel time and number of jobs all increased from Submarket 1 to Submarket 4, while number of employment centres with at least 100 jobs available by public transport/walk and number of employment centres with at least 100 jobs available by cycle remained largely the same across the four submarkets. The general increase in job accessibility from Submarket 1 to Submarket 4 is consistent with the spatial distributions of the four submarkets as shown in Figure 1. Properties became more centrally located in the higher price bands, and there were more public transport services and larger employment centres in the central areas.

Table 6. Descriptive statistics of the variables for the full sample and the four submarkets

--	------	---	------	-----	------	-----	------	-----	------	-----

For environmental quality, percentage of homes with deficiency in access to nature decreased from Submarket 1 to Submarket 4. Nevertheless, Submarket 1 has higher ratio of open green spaces and lower ratio of buildings in land cover than the other submarkets. Both annual average NO_x concentrations and PM2.5 concentrations increased from Submarket 1 to Submarket 4. Again, these environmental quality differences are linked to the more central distributions of properties in the higher price bands, as there were more built-up areas and higher air pollutions in the central areas but with a good coverage of Sites of Importance for Nature Conservation. Annual average road noise level and rail noise level were largely consistent across the four submarkets, as in each submarket only a small part of the properties with close proximity to major roads or railways were affected by the noise.

Figure 2 compares the trade-offs between availabilities of job accessibility and environmental quality in the four submarkets, using number of employment centres with at least 500 jobs available by public transport/walk and annual average NO_x concentrations as indices. It shows that in all the four submarkets, number of employment centres increased with NO_x concentrations, and the increasing rates were generally the same across the four submarkets. However, properties in the higher price bands were more likely to be in the high-accessibility-and-high-pollution end.

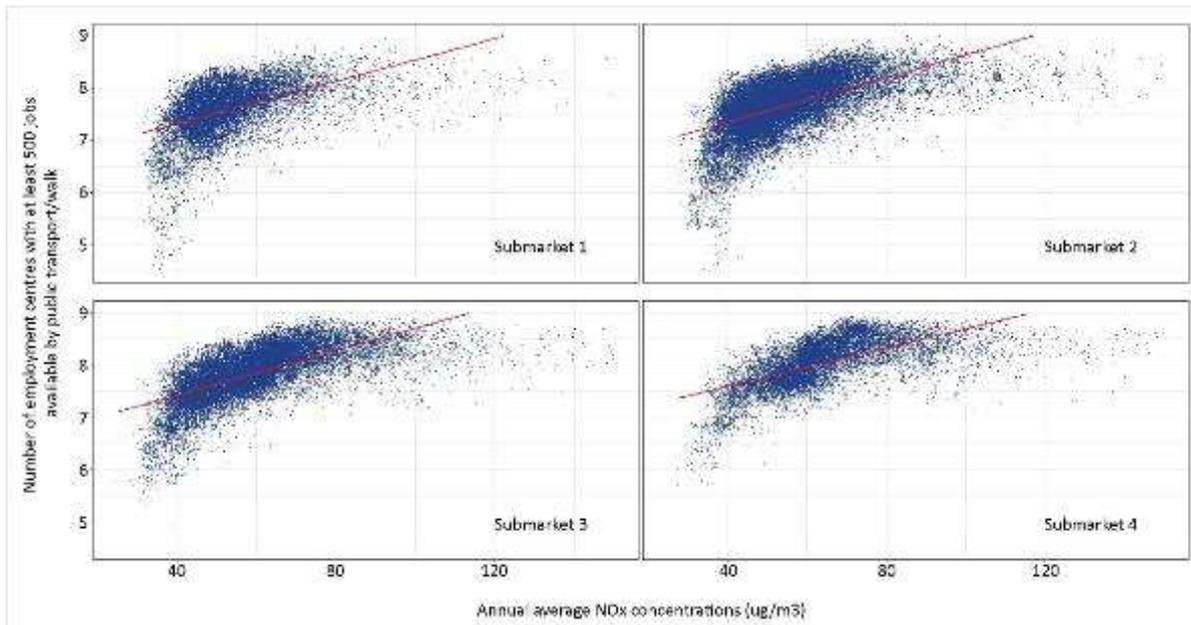

Figure 2. Trade-offs between availabilities of job accessibility and environmental quality in the four submarkets, using number of employment centres with at least 500 jobs available by public transport/walk and annual average NO_x concentrations as indices.

5.2. Marginal prices of job accessibility and environmental quality

Hedonic price models in Table 5 show that property type was the most important attribute affecting house price in all the four submarkets. Being a house instead of a flat could lead to around 10% to 20% increase in house price in Submarket 1, 2 and 3, and more than double the price in Submarket 4.

For job accessibility, one score increase in Public Transport Accessibility Levels led to 0.8% increase in house price in Submarket 1, but 0.4%, 0.5% and 3% decrease in Submarket 2, 3 and 4 respectively. This might be associated with the distribution of property type in each submarket. As shown in Figure 2, in Submarket 2, 3 and 4, properties in the central areas where Public Transport Accessibility Levels were higher were mostly flat, while in the outer areas properties were mostly terraced houses of which the prices were higher, and in the peripheries, properties were mostly detached and semi-detached houses of which the prices were the highest. Given that property type had stronger impacts on house price in these submarkets, it masked the positive impacts that Public Transport Accessibility Levels could have on house price. On the other hand, properties in Submarket 1 were dominantly flats so the impact of property type was much weaker.

Significances of the impacts of available employment centres varied across the four submarkets, as well as the signs of them. In general, it suggests that increase in medium employment centres available at a reasonable travel time by public transport slightly increased the house prices in Submarket 2 and 3, and largely increased the house prices in Submarket 4, but slightly decreased the house prices in Submarket 1. Whereas, increase in small employment centres available at a short distance slightly decreased the house prices in Submarket 3 and to a larger extent in Submarket 4.

The index of job accessibility by car considering travel time and number of jobs had a much clearer sign. One score increase in the index led to 0.5%, 1.2%, 1.3% and 5.5% increase in house price in Submarket 1, 2, 3 and 4 respectively, indicating higher marginal prices even in relative to the house prices in the higher price bands.

For environmental quality, increase in homes with deficiency in access to nature in the ward by 1% led to very slight decreases in house price in Submarket 1, 2, and 3 by around 0.01% to 0.02%, and slight decreases in house price in Submarket 4 by 0.1%. Similar sign was found in ratio of open green space in land cover, where 1% increase in open green

space in land cover led to 0.02% increase in house price in Submarket 2, 0.04% increase in Submarket 3, and a larger increase of 0.1% in Submarket 4. Thus, in general, marginal prices of nature and open green spaces were higher in the higher price bands even in relative to the house prices.

Significances of the impact of air pollution and noise varied across the four submarkets, but in general, negative relationships between house prices and them were indicated. Decrease in annual average NOX concentrations by 1 ug/m³ led to increase in house price by 0.1% in Submarket 1, 0.03% in Submarket 3, and 0.3% in Submarket 4. Decrease in annual average rail noise level by 1 Lden led to increase in house price by 0.2% in Submarket 1 and 2, 0.1% in Submarket 3, and 0.6% in Submarket 4. Thus it indicates that marginal prices of air quality and sound environment were highest in Submarket 4 even in relative to the house prices, and were slightly higher in Submarket 1 than in Submarket 2 and 3.

6. CONCLUSIONS

Using Greater London as the case metropolitan region, this study examined the existence of housing submarkets by price bands, and explored the differences in the availability, prices and trade-offs of job accessibility and environmental quality between the submarkets.

Four submarkets were identified, defined by price bands of below £190,000, £190,000 - £320,000, £320,000 - £595,000 and above £595,000. In general, job accessibility increased from submarkets of low price bands to high price brands, whereas, air quality and availability of open green spaces decreased by the price bands. Similar trade-offs between availabilities of job accessibility and environmental quality in the four submarkets were indicated. However, properties in the higher price bands were more likely to be in the high-accessibility-and-low-environmental-quality end.

In general, marginal prices of job accessibility were higher in the higher price bands even in relative to the house prices. Similar differences between the submarkets were found for marginal prices of nature and open green space. Marginal prices of air quality and sound environment were highest in the highest price band even in relative to the house prices, and were slightly higher in the lowest price bands than in the medium bands. Thus, there seemed to be no trade-off between marginal prices of job accessibility and environmental quality across the four submarkets, and generally both marginal prices of job accessibility and environmental quality were higher in the higher price bands.

Results of this study indicate that households with lower housing budgets in Greater London were more likely to have lower job accessibility but enjoy higher environmental quality. They were also more likely to pay less, in relative to the total house price, for both job accessibility and environmental quality.

ACKNOWLEDGEMENTS

This study was funded by the Economic and Social Research Council (UK) under grant number ES/N011481/1. It was part of the ASTRID (Accessibility, Social justice and Transport emission Impacts of transit-oriented Development) project which was jointly funded by the ESRC (UK), NWO (Netherlands) and FAPESP (Brazil). The authors would like to thank all the organisations that provided valuable data to this study. Special thanks to Dr. John Pritchard (Centre for Transport Studies, University of Twente) for calculating indices of accessibility to jobs of the seven NS-SeC categories by car.

APPENDIX 1. HOUSING ATTRIBUTES USED IN THIS STUDY.

Housing attributes	Sources
Structural attributes	
Property type (flat, terraced house, semi-detached house, detached house)	HM Land Registry: Price Paid Data
whether new build	HM Land Registry: Price Paid Data
Tenure type (leasehold or freehold)	HM Land Registry: Price Paid Data
Neighbourhood attributes	
percentage of people aged 0-15 in the LSOA in 2011	ONS Mid-year estimates
percentage of people aged 16-29 in the LSOA in 2011	ONS Mid-year estimates
percentage of people aged 30-44 in the LSOA in 2011	ONS Mid-year estimates
percentage of people aged 45-64 in the LSOA in 2011	ONS Mid-year estimates
percentage of people aged 65+ in the LSOA in 2011	ONS Mid-year estimates
number of people per hectare in the LSOA in 2011	Census 2011
percentage of couple household with dependent children in the LSOA in 2011	Census 2011
percentage of couple household without dependent children in the LSOA in 2011	Census 2011
percentage of lone parent household in the LSOA in 2011	Census 2011
percentage of one person household in the LSOA in 2011	Census 2011
percentage of White people in the LSOA in 2011	Census 2011
percentage of people of mixed/multiple ethnic groups in the LSOA in 2011	Census 2011
percentage of Asian/Asian British in the LSOA in 2011	Census 2011
percentage of Black/African/Caribbean/Black British in the LSOA in 2011	Census 2011
percentage of UK-born people in the LSOA in 2011	Census 2011
percentage of properties owned outright in the LSOA in 2011	Census 2011
percentage of properties owned with a mortgage or loan in the LSOA in 2011	Census 2011
percentage of properties social rented in the LSOA in 2011	Census 2011
percentage of properties private rented in the LSOA in 2011	Census 2011
percentage of household spaces with no usual resident in the LSOA in 2011	Census 2011
percentage of detached whole houses or bungalows in the LSOA in 2011	Census 2011
percentage of semi-detached whole houses or bungalows in the LSOA in 2011	Census 2011
percentage of terraced houses or bungalows in the LSOA in 2011	Census 2011
percentage of flats, maisonettes or apartments in the LSOA in 2011	Census 2011
number of property sales per 100 properties in the LSOA in 2011	Census 2011
percentage of economically active people in the LSOA in 2011	Census 2011
percentage of economically active people as employees in the LSOA in 2011	Census 2011
percentage of economically active people as unemployed in the LSOA in 2011	Census 2011
employment rate in the LSOA in 2011	Census 2011
unemployment rate in the LSOA in 2011	Census 2011
percentage of people with no qualifications in the LSOA in 2011	Census 2011
percentage of people with Level 1 qualifications as the highest level of qualifications in the LSOA in 2011	Census 2011
percentage of people with Level 2 qualifications as the highest level of qualifications in the LSOA in 2011	Census 2011
percentage of people with apprenticeship as the highest level of qualifications in the LSOA in 2011	Census 2011
percentage of people with Level 3 qualifications as the highest level of qualifications in the LSOA in 2011	Census 2011
percentage of people with Level 4 qualifications as the highest level of qualifications in the LSOA in 2011	Census 2011
percentage of people with other qualifications as the highest level of qualifications in the LSOA in 2011	Census 2011
percentage of school children and full-time students age 18 and over in the LSOA in 2011	Census 2011
percentage of people with day-to-day activities limited a lot in the LSOA in 2011	Census 2011
percentage of people with day-to-day activities limited a little in the LSOA in 2011	Census 2011
percentage of people with day-to-day activities not limited in the LSOA in 2011	Census 2011
percentage of people with very good or good health in the LSOA in 2011	Census 2011
percentage of people with fair health in the LSOA in 2011	Census 2011
percentage of people with bad or very bad health in the LSOA in 2011	Census 2011
rate of crimes per thousand population in the ward in 2010/11 year	Safestats Query
average point score of pupils eligible for KS2 Assessment in the LSOA in 2011	Department for Education
average GCSE and equivalent point score per pupil in the LSOA in 2010/11	Department for Education

average Level 3 QCA point score per entry	Department for Education
weighted Ofsted primary school rating in the LSOA 2014	calculated using data from Ofsted
weighted Ofsted secondary school rating in the Ward 2014	calculated using data from Ofsted
percentage of household that has no car or van in the LSOA in 2011	Census 2011
percentage of household that has 1 car or van in the LSOA in 2011	Census 2011
percentage of household that has 2 or more cars or vans in the LSOA in 2011	Census 2011
number of cars per household in the LSOA in 2011	Census 2011
Accessibility attributes	
average score of Public Transport Accessibility Levels in the LSOA in 2014	Transport for London
percentage of people in Public Transport Accessibility Level 0-1 (poor access) in the LSOA in 2014	Transport for London
percentage of people in Public Transport Accessibility Level 2-3 (average access) in the LSOA in 2014	Transport for London
percentage of people in Public Transport Accessibility Level 4-6 (good access) in the LSOA in 2014	Transport for London
travel time to nearest employment centre by public transport/walk LSOA 2011	Department for Transport
travel time to nearest employment centre by cycle LSOA 2011	Department for Transport
travel time to nearest employment centre by car LSOA 2011	Department for Transport
number of employment centres with at least 100 jobs available by public transport/walk within a reasonable time LSOA 2011	Department for Transport
number of employment centres with at least 500 jobs available by public transport/walk within a reasonable time LSOA 2011	Department for Transport

1319 MIDDLE INCOME HOUSING ISSUES IN INDIA WITH SPECIAL FOCUS ON NEW TOWNS

ABSTRACT

The post 1990s period in India is marked by a housing revolution, owing to the liberal approach of the government towards the economy, and the housing demands of the expanding middle income group (MIG). Much of this demand is attributed to factors like a rise in urban immigration, disintegration of the joint family structure, congested living conditions and higher expectation of the new middle class. The incapacity of the government to provide adequate living spaces for the increased urban population has led to the breakdown of infrastructure and crowding within cities. The outcome is the steady growth of informal settlements in the cities in the form of slums and squatters, evident from the statistics that shows that slum population in India rose from 75 million in 2001 to 93 million in 2011. The economic reform of the country after 1990 period marked the onset of the affluent middle income groups (MIG), often designated as the upper middle class, owing to the better paid jobs in the emerging service sector. Simultaneously with the onset of economic liberalization policies, the Indian market was flooded with newly available consumer items. The steady growth of income and credit-based consumption patterns augmented mass consumption among the MIG, who had previously been constrained by incomes and savings. This change largely transformed the housing market where demand for high end and luxurious housing eclipsed affordable housing. In this paper, based on case studies, we focus our attention on the housing issue of the middle income groups, in the context of two major cities of India, Mumbai and Kolkata. We further discuss on the role of new towns in solving the housing crisis in the existing mega cities, with special reference to Navi Mumbai and Rajarhat New township respectively. The inability to define the MIG throughout the country has hindered the formulation of a viable housing policy targeting them. Easy availability of loans and credit-based purchasing power has made MIG housing more profitable for the construction companies. However, current pricing patterns in the major metro cities still makes the available housing stocks beyond their reach. Though newer and comparatively cheaper housing stocks are being created in the new towns, due to the distant location from the major workplaces and the weaker economic pull of the newly formed townships, these housing stocks mostly remain less attractive for the buyers. Although allied to the two major metropolises of the country, Navi Mumbai and Rajarhat new towns have not satisfactorily achieved their expected growths as new developments.

1363 DETERMINING THE IMPACT OF 'CURB APPEAL' ON THE PRICE OF SINGLE-FAMILY HOMES USING GOOGLE STREET VIEW AND SPATIAL HEDONIC REGRESSION

ABSTRACT

Price of a house is determined by several structural characteristics (number of bedrooms, number of bathrooms, floor material, roof material, availability of parking, heating and cooling facilities in the house, square footage, etc); locational characteristics (school districts, crime score, walk score, transit score) and environmental characteristics (air pollution, water pollution etc). Apart from these traditional factors contributing to the price of a house, the external appearance of a house or its 'curb appeal' plays an important role in determining its price. Thus, the objective of this study is to (i) quantify 'curb appeal' and determine its influence on the house price, (ii) determine the relation between curb appeal and the other characteristics of the house like the square footage, etc. The study is based on single-family homes sold in selected neighborhoods of Dorchester, Hyde Park, Jamaica Plain, Mattapan, Roslindale, Roxbury, West Roxbury in Boston, Massachusetts during 2015-2017. To quantify the 'curb appeal', images of the single-family homes in those selected neighborhoods were collected from Google Street View. A rubric was developed to classify the external appearance of the house based on the condition of the doors and windows; condition of the paint and roof of the house; condition of the lawns, garden, and landscaping; and overall aesthetics of the house (like painted fences, well-maintained driveways, walkways, etc). On the basis of the rubric, each house was given a score as 1=below average, 2=average, 3=good, 4=excellent. Zillow API was used to collect information on the house price, locational and structural characteristics of the house. A spatial hedonic regression model is developed to understand the impact of 'curb appeal' in the house price. Furthermore, the relationship between curb appeal and structural characteristics of the house, relation between the number of days a house is in the market and its curb appeal are shown in an exploratory data analysis framework. : Google Street View, Spatial Hedonic Regression, Curb Appeal

1500 WHAT PROJECTS FOR AN URBAN INTEGRATION? URBAN MODELS AND ARCHITECTURAL PROJECTS ON REHOUSING PROGRAMS IN PORTUGAL

ABSTRACT

Spatial segmentation of the labour market of informal workers within the metropolitan is observed globally. In India it is not only compartmentalised on gender, caste, ethnic lines but also geographically segmented by the creation of spatially disjointed markets. The present paper argues that the labour market for informal workers is segmented into smaller labour markets separated by commuting (home-work) distance. Hence, the present paper has two objectives. The first is to map spatially fragmented labour market of smaller scale within a big metropolitan market. the second objective is to understand the determining factors (age, gender, social and religion groups, migration status, educational qualifications, employment types and residential locations) forhome-workplace distance. The present paper is based on case study of labour market in Kolkata. This paper is based on data collected from field survey of 1500 households located in 6 different slum clusters. The quantitative focus is on the variable like employment pattern, workers characteristics and human capital, commuting pattern (home-workplace distance) taken from the survey. For the present study, only workers with fixed workplaces are considered. This is only to reduce the complexity in conceptualising spatial labour market boundaries. In the study it is seen that the average commuting distance (home-workplace distance) of workers are much shorter than the metropolitan-wide scale. This is true for all the locations surveyed. Often the employment field around these 6 localities (residential areas) are non-overlapping. It is indicating towards the fact that the workers in the informal employment are spatially constrained. It creates small, segmented highly localised markets within the metropolitan city. Workers in central localities travel much shorter distance compared to non-central localities. It is seen that women’s spatial access is more constrained compared to men’s. Similarly, the self-employed workers have much spatially confined markets compared to regular and casual wage workers. The home-workplace distance increases with increasing level of education.

1720 A MUNICIPALITY DSS - ASSESSING IMPACTS OF HOUSING POLICY DECISIONS**Marques, J.L. *, Borges, M., Wolf, J.**¹ Department of Social, Political and Territorial Sciences (DCSPT), Research Unit on Governance, Competitiveness and Public Policies (GOVCOPP)* E-mail: jjmarques@ua.pt, Tel +351 234 370200**ABSTRACT**

The aim of this paper is to present a conceptual Decision Support System (DSS) to model the drivers of urban transformation, with the main purpose of assessing the impact of policy decisions on the territory. This integrated tool encompasses six main drivers: two at the regional level (economy and demography) and four at the municipal level (location preferences, housing, general interest services and infrastructures). This paper is based on ongoing research and thus presents a prototype, which considers three interdependent key dimensions of the urban system: i) population – estimated at sub-municipal scale, using a cohort survival method; and ii) housing – analysed in terms of its characteristics (age of dwellings, type of occupation, etc.), using a life cycle approach. The development of these models is challenging, not only regarding the collection of primary data, but also methodologically, given that all the dimensions are dependent and interact in a complex set of territorial dynamics. These aspects are more relevant as we move towards a micro scale analysis. The estimation of the population is stimulating not only for less-developed countries, where, usually, there are problems related to the scarcity and quality of demographic data, but also for more-developed countries, mainly when a more disaggregate spatial level is considered. One of the major challenges is estimating net migrations, but there are more: heterogeneity of fertility across age groups; strong spatial dependence; time trends of fertility rates, which are heterogeneous in terms of space and age groups. These arguments justify the integration of other socio-economic components as a condition to perform accurate demographic estimations. The integrated methodology presented in this paper was applied to a Portuguese municipality, as an example of the importance of analysing and assessing territorial dynamics. This work is policy oriented and aims to support planning strategies in the context of the physical morphology, and socio-economic and environmental outcomes. In other words, it allows evaluating the consequences of certain policy decisions under certain restrictions and exogenous scenarios. The main outcomes of this work concerns the link between public policy decisions, individual choices and spatial configurations of the urban structures.

Keywords: DSS; demographic projections; housing; general interest services, public policy.**1. INTRODUCTION**

Urban systems are constantly changing, according to the rise of new patterns of mobility, transport or communication systems, cultural preferences or (spatial) social and economic relations. This constant change has led to increasingly complex and fragmented urban systems, where different patterns and rhythms coexist: in the EUA much of the urban growth has, for example, been done in undeveloped and low-density areas in ways that often favour the availability of space (urban sprawl), while in Europe sprawl coexist with dense and traditional urban centres (Cheshire et al., 1999).

The changes in urban system are also very dependent on the scale. At the broad scale, the urban system have been marked by a growing polarization, with an unproportioned share of growth occurring in large agglomerations which are increasingly decoupled from their regional context [a trend Stratmann (2011) has called the deregionalization of urban development], while many of the smaller urban areas are growing more slowly or even declining (Turok & Mykhnenko, 2007). At the urban scale, the main trend has been towards a diffuse development, dominated by sprawl, the rise of new centralities or a fragmented and, often chaotic, development (Antrop, 2004; Carvalho, 2013; Glaeser, 2011). Coexisting with sprawling land-use, many consolidated urban centres have been subject to a major gentrification push, influenced by tourism and the substitution of residential uses of space with economic ones (Pinkster & Boterman, 2017). Underlying these phenomena, are non-Euclidian and multidimensional spaces (Marques, 2012) where cultural preferences and lifestyle choices spread in a more networked and less predictable ways. Therefore, different territorial context cannot be analysed in a strictly hierarchical way, but must be understood as nodes in relational contexts, where the meaning and the composition of these relations define the relevant scale (Murdoch, 2006).

Notwithstanding this complexity, there has been constant attempts to understand these changes which have, typically, been focussed on two aspects: the intrinsic character of a given space (locality – meaning the analysis of patterns of spatial heterogeneity); the way in which it relates to the broader context (location – meaning the analysis of spatial dependency structures) (Marques, 2012, Bhattacharjee et al., 2012). Other approaches have focussed the broad structural changes which explain the different historical cycles: growth, suburbanization, decline and (eventually) reurbanization (van den Berg et al. 1982; Champion 2001; Hall 1971). The main drivers of urban change, assumed by these models, are economic, technological, demographic or environmental and their consequences are complex patterns.

From a planning perspective, the main challenge lies in understanding these trends, and the capacity to generate strategies and governance approaches that can influence them in a way that helps to achieve broad public policy goals such as quality of live, equity or sustainability. Given the complexity and multidimensionality of urban transformation, instruments for aiding urban policies are challenged to find methods that, on the one hand, are able to capture the logic of these spatial structures (heterogeneity and spatial interaction) and monitor their development and, on the other hand,

allow understanding the impact of different policy decisions. In this paper, the potential, limitations and requirements of a Decision Support System will be discussed, that aims to model the relations between the main drivers of urban transformation. This discussion will be based on the presentation of a prototype, that will allow to highlight some of the methodological and conceptual challenges from a practical perspective.

The paper is divided into four parts: the first one briefly reviews Decision Support Systems (DSS), its different approaches and assumptions; the second one discusses the use of DSSs for modelling urban systems; and the third presents a prototype of a DSS, that links housing and demography and that has been applied and, finally, the main challenges and further work is discussed.

2. DECISION SUPPORT SYSTEMS TYPES

Decision Support Systems (DSS) have been developed and implemented since the mid-1960s (Power, 2008). Over time, the concept has evolved very quickly, in order to integrate an increasing number of dimensions that interact and have multiple impacts [(in)direct, (in)tangible, (sub)objective, short- or medium-term] on urban development and, thus, on decision-making. The application has assumed the most diverse contexts, from the operational to strategic management (Arnott et al, 2005; Eom et al, 1990; McCosh et al, 2006). To comprehend a DSS there must be a complex debate about the main dimensions that should be part of such a system. Power (2008) and Hättenschwiler (2001) present an interesting and complementary work of what should be the design of a DSS. Power concentrates on the inputs that support a decision and shows these can be associated with: i) using ICTs to improve and accelerate the process; ii) information gathering through document analysis; iii) time series analysis to produce relevant indicators; iv) optimization and modelling to guide the definition of actions; and v) using specialized knowledge. Hättenschwiler, on the other hand, focuses on the decision-makers as a user of this information who may have multiple roles. As such, he defines three large groups of DSSs: i) passive, which use information to aid the process but have no influence on decision-making; ii) active, who are decisive in defining and choosing solutions; and iii) cooperative, whose decisions, based on structured information, are consecutively discussed until reaching a consensual definition of the most appropriate actions.

The context in which DSSs are applied explains the adopted approaches. It is broadly recognized that a DSS should follow an interdisciplinary perspective and an integrated structure able of dealing with: i) the available information; ii) the multidimensionality of the decision context; iii) the uncertainty of the evolution pattern of the main drivers of the decision; iv) the need to combine objective and subjective issues; and v) the perceptions, expectations and preferences of decision makers and overall community.

The assumption of such integrated dynamic suggests DSSs play a decisive role in the way information is collected, analysed and interpreted. Among the challenges, besides data collection (documentary, statistical sources, or surveys) and the development of formal analytical models, are the implementation of strategies or methodologies that deal with cognitive and dispersed knowledge accumulated by different agents, by giving meaning and transforming it into decision inputs. As a proposal to link the various contributions in terms of decision support, a classification of categories of DSSs is presented. This proposal is structured in three types or levels that depend on the information used and the type of outputs: i) situational (diagnosis); ii) forecasting (prognosis); and iii) interactive (prospective).

The Situational or diagnostic DSSs (*DSS Level 1*) have a strong analytic dimension. They aim to gather and systematize a set of variables that can be transformed into monitoring indicators of the territorial dynamics and the overall strategy, in order to measure the deviations from established goals. The level 2 (*DSS Level 2*) consists in predictive or prognostic DSSs which are supported in forecasts that allow to anticipate decisions that respond to the evolution of an expected future. The models developed here are based on rigorous analytical formalisms and depend on the availability of time series, under the assumption that they are sufficiently representative of the reality. It is also assumed that there are no exogenous variables capable of producing meaningful changes on the time series of the forecast (Marques et al 2016). At the Level 3 (*DSS Level 3*), interactive or prospective DSSs are considered. They have a more complex and interdisciplinary nature. The models developed here provide a systematic mechanism to deal with the complexity, interdependence and subjectivity of information, thus contributing to the formulation of policies where the integration of multidisciplinary activities is of vital importance (Martin and Irvine, 1989, Borges, 2012).

Even though adjusted to decision contexts, ideally a DSS should consider each of the abovementioned levels. In many cases, the development of a DSS is already the outcome of an integrated approach. When dealing with the specific challenges of urban transformation, for example, the different levels that are considered by a DSS allow a broad understanding of the relevant phenomena, therefore improving the decisions-making process. This includes: i) monitoring - levels 1 and 3; (ii) *ex-ante* evaluation - for levels 2 and 3; and, finally, the strategic definition, where all three levels complement each other to assess development strategies, policy options and their impacts.

3. DECISION SUPPORT SYSTEMS FOR MODELING URBAN TRANSFORMATION PROCESSES

In this section, a conceptual approach of a DSS is presented, that is being developed for assessing the impact of a sectoral policy considering key factors in urban transformation processes (figure 1). This approach intends to highlight the challenges in modelling six fundamental urban subsystems: 1. economy, 2. demography, 3. location preferences, 4. housing, 5. general interest services, and 6. infrastructures. The various dimensions are considered in a hierarchical way. In practice, this implies analysing sectoral policies showing, afterwards, the impacts induced on the other dimensions of the urban system. Considering, for example, the case of an active rehabilitation policy, which increases the available housing in certain market segments. This policy, combined with the preferences and economic resources of the

population, will bring changes at many levels. It will, namely, alter the distribution of the population which, in turn, will impact on the provision of infrastructures or general interest services. These changes can be expected to exert a direct influence on the valuation of different areas of the city.

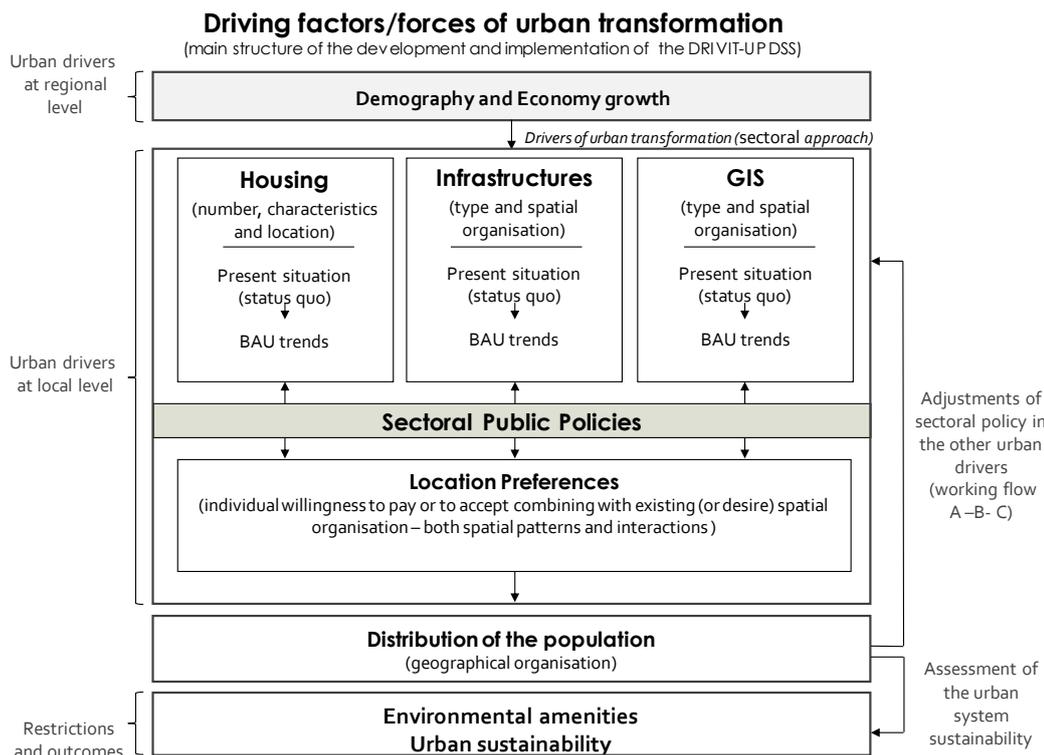

In an operative sense, some subsystems are considered at a more macro (regional) level (1. economy and 2. demography), while others are considered at the micro (municipal) level (3. location preferences, 4 5. services of general interest and 6. infrastructures).

Methodologically, this DSS combines two different types of models: i) formal mathematical and analytical tools, such as econometric models, demographic projections, Bayesian estimation methods, optimization and genetic algorithms; ii) informal approaches for dealing with opinions, individual preferences (e.g. using multi-criteria analysis) and guiding action towards possible future (through foresight methods and techniques). The development of this type of model is challenging, not only concerning data collection, but also methodologically. The design of a DSS has to incorporate the complex set of territorial dynamics, which reflect in the way each dimension interacts and relates (Bhattacharjee et al, 2012). These aspects are even more relevant and critical as we assume a more localized scale of analysis, in the concrete case at the municipal and urban scales.

Generally, the proposed methodology assumed the challenge of developing a decision support tool able to model the main drivers of urban transformations at the local level and therefore to provide a sound and effective decision-making. Recognizing that territorial attractiveness is largely defined by the ability of territories to provide adequate living conditions according to the interests and expectations of the population, it is relevant to understand how public policies and strategic options lead to different territorial configurations and demands. The housing dimension refers both to its physical characteristics and quality and to housing prices, as key dimensions of demand, as preferences are combined with the willingness of households to pay for and support all charges associated with housing. Regarding general interest services (namely public services, health and education facilities) they are expected to answer to the population’s needs, according to the age structure, qualifications and individual preferences. The infrastructure network must also evolve accordingly to supply basic services (accessibility, public water supply and sewage system).

At another level, the economic dimension plays a central role in turning territories more attractive. The demographic component arises as an additional (and complementary) layer, explained either by the importance of the working age population that influences the demand and supply of employment, or by the younger (or older) population, which explains different mortality and fertility rates. In particular, employment issues have a special meaning at the local level, as people also tend to choose their place of residence, in addition to the local amenities, according to employment opportunities. The demographic projections, which at the local level is stimulating and demanding, are the basis of this system modelling. Small-scale estimations (Castro et al. 2015) are relevant for less developed countries, where, often, there are problems related to the scarcity and quality of micro demographic data (mortality, fecundity and migratory flows), but also to more developed countries, as is the case of Portugal, especially when considering such a disaggregated level of spatial analysis. As the natural balance is a component with a low micro-spatial impact, it is the migratory component (in particular, immigration) that challenges the demographic modelling and forecasting at the municipal or urban scales.

Figure 1 – DSS conceptual approach

Analysing in more detail each of the subsystems:

1. **Demography and economic development** – despite its application at local (municipal) scale, this DSS considers that these two drivers act at the regional level. The modelling of these two subsystems is based on macroeconomic scenarios (DSS - Levels 2 and 3) in order to assess their impacts on employment dynamics and consequently the direct implications on migrations, especially in the working aged population. Thus, the estimated population, by age group, considers the economic dimension as a key component of the net migration; and the natural growth variables (mortality and fecundity) are estimated according to past trends – forecast models (DSS Level 2). For the integration of these components, a cohort survival method is used (Wolf, 2013; Castro et al, 2015; Gomes et al, 2016).
2. The modelling of **housing** subsystem consists of understanding the evolution of the housing stock, based on: the a life cycle of a dwelling (DSS level 2) and on the new houses that appear in the market, through rehabilitation or new construction. This will imply to understand the impact of rehabilitation and construction rates on the number and location of new houses that emerge in the market (DSS level 3) (Marques *et al*, 2016).
3. Many dimensions (communication routes, water supply services, waste collection etc.) can be considered within the **infrastructures**. Thus, the analysis of this section involves the identification of the most important infrastructures in development of an integrated urban system (DSS level 3) and assessing its Load-Carrying capacity (DSS level 2 and 3).
4. **General Interest Services** are analyzed in order to define optimal locations and location preferences that satisfy a set of criteria and requirements that determine the organization of this service network (SAD level 2 and 3). Gravitational models and genetic algorithms are used to analyse the coherence of the integrated network, ie, the balance of adjustment between the supply to and the future demand (Marques et al 2011)
5. The expectations of the population, in particular the **preferences** for housing, General Interest Services (school, sports, cultural, etc.) and infrastructure are decisive for the choice of any solution or alternative. In this context, revealed or declared preferences methodologies are used: hedonic analyzes and multicriteria – SAD level 1 and 3 analyzes (Marques et al., 2012).

4. A DSS PROTOTYPE PROPOSAL

The DSS presented below was developed as a prototype of the conceptual approach suggested in figure 1, focusing on the drivers of housing and demography. Here, the challenge concerns the assessment of the impact housing policy options (at the municipal level) might have on the territory. This DSS reflects the effort in developing an integrated model and suggests the need to broaden the sectoral perspective, moving forward with an interactive logic as described in section 4.

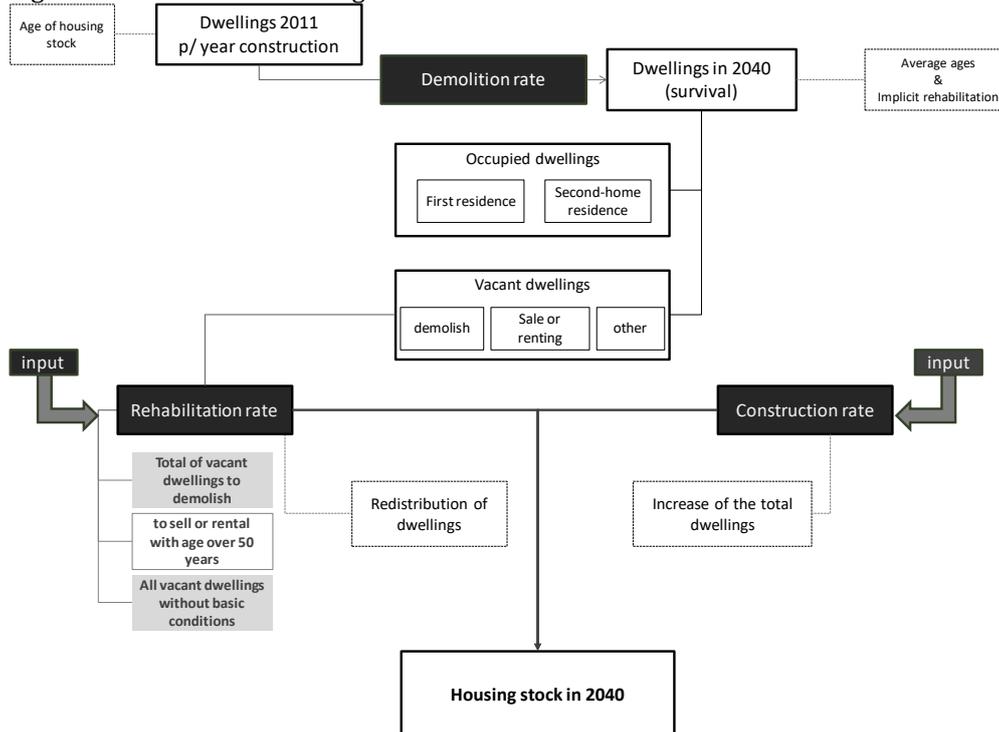

For modelling purposes, it is assumed that future policy options have to be informed by prospective dynamics. It was this consensual notion that led to a research work that took as its starting point the analysis of socio-economic dynamics (DSS level 1) and its expected evolution over a time horizon of 20 years (DSS level 2). With a focus on the second dimension, the analysis considers the behaviour of economic and demographic variables, by modelling the interaction of employment, fertility rates and migrations (as a linking element between economy and demography). But if, at a macro scale, population estimates can be defined by employment patterns and by migrations that adjust to macroeconomic scenarios, at the local level, for distributing population and migratory flows complementary information is needed. Thus, understanding the impact of sectoral policies becomes crucial, as population flows are determined by their preferences and expectations regarding employment opportunities, living conditions and the opportunity to access to a wide range of urban amenities.

After a first territorial analysis which provided a broad understanding on the demographic evolution, as well as on the economic dynamic (DSS level 1), it was decided to analyse the feasibility of housing policy options, by adjusting construction and rehabilitation rates to the different demographic scenarios. The housing driver assumed a prognostic approach (DSS level 2), where the past trends of the housing stock and its physical characteristic patterns were extrapolated for the same 20-year time horizon. For this purpose a DSS interface (figures 3 to 7) was developed, showing the balance between demand (defined by the expected population) and supply (obtained by the dynamics of the housing stock).

This DSS is an innovative public policy tool that focuses on understanding the territorial configurations resulting from impacts associated with strategic options. More than a research work, which allowed the development of an integrated model, this DSS is an opportunity to produce relevant and structured information for the decision-making process, even though it has been developed for a specific sectoral area. The methodological options for linking demography and housing resulted from a deep debate about housing strategies able to overcome expected needs, which are influenced by: a) the decrease of the average size of the families (in line with the last three decades trend) or b) the maintenance of the average size of families verified in 2011 (last Census). Regarding housing characteristics, two situations were considered as follows. One, considering only first residence dwellings, to discuss if the maintenance of the distribution structure of the dwellings according to the form of occupation (occupied, vacant, ruined *in* Census 2011), it would be possible to overcome the demand for housing in each of the demographic scenarios. The second hypothesis concerns to the assumption that first residence dwellings do not satisfy the demand, and therefore it leads to a broad discussion of the incentives that change the sale and/or rental market.

The scheme presented below illustrates the methodology.

Figure 2 – Flows of the housing urban transformation driver

The housing stock in 2011 was the basis to define the number of existing dwellings in 2040, according to three conditions. One relative to the age of the housing stock, given by the buildings' year of construction. Another illustrative of the dynamics of conservation and construction of the housing stock, defined by demolition rates (associated with the longevity of dwellings, and an average age of 53 years), and by rehabilitation and construction rates. Another concerns the occupancy structure of the housing stock as defined by the Portuguese National Statistical Institute (occupied for first and second-home residence and vacant dwellings, which are available in the housing market for sale or renting, or other situations such as dwellings to demolish or without basic living conditions).

Additional assumptions made possible the adjustment of the life cycle of the housing stock, defining the total of housing that would be subject to rehabilitation interventions. After applying the mortality rate, the dwellings subject to rehabilitation include those in the 'to demolish' category, those which not satisfy basic living conditions, and dwellings available on the housing market built before 1990 (which by 2040 require structural intervention). The number of vacant dwellings is influenced by the construction rate, which increases the number of total dwellings, while keeping the distribution of the different forms of occupation.

The conditions for comparing the results derived from the application of rehabilitation and construction rates, according to the local strategy, are established. The application of the rehabilitation rate has an effect on i) the maintenance of total housing quantity; ii) the reduction of vacant dwellings to demolish or without basic living conditions; and iii) the increase in occupied dwellings, maintaining the proportion observed in 2011. The application of the construction rate increases i) the total number of dwellings; ii) the number of occupied dwellings, considering the proportion verified in 2011; and iii) the number of vacant dwellings available in the market, considering the total weight that the "vacant" category assumes in 2011.

Thus, in order to determine the housing needs, the population expected for 2040 and the size of the households are confronted, which enables the definition of the number of occupied dwellings that overcome the expected demand. It is the difference between the number of necessary occupied dwellings and the number of first residence dwellings existing in 2040 that defines the number of total housing needs.

Notwithstanding the contribution of this tool and the related debates to support the decision-making process, other specific considerations on the territorial context territorial have to be added. Furthermore, the assumptions for modelling the housing life cycle can be subject to other approaches, namely those explained in DSSs level 3. As an example, the housing average age and the mortality rate could be adjusted to comprise local dynamics. Corrections at this level may be explained by the impacts derived from certain policies, such as recent opportunities for financing rehabilitation. To deal with this challenge, as there is no information available, it is required to meet experts in the field, or territorial agents with a high local knowledge, through structured meetings, expert panels, or Delphi questionnaires. Regarding the demographic component, some adjustments can also be made to distribute population at the microscale. An example of this is the methodology implemented in the DONUT research project, where demographic projections served as a point of reference for a group of experts who, for extreme scenarios, adjusted this distribution according to future individual preferences. The use of DSSs level 3 allow for dealing with needs, expectations and preferences, which no other way are considered.

To conclude, it is referred the advantages of combining different logics of DSSs, namely as a way to bridge the lack or inconsistency of data to model the urban transformation phenomena. In some cases, the way data is collected may carry doubts and misinterpretations. An example is the available data of the housing stock related with conservation, which depends on the way surveys are implemented. Also, on the occupation structure, for example, what is considered in the category of second homes or seasonal residence and vacant housing available for sale and renting, there might be biases arising from the interpretation of the respondent. In other cases, the modelling can depend on the use of information that does not publically exist but is possible to obtain through alternative mechanisms.

In summary, analysing the prototype model presented there is room for improvement. DSSs level 1 provide the systematization of available information, which, assuming a diagnostic logic, also contributes for monitoring and defining relevant indicators and data to be used on DSSs level 2 and 3. In a more informal but structured nature, DSSs level 3 help the decision maker to position itself in a long-term context, which is highly uncertain. At the same time, it allows for adjusting dimensions worked on DSSs level 1 and 2. Thus, DSSs level 2 have a link function between level 1 and level 3, as it is through combination, that in a complex multidimensional system, the information is integrated and operationalized.

In the figures that follow (from 3 to 7) the tool interface is shown. Through population estimates for 2040, and their territorial distribution, it is possible to assess how many dwellings will be needed (supply) to meet the future expected demand, either by new dwellings or through rehabilitation interventions.

Figure 3, presents the expected housing stock for 2040, considering the typical life cycles of a dwelling. Figure 4 presents the layout of the expected population in 2040, where it is possible to see that the places (parishes) where this dynamic is more favourable (yellow) or more unfavourable (red). At the intersection of the two previous information we have an assessment of the needs (figure 5) where it is possible to verify that assuming null construction and rehabilitation rates, there are housing needs (so the map is represented in red). In order to simulate the construction and rehabilitation rates that meet expected demand, two simulations are shown in Figure 6 and Figure 7. In the first, a rehabilitation rate of 5% per year would not overcome the needs – in the whole municipality, only one parish (represented in red) would have a housing stock in sufficient quantity for the people, which are believed to exist there. In a second simulation (Figure 7) the construction rates are changed in order to respond to the needs.

5. CONCLUSIONS

This paper presents the challenges in analysing and understanding the processes of urban transformation, which have been defined by contradictory trends and great complexity, namely on the identification of the main factors of this transformation, that assume multiple configurations over time and space (scale of analysis). The unpredictability of these factors and the way they interact justify the development of methodologies able to deal with this complexity as well as with the high amount of information and ICT capacity that currently exists. In planning, the DSSs assume greater importance by enabling the systematization of useful and necessary information, and therefore promoting informed, transparent and consequent decision-making.

However, acknowledging the potentialities of these tools does not imply a blind reliance on such instruments. On the one hand, DSSs are not substitutes of political decision-making as the nature of the problems does not allow (or advises) limiting these options to purely objective, universal, inflexible or definitive criteria. On the other hand, simulating decision-making in complex contexts implies the assumption of fundamental premises about the models to be used, the dimensions to be considered and the way in which they are related. That is, the application of a DSS has implicit a broad set of theoretical-conceptual assumptions and frameworks that are not detached to the outputs.

The utility of the DSSs therefore depends on their ability to provide the adequate tools for assessing different development strategies (territorial or sectorial) according to criteria whose definition and assigned weights depends on technical/scientific knowledge, as well as on political concerns.

This paper aims to contribute with a methodological and conceptual framework, with an empirical application that, without neglecting the complexity of urban transformation processes, evidences the need to advance with an integrated, structured and interrelated approach. In particular, the proposed DSS logic assumes a combined analysis of a set of aspects for understanding an urban phenomenon: the assumption that the urban patterns results from individual choices (in the housing market) combined with legal-administrative decisions (with impact on, e.g., the configuration of services and facilities and construction options); and the integration of different techniques and methodological approaches.

1616 HOUSING PROGRAMS AND THE LABOR SUPPLY: EVIDENCE FROM A HOUSING LOTTERY IN BRAZIL

ABSTRACT

Housing policies to increase the quality of life of the poor have been implemented for a long time. In developing countries, urbanization has increased the number of slums and people living in poor conditions throughout the last decades, causing the countries to respond with housing programs that aim to build houses for poor families. That's the case of Brazil and the Minha Casa Minha Vida program (My House My Life), that has provided a record number of 3.5 million houses to families in Brazil since 2009. Despite that, a lot of studies have pointed out that the houses are built in poor locations, far from job opportunities and infrastructure, raising questions about the policy's true impact. To estimate the impact of the program, we use the fact that three separate lotteries randomly selected a total of 23,467 individuals to participate in the program in 2011 in the city of Rio de Janeiro. We observe significant non-compliance, with only 30.2%, 20.6% and 12% accepting the offer to participate in the program in the first, second and third lottery, respectively. We combine data from the lotteries with administrative data of the formal labor market (RAIS dataset) and the register on low-income families of Brazil (Cadastro Único). We show that accepting a position in the program decreases the probability of being employed (formally) in subsequent years and increases the probability of participating in Bolsa Família, Brazil's biggest conditional cash transfer program. In this paper, we provide one of the first evidences from Brazil's biggest housing program, contributing also to the literature on housing programs of developing countries.

RS10.1. Regional and Urban Policy and Governance

1051 REGIONAL PATTERN OF RURAL LIVELIHOOD OPPORTUNITIES AND CAPITAL IN SUB-HIMALAYAN WEST BENGAL, INDIA**Manoranjan Ghosh¹, Somnath Ghosal²**1. Doctoral fellow (UGC-JRF), ghoshmanoranjan.99@gmail.com2. Assistant Professor, somnath@iitkgp.ac.in, Rural Development Centre, Indian Institute of Technology Kharagpur, Kharagpur-712302, India**ABSTRACT**

Understanding the complex rural multidimensional livelihood issues at the micro level is important for implementing the sustainable development goal. In recent livelihood research, measuring regional variations of livelihood capital and opportunities is the burning theme of investigation. In this paper, thirteen community development blocks have been taken as regional identity under Jalpaiguri and Alipurduar districts of the state of West Bengal as case study area. The entire region is dominated rural in character. Five thematic maps have been put in order to understand the five separate dimensions of rural capitals, such as natural, physical, financial, social, and human. Here, total eighteen variables have been considered for analysing these five capitals. While, the traditional method of livelihood analysis includes only socio-economic variables, but here environmental dimension of rural livelihood generation in the form of natural capital has also been considered. Data analysis shows that region, where natural capital base are quite rich, financial and human capital base, are weak and vice versa. In terms of rural livelihood opportunities, it is noticed that rural workforce participation rate of this region decreased since 1951 till 2011, it is because of high population growth. The measured livelihood opportunity shows that Alipurduar 1 and 2, Falakata, Maynaguri has less chance of work compared to Kalchini, Madarihat-Birpara, and Matili. The reasons are high population density as well as high growth rate. Region, where, the agricultural work opportunity is low household cottage and small-scale industry worker percentage is higher and vice versa. After all, these regional variations of livelihood capitals and opportunities help in decision-making for the design of suitable policies for transforming the rural standard of living.

Keywords: Multidimensional livelihood index, Thematic map, Livelihood capital, Livelihood opportunity, Rural workforce.

1. INTRODUCTION

It is essential to understand livelihood opportunities in context to build sense that how the rural people have engaged in different economic activities with their special ecological setting. Different geographical and ecological environment project distinctive diversified livelihoods with respect to particular society itself (Asselin and Ki, 2009). People often utilize the natural and human resources in an optimum way following their traditional social practice and strategies. Livelihood strategy is a combination of different aspects such as accessibility of human and natural resource, availability of technologies, existing infrastructure and value system in respect of societal existing problems (Donohue and Biggs, 2015). The term 'livelihood' has widely used in contemporary literature of poverty, rural development and community planning, where livelihood may be defined as comprises of the assets, (natural, physical, financial, social, human) activities, and access to those (mediated by institution and social norms) that together determine the living strategies undertaken by household to provide a means for living (Ellis, 1998). However, in Himalayan foothills of West Bengal, villages having special characters like remoteness, marginality, environmental complexity with diversified race, cast and societal issue, which affect the rural economic activities and daily livelihood (Dutta, 2015; Jha, 2010; B. P. Roy, 2014; S. Roy, 2011). The economy of this region describes as mixed agriculture in a fragmented land with inadequate irrigation system but the dependency of agriculture and forest sectors are much higher compared to others (Hussain, Rasul, Mahapatra, and Tuladhar, 2016). Rural farm activities are the prime source of livelihood opportunities, that is why measure and appraise of the livelihood opportunities is crucial for building sustainability. In addition of understanding the opportunities, incorporating of livelihood capital is also important. Before the establishment of the concept of sustainable development and human development during the last decade of the twentieth century, we had only monetary approach to measure the human livelihood, capital, and overall welfare. This monetary approach was only economic scrutiny in character. However, after the long critical analysis, human development index has received a multidimensional outlook considering the income, health, and educational aspects (Donohue and Biggs, 2015; Liu and Xu, 2016). As we know that scientific paradigm is always changing for effective understanding. Recently, a new multi-dimensional livelihood index or capital index has developed considering the five dimensions of rural lives, such as natural, physical, financial, social, and human. It because of earlier methodologies did not consider the environmental factor for measuring or quantifying the rural livelihoods (Erenstein, Hellin, and Chandna, 2010). Scholars have already proven that there is a strong correlation between natural environment or resource with livelihood opportunities, particularly in rural areas (Ghosal, 2014; Nath and Inoue, 2009). The heterogeneous nature of rural livelihoods is difficult to measure by using any particular analytical tool because it is related to the spatio-temporal pattern of resource availability, uses, and changing behaviour of rural people (Davis, 2003; Donohue and Biggs, 2015; Rahman and Davis, 2005). Presently, livelihood capital approach that is multidimensional in character is a major focus for spatial demarcation of rural poverty (Liu and Xu, 2016). In this paper, the rural livelihood opportunities and capitals have been critically quantify and analyses the regional pattern in the sub-Himalayan West Bengal, India.

The rest of paper organized as follows. The first section deals details about livelihood opportunities and capital approach and their importance. The second section of the research frames location, demographic changes. In the third part, the

details about research methodology have explained. The fourth part is the result and discussion, according to our methodology this part have divided into two sections. The first section is the livelihood opportunities and second section is the livelihood capital. The last section is the conclusion part, where the present situation of rural Sub-Himalayan West Bengal regarding livelihoods capitals has been elaborated.

2. OVERVIEW OF RURAL LIVELIHOOD OPPORTUNITIES AND CAPITAL

A rural area may consider as simply where agriculture and forestry are the dominant forms of economic activities (Whitby and Willis, 2017). In rural areas, distribution of natural resources produces services and opportunities, which meets the basic needs of local people. Creation of optimum livelihood opportunity for all section of people is now the prime strategy for the developing countries to address the three broad domains of sustainable development, namely economic growth, social justice, and environmental sustainability (Levine, 2014). Environmental and socio-economic inter linked potential factors strongly affecting the basis of rural livelihood opportunities and capital of a particular region. Suitable livelihood opportunity is fundamental of a good life, so the standard of living for rural people depends on the diversified opportunities, such as agriculture, forestry, animal husbandry, wage-labouring, handloom industry, weaving, and so on.

The Capital approach of livelihood helps us to understand the rural lives more clearly than the traditional method. There are five dimensions of rural livelihood capital. The natural capitals, such as forest, fertile soil, are important as a source for income of people living in the villages. In general, there are opposite relationship between the availability of natural capital and village economic vulnerability. Rural natural capital base plays a essential role in livelihood strategy. It also helps in case of infrastructure development, for example, the plain topography is always suitable for development of road network compare to undulating land. On the other hand, human capital helps rural people to achieve or pursuit the different kind of livelihoods. The formation of social capita is also very crucial for community development. After all, the livelihoods capital approach has recognized as a tool for the understanding development of any region. In India, fewer amounts of studies have been done based on livelihood capital approach. Although, the founding work of Erstein (2009) on the spatial mapping of rural poverty in Indo-Gangetic plains based on the multi-dimensional livelihood capital is the pioneering work and very much vivid to understand the rural poverty. India is facing severe catastrophe of quality of rural livelihood sector, such as 70% agricultural household cannot meet there basic consumption needs (Basole, 2017). In the Indian state of West Bengal, the rural standard of living is not well distributed, most of the district still lacking behind due to various reason. Spatial heterogeneity in rural livelihood is the result of geographical and others socio-economic factors such as natural resource distribution, agricultural accessibility, lack of education, health and others deterministic reason. Some scholars believe that there is a strong co-relation between outcomes of rural livelihood and environmental condition such as distribution of good quality soil, forest, and plain topography (Adjei, Buor, and Addrach, 2017; Bhandari, 2013; Dula Etana, 2011; Wang, Felbermeier, Kateb, and Mosandl, 2015). It is necessary to examine inter block level spatial pattern of multi-dimensional livelihood of each district of the country. The sustainable multidimensional capital approach has applied in this paper because more than 70% of rural people of India depend on natural resource (Srivastava et al., 2004).

3. THE STUDY AREA

Geographically, the study area is comprised of the district of Jalpaiguri and Alipurduar of West Bengal, lies between latitude 27°00' N to 26°16' N and longitude 89°53'E to 88°25'E which is part of Himalayan foothills also known as Dooars.²⁶⁹ As indeed, this region makes the connectivity with Bhutan, Nepal, and whole northeastern part of the country. The Northern part of the study area is characterized by undulating terrain covered by tea garden and jungles, relatively less populous compared to the southern part. On the other hand, the southern part of the region is agriculture dominated (Jha, 2012). The whole study area has been aptly named as the land of tea, timber, and tourism. However, the region is relatively backward compared to rest of the state as well as the country. The presence of vast hilly tracts covered with dense forests, and sparkling streams flowing through them attracts tourists. Forest covers about 27.8 percent of the total geographical areas, forest fringe are home to world thirty indigenous communities. The majority of the people are engaged in agriculture and plantation activities. Table 1 shows the scenario of growth of rural population and work participation rate over the time.

²⁶⁹ Dooars or Duars is the distinctive geographic identity in north-eastern India that lies south of the Himalaya and north bank of the Brahmaputra River basin. This region is about 30 km wide and stretches about 350 km from the Teesta River in West Bengal to Assam.

4. METHODOLOGY AND DATA

The study has been conducted based on secondary data availed from different sources like Census of India, District Statistical Handbook of Jalpaiguri, Livestock Atlas of West Bengal, District Official Information. The main aims and objectives of the study are to determine the nature of livelihood opportunity and livelihood capital and the regional occupational structure at the block level in Sub-Himalayan West Bengal. Livelihood opportunity status depends on the availability of income or earning of the people from a different source such as forestry, animal husbandry, handloom, weaving, daily wage labouring etc. The fundamental statistical formula to measure the livelihood opportunity index is-

$$LO = \frac{P_1 + P_2 + P_3}{3}$$

Where, LO represent livelihoods opportunity

The formula giving one-third weight age to each of the components that have been used here. The first component is the ratio between total worker to total population (P_1) that is workforce participation rate indicating economic well-being and reflect strength, nature of income scenario. Second is the ratio between main workers to total workers (P_2) where main the worker denotes the worker who gets a job at least 180 days in a year. Its show the nature and quality of employment. Whereas the third component is the ratio between other workers among main worker, (P_3) reflects engagement of people in various nonfarm activities. On the other hand, livelihood capital index which is the most important and decision-making tools to examine the status of livelihood. Under this index, variables categories into five component, such as natural capital (forest land, water body, double cropland, and area under social forestry), physical capital (net sown area, irrigated land, metal road) human capital (literacy, female literacy, sex ratio), social capital (household density, the density of rural drinking water sources, cultivation land), financial capital (female cross breed cattle, female Indigenous cattle, % of rural people served by banking facility, % of rural people served by medical amenities). However, as per as variables are concerned, there are a large number of variables in all categories. In this study, only those variables have taken for statistical analysis which has an impact on regional socio-economic condition of this study region. In this study, Livelihood Capital Index (LCI) quantified considering the 17 appropriate variables covering different aspect human well-being on 13 community development block of sub-Himalayan Bengal. During the selection of variables existing scientific literature related to the particular field have also been referred. To calculate each of the individual variables scores of Livelihood Capital Index (LCI) from raw data, standard normalized method has been used. This is done to make raw data unit free and to get the relative position of each block in respect of variables. The formula is used to obtain normalized values is-

$$N_v = \frac{ActualX_{ij} - MinimumX_{ij}}{MaximumX_{ij} - Minimum_{ij}}$$

Where; N_v represent the normalized values of each variables, $i= i^{\text{th}}$ observation and $j =j^{\text{th}}$ district.

The standard normalized values always lie 0 to 1. Five different components of Livelihood Capital Index (LCI) have been calculated by given equal importance to each variable. The statistical formula of calculation each component of Livelihood Capital Index(LCI) is-

$$C_{LCI} = \frac{\sum N_v}{n}$$

Finally, the Livelihood Capital Index (LCI) has calculated by adding the all five component-

$$LCI = \sum C_{LCI}$$

Running the SPSS software package, descriptive statistics and correlation coefficient among the variables have been examined. The reason behind the selection of variables as follows-

- (1) Rural literacy rate, female literacy gap, sex ratio are the importance variables which reflect the strength human capital of any region. Balance sex ratio and high rural female literacy showing the sustainability in society as well as help to reduced rural poverty. These variables had been considered for calculating the human capital.
- (2) For justifying the social capital three important parameters have been considered. These were the density of rural drinking water sources, household density, and per capita cultivated land. The reason behind the selection of per capita cultivated land was its shows the pressure over arable land and strength of the household economy. Density of rural drinking water sources represents the infrastructure base of safe drinking water to the rural people.
- (3) Rural livestock in form of the total cross breed and indigenous cattle, the percentage of rural people served by banking facility and medical amenities are considered as financial capital because these financial services always have a favourable impact on livelihood consequence or well-being of the rural people. The lack of particular type of infrastructure considers as core dimension of poverty (Solesbury, 2003).
- (4) Any kind of rural infrastructure has been taken as essential criteria for judging human well-being. For calculating the physical capital, percentage of irrigated land to total cultivated land, net sown area, percentage of rural people served by metal road have considered. It is because of that the irrigated land and net sown area one of the fundamental foundation for rural agricultural production. Others variables are rural road facility which provides the easy accessibility of all sector of rural life (Carney, 1999; Donohue and Biggs, 2015).
- (5) For quantifying the natural capital, we consider the spatial coverage of forest land, water bodies, double crop land (considered as a proxy of good soil), and area under social forestry of each community development block.

Table 2: Descriptive Statistics of Selected Seventeen Variables Using in Livelihood Capital Index

Capitals	Variables of different capital	Minimum	Maximum	Mean	Std. Deviation	C.V.
Human capital	% of literacy	53.10	66.58	60.68	3.76	6.21
	Rural sex ratio	923.00	1005.00	957.53	25.12	2.62
	Rural female literacy	51.93	69.11	61.29	5.23	8.54
Social capital	Per capita cultivated land	.082	.775	.27	.34	123.61
	Household density (hectare)	.66	1.64	1.15	.36	30.66
	Density of rural drinking water sources	0181	.1369	.07	.03	45.31
Financial capital	Female cross breed cattle	239.00	10246.00	2979.23	2874.89	96.50
	Female Indigenous cattle	8420.00	38182.00	22404.00	7555.82	33.73
	% of rural people served by banking facility	3.70	48.81	20.18	13.58	67.30
	% of rural people served by medical amenities	59.57	99.02	85.54	10.94	12.80
Physical capital	% of net sown area	27.17	88.73	51.45	17.66	34.33
	% of irrigation area	3.32	24.71	14.28	6.17	43.24
	% of rural people served by metal road	37.35	91.10	66.69	15.39	23.07
Natural capital	% of forest land	.37	65.10	16.55	21.79	131.74
	Area under double crop (hector)	.00	29212.45	9505.59	9853.85	103.66
	Area under water body (hector)	.00	210.19	39.58	65.57	165.68
	Area under social forestry (hector)	.00	14580.75	1228.95	4021.25	327.21

Source: Data derived from following agency (1) Census of India, 2011 (2) State Forest Report, 2012 (3)18th all India Livestock Survey,

2015 (4) District Statistical Handbook of Jalpaiguri, 2014 (6) National Rural Drinking Water Program, 2017.

The findings (table:2) show that major inequality found in terms of selected variables in different blocks. For example, rural people served by banking facility is lowest in Alipurduar-1 only 3.70%, whereas highest is 48.81% in Jalpaiguri. Irrigation land to the total net sown area was minimum in Dhupguri only 3.32% and maximum in Alipurduar-1 was 24.70%. In terms of rural sex ratio, Raiganj possesses the lowermost position (923) and Kalchini at the better position (1005).

5. RESULT AND DISCUSSION

The major advantage of comparative evaluation of livelihood capital and opportunity is that it can provide a clear picture of rural poverty in the particular region. In India, regional variation of rural level of livings and poverty pattern is very complex; there is huge spatial disparity within and across the state, district, and block. Identifying the livelihoods capital score at community development block level (very important hierarchal administrative unit of India) helps policy maker to plan or building strategy for better human welfare.

5.1. The Scenario of Livelihood Opportunity

The table:1 suggests that the rural workforce participation rate of this region decreased since 1951 until 2011. One of the reasons is high population growth. However, after 2001 work participation rate is raising. One important study based on National Sample Survey data by Jatav, and Sen (2013) shown that 85% male and 94.1% female rural non-farm sector workers employed within the rural area. So it is clear that most of the rural people of India engaged in different economic activities based on locally available rural resources and opportunities.

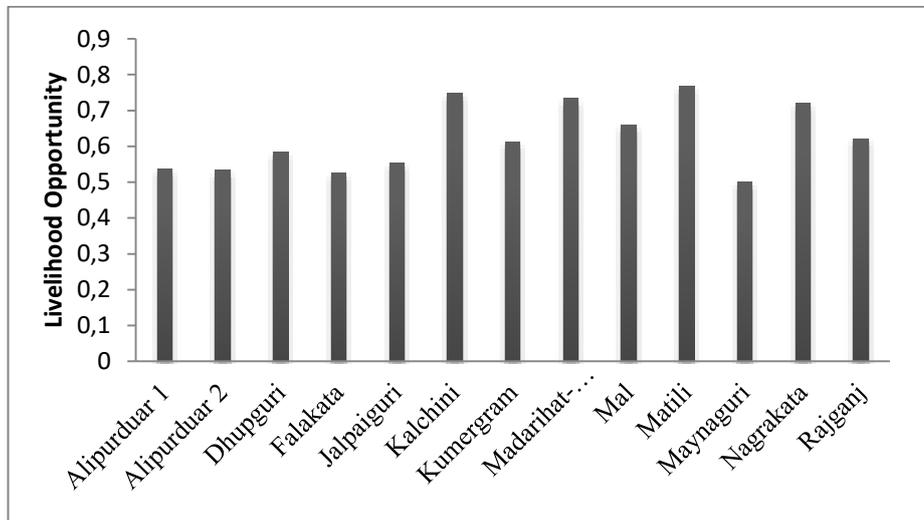

Fig 2: Blockwise Livelihood Opportunity Distribution

Our measured livelihood opportunity shows Alipurduar 1 and 2, Falakata, Maynaguri has less work opportunities compare to Kalchini, Madarihat-Birpara, and Matili. Here high population density as well as growth rate is an important reason for the low possibility of work (fig:2). The Maynaguri block has the lowest work opportunities. Table: 3 showing that blocks where agricultural work opportunity is low at same time house hold worker rate is high. Alipurduar-1 has the highest concentration of agricultural labour and Kalchini has the lowest. Jalpaiguri has lowest amount of household industry worker. Only 4% people are engaged with cultivation in Matili. The overall opportunity is high in those block where the cultivation and agricultural labour engagement is low or others worker involvement is high (fig:1and table:3).

Table: 3 Patter of Rural Livelihood Opportunity (values in %)

Name of the Block	Cultivator	Agricultural labour	Household Industry worker	Others Worker
Alipurduar 1	23.33	42.35	1.24	33.08
Alipurduar 2	23.01	39.19	2.78	35.03
Dhupguri	18.16	35.65	1.43	44.75
Falakata	23.38	43.17	1.57	31.88
Jalpaiguri	23.62	38.57	0.95	36.89
Kalchini	8.56	9.75	2.08	79.61
Kumergram	16.79	28.8	3.16	51.26
Madarihat-Birpara	9.09	12.26	1.59	77.07
Mal	12.92	21.86	1.68	63.55
Matili	4.92	11.56	1.39	82.1
Maynaguri	32.96	38.3	1.62	27.12
Nagrakata	8.5	13.99	1.68	75.1
Raiganj	17.85	25.29	2.45	54.42

Source: Calculated from District Census Handbook Jalpaiguri, 2011.

5.2. The Scenario of Livelihood Capital

Livelihood capital index have five separate dimensions of capital. As we have shown, the particular dimensions of livelihoods capital based on precise variables (table: 2). Scholar stated that spatial representation is a very helpful technique for targeting the investment sector (Donohue and Biggs, 2015; Misra, Sundaram, and Prakasa Rao, 1974). The fig:3 shows the dissemination of human capital. The highest concentration of human capital was in Alipurduar-2 block followed by Jalpaiguri and Maynaguri. More investment is needed on the human capital sector in Matili, Mal, and Nagrakata block which have lower amount of human capital. The reasons behind the backwardness in term of human capital in Matili and Nagrakata are habitats are mostly marginal migrated and concentration of tribal population is high (Census of India, 2011; Department of Planning and Programme Monitoring, 2018). A large number immigrant came from Bhutan has been settling in Matiali and Nagrakata (Field observation, 2016).

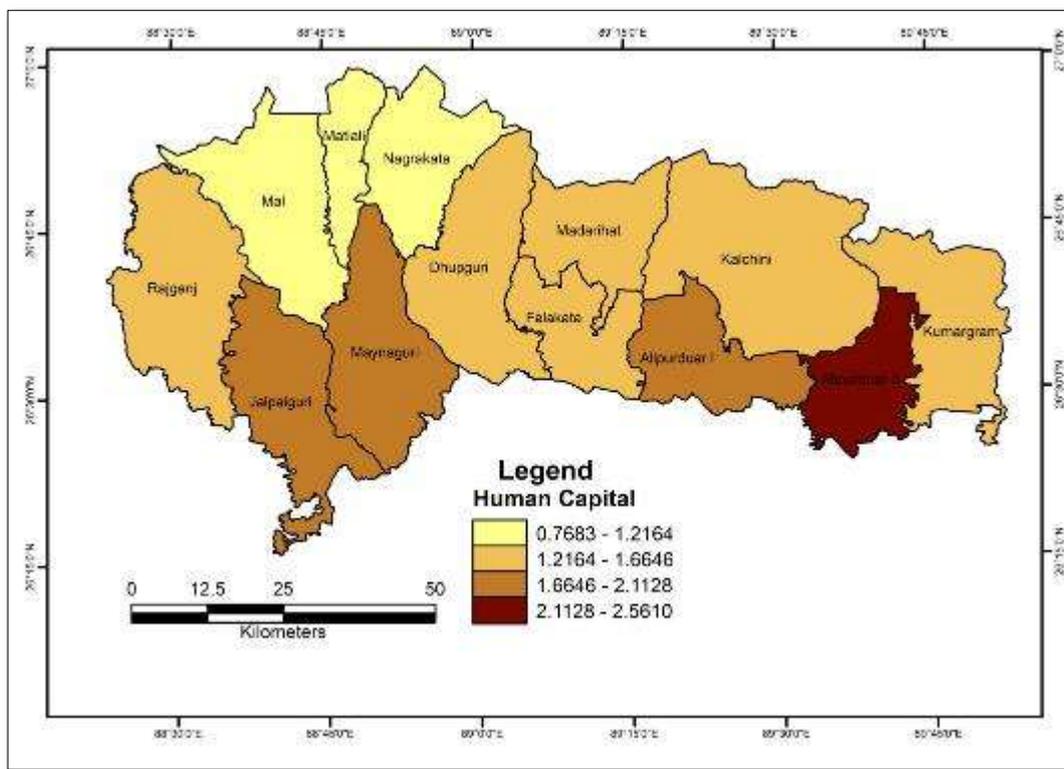

Fig. 3: Human Capital Distribution of Community Development Blocks

Fig.4 representing the social capital among the community development blocks of Himalayan foothills in West Bengal. Here, the slope of a social capital is towards eastern direction except, Alipurduar-2. However, the Kalchini and Kumergram are extremely poor blocks in the eastern part. The reason behind could be low per capita cultivated land and inadequate rural drinking water facility etc. The Western portion of the region enjoys the more benefits of social assets. Therefore, the development policy should be required a specific strategy for the northeastern stretch of the region in terms of social development.

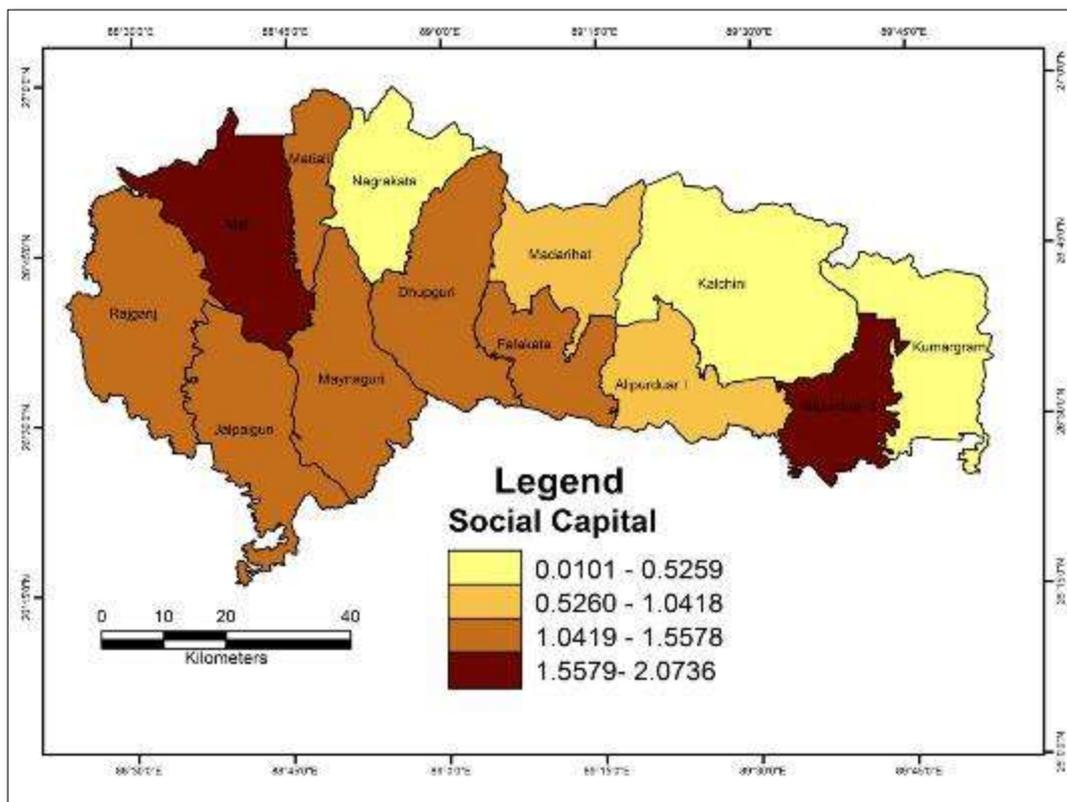

Fig 4: Social Capital Distribution of Community Development Blocks

The highest amount of financial capital (Fig.5) of the region concentrated in Jalpaiguri followed by Rajganj. The block Dhupguri, Falakata, Maynaguri has the medium concentration of financial capital. The above mentioned blocks have the higher number of crossbred and indigenous cattle as household livestock. Rural people served by the banking and medical facility is highest in Jalpaiguri and Falakata block. Matiali, Nagrakata, and Alipurduar-1 and 2 have a low financial capital base which is a vulnerable indication of rural livelihood.

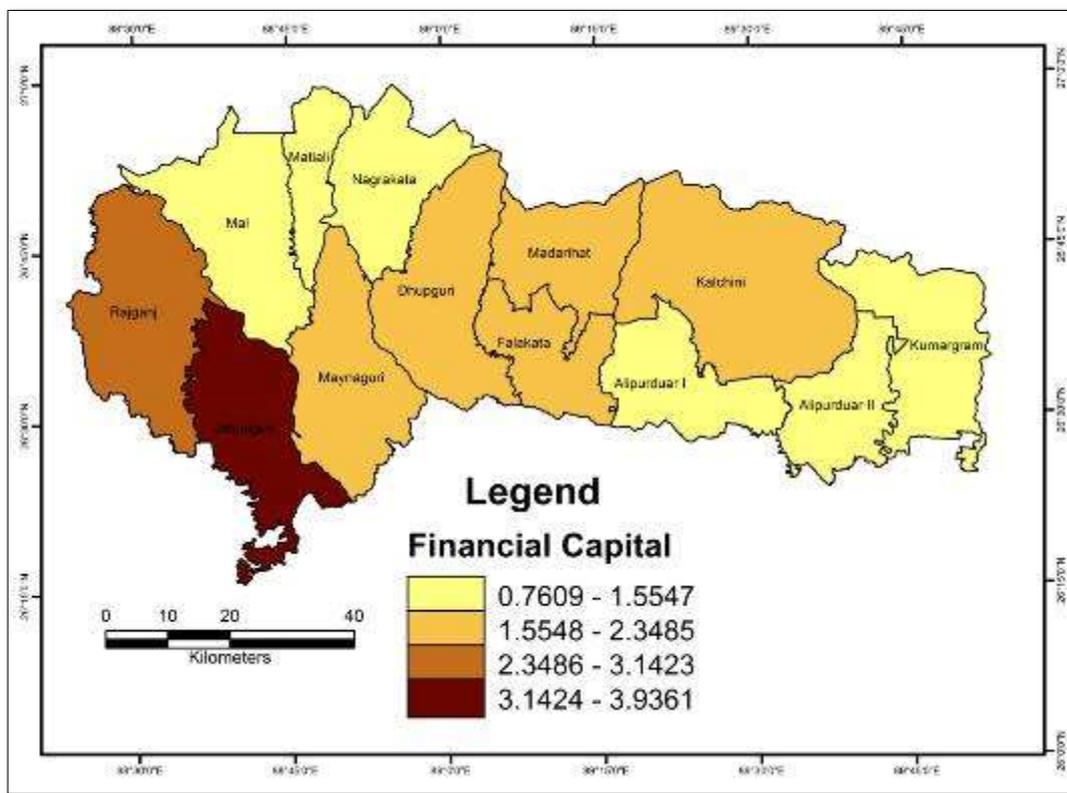

Fig 5: Financial Capital Distribution of Community Development Blocks

Rural physical infrastructure base is the main driving force of rural holistic development. Physical capital is the strength of future prospect. In the developing world, rural physical infrastructure is proportionally related to high wage rate and more opportunity in the non-farm sector (Dula Etana, 2011). Rural roads, irrigation infrastructure, electricity, and others

development indicators are significant determinants for the rural physical capital base (Borooah and Dubey, 2007). Here, the three important variables like net sown area, irrigated land, and rural metal road have been considered for measuring the physical capital in this study. The result (Fig.6) shows the entire western part and Falakata block of the Himalayan foothills West Bengal is more affluent in terms of physical capital base. Jalpaiguri, Mal, and Matiali have the maximum concentration of physical capital followed by Alipurduar-1 and 2, Raiganj. The block Dhupguri is potentially prosperous in terms of agricultural, but only 3.32% of net sown area is under irrigation. Therefore, more investment is required for irrigation sector in the above block. In the Madharihat and Kalchini block also needs investment and proper planning in the rural metal road and irrigation sector.

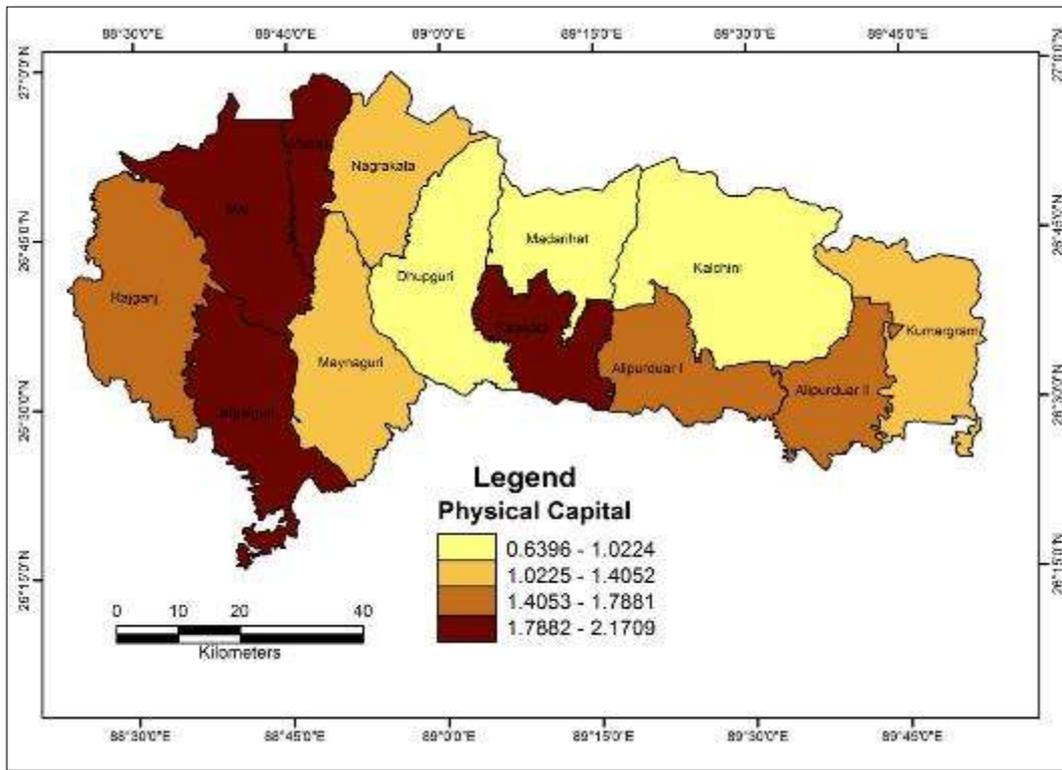

Fig.6: Physical Capital Distribution of Community Development Blocks

Experts' defined rural livelihood in different ways, according to Chamber (1983) rural livelihoods is the combination of ecological richness, social, political and temporal aspect of any rural society or region. From the above framework of rural livelihoods it is clear that the ecological services or natural resource as importance foundation of rural economic life. Forest resources, land under social forestry and double crop producing land (proxy of good soil), water body have taken as computing the natural resource base capital. In the fig:7, Mataili appear as a lowest natural capital base community block. The Western part is displaying good natural capital base due to fertile quality soil and the eastern part is showing strong in the natural capital base for forest resource.

The livelihood capital approach of measuring or understanding the overall rural livelihoods of any region is multidimensional in character; this approach is also preferred to measure the composite status of livelihood capital (Donohue & Biggs, 2015; Erenstein, Hellin, & Chandna, P. 2009). The main argument behind the calculating the overall status of livelihoods is that the essence of rural well-being is not purely economic, but also an amalgamation of social and environmental dimension.

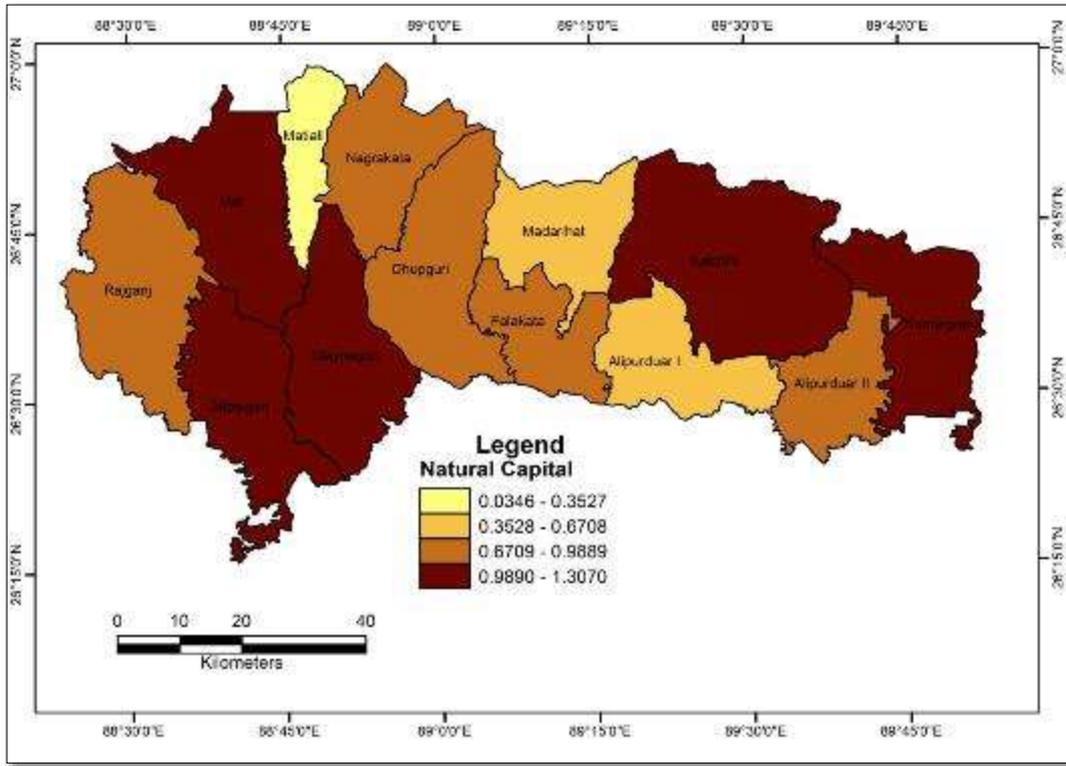

Fig.7: Natural Capital Score of Community Development Blocks

From an inter block level rural composite livelihoods capital analysis of the Himalayan foothills of West Bengal is very important in present time, specially, in post-reform period. After economic reforms (1991), there is a certain level of improvement in the standard of living of rural people but a high degree of disparity among the district and state still exist (Chaudhuri and Gupta, 2009; Deaton and Drèze, 2005). The fig: 8 which shows the pattern of overall livelihood capitals of block of the study region. It is noticed that Kalchini, Nagrakata, Matiali, and Madarihat are in a vulnerable situation, where the concentration of livelihood capitals are low. In terms of all livelihood capitals dimensions, Jalpaiguri is better position followed by Rajganj and Falakata. The western part of the sub-Himalayan west Bengal is comparatively better than eastern part in terms of livelihoods capital concentration. Similarly, the southern part is better than northern part. The rearward block like Nagrakata, Matiali are situated in northern part and the forward block like Jalpaiguri and Falakata in southern part.

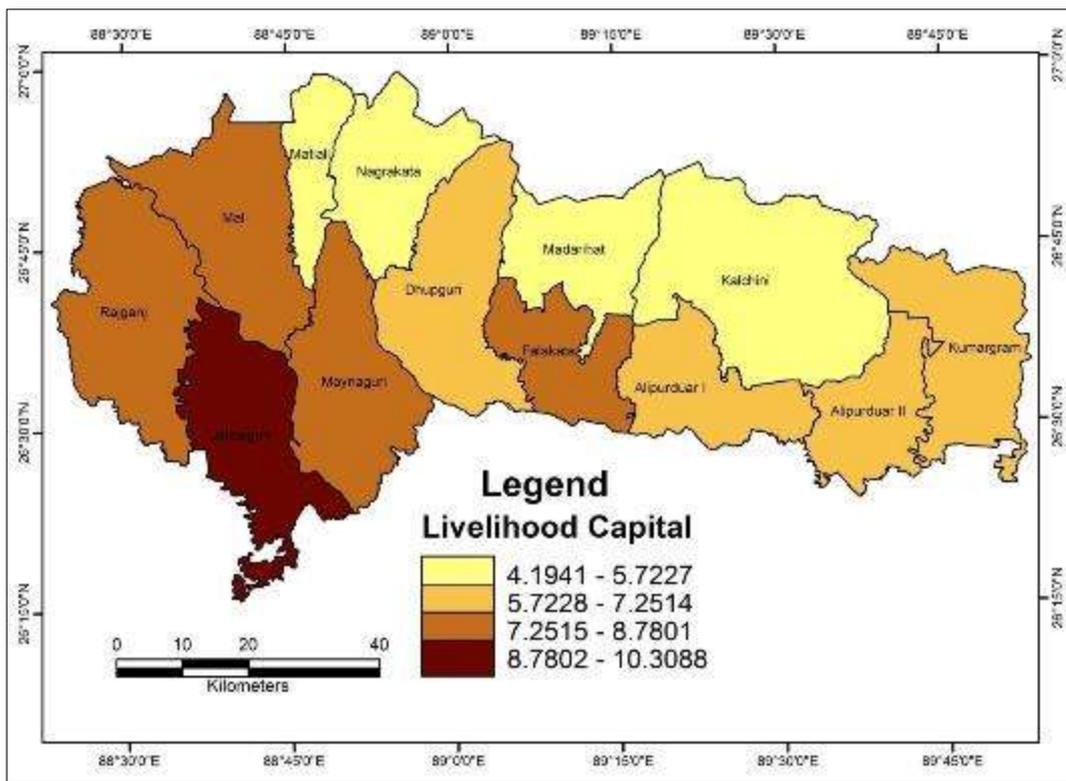

Fig.8: Composite Livelihood Capital Score of Community Development Blocks

We have applied hierarchical clustering analysis technique for more robust understanding of livelihood typology of the community development blocks based on same variables used in livelihood capital approach. The hierarchical clustering analysis technique is very relevance for the comparative analysis of composite livelihood capital score and the result of hierarchical clustering for better interpretation. The proximity matrix of squared Euclidian distance based on our specified variables as used in hierarchical clustering analysis shows the lowest distance of the matrix is 8.819, which is between Kalchini and Nagrakata block (Appendix:1 for distance co-efficient). Thus, these two blocks are most similar. Others way the block Kalchini, Nagrakata and Kumergram, Madarihat-Birpara appeared relatively similar to each other's in terms of composite rural livelihood capitals, followed by Matili and Alipurduar to certain extent. Dhuppuri, Jalpaiguri, Raiganj, and Mal have the similar pattern of livelihood, which is support for the hierarchical clustering analysis (fig: 8, 9 and Appendix:1).

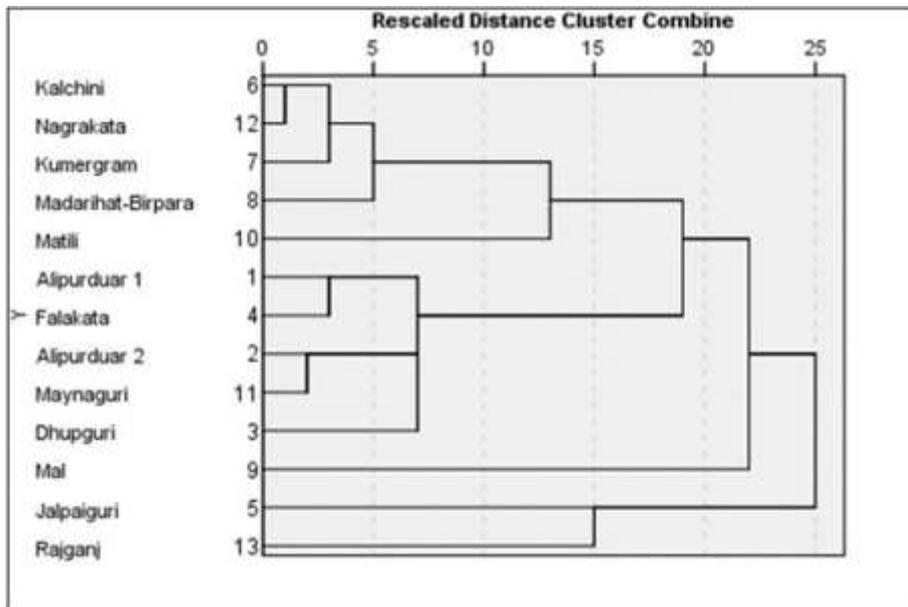

Fig: 9 Dendrogram between Groups of Community Block

6. CONCLUSION

The paper focused on two broad and integral aspect of rural livelihood, such as opportunity and capital. Except few blocks, like Dhuppuri, Falakata, and Maynaguri, agricultural workforce opportunity is very limited all over the region. Rural people are more engaged in non-farm activities in the blocks like Mal, Matili, and Madarihat. The result of livelihood capital shows that there are enormous disparities within community development block of sub-Himalayan West Bengal. Special development strategy is being need for backwards block like Nagrakata and Matiali. The block where the natural capital base is high the human capital base is low and vice versa. However, as per as methodology is the concern, there are many methods developed by geographer, economist, and others social scientist to quantifying the domain of rural livelihood. Every method has few merit and demerit. The multidimensional rural livelihood capital approaches now more acceptable at the present time. Rural poverty being more dominated in some region due to inverse natural environment condition or scarcity of natural resource (Misra, Sundaram, and Prakasa Rao, 1974). Therefore, the livelihood capital approach is relevant in sub-Himalayan regional context because it include the natural environmental dimension to quantifying the overall livelihoods status of rural lives. To preparing a development plan for this region it is very much crucial to consider the socio-economic, environmental and historical aspects at the same time. The problem of rural poverty in the Indian state of West Bengal is old and massive, therefore to deal with rural poverty it needs professional enquire and multipronged strategy.

1197 PREDICTING DEPRIVATIONS IN HOUSING AND BASIC SERVICES FROM SPACE IN THE SLUMS OF DHAKA**Amit Patel, Christian Borja-Vega, Luisa Mimmi, Tomas Soukup, Jan Kolomaznik, Tanushree Bhan, Marcia Mundt, Hyun Jung Lee**Amit.Patel@umb.edu, cborjavega@worldbank.org, lmimmi@worldbank.org, tomas.soukup@gisat.cz, jan.kolomaznik@gisat.cz, Tanushree.Bhan001@umb.edu, Marcia.Mundt001@umb.edu, HyunJung.Lee001@umb.edu**ABSTRACT**

This study adopts a novel approach to targeting poverty interventions in slums by using image-based spatial data to predict housing and basic services deprivation from space. It offers a conceptual framework to explore and compare deprivation within and across cities. With half the world's population currently living in urban areas, and close to one billion living in slums or informal settlements, cities have been struggling to deal with the pressures that rising populations pose on infrastructure, basic services, land, and housing—not to mention the environment. Moreover, megacities in developing countries have been growing at a faster pace than ever, mostly in an unplanned manner resulting in the proliferation of slums. Against this backdrop, one of the key challenges to effectively targeting interventions is the lack of data on the dynamics of urbanization in general and slums in particular. Another problem relates to moving beyond the slum/non-slum dichotomy to identify the most deprived slums and ensure interventions target the most underserved households. In a pilot of our framework and methodology in Dhaka, Bangladesh, geospatial variables such as morphology, proximity to services, accessibility, and building density were used to predict multidimensional deprivation. Specifically, distance to the central business district, arterial roads, major road junctions, railroads, average dwelling size, and street type within slums were found to increase the relative risk of overall deprivation. To the contrary, proximity to heavy industry and shoreline, building density, winding index for informal streets, low-level node connectivity ratio and proximity to various social amenities were found to decrease the relative risk of overall deprivation. The results from these models indicate their potential to predict the location and scale of current deprivation and future changes, which could support the creation of inclusive policies and targeted planning interventions to help marginalized, poor and vulnerable populations.

Keywords: Aid Targeting, Slum Upgradation, Urban Poverty, Earth Observation Data, Bangladesh

HIGHLIGHTS

- Methodology integrates household survey and Earth Observation data in an innovative model for measuring housing and basic service deprivation.
- Distance to business center, proximity to roads and industry, density and land use and land cover were notable predictors of deprivation.
- Model results from Dhaka, Bangladesh indicate the opportunity to further develop the model with additional characteristics and in new contexts.

1. INTRODUCTION

With the global population of slum dwellers exceeding one billion today and discouraging projections for the coming decades, our rapidly urbanizing world needs to address the challenges facing slums in a much more effective way than ever before. Close to 52 percent of the world's population lives in urban areas, about a quarter of which lives in slums, mostly in less developed countries UN-Habitat, 2012; 2015. . There is an urgent need for slum improvements to move beyond a few isolated success stories and adopt a programmatic approach to the challenges facing slums. Furthermore, cities need to be proactive in providing affordable housing and basic services to avoid the formation of new slums.

Designing effective projects and policies requires information on slums and the cities in which they are embedded. However, international development agencies as well as national and municipal governments rarely have access to up-to-date, reliable information on the number and characteristics of slums in a given city Lucci *et al.*, 2018, . Such evidence is critical for cities to formulate effective interventions, programs, and policies. For example, a recent study by Briggs 2018, explored whether aid from the World Bank and the African Development Bank accurately targeted poor populations across Africa, concluding that aid tends to flow to the relatively more affluent using gridded spatial analysis. This finding highlights the need for information that could help identify the most deprived slum populations in a reliable and timely manner to prioritize interventions in resource scarce settings such as those found in developing countries. Thus, a framework that could provide rapid data and information with minimal cost is essential for targeting limited resources in a more effective way.

This study proposes an analytical tool to identify, prioritize and target slums for interventions. Building on the potential of Very High Resolution VHR, remote-sensing data and advanced image processing, this approach provides a holistic strategy for understanding the needs of slum-dwellers based on the geography and spatial dynamics of each area. Remote-sensing RS, is already being used to map the number and extent of slums and a multiplicity of extraction methods for slum mapping have been developed in the last fifteen years ranging from classical visual image interpretation to Object-Based Image Analysis OBIA, to machine learning, or a combination of methods Kuffer *et al.*, 2016, . The main challenge remains how to translate a relevant set of slum characteristics into robust indicators e.g. developing a slum ontology, for image-based slum mapping that would ultimately allow for developing a global slum inventory Kuffer *et*

al., 2016, p.5. Furthermore, it is important to identify the worst conditions among slums for prioritization purposes since different slums face different levels of housing deprivation Patel *et al.*, 2014, .

Based on the premise that integrating multi-source, spatial data with locally collected data has the potential to improve the design and targeting of slum infrastructure upgrading policies, this methodology builds on two main considerations: i, the growing potential in the increasing availability, quality, and accessibility of spatial data being collected formally and empirically on slums, and ii, the growing number of household surveys collecting GPS coordinates, and the advances in mobile telecommunication and social media generating data from communities on a regular basis.

Collecting and integrating multidimensional data that can be spatially overlaid and intuitively visualized in web-maps can provide an invaluable tool for planning with more transparency and accountability. With the proliferation of open source software for crowd sourced data collection, cloud-based storage, and free software for spatial data analysis, the urban poor are organizing themselves to seek solutions to their own needs. Further, new grassroots technologies are enabling many communities to express their aspirations and needs as well as engage in slum upgrading initiatives. As a result, Geographic Information Systems GIS, tools have been created to represent previously unmapped areas. Integrating these data further leverages the complementarity of insights obtained from sophisticated Earth Observation EO, data image processing algorithms linked to the invaluable knowledge that can only be captured in close interaction with local residents of slums. Finally, identifying contextual slum typologies is an important research direction and integrating image-based spatial data with socioeconomic characteristics can help respond to this need.

The methodology outlined in this study aims to support the policy design stage by providing a comprehensive and objective framework for prioritizing and sequencing slum rehabilitation work. Moreover, this framework offers an alternative approach for engaging stakeholders—namely slum-dwellers, developers, civil society, and local governments—in evidence-based policy discussions instead of entering politically charged territory.

The article is divided into six sections. The next section provides a comprehensive review of literature related to spatial analysis of slums. Section 3 provides background and context on Dhaka, the case study city. Section 4 describes the data and methodology employed in the study. Section 5 illustrates the results of the analysis and the study limitations. We conclude in Section 6 with planning and policy implications drawn from the case study analysis and recommendations for further exploration of this novel methodology.

2. LITERATURE

Slums are a major part of the urban housing stock and an important part of the urban economy in many cities of the global South yet these areas also have a high concentration of urban poor Sliuzas & Kuffer, 2008, . UN-Habitat 2012, defines slums as areas with households that are deprived of access to safe water, acceptable sanitation, durable housing structures, adequate living space, and secured land tenure. It is estimated that most of the urban population growth over the next three decades will occur in cities of less developed countries, which means the pressure on sub-national governments to deliver basic services like water and sanitation will continue to rise UN-Habitat, 2012, . However, identifying the most deprived slums and strategies for targeting interventions is a challenging endeavor. Even defining and detecting a “slum” can be quite challenging, and the nature and severity of the deprivation endured by residents is highly heterogeneous within cities Kohli *et al.*, 2012, . The reality of fast-growing slums and unplanned urban pockets calls for improved data collection methods that are more agile and rapidly updated.

As EO data became more widely available at the turn of the century, practitioners and scholars began exploring how geospatial data could be used to map the location, extent, and various types of deprivations within urban areas, particularly slum settlements. For example, in preparation for the first World Bank ‘Geospatial Day’ held in 2016, the Geospatial Community of Practice compiled a list of over 140 projects to showcase how the World Bank and its partners leverage geospatial analytics. Practitioner reports involved RS and applications spanned all possible sectors, including: climate change; fragility, conflict, and violence; transport; urban development; and water, to name a few. Within scholarship related to this topic, a subset of studies focus on simply finding slums and informal settlements by identifying changes in Land Use / Land Cover LULC, to highlight the value and applicability of these early techniques and findings to this study. Scholarship has also been devoted to mapping the extent and growth of informal settlements; a topic with relevance to the present case regarding the vulnerability of slums due to their inhabitants’ transitory nature. Finally, various researchers have taken an interest in mapping the more nuanced changes in levels of deprivation and socio-economic characteristics within slums. Only three studies, however, have explored the use of RS data for this purpose so far. This technique is applied to the current case study using new data and modeling techniques to further advance this area of knowledge.

One of the earliest studies using geospatial data to map land use in cities established a standardized classification of LULC. Rashed *et al.* 2001, argued that land use planning at local within-city, or regional between-cities, levels requires a standardized classification. RS imagery can only record land cover, which describes the physical state of features in urban lands e.g. vegetation types, water bodies, . Thus, land cover is a more objective measure than land use, which cannot directly be linked to RS data and is prone to interpretation error because different users will have different perspectives on the classification procedure Rashed *et al.*, 2001, p.6, . They found the Spectral Mixture Analysis SMA, fractions of vegetation, impervious surface, bare-soil, and water/shade end members provided a measure of the physical properties of the dominant classes in the urban landscape, helping to reveal the morphological patterns of the Cairo metropolitan area and its surroundings. The baseline classification system developed in this study has since been further refined by many subsequent studies.

Various forms of geospatial mapping and classification have now been applied to identify urban areas from space. Shi *et al.* 2014, pp.359, used the Visible Infrared Imaging Radiometer Suite VIIRS, day-night band DNB, carried by the Suomi National Polar Orbiting Partnership Suomi NPP, satellite to extract the location of built-up areas in 12 cities of China. They argued that since the built-up areas are illuminated artificially at night, their corresponding pixels in nighttime light images have larger digital number DN, or radiance values than the surrounding dark areas. Antos *et al.* 2016, produced and analyzed land cover maps derived from high-resolution satellite imagery for five primarily African cities. While satellite imagery had been used to measure the footprints of cities, distinguishing urban vs non-urban areas, the high-resolution satellite imagery dug deeper to measure the various land cover types within the city, including the 'irregular' residential land cover type that serves as a proxy for slum areas. A similar project was conducted in Central America Augustin *et al.*, 2017, . Again, high-resolution imagery was used to create detailed land cover maps and road networks.

More relevant still, researchers have isolated slums and informal settlements within those urban areas Kuffer *et al.*, 2016. Tigny 2016, used VHR satellite imagery extracted over in four points in time to reveal some trends and patterns in slums formation, enabling a highly accurate mapping of the 2500 informal settlements in Manila. Rhinane *et al.* 2011, used an object-oriented classification approach to map slums in Casablanca, Morocco in two steps: segmentation and classification. Segmentation involved subdividing an image in the visible range into homogeneous regions. The researchers then grouped objects and assigned them a probability or degree of belonging to a given class from the robust rules of region recognition Rhinane *et al.*, 2011, p.220, . The binary image resulting from the classification was then exported to ArcGIS, and slums in the city of Casablanca were mapped with an accuracy of 85%.

Several RS approaches have also been utilized to obtain up-to-date and faster access to information on the location and growth of slums. For example, Kit *et al.* 2012, proposed using a lacunarity method to extract slum pockets from QuickBird satellite images for the case of Hyderabad, India. Lacunarity analysis is a multi-scaled method of determining the texture associated with patterns of spatial dispersion. The lacunarity algorithm is capable of identifying the core of a slum; the areas with very dense housing that are particularly vulnerable to natural and socio-economic hazards Kit *et al.*, 2012, p. 666, . Amorim *et al.* 2014, offered an approach integrating lacunarity and texture based analysis to better understand complex intra-urban socio-spatial patterns for urban planning and land-use management. This method allowed them to describe the spatial arrangement of surfaces and built materials on Very High Resolution satellite images.

There is growing interest among researchers to devise methods for time- and cost-efficient collection of social and spatial indicators to help policymakers and practitioners measure the extent of poverty and locate the hotspots of deprivation for targeted investments. Researchers like Duque *et al.* 2015, and Hofmann 2001, argue that poverty measures like individual level income and consumption require a heavy investment of time and money to conduct large-scale surveys. Thus, they often fail to capture intra-urban variation in deprivation among slums, a gap that can be fulfilled by spatial mapping of slums. In order to advance geospatial mapping techniques to the level at which they are operational for this purpose, GIS data must be integrated with statistical databases of socio-economic indicators and field surveys to evaluate the environmental and related socio-economic impacts of informal settlements.

For example, in a study integrating statistical databases with geospatial data conducted within 10 districts in the Brazilian city of Cuiaba Zeilhofer & Topanotti, 2008, , the authors extracted and scored, 35 indicators of environmental degradation pertaining to vegetation cover, street network, land ownership, and water and sanitation infrastructure from government statistical databases, field surveys, and GIS. The highest indicator scores were observed for vegetation cover and water supply. The former was impacted by the growth of informal occupation, while water pollution of urban streams was characterized by accumulation of solid waste and raw sewage. The latter points to the poor coverage of sanitation infrastructure in sampled areas Zeilhofer & Topanotti, 2008, p.10, . Higher degrees of degradation were seen in younger settlements due to a lack of infrastructure and public services. Settlements in districts with elevated declivity suffered from erosion processes due to vegetation clearing or inadequate orientation of street network. The World Bank 2016, geo-referenced household surveys built on an analysis conducted on satellite data to collect key information about living standards in cities. The use of satellite imageries for sampling design and field work increased representativeness within cities, allowing the research team to appreciate differences between regular and 'irregular' settlements often excluded or poorly represented, . Using night-time images, Zhuo *et al.* 2009, have shown that the distribution of light intensity can be used to further estimate the density of energy consumption, greenhouse gas emissions, and economic activity.

Some innovative statistical approaches to slum mapping and deprivation variability have combined RS imagery with mobile phone usage data to provide a more up-to-date measure of poverty compared to census data, in low- and middle-income countries. Steele *et al.* 2017, conducted such a study for mapping spatial distribution of poverty in rural and urban Bangladesh. Night-time lights and transportation time to the closest urban settlement were important variables to predict poverty in both rural and urban areas. Higher cell phone usage, generally, was associated with lower poverty rates in both rural and urban areas. The combination of spatial data and more frequent cell phone usage data may distinguish the transitory poor from the chronically poor Steele *et al.*, 2017, p.8. This integrated approach offers the potential for a fuller characterization of the spatial distribution of poverty and the findings and lessons learned from this research could be applied for mapping electricity deprivation in slums and informal settlements in less developed countries.

Spatial mapping of slum morphology has the benefit of identifying locational characteristics like proximity to landfill sites and the presence or type of sanitation infrastructure that may have consequences for health and social outcomes of residents living in such communities. Rahman & Alam 2015, p.4, found that 76.4% of children in three Bangladeshi slums were suffering from diseases because of poor hygiene resulting from inadequate sanitation services. In conjunction with

poor access to nutritious food, these children had high rates of morbidity that can have grave consequences for future cognitive development and socio-economic mobility. The absence or inadequate levels of other basic services in slums and informal settlements, like water supply, also have an adverse impact on school completion rates among children. In a study of 33 public schools in Delhi, India, Chugh 2013, p. 17, found that children living in slums and resettlement colonies were at a higher risk of dropping out before reaching secondary level. One of the major factors underlying this educational outcome was poor infrastructure in these communities.

In order to spatially target policy interventions to address deprivation in slums, disaggregated contextual spatial information such as access to roads, neighborhood density, building structures, and proximity to hazardous zones is needed. Such data can provide a multidimensional assessment of the challenges and needs of the urban poor. Baud *et al.* 2010, p. 360, highlight the potential of remote-sensing methods for mapping multiple deprivations by analyzing spatial variation within Delhi such as patterns of green spaces, the structure of building layouts, density of built-up areas, and urban structure i.e. arrangement of land cover, . RS can play a key role in analyzing space-time dynamics such as monitoring densification and expansion of settlements or assisting with the implementation of slum improvement policies Patino & Duque, 2013, .

A number of VHR RS products such as IKONOS, QuickBird or Pleiades, from numerous satellite data providers are now readily available to the public. New emerging missions e.g. Planet, make image data even more accessible and actionable. All of these resources can be employed more frequently for extracting information about physical deprivations across different residential areas. This urban morphology data can be then linked with socio-economic parameters e.g. access to potable water supply, sanitation, household size, and tenure status, obtained from census or household surveys to design urban development plans for a city or region. Recently, a few researchers have attempted to predict outcome indicators obtained from a pre-existing census or survey as a function of remote-sensing-derived variables Stoler *et al.*, 2012; Taubenböck *et al.*, 2014; Duque *et al.*, 2015, . In both Duque *et al.* 2015, and Stoler *et al.* 2012, , the authors model a Slum Index computed from survey and census data respectively, that measures various degrees of household deprivation. Conversely, Taubenböck *et al.* 2014, are mostly interested in how to delineate and define slum areas from a morphological point of view using remotely sensed data with a selection of explanatory variables. This study builds on these works to develop a model that could be used to predict deprivations at household and slum levels.

In sum, spatial imagery is a powerful tool to evaluate the extent and variability of deprivation in slum settlements but has thus far been rarely used for that purpose. Early attempts have focused on LULC mapping and change with respect to informal settlements. Beyond mapping slums, researchers make the case for identification of contextual slum typologies—integrating image-based information with socioeconomic characteristics—which may ultimately lead to better targeting of pro-poor policy interventions Kuffer *et al.*, 2016, . However, only a few studies have used EO data to predict access and quality of basic services such as water and sanitation in slums. This study attempts to devise a methodology for this purpose, to support planners and policymakers in the decision-making and implementation process.

3. BACKGROUND ON SLUMS IN DHAKA, BANGLADESH

The capital city of Bangladesh, Dhaka, was selected for our case study based on three criteria. First, we sought to leverage existing data collection efforts within the World Bank in cities in which rapid urbanization is accompanied by poverty in tandem with inadequate and spatially uneven housing, water supply, and sanitation services. Dhaka's recent history has witnessed an overwhelming growth of its population, chiefly through migration Lipu, Jamal, & Miah, 2013. Dhaka's current population is estimated at around 15 million residents and maintains a growth rate of four percent per year. Due to the city's topography and constrained land management, Dhaka's population growth has resulted in unplanned urban expansion and the proliferation of slums and squatter settlements. Unauthorized shanty housing has developed on abandoned private or government land, along the highway or on the side of railway tracks and industrial belts. As a result of the government increasing its guardianship over public lands, private property squatting has become more prevalent CUS *et al.*, 2006, p. 21. The Bangladesh Bureau of Statistics BBS, conducted a slum census in the Dhaka City in 1985, followed by another, extended, Census of Slum Areas and Floating Populations in 1997 in all cities and municipalities of the country. The most recent census BBS, 2014, estimates that over 2.2 million Bangladeshis or 592,998 households, live in 13,938 slums across the country. Among them, over 1.6 million reside in Dhaka City Corporation slums. Dhaka continues to experience substantial urbanization with population growth at a rate of more than four percent a year.

Despite a significant reduction of poverty over the past years, Bangladesh remains one of the poorest countries in Asia. Per the latest data from the 2010 Household Income Expenditure Survey HIES, Bangladesh has a national poverty headcount rate of 31.5% and an extreme poverty headcount rate of 18.5%. While in absolute terms, the bulk of the poor still live in rural areas, rapid urbanization is increasing the number of poor in urban areas, commonly referred to as urbanization of poverty. As of 2011, only 29.4% of the population is classified as urban. However, based on UN population projections, Bangladesh is expected to be over 50% urban by 2047 Islam *et al.*, 2013. Although national statistics show the urban population is better off than their rural counterparts, slum populations are often worse off. Because of the pressure from rapid and poorly managed urbanization, Dhaka faces many challenges in terms of its livability. The Economist Intelligence Unit's EIU, liveability ranking that examines cities in terms of population density, housing, pollution, affordability, and basic services placed Dhaka among the least livable cities, 137 out of 140 EIU, 2016, . This lower ranking of Dhaka was mostly due to the poor quality of its infrastructure. Urban populations face heterogeneous

living conditions and slum environments are an example of extreme intra-city inequality in terms of access to housing and basic services.

Most Bangladeshis have access to Tier 1 and 2 water services, improved and basic water respectively, and close to 98% of the population now has access to some kind of technologically improved water source World Bank Group, 2017, p. 26, . The Millenium Development Goal MDG, water target to halve the proportion of people using unimproved water sources by 2015 was achieved in Bangladesh. Still, higher tiers remain elusive for most; for instance, of the people classified as having access to improved water, about a quarter must still go off-premise to collect it. Moreover, having access to improved water sources does not ensure that water is clean. When considering *E. coli* and arsenic contamination, only 52% of the population has access to a clean and improved water source World Bank Group, 2017, p. 26, . Though many gains were made in water in the new millennia, Bangladesh failed to achieve the MDG sanitation target due to the high level of sharing between households. However, both urban and rural areas have witnessed significant improvements over time. Between 2006 and 2014, access in urban areas improved from 59 to 84 percent and doubled in rural areas from 32 to 64 percent World Bank Group, 2017, p. 39, .

A second important criterion—especially in view of future uses of the analytical tool by policy makers—was to focus on locations in which there was an existing mandate and/or openness to collaboration of city officials serving urban slums and informal areas. In this respect, The Government of Bangladesh GoB, has demonstrated its commitment to the Sustainable Development Goals SDGs, , including SDG 6 – ensuring availability and sustainable access to water and sanitation for all. The SDGs were taken into consideration while developing the country’s seventh Five-Year Plan for the period of 2016-2020. In addition, the Dhaka Water Supply and Sewerage Authority DWASA, has shown a significant commitment to accommodate this rapid pace of urbanization and is now capable of providing water to all of 15 million residents under its jurisdiction.

Third, the choice of pilot study site was driven by the availability of spatial data. Extensive research was conducted by cross-checking available sites with the aim of finding existing and readily available census or survey data covering the pilot city’s informal areas and slums which proved difficult, . Two timely and relevant data sources were available for Dhaka: first, the Bangladesh Urban Informal Settlements Baseline Survey BUISBS, slum survey; and second, spatial data for the VHR RS imagery and slum characterization analysis. The characteristics of these datasets and their applicability to this study will be further detailed in the following section.

4. DATA AND METHODOLOGY

Two types of data were utilized for this study: household survey data and Earth Observation data. Household survey and EO data form the dependent and independent variables respectively for the regression model. Each survey will be discussed in detail below before we discuss how the data was used in our novel methodology for analysis.

The household survey data we relied upon is from an existing dataset, the Bangladesh Urban Informal Settlements Baseline Survey, collected for the Bangladesh WASH Poverty Diagnostic in May 2016. The survey included questions on access and quality of water and sanitation services, adequate living space, type of housing structure, security of tenure, and access to electricity. The survey was designed to collect data from 600 slum households across 63 slum communities in the DCC.

The sampling was done in two stages. In the first stage, slums were selected as the Primary Sampling Unit PSU, using probability proportion to size PPS, and in the second stage households were selected from those slums using systematic equal probability sampling. The sampling frame for the first stage was generated from the 2014 BBS Census of Slums and Floating Population, which consisted of 3,360 slums. The BBS Census classified slum communities into three strata: 1, small slums 5-10 households, ; 2, medium slums 11-200 households, ; and 3, large slums more than 200 households, . The survey team decided to sample five households from each small slum strata 1, , and 10 households from each medium strata 2, and large strata 3, slum. The team also decided 50% of all household samples would come from large slums and the remaining 50% from small and medium slums combined. Table 1 provides the details for the sampling frame from the BBS Slum Census 2014 and BUISBS sample.

Stratum		BBS Slums Census				BUISBS sample		
		Slums		Households		Number		
ID	No. households	Number*	Share	Number*	Share	Slums	Households**	Cluster size
1	5-10	1,006	29.9%	7,801	4.4%	6	30	5
2	11-200	2,206	65.7%	70,481	40.1%	27	270	10
3	201-plus	148	4.4%	97,610	55.5%	30	300	10
Total:		3,360	100.0%	175,892	100.0%	63	600	-

Table 1. Sampling frame and sample for BUISBS

The BUISBS survey consisted of five modules: i, roster and individual level characteristics; ii, household characteristics; iii, housing conditions; iv, water and sanitation; and v, consumption of food, non-food, and durables. Data were collected over a period of 16 days between May 12 and May 28, 2016 with 30 teams of two interviewers. Teams were assigned slum communities based on practical considerations e.g. distance to informal settlements. The completed survey was representative of all slums in the DCC and the final sample included a total of 588 slum households 98 percent response

rate. The sample distribution included 30 households from small slums, 259 households from medium slums and 299 households from large slums.

The original dataset did not include the geographic locations of the surveyed households required to link household survey data with the EO data. These data were collected separately in June 2017 for all 63 slums. However, it was no longer possible to collect household level locations due to time and resource constraints. Consequently, most of the analysis relies on aggregate measures at the slum level for this pilot study. Relevant data were extracted from the first four modules to construct housing deprivation measures and indices which will be described in more detail below.

Table 2 summarizes the profile of slum households and residents. A typical slum household has 4.3 members, household heads are on average 39 years old and have been living in the slum for around 8.6 years, suggesting housing deprivation is rather permanent. Most adult members in the household are income-earners, with some gender imbalance in work participation with 89% of males and 50% of females engaging in economic activities.

Characteristic	Small	Medium	Large	Total
Number of slum residents	167,488	2,907,968	4,140,496	7,215,952
Number of slum households	37,947	686,637	959,623	1,684,207

Electricity is main source of light %,	100.0	99.2	93.6	96.1

Table 2: Basic profile of slum households and slum residents Source: unpublished manuscript titled “The Informal Markets for Water and Sanitation Services in Urban Slums: A case study of the Dhaka City Corporation in Bangladesh” by Arias-Granada, Y., Haque, S., Joseph, G., Yanez-Pagans, M., .

Overcrowding, poor housing conditions, and fear of eviction are salient features of lives in slums. One room is normally shared by three people and rooms are on average 12 square meters in area. Housing structures are largely constructed using low quality materials including tin-sheds 59% of housing structures, and semi-pucca 29% of housing structures, . Only 12% of housing units are constructed with permanent construction materials. Over half of slum residents live under fear of eviction. Slums are also dynamic rental housing markets with more than 70% of slum residents reporting renting their dwelling. Around 61% of slums in Dhaka are located on land reported to be government owned, while 35% are

located on privately owned land. Interestingly, access to public services such as water and sanitation in slums is very high.

The remote-sensing part of the study was completed under the EO4SD-Urban program 2016, and showcased one of the products provided by the EO4SD-Urban consortium called “Extent and Type of Informal Settlements/Slum Areas.” This analytical product targets the spatial location, extent, characteristics and spatial-temporal development of building agglomerations that can be classified as informal settlement/slum areas. These areas share a number of physical and morphological characteristics, patterns and contextual parameters compactness, patch size, density and size housing structures, land cover share, proximity to infrastructure, etc., that allow their discrimination from other residential areas using VHR satellite imagery. Considering these areas are often found in specific locations like river banks, close to transport networks or next to industrial or commercial units, this analysis is based on the premise that the physical appearance of a human settlement consistently reflects certain socioeconomic and demographic characteristics.

Informal settlement features in Dhaka were obtained via an expert analysis of very high-resolution multispectral satellite images acquired at two points in time 2006 and 2017. All variables have been derived from EO or open source data OpenStreetMap, on a semi-automated basis. Analysis utilized knowledge-based labelling of classes by classification and interpretation similar to procedures utilized for LULC urban mapping production workflow. Key characteristics of informal settlements such as growth in terms of location and area, and type such as established/permanent or new developments, were the primary physical patterns emphasized. Spatial metrics and indicators such as compactness, patch size and density of buildings, spatial patterns such as built-up density and proximity to infrastructure assisted in definition and delineation of these settlements. The spatial context of the settlement with respect to hazard and risks such as flood risk, derived EO imagery or spatial analysis of additional geospatial products that typically support risk reduction and mitigation measures. Metrics and typologies attributing detected slum patches provided the means to define custom thematic classes either from individual variables or by combination of multiple variables. As these informal settlements are in a dynamic environment with frequent population fluctuations, temporally and spatially, the data also tracked the evolution of changing locations and attributes of informal settlements.

The study area corresponds to the administrative boundary of the Dhaka Metropolitan Area, which is a police jurisdiction area that comprises forty-one “*Thanas*” the lowest among four administrative tiers in Bangladesh, with an area of about 300 km² and a population of 8,906,039 BBS Census, 2011, p. xi. EO data were obtained via analysis of Very High Resolution with pixel spacing in the range of 0.5 – 0.6 m, multispectral satellite images acquired for two reference years 2006 and 2017. In addition to EO data, open data spatial datasets, such as OpenStreetMap, were also used.

The initial slum identification and delineation step was facilitated using historical datasets obtained and shared by a research consortium led by Columbia University see Gruebner *et al.*, 2014. The final shapefiles polygons, show all the slum neighborhoods and patches the researchers detected in Dhaka in either 2006 or 2010. Once the slum polygons were identified and delineated, several dimensions related to housing that could be extracted from EO data that may explain variation in housing deprivation in slums were derived. These dimensions included measures on locational aspects e.g. proximity/distance to central business district, , access e.g. proximity/distance to arterial road, , hazard susceptibility e.g. terrain slope, , morphology e.g. built-up area’s homogeneity, , relational measures about space e.g. built-up density, , and structural measures e.g. dwelling size, . Several measures within each of these categories were used as explanatory variables for the statistical models. These measures were extracted for the 63 slum communities for which location was available.

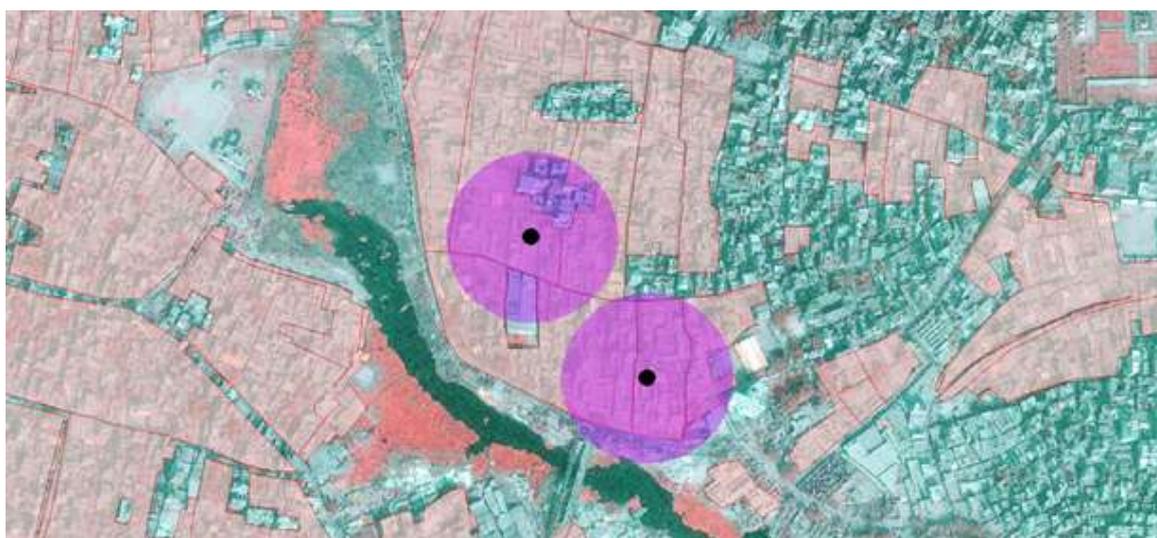

Figure 1. Example of location of slum communities as derived from WASH-POV. Slum areas in pink, and buffers around slum communities in purple, .

Figure 2. Example of LU/LC classification within slum and surrounding areas used for LULC structure indicators

Figure 3. Example of quad-tree segmentation within built-up mask used for an estimation of area homogeneity indicator

Figure 4. Example of mean dwelling size derived comparing units with different size settings

The goal of our statistical model is to predict housing and basic services deprivation in slums using EO data requiring measures of housing and basic deprivation. To do so, we constructed a comprehensive measure of overall deprivation that combines multiple indicators into a single index, the Slum Severity Index SSI, first developed by Patel *et al.* 2014. Six variables from the household survey were used to derive measures of housing deprivation: i, access to drinking water, ii, access to sanitation, iii, adequate living space, iv, permanent structure, v, security of tenure, and vi, access to electricity. All the outcome variables were negatively coded and dichotomized: 1 for lack of access, and 0 otherwise. Table 3 provides summary statistics for each of the measures included in the SSI for the sampled households in Dhaka. Lack of adequate space is the most prevalent problem in slums whereas access to water and electricity seems almost universal. These decomposed measures provide a better understanding of housing deprivations compared to a simple slum/non-slum dichotomy for urban planners and policymakers. In addition, they provide readily useful inter- and intra-slum information for policymakers by rapidly identifying which dimension of housing and basic services requires attention.

Housing Deprivation	% Households
Lack of Access to Water	3.6%
Lack of access to sanitation	12.8%
Lack of adequate space	74.5%
Lack of Durable House Structure	58.2%
Lack of secure tenure	46.6%
Lack of Access to Electricity	3.6%

Table 3. Types of Housing Deprivation in Dhaka slums Source: BUISBS, 2016.

The six binary variables of housing deprivation described above were used to construct a the SSI to derive an aggregate measure of housing deprivation. The original index is an aggregate measure of housing deprivation across five aspects of housing as proposed by the UN-Habitat’s 2010, definition of slums. In this project access to electricity has been included as the sixth housing dimension to construct a more comprehensive SSI. The SSI ranges from 0 to 6; a score of 0 indicates the household is not deprived of the measures described above, and a score of 6 indicates the household is deprived of all six elements.

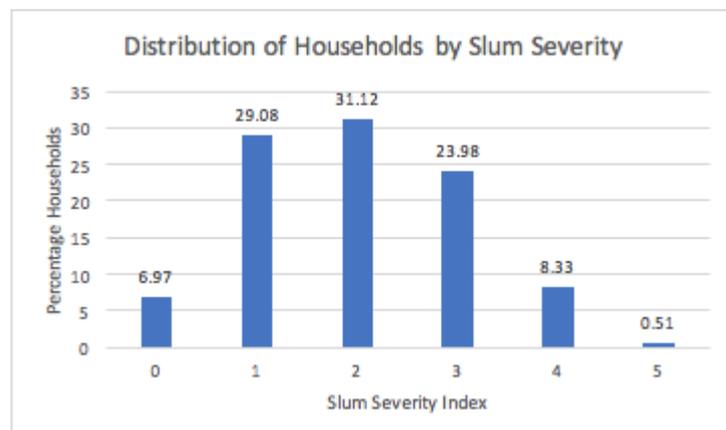

Figure 5: Distribution of Households by Slum Severity in Dhaka Source: BUISBS, 2016.

Figure 5 provides the distribution of households by slum severity. While no households in the surveyed sample lack all six elements of housing and basic services, one quarter are deprived in three or more areas. Interestingly, seven percent of households are not deprived in any of the six areas despite being located in official a slum neighborhoods. This exemplifies how this comprehensive measure could help policymakers identify the most deprived slums in the city.

Individual measures of deprivation as well as the SSI are flexible in the sense they could be aggregated at slum level. Slum level measures of housing deprivation were created by calculating the percentage for each slum e.g. percent of households deprived of water, . Similarly, household level SSI was aggregated at the slum level by taking a simply averaging the household scores within a given slum.

The BWPD classification of levels of access and quality of water and sanitation services was used and access and quality were divided into four tiers each. A four-level variable, measuring service levels in addition to the simple binary variable described in section 6a, was also created. The SSI could potentially be created using these measures. Such an index would provide more nuanced measures of deprivation and capture the heterogeneity across slums in a greater detail.

Access and quality of water in the slums of Dhaka, Bangladesh is reported in Table 4. It is important to note that while only 3.6 percent of households had a complete lack of access to improved water, when considering tier 4 which represents piped water supply on premise, , 37.2 percent of households are deprived. A tiered approach adds quality to the simple binary access measurement and hence is important for policymaking that aims to focus on improving quality of service.

Levels of Access and Quality of Water	% Households	BWPD classification
Total Unimproved T0,	3.6	Unprotected springs, unprotected dug wells, cart with small tank/drum, tanker-trunk, surface water, bottled water
Total improved T1,	96.4	Piped water to yard/plot, public taps or standpipes, tube wells or boreholes, protected springs, rainwater
Improved + 30 min T2,	92.4	Satisfies JMP “Improved” technology and w/in 30 min round trip collection improved and proximal,
Improved on premises T3,	70.1	Satisfies JMP “Improved” on premise
Piped on premises T4,	62.8	Satisfies JMP “piped water” on premise

Table 4. Access and quality of water in slums of Dhaka, Bangladesh.

Access and quality of sanitation is reported in Table 5. The vast majority of households 92.6%, have not achieved the highest level of access and quality, tier 3 which represents private sewer connection and private unshared sanitation facility, .

Levels of Access and Quality of Sanitation	% Households	BWPD classification
Open Defecation	2.9	
Unimproved T0,	12.8	No facilities/bush or field use of bucket, hanging toilet/hanging latrine, flush/pour to elsewhere
Improved including shared, T1,	78.7	Shared “improved” facilities including flush toilet to piped sewer system, septic tank, or pit latrine; ventilated improved pit latrine VIP, , pit latrine with slab, composting toilet
Improved excluding shared, T2,	8.5	Unshared “improved” facilities
Private Sewer connection T3,	3.4	Unshared improved sanitation facility that is connected to sewer

Table 5. Access and Quality of Sanitation in slums of Dhaka, Bangladesh.

A similar approach to that described above but using additional dimensions was used to assess the SDGs Table 6, . Similar trends were observed in SDG indicators; lack of access to water and sanitation were high and comparable to the highest tier of services. Since SDG focuses on both quality and access of these services, it is worthwhile to note that Dhaka is far from providing services to meet these goals for slum-dwellers.

SDG Indicator	% Households
Lack of Access to Water	35.5
Lack of Access to Sanitation	78.7

Table 6. Access and Quality of Water and Sanitation by SDG definition in slums of Dhaka, Bangladesh.

After identifying and classifying “slum-like” neighborhoods, a list of indicators Table 7, was compiled to characterize informal settlements/slum areas at neighborhood and/or household level. These are based primarily on VHR imagery, interpreted EO-based products e.g. EO4SD LULC, EO4SD Flood, or other open data e.g. OSM, or these any of these datasets combined.

Indicator Group / Indicator	Indicator type	Input Data
Neighborhood locational		
Location type	Qualitative	Imagery, LULC
Distance to paved road	Quantitative	OSM, LULC
Distance to railroad	Quantitative	OSM, LULC
Distance to center/CBD	Quantitative	LULC
Distance to nearest important connectivity node	Quantitative	OSM, LULC
Distance to heavy, industry	Quantitative	LULC
Distance to shoreline river, canal, lake or sea,	Quantitative	LULC
Distance to any user provided feature set water distribution points, sewage, etc.,	Quantitative	Field survey / GPS
Neighborhood accessibility		
Distance to arterial capacity, road	Quantitative	OSM, LULC
Distance to selected, public services	Quantitative	OSM / GPS
Occurrence of feature within X meters	Qualitative	OSM, LULC
Road network "winding index"	Quantitative	OSM
Density of road network	Quantitative	OSM
Structure of road network typology	Qualitative	OSM
Road connectivity - end point nodes	Quantitative	OSM
Road connectivity - junction point node weights	Quantitative	OSM
Road connectivity - junction point nodes	Quantitative	OSM
Neighborhood vulnerability to environmental hazards		
Terrain slope	Quantitative	DEM
Geomorphology of terrain	Qualitative	DEM
Landslide risk	Qualitative	DEM, soils
Flood inundation risk river, tsunami, storm surge,	Qualitative	EO4SD Flood product
Distance to technological hazards	Quantitative	LULC, GPS
Open sewers	Qualitative	GPS
On dump and hole garbage filling	Qualitative	GPS
Neighborhood shape morphological characteristics		
Area	Quantitative	GIS
Perimeter	Quantitative	GIS
Shape compactness	Quantitative	GIS
Neighborhood LULC proportional characteristics		
LULC structure in surroundings	Quantitative	GIS
Neighborhood internal structure		
Built-up homogeneity	Quantitative	OBIA
Built-up density	Quantitative	OBIA
Open spaces density	Quantitative	OBIA
Greenness density	Quantitative	OBIA
Neighborhood dwelling characteristics		
Mean dwelling size	Quantitative	Imagery
Main direction	Quantitative	Imagery
Compactness	Qualitative	Imagery
Mean dwelling separation	Quantitative	Imagery
Mean estimated dwelling height	Quantitative	Imagery
Roof heterogeneity	Quantitative	Imagery
Roof & masonry material	Qualitative	Imagery
Estimated dwelling age	Qualitative	LULC
Lacunarity of housing structures	Quantitative	Imagery

Table 7. List of candidate characteristics indicators, derivable for informal settlements/slum areas

Slum level models were created using aggregate dependent household survey, variables. Since most aggregate measures can be treated as count variables e.g. total number of households lacking a housing element in a slum, Poisson regression modeling was applied. In the case of overcrowding, assumptions for Poisson regression did not hold hence an Ordinary Least Square OLS, regression model was constructed using the percent of households deprived as an outcome measures. There are seven models in total six for each of the measures of deprivation in housing and basic services, and the seventh for the aggregate SSI, ; six of them used Poisson regression and one of them overcrowding, used OLS regression.

Equation 1 presents a generic equation for all six Poisson regression models.

$$Y = e^{\ln E + \beta X} \quad 1,$$

where Y represents the expected count of deprivation in a slum. X represents explanatory variables derived from EO data e.g. locational aspects, access, hazard susceptibility, morphology, relational measures about space, and structural measures, and E represents the number of household surveys.

Equation 2 presents the equation for the OLS regression model.

$$Y = \beta_0 + \beta X + \varepsilon \quad 2,$$

where Y represents a dependent variable overcrowding, in slums and X represents the explanatory variables derived from EO data.

Explanatory variables were selected using the standard stepwise regression procedure that involved selecting the variables that minimize the model's AIC value through progressive steps, wherein improvements are made to the fitness of the model as each variable is included forward option, or excluded backward option, from the initial model. All stepwise regressions were run using Stata 15 software. Over-dispersion in count data was verified and the likelihood ratio test of alpha used to check if Poisson regression was appropriate or if negative binomial regression should be considered to tackle potential over-dispersion.

The percent of households with a lack of access to a particular housing element in each slum could have been calculated and used as dependent variables. Similarly, the average SSI for each slum could have been calculated. Since both percentages and average SSI could be treated as continuous variables, Ordinary Least Square OLS, regressions may have worked for each of the indicators. However, estimations from percentages and averages based on a sample of only five to ten households per slum would have likely suffered as a result of the small sample size.

In addition, the survey dataset includes a relatively small sample of 63 slums, which provides limited statistical power for estimating a model. This is especially true for a count model such as Poisson regression that usually requires a larger sample size. Different model specifications OLS, Poisson and Negative Binomial as well as inclusion or exclusion of certain variables, produced very different results in terms of coefficients, directions, and significance for some of the explanatory variables. Therefore, this project seeks only to demonstrate the approach and models have been constructed primarily for illustrative purposes. This is not to say the results will not hold with a larger sample as intended in second phase of this project, , however, given the limited statistical power due to small sample size they should be interpreted with caution. The approach will nonetheless remain the same for larger sample sizes, which are expected to improve estimations.

As noted earlier, the goal is to provide a framework that serves as a basis for designing appropriate policies for slums and targeting interventions in the most efficient manner possible. For example, some slums may require improved sanitation while others may need interventions to improve the quality of water services. For specific slum policies such as in-situ slum upgrading, it may be important for policymakers to identify slums where secured tenure may be a challenge since it is generally the first step for in-situ upgrading. Even if slum upgrading may not be a possibility, a map indicating various levels of services could benefit local governments and utilities to identify areas where they could find opportunities to provide new services or improve existing services such as for water and electricity. However, estimating these needs in a timely manner and in a cost-effective way is not an easy task.

As outlined in Figure 6 below, evidence for the entire city could be developed with a comparatively small number of data points from existing households surveys by integrating those data with data obtained from satellite images and employing regression analysis. Using the resulting regression models, deprivation measures could be predicted for all the slums in the same city. Ultimately, a series of maps could be generated to provide an overall picture of slum severity in the study city.

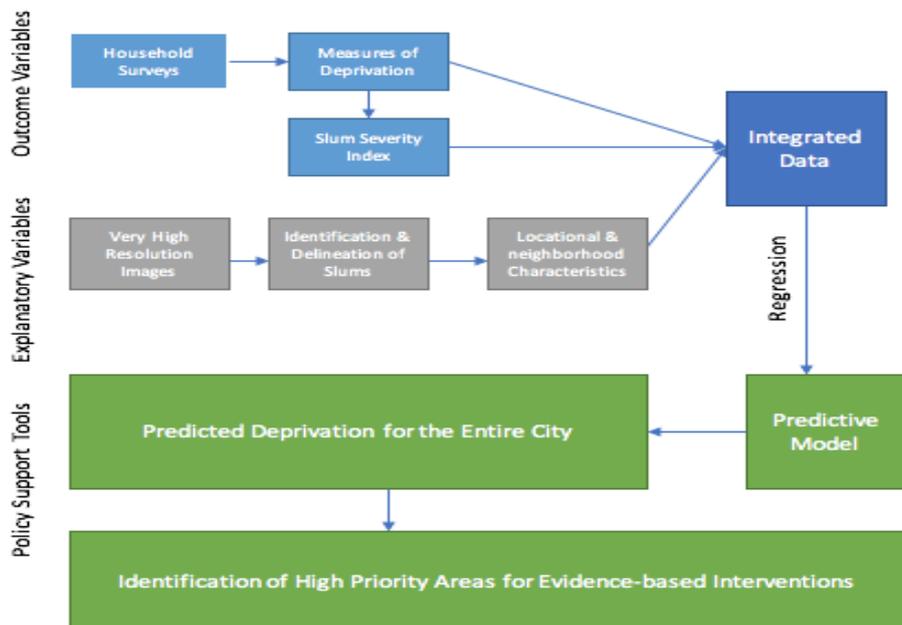

Figure 6. A framework for evidence-based slum policy-making.

This paper does not advocate modeling for the sake of modeling. Nor that models and procedures must be advanced and complex to be of value. Rather, a lot could be gained by simply combining existing datasets in the proposed analytical framework at a much lower cost with minimal time to inform policy making as well as to conceive new interventions.

5. RESULTS

The regression modeling with housing and basic service deprivation measures as a function of EO based variables revealed important relationships as originally hypothesized. Table 8 provides a summary of each of the seven multiple regressions.

Earth Observation Variables	Outcome Variables						
	SSI	Water	Sanitation	Overcrowding	Structure	Tenure	Electricity
Locational Characteristics							
Distance to Central Business District (in km)	↑	↑		↑	↓		↑
Distance to Paved Road (in km)		↓	↓	↑	↓		
Distance to Arterial Capacity Road (in km)	↑	↑		↑		↓	↑
Distance to Railroad (in km)	↑		↑	↑	↑		
Distance to Heavy Industry (in km)	↓	↓		↓	↑

Table 8. Multivariate Regression Results Summary for Deprivation measures as a function of EO data

Many of the locational characteristics of slums derived from EO data were statistically significant predictors of housing and basic services deprivation. Of note is the distance to Central Business District CBD. With increasing distance, slums were more deprived of services water and electricity, whereas it had no association with sanitation, overcrowding, or structure. With the exception of sanitation, this finding concurs with what is generally referred as “peripheralization of slums”, indicating decreasing access to services as new slums form in the peripheries of a city.

Another interesting set of indicators was related to proximity to transportation networks and employment opportunities such as heavy industries. Generally, deprivation in slums was lower for slums close to roads, in particular water and electricity services improved for those who were closer to arterial roads. Interestingly, as slums moved farther away from railroads or major road junctions, their housing deprivation increased. Proximity to heavy industry also resulted in higher housing and services deprivation indicating a potential trade-off between residing near a workplace at the cost of lower quality housing, a phenomenon that is generally observed.

All indicators of density were associated with an increase in housing and basic services deprivation. Average dwelling size and average distance between two dwellings essentially measure housing density. In addition, percentage of built-up area in any slum neighborhood is another direct measure of overall density. Effectively, the more crowded the slums were, the more deprived they were. This is not surprising since residential density is often a signature manifestation of living conditions in slums.

Distance to social amenities such as schools, universities, hospitals, and places of worship could be important predictors of housing conditions. The hypothesis here was that proximity to social amenities is a desirable characteristic that might be associated with improved housing conditions yet the results were mixed. As the distance from amenities increased, some housing conditions improved while others worsened. The relationship between distance to amenities and housing conditions might not be straightforward and may require additional data to make plausible sense of these findings.

Various land use and land cover characteristics were significant predictors of housing and service deprivations in expected directions. For example, as the percentage of high-density residential urban fabric increased for a slum, housing deprivation decreased. Similarly, commercial and industrial land use and percentage of water bodies also reduced housing and basic service deprivation. Finally, housing deprivation also decreased with increasing percentage of green space. Several measures of street patterns within slums were associated with housing and basic services deprivation. As expected, higher percentages of informal roads and winding roads were associated with higher service deprivations. Slums with road networks that had lower level accessibility were also more deprived in terms of services. There were some mixed results in this category that may require further investigation with larger datasets.

While the results presented here are very promising, there are some limitations in this pilot analysis that are worth noting. Most of these arose from the lack of an enhanced dataset limiting the benefits that could be derived from the proposed framework. Four particular limitations should be highlighted at this stage of our framework's development. First, while the original sample was a sizeable 588 households, location data were only available at the slum level, which reduced the aggregated sample to 63 slums. In addition, only five to ten households had been surveyed in each slum and aggregate measures e.g. percentage of households with water deprivation, suffered from generalizations as a result of the small sample size. As a result of the aggregation and subsequent smaller sample size Poisson regression was employed. However, any regression specification that is meant for count data such as Poisson regression requires a much larger sample size. While the results may not be inaccurate with a sample size of 63, they will be much more robust with a sample size greater than 100. In fact, a sample size over 500 is desirable for Poisson regressions. Furthermore, policy responses differ based on the type of deprivation Nandi and Gamkhar, 2013. Often, household level data are aggregated to the neighborhood level, resulting in a loss of heterogeneity among households. While such aggregations are useful for community level interventions and city level comparisons, they are less useful for household level interventions.

Second, the actual deprivation indicated in our models may be underrepresented owing to narrow definitions and inherent assumptions used when measuring deprivation. The UN-Habitat 2010, definition of slums upon which this model was based is conservative in the sense that it underestimates the deprivation of slum households. This is primarily because the definition is restricted to the physical and legal characteristics of slums and eschews the social dimensions e.g. concentrated poverty, that are often difficult to measure Davis, 2006, . Nonetheless, we can expect that the underestimation is partially corrected as physical deprivation is highly correlated to social and economic marginalization Arimah, 2001; Begum & Moinuddin, 2010, . In addition, when a slum dweller responds, "yes" to a water availability question, it may not accurately capture access to water since the question does not focus on quantity or quality, time spent collecting water, etc.

Third, we had limited local expertise and low quality geo-referencing data that may increase the uncertainty of our slum identification strategy. RS identifies *probable* informal settlements by localizing areas with visible physical characteristics typical of slums in the area and is capable of recognizing patterns of deprivation in areas that have yet to be formally identified. However, local expertise and/or field validation are needed to confirm the results. Further, the accuracy of matching EO-derived characteristics with household survey data depends on the quality of geo-referencing data. While buffer zones can help limit these uncertainties, ideally household surveys should strive to include high quality geo-referencing data at the outset.

Fourth, we did not analyze the impact of vertical infrastructure growth on slum deprivation in detail. The morphological patterns of some slums especially in Eastern Dhaka and Southern Dhaka near the river, underwent transformation from an originally quite homogeneous state to a more complex state. For example, a substantial proportion of mostly multi-story high-rise buildings was erected within the original slum neighborhoods, mostly in a scattered, spatially inconsistent, and organic manner. Rather than reflecting a change in soil sealing imperviousness, or structural patterns which could be reflected by standard variables derived from optical EO data, , this process is attributed to a change in 3D zoning—the average height of building blocks increased over time. Still, the prevailing major proportion of built-up retains

its slum character. For the time being, the image analysis used for this report does not fully reflect this internal process in slum areas.

Moving forward, regression models will be constructed using household level data increasing the sample size and the statistical power significantly. The second round of BUISBS has already been concluded and includes household level GPS locations for all 600 households surveyed. Future model specifications will be logit and probit for binary deprivation measures e.g. a household's access to water, and ordered logit for the SSI that will range from 0 to 6 for each household. This approach will overcome the aggregation bias, which is inevitable in slum level analysis using household survey data and allow planners and policy makers to design and implement more targeted slum policies. In a second phase of this project, we will also utilize a multi-tiered approach to capture various aspects of access and quality for water and sanitation. The details for each measure captured e.g. levels of access and quality for electricity, will be used to construct nuanced versions of the dependent variables including an enhanced SSI.

Despite several limitations of sample size and data, these models demonstrated a high degree of goodness of fit and indicators derived from EO data successfully predicted housing and basic service deprivation at the aggregate level e.g. SSI, as well as the decomposed level e.g. individual elements such as water and sanitation. This promising approach could provide useful insights for planning and policymaking. Further, using only a small subset of data, these models could predict deprivation as a function of EO data for the entire city.

6. CONCLUSIONS

Kuffer *et al.* 2016, conducted a review of 15 years 2000-2015, of slum mapping using RS information. One of the main contributing aspects highlighted from this review is the need to identify the “contextual slum typologies as an important research direction” in addition to slum identification. They argued, combining “image-based information with socio economic characteristics may ultimately lead to a better targeting of pro-poor policy interventions” p. 474.

Policy makers and city planners need the appropriate tools and evidence to provide full standards of basic services in changing environments of urban settings. Current planning and policy approaches rely on household surveys to estimate demand for urban services such as water and sanitation. However, these surveys are often expensive and time-consuming. Consequently, they are not conducted on a regular basis. On the other hand, resolution, availability, and affordability of EO data have improved drastically in the last two decades. This model provides a pathway to estimate demands for urban services by leveraging this readily available EO data. This approach also provides almost real-time estimates that could be especially useful given slums in the developing world are rapidly growing and constantly changing.

For national governments, this methodology provides an efficient and cost-effective way to estimate household deprivation and demand for city services nationwide. Given that RS images are available for entire nations simultaneously, there is far less time lag between data acquisition and use in decision-making than traditional survey-based methods of data collection and analysis. Additionally, due to the growing availability of technologies like OpenStreetMap that allow residents to contribute data, geospatial analysis can also take place in real-time using updated information. The possibilities of targeting public expenditure and development on the communities and regions that most need assistance is close at hand. International development organizations, likewise, can now use this methodology to inform both national and global interventions. By estimating global housing deprivation in real-time, without conducting large-scale surveys, funding can be directed to the nations with the most pressing need for infrastructure development.

Additionally, although this study covered a single city, Dhaka, the approach is applicable to other cities in developing countries since similar surveys are routinely collected around the world and remote sensing data are increasingly become available for all these cities. While a survey alone cannot support citywide program implementation, this approach provides a framework that could be applied to predict citywide deprivation once a model is constructed. It is clear that decision-making should be neither driven by data availability nor by statistical techniques. It is important to first develop a clear model. Data on deprivation could be collected and statistical techniques applied only after a clear model is established. To this end, this study contributes to the development of such a model in the context of measuring housing and basic services deprivation from space, which could precede data collection on deprivation at the household level for future surveys and censuses in any city where slums are prevalent.

In an era of increasing urbanization, this study and the use of EO data for exploring housing deprivation have particular relevance and life-changing implications for residents of slums and informal settlements. Given it has been traditionally challenging to chart even the location and growth of slums due to their transient nature, this method will greatly increase the efficiency in designing and implementing, prioritizing or even expanding, basic services in impoverished informal settlements. The success of upgrading services in slums is directly linked to how well the project is planned and executed and how well the interventions are operated and maintained. The process of implementing a slum upgrading project or expansion of basic services, like water supply and sanitation, depends on the quality of information supporting the activities, the analysis of factors that impede households to access services, and the analysis of all possible options of the intervention, prioritization, and sequencing. All of these aspects have been addressed in this report for the case of Dhaka, Bangladesh. Still, there are more possibilities of exploiting the model to identify characteristics that contribute to determine specific parameters for planning and rolling out interventions in an effective way.

These types of approaches ultimately contribute to increased knowledge transfer capabilities amongst countries and sector's institutions to further strengthen urban monitoring systems and the evidence presented. They should not be

seen only as a slum mapping exercise but rather as slum characterization, which is useful to identify pockets of poverty, spaces where development is lagging and areas with scarce provision of basic services. EO data offer a distinctive source of commensurable information that can be further combined with administrative, social and economic information at multiple scales for in-depth policy analysis. Continued investment in the advancement of this technology and research using this methodology will, in the long-term, open new doors to improving the quality of life for over a quarter of the world's urban population that live in slums today.

ACKNOWLEDGEMENTS

The work presented in this report was conducted as a collaboration between the World Bank's Global Water Practice Luisa M. Mimmi and Christian Borja-Vega, the University of Massachusetts Boston Prof. Amit Patel, Tanushree Bhan, Hyun Jung Lee and Marcia Mundt, and GiSat/ESA-EO4SD Tomas Soukup and Jan Kolomaznik, .

The team worked under the guidance of R. Mukami Kariuki and William Kingdom with support from Amanda J. McMahon Goksu, Swati Sachdeva, Lizmara Kirchner and Clementine Stip. Crystal Fenwick edited the final paper. The team is especially thankful to George Joseph, Sabrina Haque and Sophie Ayling for sharing survey data collected in Dhaka. Throughout the design and implementation stages, the study benefited from comments and feedback from Victor Vergara, Gayatri Singh, Ellen Hamilton, Phoram Shah, Nancy Lozano Gracia, Nagaraja Rao Harshadeep, Chris Heymans, Oscar A. Ishizawa, Aleix Serrat-Capdevilla and David Locke Newhouse. Alvaro F. Barra, Jon Exel, and Balakrishna Menon Parameswaran greatly supported the ongoing dialogue with other Global Practices, while Christoph Aubrecht helped establishing the collaboration with the European Space Agency ESA, . We are also grateful for comments received from participants at the presentation session held on September 14th, 2017 in the World Bank in Washington D.C. Advanced expertise in satellite-based urban geospatial products, image processing and GIS analysis for the study was provided under the ongoing partnership between the World Bank and the European Space Agency on Urban Development within the EO4SD Earth Observation for Sustainable Development, initiative. EO4SD is the ESA initiative for large-scale exploitation of satellite data in support of international sustainable development activities in selected thematic areas. The EO4SD Urban Development Service Cluster, focused on utilization of EO-based urban products and services for sustainable urban planning, is composed of the following European companies: GAF lead, , GISAT, SIRS, EGIS, DLR, NEO, JOANNEUM RESEARCH and GISBOX.

1798 FACTORS INFLUENCING HIV/AIDS AND REGIONAL PATTERN OF FINANCING

ABSTRACT

HIV is a virus that attacks the immune system, which is our body’s natural defence against illness. The virus destroys a type of white blood cell in the immune system called a T-helper cell, and makes copies of itself inside these cells. T-helper cells are also referred to as CD4 cells.If HIV is left untreated, it may take up to 10 or 15 years for the immune system to be so severely damaged that it can no longer defend itself. However, the speed with which HIV progresses would vary depending on age, health and background. Though quality of life has been prolonged with advanced treatment for clients with HIV,yet there is no cure to this infection.There is an increase in HIV/AIDS cases among developing countries.The earlier HIV is diagnosed, the sooner treatment can start – leading to better long term health. While younger age group are more prone to HIV/AIDS in the community, other reasons include drug trafficking corridors in certain countries ; availability of Sex workers;People who inject drugs (PWID) and are HIV positive;Unsafe Sex and Low Condom usage;extramarital sex within specific communities, poverty, low literacy, gender inequality and trafficking of women and girls (prostitution).This paper attempts to determine the factors influencing HIV/AIDS in selected developing countries and reveal prevalence of HIV /AIDS among individuals and find out the approximate funding provided to these countries for early and sustained HIV prevention programs targeting high risk groups

RS10.2. Regional and Urban Policy and Governance

1211 WHAT DRIVES WHICH CITY? SPATIAL HETEROGENEITY AND ROBUSTNESS OF DETERMINANTS OF EUROPEAN CITY GROWTH

ABSTRACT

European cities have become increasingly more economically successful, demographically popular and socio-economically vibrant in the last decades. However, previous research has shown that this does not account equally for all cities in Europe. This variation in (economic) growth raised a large literature on policy instruments that could spur economic growth, such as investments in accessibility and public R&D, political stability and educational programs. However, not much research has been done on the robustness of these instruments and whether each instrument is equally applicable to each city. This paper shows that (i) most of the policy instruments are not very robust in their impact on economic growth, (ii) some instruments only work conditionally on specific regional characteristics and other instruments, and, finally, that (iii) there is spatial heterogeneity in the effectiveness of most policy instruments.

1108 SOUND MACROECONOMIC CONDITIONS, STRUCTURAL REFORMS AND PRODUCTIVITY GROWTH IN LESS DEVELOPED REGIONS IN THE E.U.

ABSTRACT

In order to better target regional policy in the post-enlargement context, the EU categorizes 47 lagging regions into low-growth and low-income regions. In addition to their differences in levels of economic development, the lagging regions also differ in their industrial structure, their local labour force or their endowments in natural resources. Catching-up across the EU is therefore a regional issue, yet the reforms that could bring faster growth, lower unemployment and better livelihoods are being decided and applied at the national level. These reforms can take the form of a softening of labour laws by relaxing the rules governing the hiring and firing of temporary or permanent employees, an overhaul of rules around the creation of new firms or of the compensation awarded by the State during unemployment periods, or changes in the taxation of corporations or of labour. In this paper, a regional growth model is estimated whilst identifying the effects of country-level macroeconomic imbalance indicators such as inflation, government debt and the real effective exchange rate (REER) as well as structural policies such as labour market reforms (EPL) and product market deregulation on the productivity growth of subnational regions. As in Bourlès et al. (2013), the effect of the country's frontier region's productivity growth is simultaneously estimated. The results are based on a sample of 199 regions in 22 E.U. countries, over the period 2001-2013. The effects of policies before and after the financial crisis of 2008 can therefore be separately estimated. In order to better interpret the results, the effects of policy changes on regional employment rate growth are also investigated. Policies indeed have very different effects on lagging regions compared to base regions. Inflation has a strong negative effect on low growth regions whilst there is no significant effect on base regions. Increases in government debt lower regional growth for all types of regions: For base regions, an increase in government debt of one standard deviation leads to a reduction in productivity growth of 0.6 percentage points, but the effect is stronger on low growth regions (-1.4 points) and the highest for low income regions (-2 points). A one standard deviation increase in REER (i.e. an appreciation of the domestic currency) yields 0.9 percentage points lower productivity growth in low-income regions. EPL reforms have very different effects depending on whether temporary or permanent contracts are being reformed. Although relaxing constraints on temporary contracts and agency work has a negative impact on the growth of lagging regions, lifting restrictions on regular labour contracts results in higher productivity growth for all types of regions. Lowering the regulatory burden on firms has no significant effect on either type of regions. Deregulation has an initial positive effect on lagging regions' productivity growth but that this effect goes away after two years. This is coupled with a strong negative employment effect for low growth regions, which highlights the need for complementary policies to alleviate the negative impact on jobs in lagging regions.

1329 ASSESSING ACCESSIBILITY, USABILITY, ACTIVITY PROFILE AND AGE APPROPRIATENESS OF URBAN INDIAN PARKS: COMPARATIVE ANALYSIS OF THREE INDIAN CITIES

*Divya Subramanian*²⁷⁰, *Arnab Jana*

Centre for Urban Science and Engineering, Indian Institute of Technology Bombay, Mumbai, India. Email: divyasubramaniansuresh@gmail.com, arnab.jana@iitb.ac.in

ABSTRACT

Background and Purpose: Proximity and accessibility to parks alleviates human health and well-being by providing the opportunity for play and recreation. For a conducive neighbourhood, providing inclusive public spaces for people with all range of movement capabilities across all age groups is essential. The study of accessibility and usability of a park, as a physical factor of design function, and the quality and availability of age specific services is crucial to understand the age appropriateness of public parks.

Objectives: Few studies have been conducted in India to understand the performance of parks with respect to their design and available amenities. There is a knowledge gap in analytically understanding the implications of landscape design on the feasibility of access and use of parks. To fill this gap, an empirical study of selected neighbourhood level parks across three Indian cities was undertaken to evaluate their accessibility and age appropriateness performance using a multivariate model of analysis.

Methods: A selection of neighbourhood level parks was made based on their location, size, and available amenities. A total of 21 parks were selected, seven each from Mumbai, Bengaluru and Chennai for the empirical study. Primary data that included qualitative and quantitative aspects of physical profile, immediate surrounding, amenities, usage patterns, temporal patterns, and management and maintenance aspects were collated from these selected parks. Statistical models were utilised to analyse these data variables.

Results: The findings indicate a great shortfall in basic entry convenience of public parks for people with movement disabilities. Further, the study reflected the deficit of age specific amenities in most parks. The available park amenities lacked appropriate landscape design principles driving the layout. The activity profile of women was observed to be drastically lower, especially so in women between ages 10 and 40.

Conclusions: The study revealed the dire need of incorporating universal design with barrier free concepts while designing and developing a public park. Also, the study highlighted the gender disparity in the user activity profile.

Implications for Practice and Policy: In this study we further discuss the design strategies that could be incorporated in existing parks and future projects, to make them more accessible and inclusive. Also, detrimental practices in park design causing gender and age-related usage disparities are identified to aid policy guidelines in the design of Indian public parks.

Keywords: Neighbourhood Parks; Universal Design; Amenities; Age appropriateness; developing nations.

1. INTRODUCTION

Recreational open spaces like parks and playgrounds are vital urban amenities that offer crucial contact to nature while providing an opportunity for play and recreation, building a sense of social identity (Matsuoka & Kaplan, 2008). The ability to access these public amenities is an essential factor in improving the quality of urban life (del Saz Salazar & García Menéndez, 2007; Lee & Hong, 2013) irrespective of any categorization of gender, age, physical capacity, race or economic status (Francis, Giles-Corti, Wood, & Knuiiman, 2012). The existing urban India shows a significant lack of open spaces given the WHO recommended standard of nine square meter of open space per person is met only in few Indian cities (MoUD, 2015). Also, there is a lack of an evidence-based decision-making system in place for urban open spaces management in many Indian cities. This results in underperforming open spaces that tend to cater only to a certain section of the society. The sustainable development goals (SDG) as recommended by UNDP (Egmond, 2016), suggests achieving sustainable urban growth by investing in improving urban open spaces with appropriate amenities and design, making them inclusive and participatory for all.

Neighbourhood parks (NP) are recreational open spaces that are public amenities provided at the neighbourhood level for a population of 10,000, located at walking distance from the residential areas and their size ranges between 2000 to 4000 square meters (MoUD, 2014). The Urban Greening Guidelines 2014 published by the Ministry of Urban Development, India enumerates the various ecological, social, physical, cultural, and economic benefits of parks and open spaces, especially in the neighbourhood scale. Given the importance of neighbourhood parks, especially in the developing nation's context, few studies have been conducted in India to understand the performance of parks with respect to their design and available amenities.

The provision of neighbourhood parks in urban India is significantly low when compared to the WHO standards of a minimum of 9 square meters of green open space per person (MoUD, 2014). The Town and Country Planning organization of India report describes the provision of open spaces in Indian cities to be abysmally low and stipulates goals to achieve the international minimum standards by concentrating on various greenfield development. However,

²⁷⁰ Corresponding Author

little importance has been given on the existing parks and developing ways of improving the same. With rapid urbanization in India and swift densification of cities, providing well performing, sustainable parks will be necessary for a conducive urban quality of life.

Various studies conducted on urban green amenities look at specific age groups like children (Reyes, Páez, & Morency, 2014) or the elderly (K, O, & W, 2017) for their assessment of amenities provision or design performance. Most of the studies are concentrated in the global north and developed nations with some upcoming research observed from China and South East Asian countries (Fors, Molin, Murphy, & Konijnendijk van den Bosch, 2015). There exists a significant research gap in evaluation of neighbourhood parks in the urban Indian context, considering the needs of people belonging to all age groups and both genders. To fill this knowledge gap, an empirical study of selected neighbourhood level parks across three Indian cities was undertaken to evaluate their performance with respect to users of different age groups and genders.

2. METHODS AND MATERIAL

An empirical survey was designed with the intention to comparatively analyse the existential conditions of neighbourhood parks in different cities for a better representation of the country. Mumbai, Bengaluru and Chennai were selected as the three tier 1 cities where a selection of 21 neighbourhood parks, 7 per city was finalised post selection from 50 shortlisted parks. The selection of parks was made based on their size acreage, location within a residential zone, available amenities, functional hours and management profile. Private parks, regulated public parks, specialised parks, parks within special zones etc. were excluded from the selection.

The 21 selected parks were each allocated one day of study, with three observations made of 1 hour each in the morning, afternoon and evening hours the day. This was done with the intention to derive a temporal variation of activity profile and usage of the parks. A detailed survey questionnaire was designed by the authors post a detailed literature review encompassing physical built elements, amenities, universal design features, design quality and maintenance along with the study of user behaviour and their activity profile. The WHO defines 'universal design' as a design process that increases the usability, safety, health and social participation of an environment, space, system or product, making it inclusive to the needs of diverse people with diverse abilities (World Health Organization, 2011).

With the study of 21 neighbourhood parks, a total of 2131 users were observed. 56% of the total number of users were male and 44 % female. The users were also divided into 5 age groups of toddlers (0 – 4 yrs.), children (5 – 12 yrs.), young adults (13 – 24 yrs.), adults (25 – 59 yrs.) and the elderly (60+ yrs.). The observed percentage brake-up of these age groups were 13% toddlers, 18% children, 24% young adults, 22% adults, and 23% elderly of the total observed users. Temporal user profile was also captured with 40% morning users, 8% afternoon users and 52% evening users of the neighbourhood parks studied. From the basic descriptive of the user study, it is observed that neighbourhood parks are most popular in the evenings followed by mornings. The usage drops drastically in the afternoon time of the day. From this, we could infer that user comfort within the neighbourhood parks also is not conducive enough to attract users in the afternoon. Also, the working class would be occupied in the afternoons, and so their percentage drops. Also, the dependent age group of toddlers and children users, who rely on adults to escort them to parks also are reduced. Young adults of 13 – 24 years is the highest user group observed, closely followed by the elderly while toddlers were the lowest user group.

The observed neighbourhood park users engaged in various activities which were classified into 5 main groups of walking, sitting & socializing, exercising, active play and miscellaneous activities. The user performed activity was mapped and analysed per the city location as well. Figure 54 explains the activity pattern of the users observed where walking is the most performed activity followed by sitting and socialising. Bengaluru users were found to be most active while Mumbai users were comparatively less active. Miscellaneous activities like engaging in social groups like laughing clubs, yoga club etc. was observed highest in Chennai and lowest in Bengaluru. There is a visible drop observed in the activity of exercising in Mumbai. This can be related to the lower provision of outdoor gym provision noted in Mumbai when compared to Chennai and Bengaluru as explained further in the paper.

The neighbourhood park users of Mumbai, Bengaluru and Chennai when distributed and compared by gender and age, revealed certain city specific aspects of usage. As seen in Figure 55, with males represented in blue and female users in orange, there is a considerable gender disparity in user profile observed in all three cities. The highest gender disparity is seen in the 13 - 24 age group of users in Mumbai with Bengaluru reporting the least gap. Interestingly, 25 - 59 years Bengaluru users showed inverse relationship with the female users exceeding the male users. This is not seen in any other age groups of other cities. There is an upward trend with age in female users of Bengaluru and Chennai, especially rising in the adult and elderly age groups. Only Mumbai reports higher female users in the 13 – 24 age group. The gender gap is lowest in the toddler and children groups of Mumbai and in the elderly group in Bengaluru. Highest gap in the children's group 5 – 12 years is seen in Bengaluru and Chennai. Highest number of 13 – 24 years male users was reported in Mumbai among all cities and age groups.

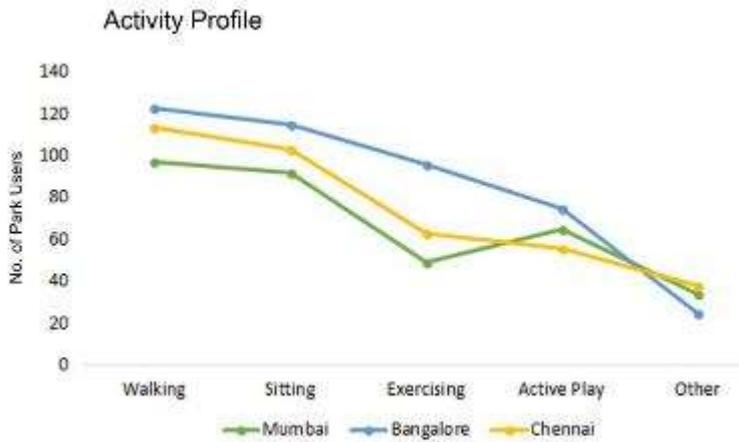

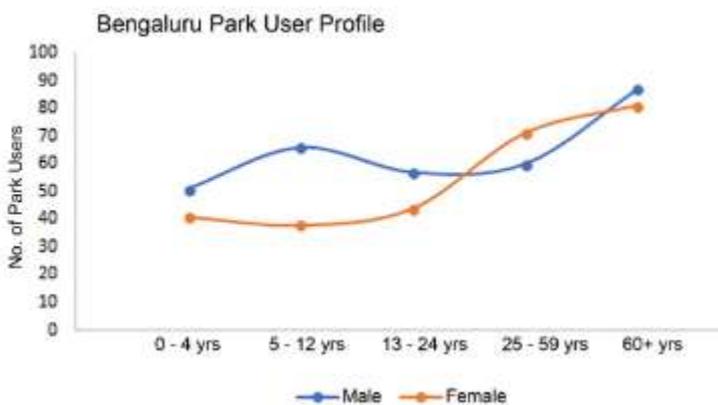

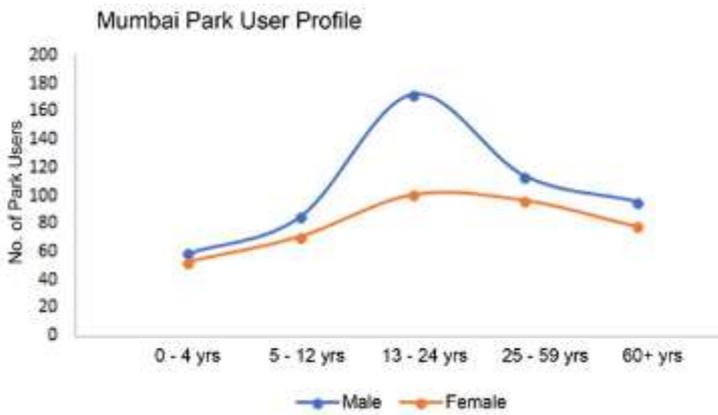

Figure 54 City wise activity profile of neighbourhood park users

Neighbourhood park amenities and universal design features

The empirical study was designed to record the park amenities and UD features with the intention to evaluate the age appropriateness, usability and inclusiveness of the parks as a function of their feature provision. Aspects studied for evaluation were presence of paved walkway, seating benches, toilets, security staff, shading devices, kid’s play area, entry cost, drinking water outlets, universal entry, tactile flooring, maps and signages, handrails and ramps, parking, cleaning, street connectivity, boundary profile, street lighting etc. Out of these features, using dimension reduction factor analysis, 10 aspects were finalised for further evaluation. These were 7 amenities of walkway, seating, entry cost, boundary wall, security staff, shading devices and kid’s play area and 3 UD features of tactile flooring walkway, legible maps and signages and presence of handrail and ramps.

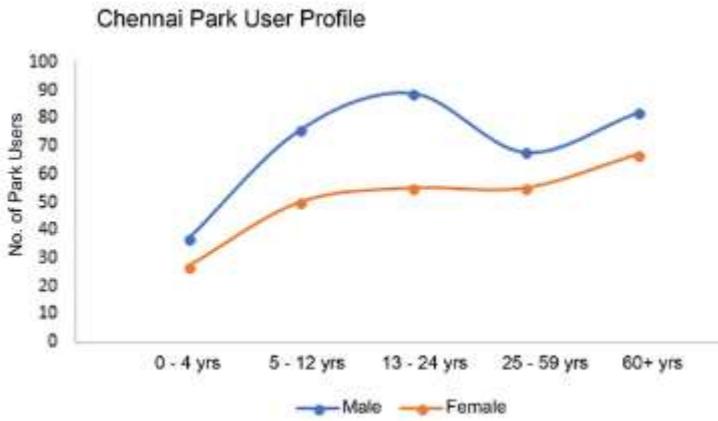

Figure 55 City wise user study distributed by gender and age groups

The selected 10 aspects of neighbourhood parks were further analysed based on design quality and maintenance with scoring done on a scale of 1 being least and 10 being highest per aspect for all parks studied. Each aspect was given equal weightage and the cumulative of all the scores was then collated as the park performance. This performance score, out of hundred, was further analysed with the user footfalls categorised by gender, age and city to assess their impact on usage and user footfall.

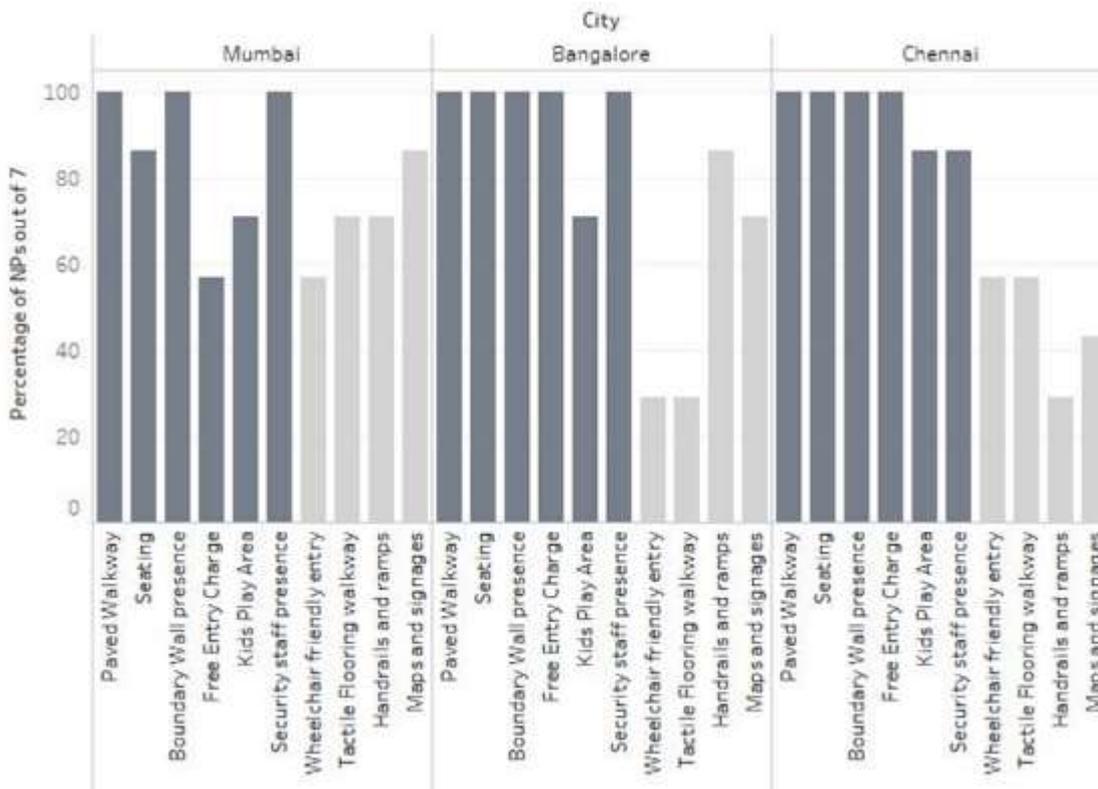

Figure 56 City wise neighbourhood park performance comparison

3. RESULTS

The performance scoring derived for each park were compared city wise. The highest scoring park (95) was observed in Bengaluru and the lowest scoring in Mumbai (31). The highest score in Mumbai parks was 91 and lowest was 31. The highest in Chennai was 82 and lowest was 34. In Bengaluru, the lowest scoring park was scored 42. The seven parks' scoring per city were collated to derive a city-wise comparison. The city wise comparison of park performance across the three cities is shown in Figure 56. The bars in darker grey hue are the 6 amenities aspects and the light grey hue coloured bars are the UD features. As observed in Figure 56, consistently high performance is seen in amenities provision in Bengaluru and Chennai while higher UD feature provision score is seen in Mumbai parks. Moving into specifics, Mumbai performed the lowest in free entry. It was observed that all parks in Chennai and Bengaluru studied had free entry while 3 parks in Mumbai charged an entry fee. Provision of kid's play area was highest in Chennai. Bengaluru performed lowest in UD features of wheelchair friendly entry and tactile flooring walkway provision. Chennai performed lowest in the provision of handrail and ramps among UD features. Maps and signages of Mumbai were scored the highest while provision of handrail and ramps was scored highest for Bengaluru.

The studied neighbourhood parks' user profile was used to gauge the impact of park performance on user footfall, deriving the age appropriateness of the parks specific to the age group or gender. With this intention, the age wise

categorized user data was further classified into the male and female genders and juxtaposed against the park performance to review their impact.

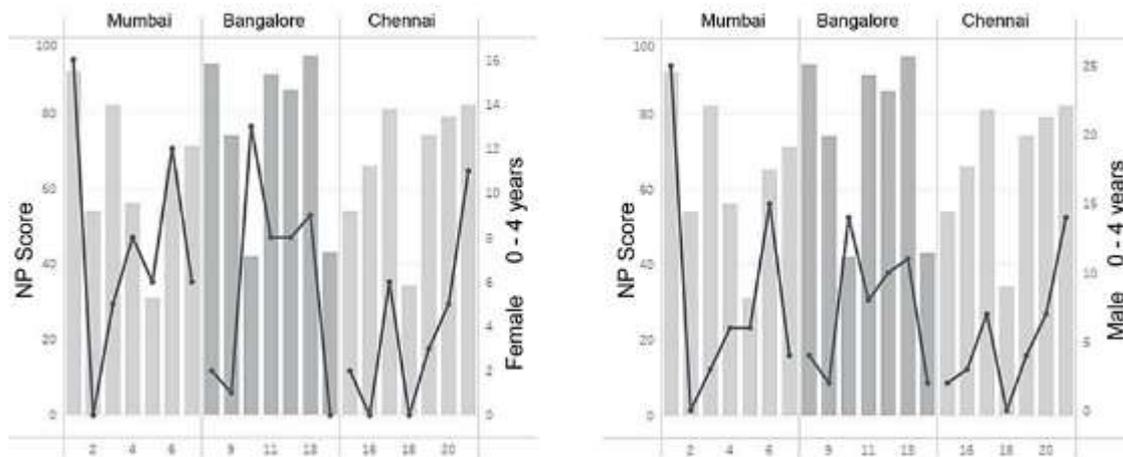

Figure 57 City-wise park performance (bars) juxtaposed with male & female 0-4 years toddler user profile (line)

As seen in Figure 57, the toddler age group user profile is superimposed on the city-wise park performance graph. The female toddler users were higher most open spaces of Mumbai, Bengaluru and Chennai. A general trend of increase in footfall with increase in performance is seen. However, there are certain exceptions seen in parks where female toddlers are responding much more in numbers with the performance in comparison to the male toddlers. Parks 3,4,6 from Mumbai and 10, 13 from Bengaluru with park 21 from Chennai showed presence of UD features which were not present in other parks. Hence the higher numbers of female toddlers in the parks.

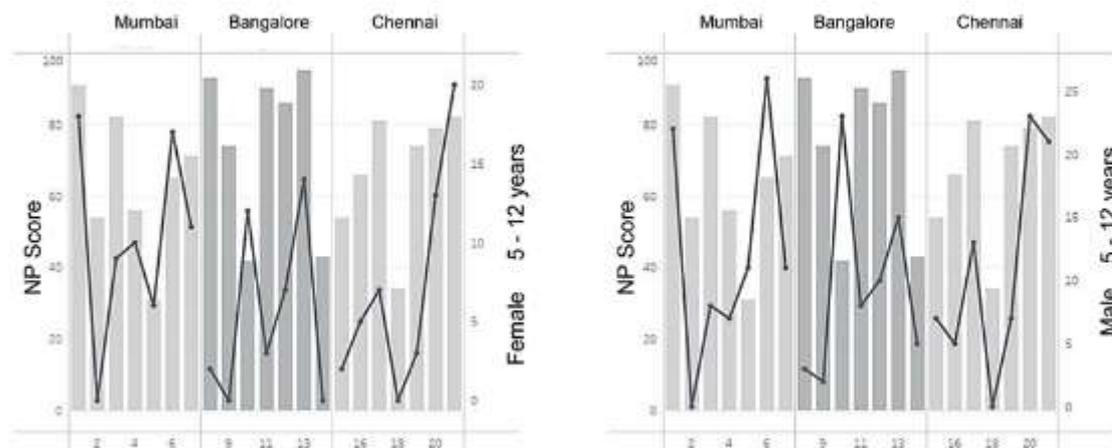

Figure 58 City-wise park performance juxtaposed with male & female 5-12 years children user profile

As seen in Figure 58, the users belonging to 5-12 years start to show gender disparity with the male users superseding the female users. The two groups respond differently to park performance with parks 3,4 of Mumbai, 13 in Bengaluru and 21 in Chennai being more conducive to female children. From the graph it could be deduced that parks 5 in Mumbai, 11, 14 in Bengaluru and 15 in Chennai had certain detrimental factors that reduced the female users drastically. These parks were found to lack in provision of shading devices and UD features.

Figure 59 demonstrates the high number of 13-24 age group users of Mumbai and Chennai, especially the male users. Bengaluru showed lower numbers compared to the other cities. As seen in the figure, there is a considerable drop in female users in Mumbai parks 2, 6, Bengaluru parks 10, 11, 13, and Chennai parks 16, 18 and 19. When checked with the amenities provision of these parks, it was observed that some parks had certain features lacking like kid’s play area, seating provision and security staff presence. Also, the drastic drop of female users seen in parks 2,16 and 18 relates to the missing UD features and shading devices provision.

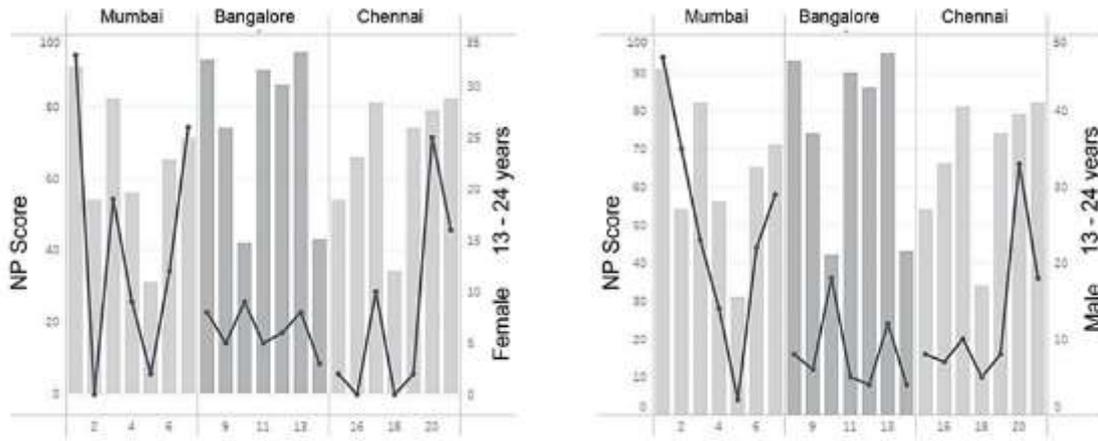

Figure 59 City-wise park performance juxtaposed with male & female 13-24 years young adult user profile

As seen in Figure 60, a drop of female users is seen in parks 2,14 and 18 more drastically than others. The factors missing in these parks were shading devices and UD features. There is considerable gender disparity in male and female users observed in this age group as well. However, certain exception cases in Bengaluru are seen where the female users exceed the male users.

As seen in Figure 61, the gender gap is not as evident with female and male users being more equitable. There are many parks where female elderly users are exceeding the male elderly. The parks where female elderly is showing a downward dip are the same ones observed in earlier age groups that lacked amenities like shading devices and security staff along with UD features.

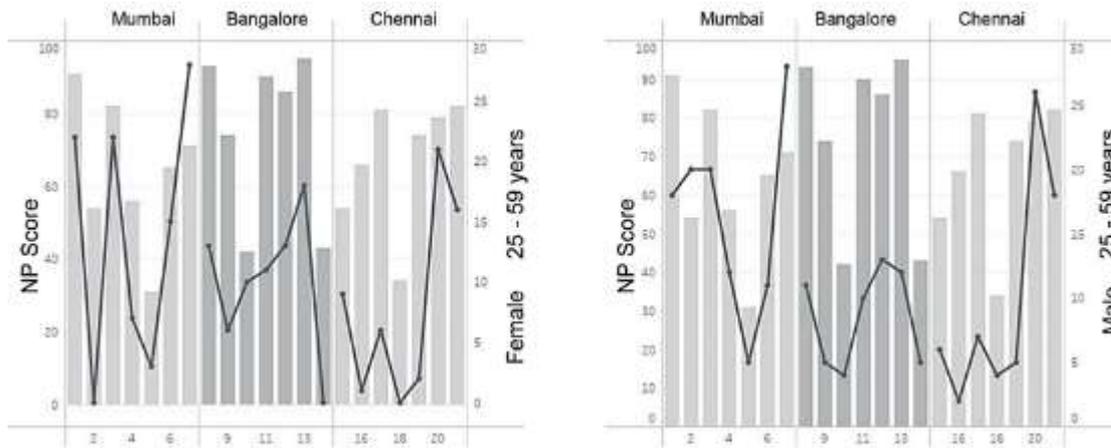

Figure 60 City-wise park performance juxtaposed with male & female 25-59 years adult user profile

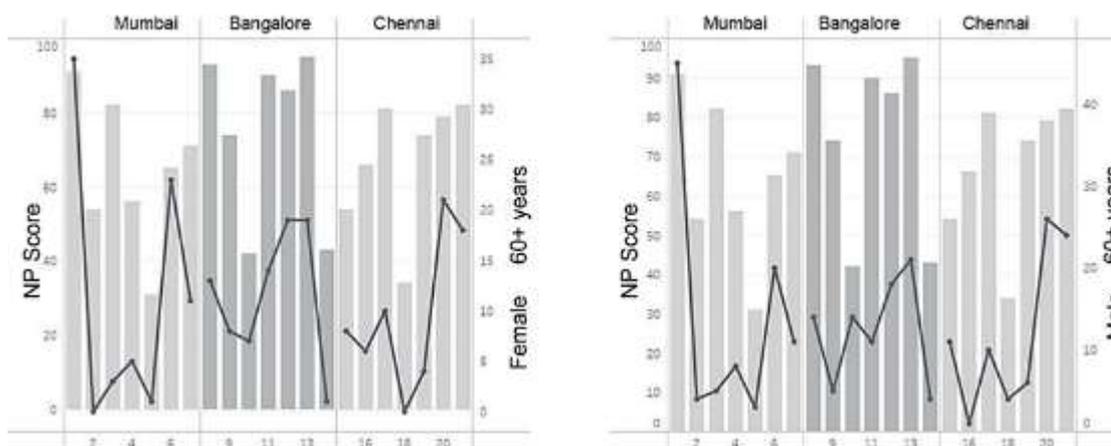

Figure 61 City-wise park performance juxtaposed with male & female 60+ years elderly user profile

Gender disparity of users

From the comparative analysis study, across age groups and divided into genders, it is easy to observe the usage pattern is greatly dependent on the provision of amenities and certain amenities are of more affinity to the female users with their absence causing a significant drop in usage. These features are mainly UD features and amenities like shading devices, security staff and seating provision. The male numbers show a similar trend across all age groups. Gender disparity is lowest in pre-puberty and elderly age groups. Higher disparity is seen in young adults and adults age groups. This could be associated with the sense of safety and how the societal and cultural norms, combined with lack of amenities

causes less females of the young and adult age groups to use neighbourhood parks. To further test the hypothesis that the presence of amenities and UD factors impacts the users based on their age and gender, multivariate analysis was conducted using linear regression for the dependent variable of park performance and independent variable of users of different gender and age groups. As seen in Table 22, five models representing the five age-group of users studied classified by their genders were regressed on the dependent variable of park performance.

Table 22 Multivariate analysis of user groups gender and age wise as a function of park performance
Dependent variable: Park Performance Scoring

	t-stat	sig	R ²
Male 0 to 4	1.044	0.310	.147
Female 0 to 4	-0.484	0.635	
Male 5 to 12	-0.903	0.378	.158
Female 5 to 12	1.531	0.143	
Male 13 to 24	-0.945	0.357	.252
Female 13 to 24	2.176	0.043**	
Male 25 to 59	-0.290	0.775	.359
Female 25 to 59	2.270	0.036**	
Male 60+	-1.691	0.108	.518
Female 60+	2.992	0.008***	

Note: ** significant at 95%; *** significant at 99%

Model 1 which looked at the toddler age group showed insignificant impact of park performance on their numbers. This could be caused by the fact that toddlers are not the decision makers with respect to the choice of parks to visit. Similarly, model 2 showed insignificant impact. In models 3,4 and 5, the results are more significant with female users 13-24 and female users 25-59 showing significant association with the park performance at 95% confidence levels. In the model 5, the strong positive impact of park performance on female elderly users is seen significant at 99% confidence level. The other aspect to notice is that except in the first model of toddlers, male users show negative association with the park performance reflecting that their usage is not as impacted by the park amenities provision.

Table 23 Pattern matrix showing PCA results for user groups

Pattern Matrix	Component	
	1	2
Male 0 to 4	1.077	
Female 0 to 4	1.008	
Male 5 to 12	0.923	
Female 5 to 12	0.801	
Male 60+	0.782	
Female 60+	0.795	
Male 13 to 24		0.834
Female 13 to 24		0.771
Male 25 to 59		1.105
Female 25 to 59		0.744

Note: Extraction Method: Principal Component Analysis. Rotation Method: Promax with Kaiser Normalization.

To further investigate the user age groups and their interrelationship, we performed a principal component analysis taking the five male and female age groups giving ten factor dimensions. Principal component extraction method based on an eigen value greater than one was conducted using Promax rotation of kappa value four. The resultant model was tested to be significant with a KMO value of adequacy of 0.786. The model cumulative explained 85% variance giving two factors. The Table 23 represents the principal component analysis model.

From the PCA analysis, there are two groups of users that we could classify as independent and dependent age groups based on physical capabilities. The elderly, toddler and children are the dependents who have some movement capabilities shortcomings. The independent group of young adults and adults are presumed to have better movement capabilities.

4. DISCUSSION & CONCLUSION

The intention of this study was to evaluate neighbourhood parks across India to evaluate the relation between provision of amenities & universal design feature and resultant user and usage profile. This study has successfully demonstrated the positive impact of amenities provision on the user footfalls and has detailed out the various factors that are essential for user comfort for users based on their age groups and gender. Various studies that have looked into the association of accessibility to parks as a measure of its attractiveness or usability (Chang & Liao, 2011; Kun, Hao, Yannan, Mingrui, & Quan, 2012; Oh & Jeong, 2007; Rigolon, 2016; Rojas, Páez, Barbosa, & Carrasco, 2016; Wei, 2017). However, few studies have looked into the importance of parks amenities and universal design features on their performance (Fors et al., 2015). The current research provides substantial evidence towards significant positive impact of universal design amenities on user comfort or attractiveness and hence must be incorporated into the design process of all recreational open spaces to derive better functioning and more inclusive open spaces.

The research conducted across 21 neighbourhood parks in three cities was done with one day allotted per park. This was done due to time constraints given the authors personally conducted the empirical survey. As the study was limited in time, the temporal variation based on weekdays and weekends as well as seasonal variations could be the way forward to better understand the user requirements and map usage patterns in detail. Also, the study of other types of open spaces like playgrounds, district parks, public squares could be undertaken to devise a better framework or model for ameliorating urban Indian open spaces.

The study also highlighted the dire need to incorporate universal design and barrier free concepts within the design process while developing public parks. The results from this study could be utilized in making better informed decisions to improve urban open space quality. With an evidence-based decision-making process regarding parks and open spaces, the process to achieve sustainable development goal 11.7 set by UN of providing universal, inclusive and safe open spaces with focus on women, children and elderly could be successfully achieved.

RS10.3. Regional and Urban Policy and Governance

1775 REGIONAL DISPARITIES IN LEVELS OF DEVELOPMENT IN KOLHAPUR DISTRICT OF MAHARASHTRA

Ujjwala Khare, Prajakta Thakur

Research Centre and Post Graduate Department of Geography, Nowrosjee Wadia College, Pune. Khare.ujjwala@gmail.com, Prajaktathakur9@gmail.com

ABSTRACT

Population of any region plays a vital role in the development of the region. The study of population by age and sex composition, composition of religions, economic status, marital status, education status reveals real picture of the society. In order to deal with problems and ensure development of the region planning policies in terms of quality and quantity of population resource are required. The socio-economic development of any region reflects in these elements. Levels of development can be defined as the position of rank or a scale that a region or a state or a country or any other unit has attained in terms of development. Development is a multifaceted process; it imbibes economic, social, political and ecological dimension of development. In the recent years there has been a surge of interest in the geographical aspects of development and the study of regional disparity. The study area includes the district of Kolhapur which is one of the industrial districts of the state of Maharashtra in India. Census data has been used for analyzing the social and economic conditions of the study area, Demographic, agricultural and infrastructural indicators have been selected to study the disparities of development. Sources like District Economic and Statistical Bureau, socio-economic abstracts of the region and periodicals have been used for the research, economic profile of the region. Development is a process which is continuous in nature. There are several methods for estimating the level of development but most of them are having their own limitation. A total of 33 development indicators have been used in the present study to analyze the level of socio-economic and demographic development of different sub-units of the Kolhapur district. A composite index has been prepared taking into account these indicators of development. Regional disparities have been studied using the index.

INTRODUCTION

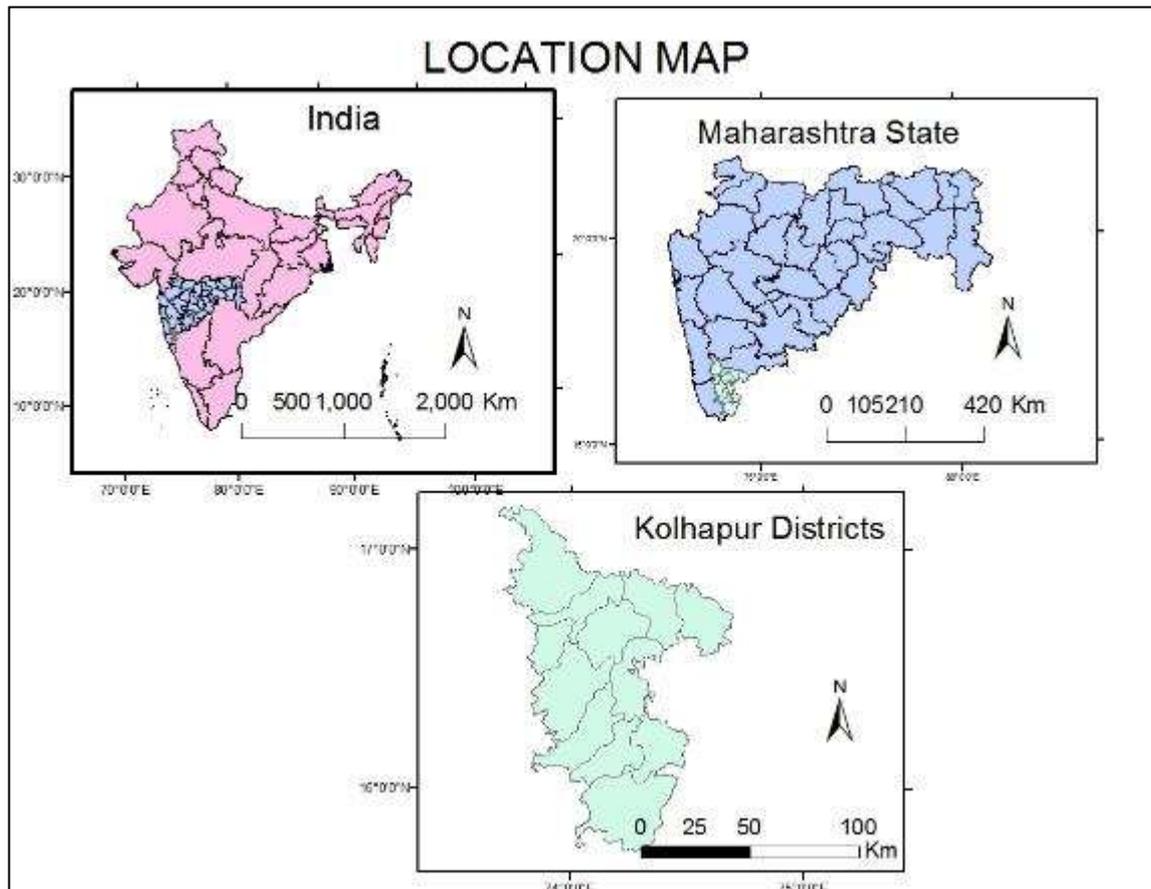

Development is a dynamic concept; it varies from area to area and many other changes from time to time within the same area. What our fore-fathers perceived as development may have been left far behind by future generation. Thus, there is no permanent and universally accepted definition of development. Development is a relative term-the extent to which a country region is developed can be determined if one compare that country region to other. In its strong sense, development means more of everything for everyone in the context of a lot more for a few. Development is associated with growth and refers to growth with social justice. The ultimate purpose of development is to provide increasing opportunities to all people for raising their living standard. Levels of development can be defined as the position of rank or a scale that a region or a state or a country or any other unit has attained in terms of development. Development is a multifaceted process; it imbibes economic, social, political and ecological dimension of development. In the recent years there has been a surge of interest in the geographical aspects of development that is, in the question of where economic activity take place. This research helps to analysis dimensions of development and typology of backwardness and also useful to formulate a future Plan for the balanced regional development and a relevant strategy to minimize spatial variation in the level of development at micro-level. (Dr. Pawan Kumar Sharma.) Composite index, Development indicators, Model districts, Potential targets, Regional disparities these are the core analysis done to study the overall regional development. (Prem Narain, 2001). The study of Regional Geography on Iran, on the basis of social and economic factors of Iran, he has made an attempt to find out the level of development and region (Keramathollah Ziari 2006)

AIM AND OBJECTIVES

The major aim of the study is to assess the overall levels of development of Kolhapur district. The objectives are as follows:

1. To observe the regional disparities in agricultural, Infrastructural and Demographical development at tehsil level.
2. To ascertain the developmental disparities between the tehsils

STUDY AREA

The Kolhapur district is one of the southernmost districts of Maharashtra state. The total area of district is 7,685sq km. It lies between 1543' to 170 17' North latitude and 73040' to 78042, East longitude. The length of the district South to North is 160 kms. And to west is 60 Km. the Sahyadri ranges to the west and Warna River to the north. The river Krishna and Belgaum district to the South and East, forms the natural boundaries of the district.

DATA AND METHODOLOGY

Secondary data were used for study

Data type	Demographic	Agricultural	Infrastructural
Source	Census of India Publications (2011)	District Economic and Statistical Bureau, Socio-Economic Extracts and Periodicals. (2013)	

METHODOLOGY

Development is a multi-dimensional process which is continuous in nature. There are several methods for estimating the level of development but most of them are having their own limitations. The major limitation arises from the assumptions made about the developmental indicators themselves and their weightage in aggregate index. From the detail literature survey carried out the following method was thought to be apt for the present study and thus the same was adopted.

Method of Estimation of Composite Index of Development.

The following statistical procedure for estimation of composite index of development is adopted in the study.

Let [X_{ij}] be the data matrix.

$I = 1, 2, \dots, n$ (Number of area unit)

$J = 1, 2, \dots, k$ (Number of indicators)

Since [X_{ij}] come from different population distribution and they might be recorded in different units of measurement they are not quite suitable from the simple addition for obtaining the composite index. Therefore, [X_{ij}] are transformed to [Z_{ij}] as follows.

$$[Z_{ij}] = \frac{X_{ij} - \bar{X}_j}{S_j}$$

S_j

Where, \bar{X}_j = Mean of the j^{th} indicator

S_j = Standard deviation of the j^{th} indicators

Z_{ij} = is the matrix of standardized indicators

from [Z_{ij}] identify the best value of each

indicator let it be denoted by Z_{0j} .

The best value will be either the maximum value or minimum value of the indicator depending upon the direction of the impact of indicator on the level of development for obtaining the pattern of development, calculate P_{ij} as follows:

$$P_{ij} = (Z_{ij} - Z_{0j})^2$$

Pattern of development C_i as given as

$$C_i = \left[\sum_{j=1}^k P_{ij} / (c.v.)_j \right]^{1/2}$$

Where $(c.v.)_j$ is the coefficient of variation of the j th indicator in X_{ij}

Composite index D_i is given by

$$D_i = C_i / C \text{ for } i = 1, 2, \dots, n$$

Where, $C = \bar{C} + 3D_{D_i}$

\bar{C} = Mean of C_i and

S_{D_i} = Standard deviation of C_i

Smaller value of D_i will indicate high level of development and higher value of D_i will indicate low level of development.

For classificatory purposes, a simple ranking of the Taluka indices will suffice. However, a more meaningful characterization of different stages of development would be in terms of suitable fractile classification from the assumed distribution of mean of composite indices. For relative comparison, it appears to assume that the Talukas having the composite index $\leq (\text{Mean} - SD)$ are leveled as high developed, districts having composite index $> (\text{Mean} + SD)$ are low level developed.

Indicators of Level of Development.

A total of 33 development indicators have been used in the present study to analyze the level of socio-economic and demographic development of different talukas in the Nashik district.

Indicators used to measure level of overall development.

A. Infrastructural Indicators.

- i. Number of PCO
- ii. Total of Primary Schools
- iii. Total Secondary Schools.
- iv. Total Higher Secondary Schools.
- v. Total Colleges
- vi. Number of Medical Facilities.
- vii. Number of Banks.
- viii. Road length.
- ix. Electricity Consumption.
- x. Veterinary.
- xi. Number of Post Offices.

B. Agricultural Indicators.

- i. Number of Total Agricultural Pumps.
- ii. Total Cultivated Land.
- iii. Barren land
- iv. Total Agricultural Land
- v. Total Non-Cultivable Land.
- vi. Chemical Fertilizers in Metric Ton.
- vii. Total Cereals.
- viii. Total Pulses.
- ix. Total Food grains.
- x. Total Fruits.
- xi. Total Vegetables.
- xii. Total Fodder.

C. Demographic Indicators.

- i. Total Population.
- ii. Recorded Deaths.
- iii. Recorded Births.
- iv. Infant Deaths.
- v. Maternal Deaths.
- vi. Total Urban Population.
- vii. Male Literates.
- viii. Female Literates.
- ix. Total Rural Population.

RESULTS

The Level of Development

Composite Index Of Development in Kolhapur District (2011)

Sr. no.	Taluka	Agriculture		Demography		Infrastructure	
		C.I.	Rank	C.I.	Rank	C.I	Rank
1	Shahuwadi	0.624612	7	0.389703	3	0.309543	3

2	Panhala	0.624264	6	0.388044	2	0.504107	8
3	Hatkangle	0.388605	1	0.588320	9	0.280272	2
4	Shilol	0.467295	4	0.416027	5	0.467782	4
5	Karveer	0.393532	2	0.326560	1	0.017204	1
6	Gaganbawda	0.857591	12	0.823780	12	0.817066	12
7	Radhanagri	0.651854	9	0.591691	8	0.479762	5
8	Kagal	0.413445	3	0.514571	7	0.483472	6
9	Bhudargad	0.712555	11	0.395245	4	0.546019	10
10	Aajra	0.690548	10	0.446300	6	0.618913	11
11	Gadhinglag	0.532426	5	0.721058	10	0.517109	9
12	Chandgad	0.631067	8	0.745233	11	0.497616	7

The composite indices of development have been worked out for different taluka separately for agriculture, infrastructural service and demographic development. The talukas have been ranked on the basis of development indices. It shows the composite indices of development along with the ranks of different talukas. In this table, a simple ranking of the talukas on the basis of level of development has been presented. This is sufficient for classificatory purposes.

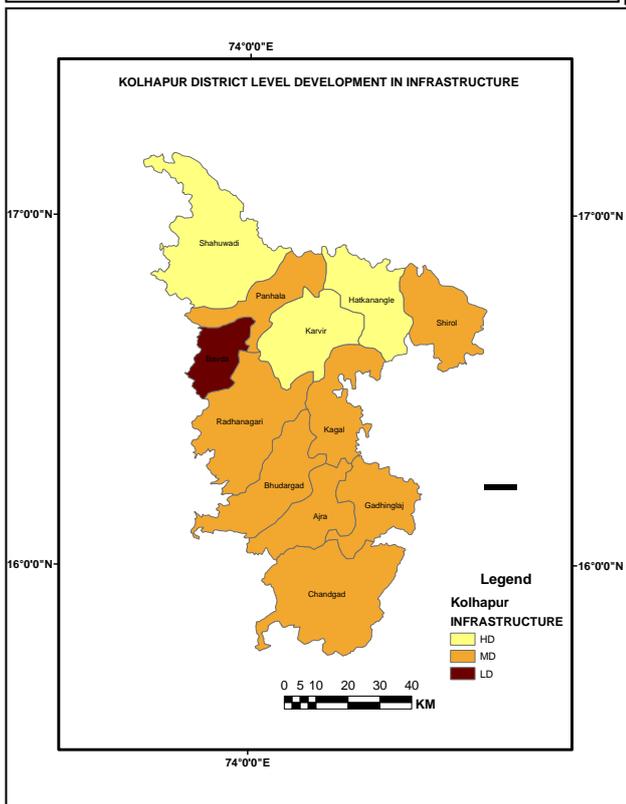

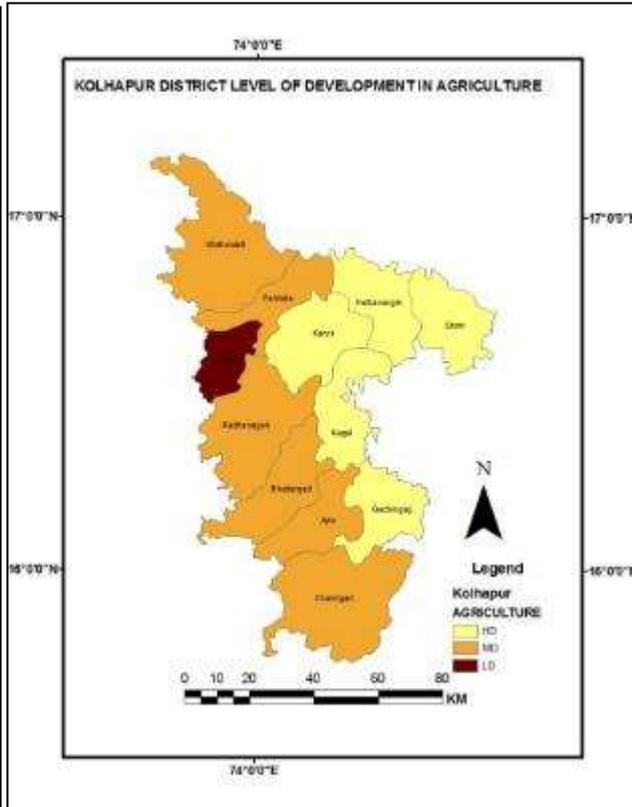

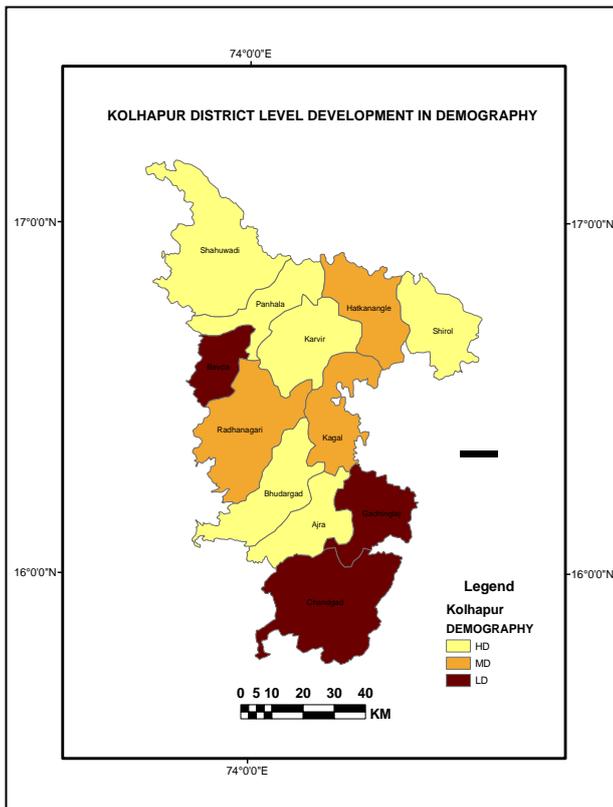

Scope of Development

- Assessment of city infrastructure including preliminary surveys.
- Gap analysis and investment potential.
- Master planning of Mahalaxmi Mandir Parisar and surrounding investment.
- Requirement for upgradation the city infrastructure.
- Project outlay and investment sharing pattern.

Area under different levels of Development (2011)

Sr. no.	Sector of Development	Levels	No. of Tehsils	Area%
1	Agriculture	High(<0.39)	2	16.03
		Moderate (0.39-0.69)	9	68.7
		Low (>0.69)	1	15.27
2.	Demography	High (<0.38)	1	16.24
		Moderate (0.38-0.69)	8	78.05
		Low(0.69)	3	5.71
3.	Infrastructure	High (<0.21)	1	16.03
		Moderate (0.21-0.61)	10	66
		Low (>0.61)	1	17.97

Above table shows that classification of the tahsils can be made by using the average level of development and its standard errors. The tahsils having the composite index equal to or less than (mean minus S.D.) are classified in category first as developed tahsils. The tahsils with composite index line between (mean ± sd) are classified in category second as middle level of developed tahsils and tahsils having the composite index equal to or greater that (mean + sd) are classified in category third as low level of development districts. The analysis reveals that about 16% area is high developed in all the sector. In agricultural sector, about 16.03% area is highly developed and 68.7% area is moderately developed and low level of developed tahsils cover about 15.27% area. In demographic sector, about 16.24% area is highly developed and 78.05% area is moderately developed and only 5.71% area fall in the level of low developed tahsils. In infrastructural services, about 16.03% area is highly developed and 66% area is moderately developed and 17.97% area fall in the tahsils which are low developed. It is observed that low level of development tahsils are not as thickly populated as the tahsils belonging to the category of high development.

CONCLUSION

1. In overall agricultural development, out of 12 tahsils of Kolhapur district, Karveer is highly developed in agricultural sector and Gaganbawda has a low level of development. The rest of the tahsils are moderately developed. In agricultural sector, about 16.03% area is highly developed and 68.7% area is moderately developed and low level of development tahsils covers about 15.27% area.
2. Karveer is highly developed in infrastructural facilities and Gaganbawda is low level of development. In infrastructural services, about 16.03% area is highly developed and 66% area is moderately developed and 17.97% area fall in the tahsils which are low level of development.
3. Karveer is highly developed in demographic sector and Ajra is low level of development. The remaining tahsils like Shahuwadi, Panhala, Gadhinglaj, Radhanagari Chandgad, Shirol, Hatkanangle are moderately developed. In

demographic sector, about 16.24% area is highly developed and 78.05% area is moderately developed and only 5.71% area fall in the level of low development tahsils.

4. Karveer is found highly developed in agriculture, infrastructural and demographic development whereas Gaganbawda is found low level of development in all sectors of development.
5. Hence Karveer is highly developed in overall development whereas the tahsil of Gaganbawda is low level of development in overall development. The analysis reveals that about 16% area is highly developed in all the sectors and remaining areas are moderately and low level of development in all levels of development.
6. It is observed that low level of development tahsils are not as thickly populated as the Tahsils belonging to the category of high development.
7. To reduce the regional disparities the priorities should be given for low level of development tahsils. The state government should include these tahsils in regional planning, encourage the local people to start small scale industries, giving them financial schemes.

1789 GOVERNANCE PRACTICES ACROSS CENTRAL BANKS IN THE WORLD

Riyanka Swain, Debasis Patnaik

Department of Economics & Finance, BITS Pilani K. K. Birla Goa Campus, Zuarinagar, Goa-403726, India. **Email Id:** marikesh@goa.bits-pilani.ac.in

ABSTRACT

Past two decades have seen enormous changes in central banks and their practices, especially in reforms of how those banks are governed. These reforms are different across countries. In some countries older institutions have been fundamentally restructured. While in other countries, entirely new central banks have been established. Even certain countries have created a supranational central bank that oversees a monetary union. In all of these above situations, central bank law was either revised or newly written, while institutional objectives, practices, and structures were amended or created from scratch. As a basis for this study, central banks of top 20 economies as per GDP were analyzed: United States, China, Japan, Germany, UK, India, France, Brazil, Italy, Canada, Russia, Korea, Australia, Spain, Indonesia, Mexico, Turkey, Netherlands, Saudi Arabia and Switzerland. The above mentioned countries were classified into two major groups: advanced economies and emerging market and developing economies. Work has been carried out on parameters like organizational structure, board size, accountability, and transparency. The study is primarily based on secondary data, such as scientific papers, books, and other data sets/documents available on the central banks Internet websites. It is found that central banks in emerging market economies have a wider range of functions than in advanced economies. Each of the countries in the list has its own institutional, economic, social and cultural characteristics, which differentiates their governance models. Board size differed in all central banks as it is related to country size and country heterogeneity as well as to country's political institutions. Transparency and accountability support central bank independence and monetary policy effectiveness.

Keywords: Governance; Central Banks; Countries

INTRODUCTION

The recent global financial crisis has raised questions about the role of central banks in executing governance practice. Central banks and their business are changing at a rapid pace responsibilities are greater while demands on central bank accountability increase. Central bank governance arrangements and practices vary greatly reflecting the diversity of backgrounds, objectives and functions of the institutions, origins of the bank, the country's political system and the extent of the development of its financial sector.. This is further reflected in the board structure in terms of the number of boards and their decision-making and management functions. Accountability and transparency are complementary elements to the central banks. Central bank that shows significant improvement in clear communication across its internal and external platforms is said to have transparency. The central bank should act in a transparent manner by keeping the government and the public continually informed of its actions. In general, central banks in emerging market economies have a wider range of functions than in advanced economies. No central bank can be totally independent in the sense that it does not have to report to anyone. As a basis for this study, central banks of top 20 economies as per GDP were analyzed: United States, China, Japan, Germany, UK, India, France, Brazil, Italy, Canada, Russia, Korea, Australia, Spain, Indonesia, Mexico, Turkey, Netherlands, Saudi Arabia and Switzerland. The above mentioned countries were classified into two major groups: advanced economies and emerging market and developing economies.

Table 1: classification of countries based on GDP

Advanced economies	Emerging and developing economies
United States	China
Germany	India
France	Brazil
Italy	Mexico
Spain	Indonesia
Japan	Saudi Arabia
United kingdom	Turkey
Canada	Russia
Switzerland	Korea
Australia	
Netherland

Emerging and developing economies	Name of central banks
China	People's Bank of China
India	Reserve Bank of India
Brazil	Central Bank of Brazil
Mexico	Bank of Mexico
Indonesia	Bank of Indonesia
Saudi Arabia	Saudi Arabian Monetary Authority
Turkey	Central Bank of the Republic of Turkey
Russia	Bank of Russia
South Korea	Bank of Korea

LITERATURE REVIEW

Maxwell Fry, Charles Goodhart and Alvaro Almeida (1996) analyze the objectives, activities and independence of central banks in developing countries. They emphasize the importance of the recruitment of skilled staff for establishing independence. The authors also found a positive correlation between the recruitment of skilled staff and central bank independence, but did not further explore this relationship.

Fry, Julius, Mahadeva, Roger and Sterne (2000) construct an index of 'policy explanations' that consists of three components: (i) explanations of policy decisions, (ii) explanations in forecasts and forward-looking analysis, and (iii) explanations in published assessments and research. Their index captures many transparency issues, but does not highlight the role that different kinds of transparency play in the decision-making process. In addition, their index is constructed using survey responses from central banks.

Blinder, Goodhart, Hildebrand, Lipton and Wyplosz (2001), gave a detailed account of transparency at the Federal Reserve, the European Central Bank, the Bank of Japan, the Bank of England and the Reserve Bank of New Zealand, but do not provide objective criteria to measure the degree of transparency.

Alan Blinder (2004), stresses the need for diversity in the composition of the committee. He cites four potential benefits of member diversity: it prevents decisions based on one or few sets of beliefs and preferences; it is likely to lead to more stable monetary policy; pooled knowledge improves information in an uncertain environment; and it improves information processing in the execution of complex tasks.

Tonny Lybek and JoAnne Morris (2004), agree that diversity in education and experience is important for ensuring informed and balanced policy making. They argue that both internal and external members are important for deterring conflict of interests and encouraging such diversity.

Eijffinger and Geraats (2006), elaborated on this categorization, developed an explicit methodology for measuring transparency, and used it to code the practices of nine major central banks.

Hammadou, and Stanek (2009), show many factors that significantly affected central bankers' decisions such as professional backgrounds and even the board member's gender

[Peter T. Hughes](#), [Stefan Kesting](#), (2014) studies the central bank communication to address the questions of how economists account for the effects of speech acts and whether and to what extent discourse analysis is applied in their studies

OBJECTIVE OF THE STUDY

1. To access organizational characteristics across central bank and find differential causalities factors underlying it through literature study
2. To access the underlying functionality impacting diversity conditions in board size differences across central banks
3. To look into nature of transparency in central bank to find out the level in pace of economic development underlying the need of specific transparency attributes

RESEARCH METHODOLOGY

This research is classified as qualitative, exploratory and bibliographic. The process and its significance are the main focal points of its qualitative approach, as it seeks to interpret the phenomena without using statistic methods and techniques. The study is based on secondary data, such as scientific papers, books, and other documents available on the central banks' internet websites. Research was carried out in four stages: planning, bibliographic research, analysis, and preparation of the final report. In the planning stage, the research subject and its scope were defined. During the bibliographic research stage, besides academic papers and books, data in documents made available on the internet websites of the central banks were gathered and cross verified. Information related to the organizational structure of central banks, their board size and accountability and transparency in their decisions and actions is among the selected data. In the analysis stage, the countries and criteria used was: India, as it is the researchers' native country.

ORGANIZATIONAL STRUCTURE

An organizational is defined as the boundaries within which staff throughout the organization can perform their work .So why are the organizations are so different. The reason for this variety is that an organization's structure can make a real difference to the way it performs. Henry Mintzberg (1979) a renowned management theorist developed a well-known typology consisting of five organizational structures: the simple structure; the machine bureaucracy; the professional bureaucracy; the divisionalized form; and the adhocracy. The organizational structure of a central bank with good governance practices has many features of Mintzberg’s adhocracy structure. There appears to be significant variation in organizational structures and institutional arrangements across central banks. Table 4 states different theories of Mintzberg’s and the central and that falls into those theories.

Henry Mintzberg (1992, 2009) suggests that organizations can be differentiated along three basic dimensions: (1) the key part of the organization, that is, the part of the organization that plays the major role in determining its success or failure; (2) the prime coordinating mechanism, that is, the major method the organization uses to coordinate its activities; and (3) the type of decentralization used, that is, the extent to which the organization involves subordinates in the decision making process. Using the three basic dimensions key part of the organization, prime coordinating mechanism, and type of decentralization, Mintzberg suggests that the strategy an organization adopts and the extent to which it practices that strategy result in five structural configurations: Entrepreneurial structure, machine bureaucracy, professional bureaucracy, divisionalized form, and adhocracy.

Table 4: Theories of organizational structure

In fact, most of the major central banks that are believed to follow best governance practices generally display many of the elements of the ideal structure. However, there is likely no central bank in the world that achieves all of the characteristics above. Furthermore, the relative importance of these features will depend on the objectives, autonomy, authority and accountability delegated to the central bank. Not all central banks could achieve these characteristics because of local political, economic, structural and cultural considerations.

The entrepreneurial type of organization has a simple, flat structure it is relatively unstructured and informal. Since it is a flat structure with few top managers the decision-makers can become so overwhelmed that they start making bad decisions. The machine organization is very formalized, there are many routines and procedures, decision-making is centralized, and tasks are grouped by functional departments. There is a formal planning process with budgets and audits; and procedures will regularly be analyzed for efficiency. Functional lines go all the way to the top, allowing top managers to maintain centralized control. The professional organizations rely on highly trained professionals who demand control of their own work. So, while there's a high degree of specialization, decision making is decentralized. If an organization has many different product lines and business units, you'll typically see a divisional structure in place. In innovative organization companies typically bring in experts from a variety of areas to form a creative, functional team. Decisions are decentralized, the clear advantage of adhocracies is that they maintain a central pool of talent from which people can be drawn at any time to solve problems and work in a highly flexible way.

From the table we find US, Canada, Japan, UK, Switzerland, Australia has adhocracy organizational structure implying that decision are decentralized and they maintain a pool of talent from which people are selected from different background and focus on highly skilled employees. Also these countries’ central banks encourage innovation. Saudi Arabia has diversified structure implying the bank operates under limited vertical decentralization. Moreover further work in this area is necessary.

BOARD SIZE

The size of the central bank board, or the monetary Policy Committee (MPC), is an important feature of central bank design. It is likely to reflect costs and benefits of an increasing number of board members as well as the political environment in which the decision on MPC size is made. On the benefit side, the most prominent argument in favor of increasing the number of board members is that larger MPCs could be in a better position to process, analyze, and interpret economic information ultimately leading to better monetary policy decisions than individuals relying mostly on their own information and judgment. On the cost side, a plausible conjuncture is that larger MPCs will generally imply greater effort from all involved for a given decision problem. This may translate into less effective monetary policy making. The most important aspect is communication among members and the dynamics it creates. Larger MPCs would require more time than smaller MPCs in reaching a decision. The view that increasing MPC membership size may reduce the effectiveness of policymaking. In developing countries, the role of board of directors is far more complex due to the severe form of information asymmetries. Gender diversity in boardrooms has also become a central component of corporate governance reforms around the world. Another factor that might be relevant for MPC size is the number of central bank staff. A possible link between the two variables is that larger MPC size could be simply reflective of a larger number of functions performed by the central bank, which may require both more staff and a larger MPC if the MPC also performs other functions

Table 5: Board size and employees of different central banks

Country	Board Name	Board members	No. of female	Branches	No of employees
United States	Board of Governors	07	01	12	2919
Germany	Governing Board	06	01	35	8480
France	Monetary Policy	04	01	13	9258

Australia	Reserve Bank Board	09	03	05	1589
Netherland	Governing Board	04	0	-	1703
China	Board of Directors	12	03	09	-
India	Central Board of Directors	15	03	20	15461
Brazil	Board of Governors	09	0	-	-
Mexico	Board of Governors	05	01	-	-
Indonesia	Board of Governors	06	01	39	5820
Saudi Arabia	Board of Directors	05	0	10	2800
Turkey	Board of Directors	07	0	21	4746
Russia	Board of Directors	12	05	11	54700
South Korea	Policy Board	07	0	16	2215

The size of the respective boards should strike a balance between having a sufficient number of members to ensure an informed, balanced, and professional view, while at the same time limiting the number so that the board remains effective and avoids a dilution of individual responsibilities. Reportedly, board members sometimes feel an obligation to speak, which can be time consuming if they do not contribute with new information or perspectives. Most policy boards have seven to nine members. Supervisory boards and advisory boards, on the other hand, often have a broader representation. Where a management board exists, it tends to be smaller, thus allowing for quick decisions and avoidance of the dilution of responsibilities.

MPC size may vary systematically with a number of country characteristics:

- board's size increases with greater diversity and country size;
- board's size is larger at higher levels of development, but decreases with greater openness;
- board's size is larger in the presence of stronger democratic institutions;
- board's size is larger in the presence of higher public debt levels;
- board's size is larger in the presence of a floating exchange rate system; and
- board's size interacts systematically with other elements of central bank design, including the degree of central bank independence, monetary policy strategy, staff size and operating expenditures, and the term length of MPC members.

In today's world, board diversity has become a relevant topic and gender diversity is an important aspect of board diversity. There are scarce of studies about women's presence on the boards of directors of banks. In order to justify the low representation of women in the highest executive positions and on the boards, it is important to get evidence of the phenomenon known as the glass ceiling. This is usually defined as a set of obstacles that mean a barrier made up of procedures, structures, power relations, beliefs or habits, which complicate a woman's access to high directive positions

(Morrison et al., 1987; Powell and Butterfield, 1991). Their presence in central banks, on the other hand, is a relatively new subject of research. The issue first came to the foreground in 2012, when a group of renowned economists signed an [open letter](#) denouncing the absence of female appointees on the European Central Bank (ECB) board.

The above study (table 5) show that presence of women on boards of directors is limited worldwide. The majority of female Central Bank chairs were appointed in emerging countries. Russia has more women in the board (42%) as compared to advanced countries women on board. However in countries like Netherland, Brazil, Saudi Arabia, Turkey and South Korea there is no women in the central bank board. This implies women remain under presented in the economics profession, particularly in specialization like macroeconomics or finance which is the backbone of central banking. However many countries are recently planning to introduce a gender equality action plan. Therefore it shows diversity is lacking in the top echelons of central banking globally.

FUNCTIONS OF CENTRAL BANK

The central bank is nowadays primarily an agency for monetary policy. It also has important financial stability, employment, growth and welfare functions. But the range of functions allocated vary between countries. Central Banks generally had three main objectives or functional roles. (i)To maintain price stability, (ii)To maintain financial stability, (iii)To support the policies of the government,(iv) To maintain growth and welfare.

The table 6 reveals the objective of central banks. It is found that all central banks conduct monetary policy to achieve price stability (low and stable inflation) and to help manage economic fluctuations. Monetary policy and financial stability are intimately linked. Price stability supports sound investment and sustainable growth, which in turn is conducive to financial stability. Countries like Spain and South Korea maintains both. However central banks are not only designed to tackle monetary and financial issues but economic growth, employment and welfare are also relevant variables in countries like US, Italy ,Canada,Switzerland,Australia,India and brazil

Table 6: Characteristics of Central Banks

Countries such as France, Italy, Mexico. used monetary policy for short-term political purposes, either to finance fiscal deficits or to stimulate economic activity, and to reduce unemployment. Central banks have played an increasingly prominent role in advanced economies over the last decade. however, its role is different in emerging and developing countries .In advanced economies central bank mandates are predominantly focused on price and financial stability, whereas in emerging and developing countries central banks have a wider remit to support sustainable development and the government’s economic policy agenda.

TRANSPARENCY AND ACCOUNTABILITY OF CENTRAL BANK

Transparency relates to a central bank’s openness in explaining the rationale behind its specific policy decisions. The rationale for policy actions cannot be fully understood unless the central bank makes clear its long-term objectives, as well as its strategic goals and its short-term tactics to achieve them. The central bank should also describe the economic environment in which it expects its actions to be felt. Indeed, transparency may be regarded as one of the most important conditions of central bank independence. Transparency in the mandate of the central bank and clear rules of procedure for its operations ensure good governance and facilitate policy consistency. Transparency therefore leads to more effective monetary policy, in particular because it facilitates better decision-making by the public. Another argument against transparency is that the public may read too much and get confused in interpreting the information released by central banks, and that the more transparent a central bank becomes, the more signals it sends, the more volatile are the financial markets. The concept of transparency is closely related to accountability. In fact, some degree of transparency

is a necessary condition for accountability. Conceptually, transparency refers to mere information disclosure, whereas accountability concerns the explanation of one's actions and bearing responsibility for them, including possible repercussions when the policy outcomes fall short of the objectives.

Table 8: Transparency of central bank

	Political	Economic	Procedural	Policy	Operational

Russia			✓		
Korea			✓		

Political transparency refers to openness about policy objectives. Political transparency is enhanced by institutional arrangements, like central bank independence, because they ensure that there is no undue influence or political pressure to deviate from stated objectives. Economic transparency focuses on the economic information that is used for monetary policy. This includes the economic data the central bank uses, the policy model it employs to construct economic forecasts or evaluate the impact of its decisions, and the internal forecasts the central bank relies on. Procedural transparency is about the way monetary policy decisions are taken. And how the policy decision was reached, which is achieved by the release of minutes and voting records. Policy transparency means a prompt announcement of policy decisions. In addition, it includes an explanation of the decision and a policy inclination or indication of likely future policy actions. Operational transparency concerns the implementation of the central bank's policy actions. It involves a discussion of control errors in achieving the operating targets of monetary policy and (unanticipated) macroeconomic disturbances that affect the transmission of monetary policy.

From the table we find that Fed place strong emphasis on ensuring the transparency of the decision-making process. The Fed is ultimately accountable to the Congress, which can amend the Federal Reserve Act legislation at any time. whereas in Germany Shareholders and the public are regularly kept up-to-date through the 20-F Report and the Financial Report, including the Consolidated Financial Statements, as well as the Interim Reports. The reporting of Deutsche Bank Group is in accordance with International Financial Reporting Standards (IFRS). This provides for a high degree of transparency in financial reporting and facilitates comparability with international peers. All of the measures that make up the Basel III reforms are expected to be in force by 2022 (with phase-in provisions in some cases).

GOVERNANCE PERSPECTIVE FROM INDIA

Transparency, continue to be the mainstay of the Reserve Bank of India's communication strategy. The Reserve Bank endeavours to strike a chord with the public through communication that is dynamic, evolving and responsive to domestic and international developments.

The Central Board of Directors is the apex body in the governance structure of the Reserve Bank. There are also four Local Boards for the Northern, Southern, Eastern and Western areas of the country which take care of local interests. The central government appoints/nominates Directors to the Central Board and Members to the Local Boards in accordance with the Reserve Bank of India (RBI) Act. It comprises of the Governor, who is the Chair, and four Deputy Governors of the Reserve Bank; four Directors nominated by the central government, one from each of the four Local Boards. Ten Directors nominated by the central government and two government officials nominated by the central government. The Central Board held seven meetings during the accounting year 2016-17 in Bengaluru, Mumbai, Kanpur, Kolkata, New Delhi (twice) and Chennai. The present RBI Act does not provide for any Monetary Policy Committee and it would not be possible, under the extant legislative framework, to set up a Committee independent of the RBI Board. It would, however, be possible to take a cue from the institutional framework worked out while setting up the Board for Financial Supervision (BFS). The Advisory Group recommends that, even without any legislative changes, the RBI should set up a Monetary Policy Committee (MPC) as a Committee of the RBI Central Board. There could be a seven member MPC consisting of the Governor, the three Deputy Governors and three other members drawn from the RBI Central Board; concerned Executive Directors and Departmental Heads dealing with monetary policy, internal debt, exchange rate management and economic analysis could be permanent invitees. The tenure of non-executive MPC members could be

coterminous with that of the Central Board Directors, i.e. four years, with a clause for reappointment. There should be a convention under which the members are appointed for different periods to ensure periodic new appointments while ensuring continuity. The members of the MPC should be knowledgeable in the areas of macro economics, monetary analysis, central banking policy and operations and banking and finance. More importantly, to ensure against any conflict of interest, the three Board members who would be on the MPC should be independent professionals. It would be desirable to delineate the role of the non-executive members vis-a-vis the executive members; moreover, the question of information access and staff support as between non-executive and executive members should be addressed upfront to head off any inherent conflicts. The Advisory Group recommends that the MPC be set up early so as to give the MPC some time to work out its modalities and to undertake a few trial runs before the formal procedures are put in place starting from say the next financial year.

CONCLUSION

The matrix in governance structure taken in this study was divided into 4 categories i.e. organizational structure, characteristics of central bank, board size, transparency and accountability. Each of these characteristics is looked into taking the theories into fold .Through these criteria it can be concluded that a further way out of this approach understanding the parametric specificity of the central bank would be pointing out to diversity and need of socio, economic, political outcomes and fulfillment of those needs via allocation and control of fund flow into the system.

ABSTRACT

The lecture covers the concept of spatial structure, the connecting interpretations and seeks to support the background of the definition from three approaches. In the lecture, we also deal with the definition of the region itself, to which two levels of explanations are presented. The regions can be distinguished and compared in terms of the spatial structure (economic, social, historical, geographic, etc.) and this allows for the creation of different groups, which is actually the main challenge of the regional approach. The aim of spatial structure analyzation is to identify the common features of a larger territorial unit - a country or a group of countries -, by analyzing the kind of measures that are used to differentiate them, and in what direction they may evolve, may change in the future. Many analytical methods are known or are currently being developed to measure the territorial levels, to register their status and to compare them. In the lecture we intend to present two possible directions of analysis, which can be the starting point and the basis of these methods. In addition to current and future development zones, in the 1990s, temporary regions with different characteristics were also present in Central Eastern Europe, some of which demonstrate the special features of the region well. The conclusion drawn from the spatial structure study shows slow changes, while when it comes to competition, it highlights significant differences. The territorial features of the region highlight the growing competition space, the concentration of the increasingly powerful resources of the capital, which is very much central to the European spatial development thinking. The presentation focuses on what the regional centers lack when it comes to co-operation especially regarding mutual spatial planning. It also emphasizes that the automotive industry has become the dominant economic sector in these regions, which can increase the competitiveness amongst them. Based on the results of the analysis, a certain ranking of competitiveness can be set up amongst the regions, which gives a clear picture of the spatial structure of the Central Eastern Europe region. In our view, Central Eastern Europe will not become a new development zone in Europe, but the capitals and some regional centers and their neighborhoods can successfully catch up while the spatial differences in the region are spectacularly increasing. Basically, Central Eastern Europe still shows some of its 1990' characteristics when it comes to integration or the renaissance of the former Eastern nation states and this can be demonstrated by both political and economic processes. The construction of the examined spatial structure can be considered both complex and macro-regional, not necessarily characterized by socio-economic homogeneous zones, but we can establish common features. The division of the large area is even more spectacular, and it becomes clear that significant developmental disparities have emerged between some parts of Central Eastern Europe. Our findings also extend to the growing competition and its main characteristics between the countries of Central Eastern Europe. The conclusions can contribute to developing policy directions for each region.

Keywords: regions, Central Eastern Europe, spatial structure, regional approach

INTRODUCTION: THE EXAMINED AREA

What do we consider Central Eastern Europe? In recent years the number of domestic studies and studies on great region research has increased dramatically, which clearly indicates that this region has become the focus of professional interest. The announcements also indicate that there are significant differences in the definition of large areas. One of the research groups focuses on the countries of the Visegrad Cooperation (V4), which was founded in 1991 (Czech Republic, Poland, Hungary, Slovakia), and more are complemented by Austria and thus represent Central Europe. Other analyses also link the eastern provinces of Germany, possibly Bavaria and the Western Balkans (Horváth 2010) to Slovenia and Romania, so they are talking about a wider Central Eastern Europe.

In this study, a broader approach is justified to be used. On the one hand, most of the countries have joined the European Union already, or will soon join (Serbia is still insecure). On the other hand, looking from the Hungarian perspective, we can discover a number of identities in the common historical foundations of this region, but in the twentieth century, the individual countries, and thus the whole region, are linked together by millions of economic, commercial and millions of historical-cultural relations. Furthermore, this part of Europe has been characterized by the same political system, and we are also seeing similarities in the simultaneous elimination of it. And last but not least, the specific geopolitical situation characterizes these countries, since they are located in the middle of West and East, and in changing political polices this position can be validated in the past, but in the future in a specific way.

Therefore, our research is focused on a larger, more coherent, developmental and moving area, and so we consider Central Eastern Europe as the eastern and southern provinces of Germany, Austria, Poland, the Czech Republic, Slovakia, Hungary, Slovenia, Romania and Bulgaria. In this country group as a European large area we are attempting to outline the spatial structure and register its changes.

ABOUT THE SPATIAL STRUCTURE

²⁷¹ "This publication is supported by the "Introducing internationalization, teaching, research and student supply, developing knowledge and technology transfer as tools for intelligent specialization at the Széchenyi István University, supported by EFOP-3.6.1-16-2016-00017."

Pál Szabó summarizes the Hungarian interpretations of the spatial structure in an excellent study (2009) and in his habilitation thesis (2015). It gives you three approaches of using the concept. In the first case, the elements (constituents) and their spatial arrangement can be considered as the basis of the definition, while in the other sphere the terms emphasizing the constituents of the space are categorized. Finally, the third group lists those studies in which the analysis of the spatial form of the spatial elements, ie the differences in the structures and the distribution of spatial formations as their distributions, is the focus. To illustrate the differences in spatial development, we can attach the other groupings mentioned by the author, which can be made in geographic and regionalistic (spatial development) approach. Szabó considers the interconnection of the terms of the region and of the spatial structure, or the description of the geographic spaces it has spawned in network elements (transport, settlement networks, infrastructure systems). For the regionalist view, it lists those who define the boundaries by quantitative and qualitative differentiation between spatial units, and then define the spatial development directions accordingly. Analyses for a country may also target administrative units (municipalities, micro-regions, counties, planning-statistical regions) that may appear in different types of spatial formations. These can be distinguished by the common features, from the unique spatial shapes found in the particular analyses. Separation is also a confrontation, it is capable of a presumed or real level of development that can form the basis for statements about spatial structures.

In our opinion, the regional approach is aimed at defining spatial developmental directions. Describing the processes and system of factors that can be used to describe the developmental characteristics of a country and continent. Spatial distributions and differentials can be identified and point to directions for development interventions, to identify desirable political or ideological goals in the spatial structure, and to determine the tools and institutions that can be assigned to them.

It may be justified, but the study does not aim to explain further general determinations of the spatial structure.

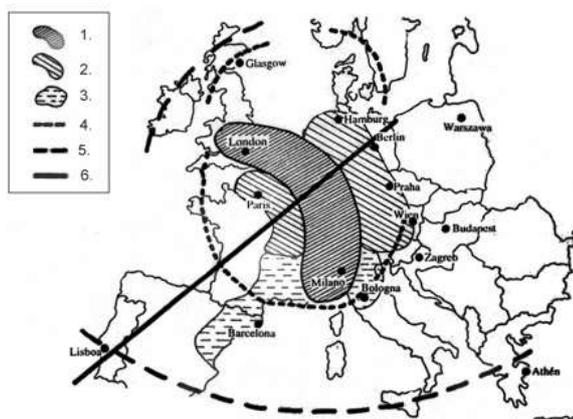

CENTRAL EASTERN EUROPE IN THE EUROPEAN SPATIAL STRUCTURE

The spatial structure models in Europe appeared in the eighties and nineties of the last century, with the aim of illustrating the evolution of the European space. The depictions and the territorial delineations are based on the classical principles of the centre-periphery model. Centrum regions - whose hubs were the centers of the Western European - economic resources - but all institutions of political decision-making - were concentrated, and in this well-defined space the economy was renewed and the aggregation of innovations took place. Thus, Blue Banana was created as the economic - historically interpretable - European zone of high prestige centers that displayed the dominant centers of Western Europe and their attraction (Brunet 1989). The extension of this zone takes place in the reflection of the models, as part of the development zone that has formed with the agglomeration areas of the megacentres and the integration of new centers has occupied the dominant centers of Europe and their influence fields from London and Paris, from the Ruhr country to Milan, and Kunzmann (1992).

Outbound development zones continued to emerge in the 1990s. The South -European development zone, comprising the major centers and agglomeration areas of Barcelona - Lyon - Marseille - Genova - Milan - Venice - Rome, will be featured. This has been called the developmental axis of the North, the European Sunbelt or the Second Banana (Lever, 1995) with special functions (service orientation, tourism, growing local economies, new types of production systems and regional connections).

Along with this, the European high-tech ring, which, starting from Glasgow to Barcelona via Milan, entering Vienna - interrupted in Central Europe - returning to Malmö in its starting position. This is the first Vienna to appear here, as the last station in Europe at that time, which is beyond the peripheral regions, such as Central Eastern Europe, with its unknowingness and unopposedness (Figure 1).

In the early nineties, regional processes clearly indicated that the economic integration of Central and Eastern European countries would inevitably take the form of regional integration (Enyedi 1996). The Visegrad Cooperation, which the economies and institutions of their countries could in principle be suitable for economic integration, these effects could

simultaneously initiate territorial integration processes, not just the neighboring countries of the then European Community but also the Eastern and post-socialist countries. Certain aspects of this integration process were recognized in macro-regional structures emerging in Central and Eastern European countries (Gorzalak 1996, Rechnitzer 1998, Rechnitzer, Smahó 2011), which showed a number of specificities and some developmental directions (Figure 2)

Figure 2: The spatial structure of Central Eastern Europe in the 1990s

Source: Rechnitzer, Smahó 2011, 55.

In the macro-regional structure, urban regions are the embodiment of relationships. In Hungary, the agglomeration in Budapest, the agglomeration of Prague and Brno in the Czech Republic, Warsaw, Poznań, Wrocław, Gdansk, Krakow in Poland, Bratislava and its area, and the region of Košice in Slovakia. The west-east development slope was already prevailing in the countries, but it was close to the eastern borders, and it was broken and staged in another level of development that was much worse than the previous one. Thus, essentially, the Western border regions of the countries of the Central and Eastern European region were regarded as the founders of the macro-regional cross-border cooperations considered to be unfolding, while the eastern regions were the real periphery with the poor chance of catching up.

The Western growth zone of Central and Eastern Europe has been analyzed as "Central Eastern Europe banana (boomerang)" in the Gdansk-Poznań-Wrocław-Prague-Brno-Bratislava-Vienna-Budapest metropolitan areas. Here, the capital cities and the major industrial and administrative centers were concentrated and their organizations were in direct contact with the Austrian and German economies, large and medium-sized investors settled in these areas, and these centers were also suitable for receiving services and shopping tourism from the West in the middle of the nineteenth century.

Another speciality, is that for the very first time within this zone have met the relatively developed infrastructurally advanced decisively industrially potent central eastern european regions with the correlatively undeveloped Austrian and German regions, the latter representing major transformations. Therefore a natural competition evolves among these areas, that was not only valid for the Austrian-German relationships but also effected the intraregional relations of the individual countries. By which we mean that due to the inflow of foreign capital in the aforementioned western or the metropolis-based regions the economy went through a faster and as a matter of fact a more successful transition, thus the western-eastern and metropolis-countryside divisions have not decreased by time, rather they further increased within the particular countries.

The Central Eastern European banana (in other denomination the boomerang) could be starting or has already started two potential developmental zones and extensions. One of which has Prague and the former East German cities (Berlin,

Leipzig), connecting to Berlin, in focus, curving back to the area of the Czech capital with Poznan. Indicating the spectacular formation of the Berlin-Warsaw axle, which not only could serve as a new transportation and communicational passageway (II. transportation corridor) in direction to Minsk and Moscow in the future, but can also be reviewed as an innovation axle. This can also result in the dislocation of the hub in the Central Eastern European configuration, beguiling major movements of goods and marking out new economic directions, that could call for the devaluation and dislocation of the preceding spatial contacts and may cause the realignment of the spatial structure²⁷².

Another potential extension of the Central Eastern European banana is yet a north-south cooperational direction, where it connects the Adriatic coastline with the Northern Sea. In this hypothetical expansion the Berlin-Warsaw axle could more expressly prevail, also Slovenia, Croatia and the eastern and southern provinces of Austria may gain activity. In view of the particularity of the spatial structure it can be presumed, that the joining of the northern and southwestern developmental areas of Central Eastern Europe can come into existence on the Prague-Brno-Vienna-Bratislava-Győr-Budapest axle. Here can shape an economic and spatial structure 'turning disk' (Central Eastern European mushroom), that can interweave in the following decades the future renewal zones of Central Eastern Europe in the direction of Eastern Europe – decisively Eastern Slovakia and The Ukraine – and the Balkan, mostly Romania Serbia and Bulgaria, transmitting the capital, the knowledge and the innovations towards their regions and major centers.

Beyond the current and future developmental zones other different transitional areas have been apparent in the 1990's in Central Eastern Europe with their unique characteristics. Part of these are the traditional industrial areas, the areas of the transitioning agriculture or the mountainous territories worth the renewal through tourism, as well as the bigger municipalities that are willing to participate in cross-border cooperations and the traditional peripheries. The 'eastern wall' was able to be traced out, the one that broke the developmental slope and involves the eastern peripheral border territories interlocking Belarus and The Ukraine. In these mostly rural areas based on agriculture characterized by a settlement of villages and small towns and an unfavourable and domestically subaverage level of infrastructural supply. In other rural regions the internal resources that serve the renewal were far too poor, the interest of foreign capital is minimal, the employment and social tensions are intensified. Beside the numerous disadvantages of the peripheral condition the fact that the post-soviet areas border on quasi developed 'western' regions signify an advantage as it serves the possibility to activate certain elements of resources and create new fields of relations. The destruction of the 'eastern wall' was permanently obstructed by the anachronistic and bottleneck transportation (and border-connective) infrastructure, the slowly forming institutional structure of the post-soviet states, the intensifying eastern border security of the European Union, the pullulating black economy and the specifically bad public safety.

THE COMPETITIVENESS OF THE CENTRAL EASTERN EUROPEAN REGIONS

The research is continued by the analysis of the competitiveness of the self-interpreted Central Eastern European large regions (NUTS 2). Our main goal on the one hand was to provide those coefficients, thus economic, social and institutional factors, that are intensely determine the whole of the examined large region, its internal and correlated structure, on the other hand positioning the Hungarian regions allows us to draw recommendations in order to improve our position assessing and later strengthening our competitiveness.

Our analyses contributed to the evaluation of the theoretical models of competitiveness, and the researches about it, in a way that new elements have been introduced to the already existing models (Lengyel 2000, 2012). The classic main categories of productivity of labour and employment have been refined, thereupon beside the main factors regarding the research and development, the human capital and the working capital, new social capital factors have been built in, as well as new parameters regarding the traded sector (industries producing to export).

We have compared the NUTS 2 units of eight countries, which mean 93 regions, we based the analysis on 25 variables²⁷³, which we evaluated through different mathematical-statistical methods.

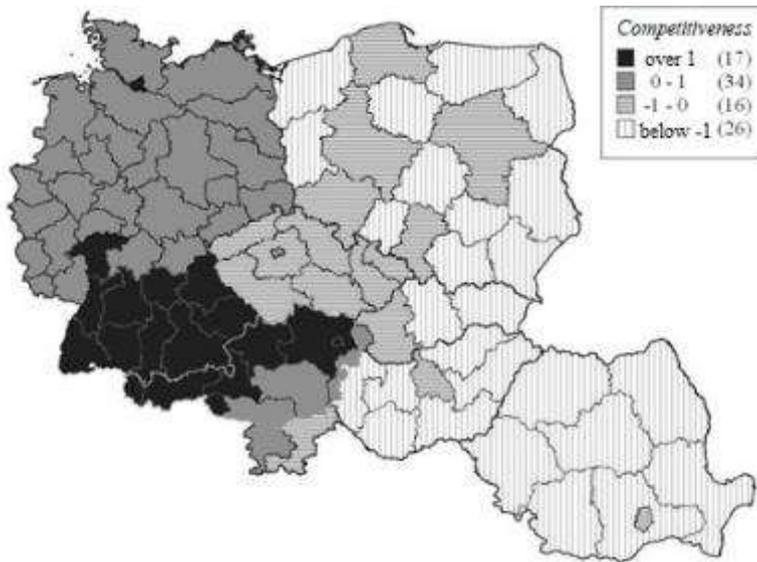

While analyzing the constituting factors of competitiveness, such as the productivity of labour and the employment it can be determined, that the large region is heavily differentiated, an easily distinct fault-line could be drawn. The seclusion may be characterized overall by the phenomena that two areas – the developed western European market economies (Germany, Austria) and the Central Eastern European regions that are closing up – are unequivocally separated from each other. Within the former high employment rate couples with high productivity, while the latter can be described by the opposite, namely low employment and low productivity.

The large region is strongly divided – as the researches confirm the known disparities between west and east, the concentration of resources in the capital cities in terms of the former socialist countries, the major differences among regions, – so the developmental zones (measures of contiguous, equally developed regions) could be recognized in a relatively small number, as against the huge blocks of weakly developed, decisively peripheral regions (Figure 3).

Figure 3: Competitiveness of the regions of Central Eastern European

272 The actuality of this new direction is shown by the fact that Poland strongly seek the reception of the Russian railway transportations, herewith intermediating the further Asian connections towards the core area of the European Union.

273 The 25 variables have been divided into six groups, thus beside the general income state (4 variables) we have examined the distinctiveness of research and development (5 variables), the composition of the human capital (5 variables), the parameters of the working capital (1 variable), the traded sectors (2 variables) and the social capital with its institutions (8 variables).

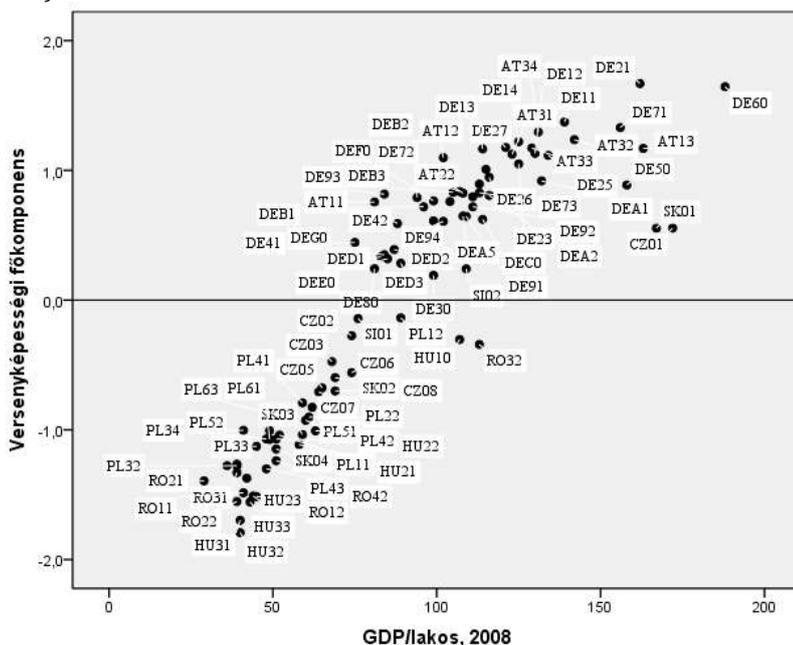

Source: Lengyel, Rechnitzer 2013, 113.

The Hungarian regions compared to the regions of the other post-soviet countries within the major area are in a rather unfavourable position. Solely Central Hungary, that contains the capital, and also Western Transdanubia can be marked with an appraisable competitiveness, the remaining regions are broken away being rated to the weak competitiveness category. This can be confirmed by the examen, when the main competitiveness component, as the concentrated expression of the analyzed factors, are compared with the GDP per capita and the connections are ranged into a two-dimensional graph (Figure 4).

The division of the large region is even more apparent and obvious in the significant developmental differences that have been evolved in Central Eastern Europe. The fault-line (the average rate of competitiveness) could be stepped across beyond the foresaid German and Austrian regions only by the Prague and Bratislava region among the areas of the formerly socialist countries²⁷⁴.

The Hungarian capital merely flips over the average rate of the broad region with the prominent level of competitiveness and a favouring specific GDP, nationwide. The GDP supply of the Western Transdanubian and the Central Transdanubian region is also still sensible, however it disposes a low level of competitiveness, which is even more vigorously present at every other Hungarian region, that are located on the bottom of the heavily lagging block, rather than its midfield.

Figure 4: The relationship between the main component of competitiveness and economic development (GDP per capita, 2008)

Source: Lengyel, Rechnitzer 2013, 112.

274 The latest regional GDP datas (2012) simply strenghten this result, as among the 20 most developed regions of the European Union the Bratislava region (Bratislava kraj) sits ont he sixth place, with 179 % of the EU average, the Prague region (Praha) is on the ninth place producing a 172% result, Vienna (Wien) 12th ont he same list with 162% of the EU average, and Central Hungary containing Budapest is permanently between the 96th to the 98th place continuously, barely being over the EU average.

Further researches – mainly the internal analysis of the factors which affect competitiveness – have found, that basically two of the coefficients determine the competitiveness of the regions. One of those is the human capital – this factor contains the development of the labor force, the ability of labor attraction and the presence of patents –, that strongly divide the large region, providing a more subtle picture in terms of the derivation. Amongst the Hungarian regions the two fore-mentioned, namely Western and Central Transdanubia, stand closer to the Czech and Polish regions that approach the confine. The rest of the Hungarian regions then again are significantly lag behind showing similar rates to the peripheral Romanian and Polish regions.

The Research and Development factor – R&D expenses, the proportion of employed in the high-tech sector, fixed capital formation, successful framework programmes – symbolises the presence of the knowledge-based economy and the innovative sectors, which coefficients expand through the Central Eastern European area. Within this division taking the shape of a mushroom the Hungarian regions are even more prominently break away from primarily the Czech and Polish regions. The analysis once again confirms the Hungarian – but as it were also a Central Eastern European – particularity, that the capital characteristically dissever from the rest of the regions – in our case Budapest –, and its numbers rather converge to the western European areas, being closer to the 'head of this mushroom'. In the 'stipe' as the lagging block, one can find the remaining Hungarian regions, indicating a rather unflattering R&D potential, and herewith a specifically weak competitiveness in Central Eastern Europe.

SUMMARY: TRENDS AND DIRECTIONS IN THE SPATIAL STRUCTURE OF CENTRAL EASTERN EUROPE

Based on the ongoing researches it is anything but easy to summarize the directions and the possible routes of development of the spatial processes in Central Eastern Europe.

Our first conclusion is that the countries and areas of the large region are more heavily getting into the course of competition, as the contest is sharpening, mainly when it comes to receiving and settling foreign investments, and being able to show the attractions offered by the capital cities and the larger regional centers (service-providing institutions, research and development, supply of academic qualification, the receiving of international organizations, supply of tourism, appealing environment, etc.). This course of competition is constantly rearranging, thriving with newer and newer elements, as some countries and regions emerge, whilst others, setting off from a more prosperous position, find themselves in a competitive disadvantage, and whereas for several, the process of going ahead is rather slower and not spectacular at all.

The competition is consequently intensified, as this phenomena is even more easily recognizable in case of the capitals (Horváth 2007; Csomós 2011). The European tendency, that the incomings are increasingly concentrated in the capital cities, is confirmed, as we see that in every Central Eastern European capital and in its region the GDP per capita is nationwide the highest, and its concentration rises steadily in course of time. It can be said, that three capitals exceed in this competition. For years – with varying rankings – Bratislava, Prague and Vienna stand amongst the twenty most profitable regions of Europe, however amongst the emerging regions not only Warsaw and Budapest but Ljubljana, Zagreb and even Belgrade can be found. These centers may not entered the contest of the European metropolises, as those capitals are more successful at receiving international organizations, in settling them they achieve a leading role within the larger region (extending over more countries), or even at a European level. Apart from this their supply of metropolitan functions, and the factors describing the quality of life is ever more broader and diverse (Csomós 2011).

Besides the income and function of the capital cities and concentration of the population we may consider another typical spatial structure characteristic, which is the *sub-urbanizational processes*, that are accelerated around the centers of the countries, moreover these population-clustering tendencies seem to be discovered in specific regional centers as well. Namely the capitals and some larger municipalities, regional centers offer favourable possibilities of employment, secure more easily accessible services, and develop better conditions in terms of the quality of life, therefore becoming a more and more significant target of internal migration. In opposition to this, the geographical territory of the *emptying areas* are expanding, the ageing of the extant population, the falling of municipal-level services, unfavourable work conditions, the appearing of disadvantaged social groups and sets of people, then their concentration in certain areas. All these follows the European trends, although in case of Central Eastern Europe they are more spectacular, moreover the balling of lagging areas is not even interrupted by the national borders. The peripheries of the peripheries are outlined within the large region, and the elimination or the moderation of the spreading of these territorial 'black holes' consume significant sources, that most countries cannot or would not like to obtain.

Securing the fast accessibility of the *spatial disclosure* of the countries, – that is e.g. the capital and regional centers, as well as the linking of those, – is not consistent, the individual countries followed differing network development philosophy and practice, therefore the internal connections and interweavings of the large region are uncertain. The European long-range transport network development goals seem purposeless, as the road-system is constructed on a limited speed, not always tracking the most favourable directions or the accessibility of the centers. *Connections along the national borders* however smarten up, the interoperability gradually comes into existence – relatively poorly in peripheral areas –, but even in this spatial segment the ever-keener competition is present, therefore it is quite frequent, that the neighbouring regional centers undertake parallel developments, neglect relations and assign projects to internal needs (e.g. airports, universities, R&D bases, industrial scientific parks, etc.)

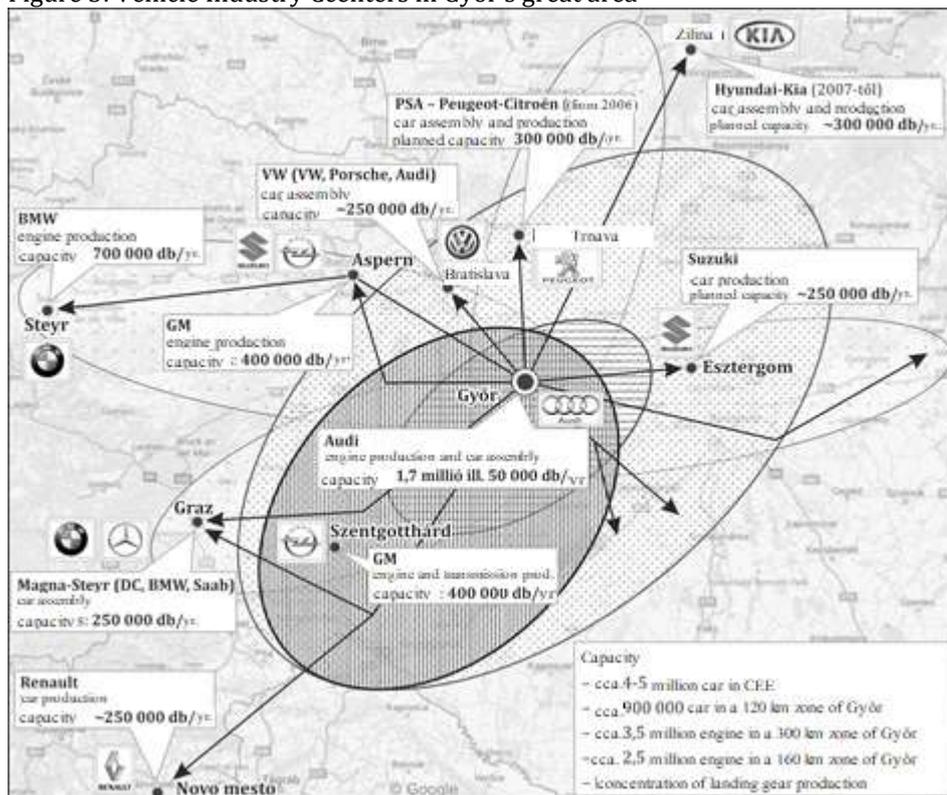

A main characteristic of the large region is that the countries – and their spatial planners – have not yet recognized the importance of the joining and 'glancing' of the *developmental conception*. Therefore in certain national spatial

developmental conception prevails an island effect, as there is yet to be a Central Eastern European dimension – or at least in case of the neighbouring, interlocking territories –, common thought about spatial structure, or even its illusion – quasi its institutional framework – is not yet found.

At last, but not least it must be mentioned, that decisively in the central european (core) region the *automotive industry* is becoming a more and more significant sector (Rechnitzer, Smahó 2012) (Figure 5). Not only because the automotive appears in numerous city – mostly the automobile assembly plants –, but also in line with that we see the settlement of diverse types of suppliers providing other european production centers as well, either being concentrated in larger towns or being scattered in different municipalities. The positive effect of the automotive concentrations is visible in many centers (supply of education and training, higher incomes, appearing suppliers, extension of services, wider consumption supply, rising immigration, development of the urban infrastructure, etc.), but the exposure of these centers are increasing as well (route-dependent local development), and the solution for it do not always have a place in the developmental notions (Molnár 2012; Fekete 2015).

Can the whole of Central Eastern Europe be considered as a new european developmental zone? The entire area presumably will not be a growth zone, as one can see non-integrated, rather strongly divided, – in terms of spatial structure – isolated elements, zones, that are recognized in core regions, surrounded by deep peripheries, or permanently stagnant, motionless places and set of municipalities. The suction effect of the centers – in truth the capitals – is easily recognizable, that only escalate the spatial differences and the system of counterpoint. The competition is intense between the capitals and the zones, and at the same time the ever more spectacular spatial differences within the countries must be treated or need to be treated. The economic and spatial policies of the countries (where there at least is one) might be following the european principles, however fundamentally they differ. Thus there is a great chance in certain countries for the capitals and a few regional centers to become an exciting, future-bearing power places, other regions – perhaps even in spite of the persistent political actors – might remain in or drift into the poorhouse of the continent.

1688 SPATIAL & TEMPORAL ASSESSMENT OF ACCESS TO HEALTHCARE FACILITIES IN MUMBAI: K-WEST WARD***Naveen Krishna Alla, Arnab Jana, Rathin Biswas***Centre for Urban Science & Engineering, Indian Institute of Technology Bombay, Mumbai-400076, India, E-mail: naveen.krishna@iitb.ac.in (Corresponding author), arnab.jana@iitb.ac.in, rathin.iitb@gmail.com**ABSTRACT**

There is a necessity of healthcare facilities (HCFs) to perpetuate human life from various kind of diseases. The demand is growing briskly day by day with the growing population in urban areas, which generates some questions like, are the HCFs well distributed over the area based on their speciality, affordability and service timing, if so then, how much area can be served by the existing HCFs, if so then, are they able to provide 24 hour service, if not then, which areas are underserved or health facilities shortage areas and in which time window, and which are the probable areas to place a new HCFs. In this paper, we analysed the current situation of HCFs both spatially and temporarily in the K-west ward of Mumbai as a study area. The spatial analysis demonstrates the spatial inequality in terms availability and accessibility of HCFs. From the results, it was found out that most of the underserved areas are low-income neighbourhoods and they are lack of affordable HCFs (i.e. public). The spatial inequality of various healthcare services was computed using the network analysis with different catchment areas. The temporal analysis considers different time frames of service timing of HCFs like morning, afternoon, evening and midnight. The results show that only a few out of 179 HCFs provide 24hrs services, of which only two are public HCFs that means lack of public HCFs, especially in night hours. This spatial and temporal analysis will give an idea to health managers, policy makers and planners where to open new HCFs, or what will be its operating time window. This methodology can be applied to other geographic areas.

Key words: Health Care Access, Spatio-Temporal Analysis, Net Work Analysis, Underserved Areas

1 INTRODUCTION

Health equity has become an important policy issue all over the world. Providing adequate access to health care providers is vital for any health care system (Bauer & Groneberg, 2016). Access to health can be defined as enabling a patient in need to receive the right care from the right provider, at right time depending on the context. Access is a multidimensional concept, it depends on both the suppliers (Health care providers) and demand (People) factors. In broad, access depends on social, geographical, personal and final factors. (Penchansky & Thomas, 1981) first proposed the theory of access in the health care system. They defined access as the degree of fit between the user needs and service provision by the providers; the better the relation, better the access. The degree of fit could be measured across five dimensions such as availability, accessibility, affordability, accountability and accommodation. All these dimensions are independent but interconnected and each is important to assess the achievement of equity in health care access. The term availability deals with the volume of health care providers or other health care services (Goddard & Smith, 2001). Inequalities in access to health care are more in urban areas as compared to the rural areas (Ministry of Health and Family Welfare, 2015). This is because of the rapid growth of urban population and stagnation of public healthcare facilities.

Urban population in India has gone up to 31.2 percentage in 2011 from 17.3 percentage population in 1951 (Government of India, 2011). At the same time, nearly one third of urban population live in slums or low-income neighbourhoods. By the year 2020, India's total slum population will increase to 200 million (UN-HABITAT, 2015). In addition, India is undergoing dual burden of disease, an incessant rise in communicable diseases and a spurt in non-communicable diseases (Boutayeb & Boutayeb, 2005; Upadhyay, 2012). Hence, the demand for healthcare is growing briskly day by day with growing population in urban areas. Assessment of healthcare access is complex in urban areas as compared to the rural areas. This is due to heterogeneous mix of population, fragmented health services and complex transport network. Which generates some of the important questions like how much area can be served by the existing HCFs, if so then, are they able to provide 24 hour service, if not then, which areas are underserved or health facilities shortage areas and in which time window, and which are the probable areas to place a new HCFs.

In India, there are no detailed policies regarding geographical location of HCFs (Rao, 2012) The location of public HCFs is based on simple metric such as threshold population. This creates geographical distribution variation of HCFs in urban areas. The spatial variation of HCFs is very high in urban areas as compared to the rural areas. It is reported that in India more than 70 percent of health infrastructure located in urban areas. Despite the supposed proximity of HCF's to urban poor their access to these facilities severely limited. This is because of high costs at private facilities and the limited public HCF's. In this context, it is very important to understand the spatial distribution of HCF's based on their speciality, affordability and service timings.

An efficient assessment of health care access is critical for decision makers to take necessary actions. Especially, it is important to identify the locations that have less access to health care facilities both spatially and temporally. The development of Geographical information system (GIS) facilitates the analysis of health care access (Higgs, 2005). The application of GIS is diverse in literature, the increasing availability of information and advanced tools in GIS has led to a number of studies that concerned with the developing measures of access to health care access (Black, Ebener, Aguilar, Vidaurre, & Morjani, 2004; Kohli et al., 1995; Luo & Wang, 2003). In addition, availability of spatially disaggregated data has led to the application of GIS in health care accessibility studies (Higgs, 2005). The healthcare access depends on spatial

factors such as location of health centers, population zones and catchment areas. GIS can be used as a tool to integrate all these factors for effective evaluation of health care access.

In literature, there are numerous methods have been used to assess the spatial accessibility to HCF's. The most widely used techniques are physician to population ratio, closest facility, average distance to HCFs (HCFs) (Luo & Qi, 2009) and the number of facilities or services within a threshold distance & time (Coker et al., 2010; Luo & Wang, 2003; Schuurman, Berube, Crooks, Bérubé, & Crooks, 2010). These methods take into consideration of both population (demand) and physicians (supply). It is very ease to compute and interpret results of these models. However, the major weakness of these models is that there are no considerations on influence of distances within the catchment. The basic assumption in the accessibility models is that people patronize to nearest services or tend to utilize the services within a threshold distance. It is evident from literature that distance and access to the facility are inversely proportional to each other. Thus, effective catchment area of healthcare facility is important for assessing the service utilization.

In the last few decades, different methodologies to defining catchment area have been developed especially in the field of health research (Luo & Whippo, 2012; McGrail, 2012; Zinszer et al., 2014). In literature, different authors have used different catchment sizes to assess the health care access based on the study area (Urban vs Rural), disease type, transportation mode (Public vs private). There is no standard catchment size for evaluating the health care access. The simplest way of defining the boundaries of a catchment area is to use distance for health care facility. The distance from a facility can be measured using different approaches such a linear distance, Euclidian distance, network distance or travel time. Of these, network based travel time is effective in assessing health care access n urban areas (Delamater, Messina, Shortridge, & Grady, 2012; Kobayashi, Otsubo, & Imanaka, 2015).

Catchment size of a facility measured using a buffer tool in GIS. Buffer analysis is a simple proximity measurement tool in GIS; it has been applied to many applications such as environmental, transportation, medical, emergency system and others (Andersen & Landex, 2009; Luo & Whippo, 2012; Parker & Campbell, 1998; Pullar & Springer, 2000). Buffer tool is used to measure the catchment size or service area on the basis of threshold distance or travel time of a health care facility (Jones, Wardlaw, Crouch, & Carolan, 2011; Ni, Wang, Rui, Qian, & Wang, 2015; Zinszer et al., 2014). As per National Urban Health Mission 2015 (NUHM) there should be a one primary healthcare centre within 500metre proximity from slum location and it can serve maximum of 30,000 population. The fixed catchment size can't capture the actual potential accessibility to HCF's. Hence, in our study we consider the multiple catchment sizes such as 500 Metre, 750 Metre and 1000 Metre from health centre. The spatial and temporal assessment of HCFs was computed using network buffer distance.

The proposed methodology is applied in a case study spatial and temporal assessment of HCFs in K west ward, Mumbai. The rest of the paper is organized as follows. Section two describes the study area details. In section three mentioned about the data collection procedure and data preparation. The conceptual framework of the study is mentioned in section four. The analysis is carried out in section five and section six. The results and discussions mentioned in section seven. The conclusions of the study mentioned in the final section.

2 STUDY AREA

The K-West ward of Mumbai, is taken as the study area, which is located at the West region of Mumbai and the Arabian Sea in North, East South, West direction respectively. It is situated at the western bank of Maharashtra on the Arabian Sea. It lies between latitude of 19⁰4'-19⁰9' North longitude of 72⁰47'-72⁰51' East. Andheri West and Oshiwara area of Mumbai comes under this ward. As per census 2011, the total population was 748,688 in 23.39 km² area, which results a population density of 32009 persons per km². There are total 179 small, medium and large HCFs located in the study area; of which two are public or municipal hospitals (one general and one maternity hospital) and remaining are private clinics or hospitals. The study area (K-west ward) is depicted in figure1.

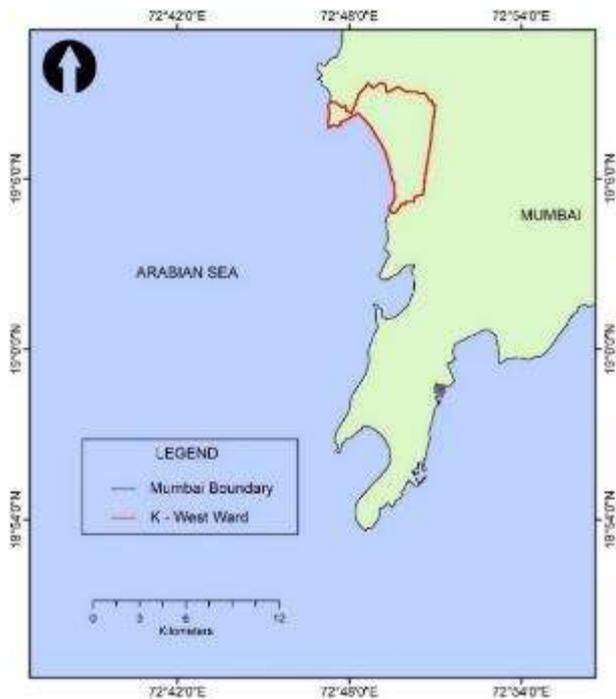

Figure1: Study area (K-west ward, Mumbai)

3 DATA EXTRACTION & PREPARATION

To do analysis in GIS, at first the shape file of K-West ward (Mumbai) was created manually and converted into KML file later on. There are no data sources available publically for the location of private HCF's in Mumbai. The location of public HCF's is available with the public health department of Mumbai. First, we geocoded the public HCFs using the google earth. Then, google earth was used as a tool to find out the location of private HCF's in K west ward. The K ward boundary KML file was projected on the google earth and searched the keyword "hospitals in Mumbai"; then all individual HCF's were extracted one by one as a KML file. While extracting the individual locations, the other information related to healthcare facility such as name, service speciality, category, type, operating timings, and address were also extracted from the web and noted down in a separate csv file.

All the individual KML files were imported into the ARCGIS software and then converted them into single shape file, which consist of location of HCF's. The final shape file was created by merging both the location information shape file and the attribute csv file.

4 CONCEPTUAL FRAMEWORK

The conceptual framework of the study is depicted in Figure2. After the data collection and preparation the final shape file was considered to assess the spatial and temporal analysis. The spatial distribution of HCF's is observed through four ways, i.e. with respect to land use, type of authority, speciality in service and diurnal operational time span (details are given in the section 4). The temporal analysis was carried out using the network work distance buffer analysis (detailed analysis was given in the section 5). Based on the results, discussions and conclusions were provided for the K west ward.

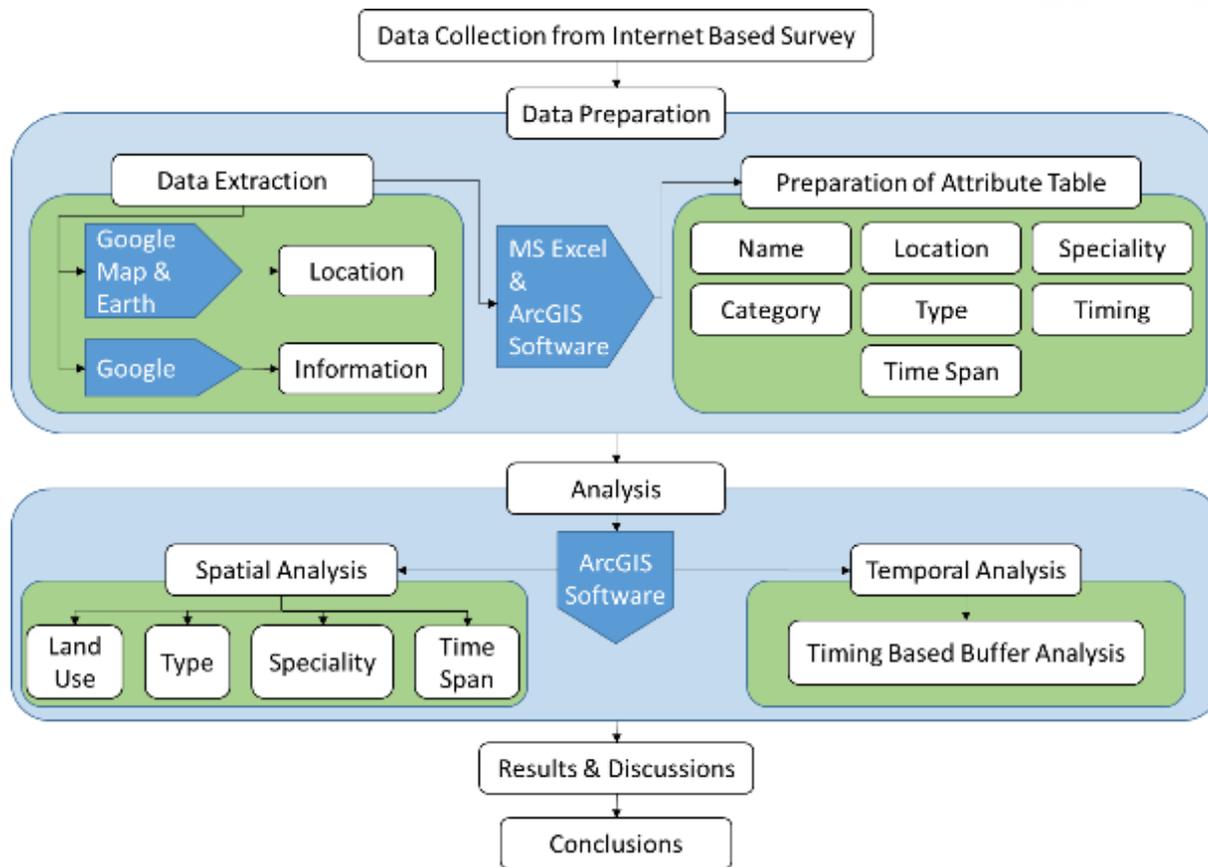

Figure 2: Conceptual framework or methodology of the study

5 SPATIAL DISTRIBUTION OF HCFs

5.1 HCFs with Land Use

To understand the spatial distribution of HCFs over the land use pattern of k-west ward, HCFs location layer was projected on the land use layer in ArcGIS. Figure 3 shows the distribution pattern of HCFs over land use of K west ward. Which indicates that most of the HCFs are located at near to any type of transport network. Further, we can also observed that most of these facilities are located distant from slum locations. It is also noticed from figure 6.3 that all these HCFs unevenly distributed over the K west ward, for example the two government hospitals are located far from most needed slum locations.

5.2 Type of HCFs

The total available HCFs in k west ward primarily classified in to two categories: Public and Private. Further, they are divided based on their ownership and size (poly clinic or multi-speciality hospital), nursing homes, clinics and individual practitioners. The four classified HCFs were projected on land use of K west ward to understand the spatial distribution pattern. From figure 4, we can observed that there are more hospitals and clinics. There are less number of nursing homes located in K west ward and most of them are located in central part of the study area. The southern part of the study area lacks with the nursing homes. Further, we can also notice from figure 4 that there are only two public HCFs and these two are located far from the slum locations.

5.3 Speciality of HCFs

The total available HCFs in K west ward are classified based on their speciality of service like multi-speciality, maternity, general, single speciality such as ear, nose etc., Ayurveda and pharmacy. Figure 5 shows the spatial location of speciality of HCFs in the study area. There are more number of general and multi-speciality hospitals located in K west ward. For example, in maternity care only one public hospital is available and the remaining maternity hospitals works under private sector. In India, Ayurveda is also followed by large number people apart from general allopathic medicine, but less number of Ayurveda facilities are located in K west ward.

5.4 Time Span of HCFs

Spatial access to HCFs is also affected by the operating times of HCFs. The operating timings of HCF's are noted first and then those are added to the three common categorised operating hours (daily basis), i.e. 4-8 hours, 10-16 hours and 24 hours. Figure 6 depict the time span of HCFs in K west ward. Especially, speciality clinics operates in a particular time period of the day either morning or evening hours. Most of the facilities operate in between 4-8 hours and 10-16 hours. The number of 24 hours working HCFs are less in number and majorly located on the northern half of the ward.

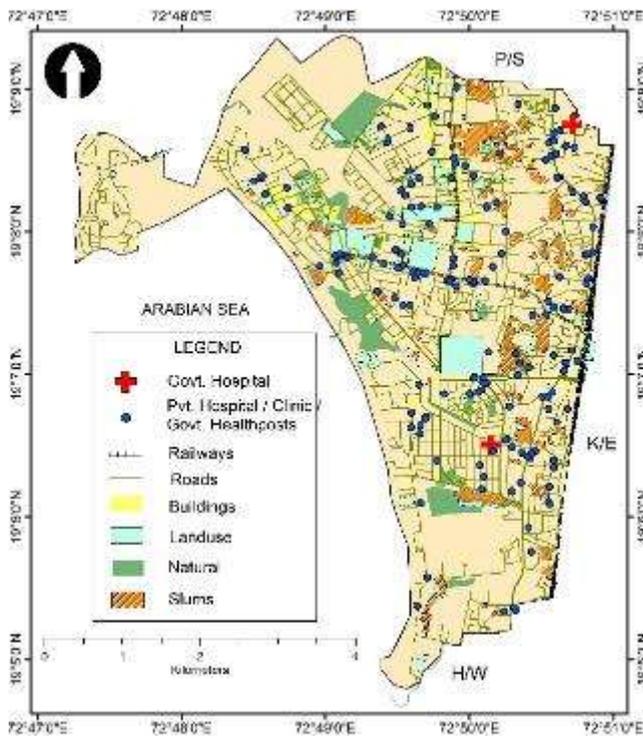

Figure 3: HCFs with land use pattern

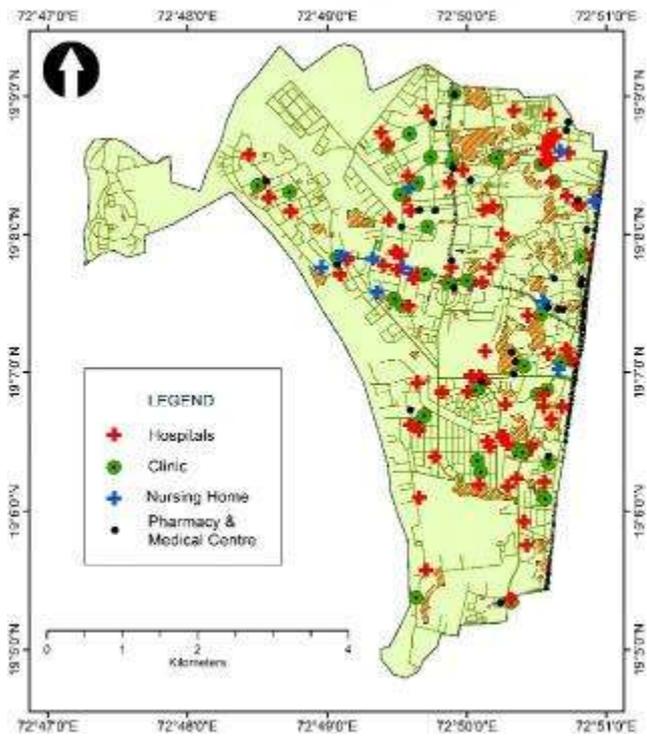

Figure 4: Type or genre of HCFs

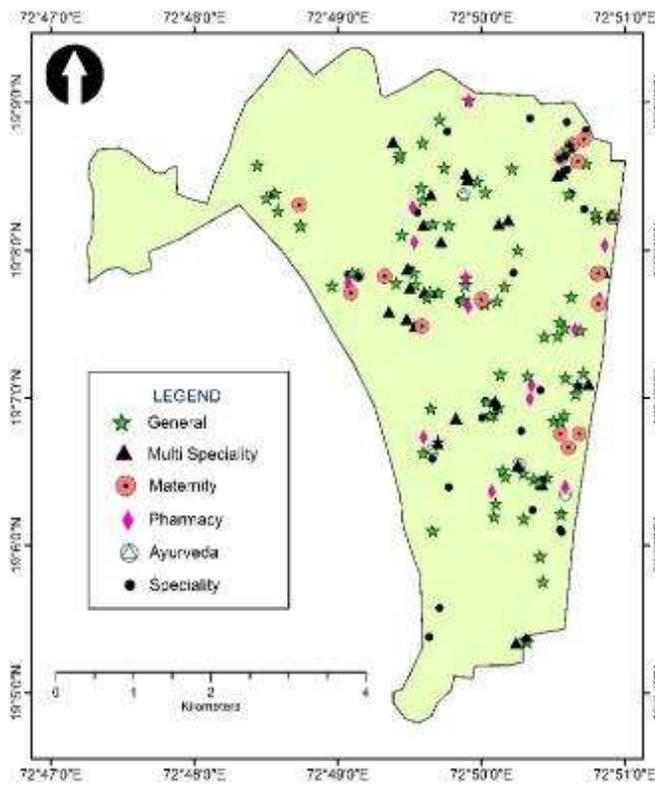

Figure 5: Speciality of HCFs

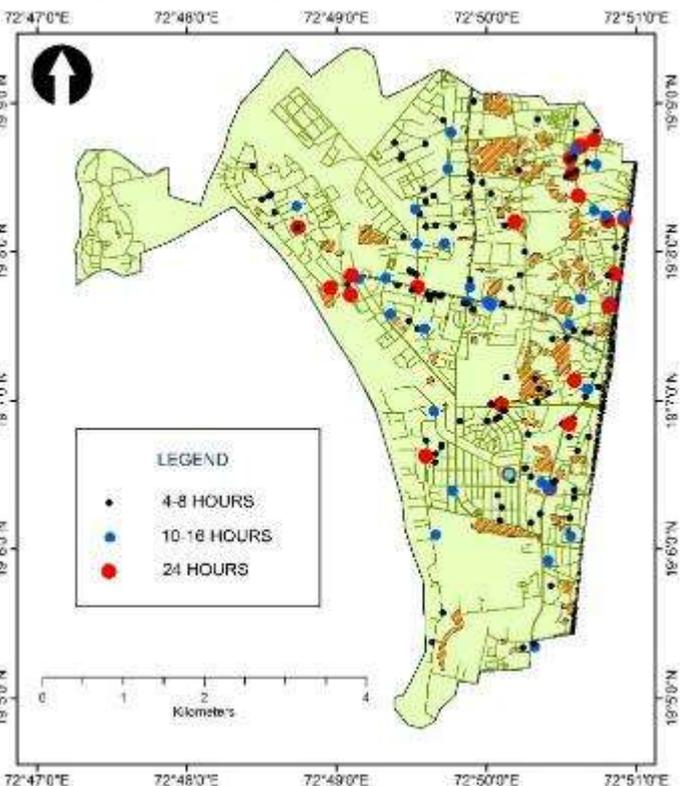

Figure 6: Time span of HCFs

6 TEMPORAL ANALYSIS

The temporal analysis was performed on four time periods of the day i.e. morning, afternoon, evening & night session. The total available HCFs are classified according to their operating timing between 06:00-12:00hrs (Figure 7), 12:00-18:00hrs (Figure 8), 18:00-24:00hrs (Figure 9) and 24:00-06:00hrs (Figure 10) respectively. This method was computed using the catchment area of a healthcare facility. The analysis was carried out separately for each operating time zone and with variable catchment sizes 500, 750 & 1000 meters network distances from the location of HCFs.

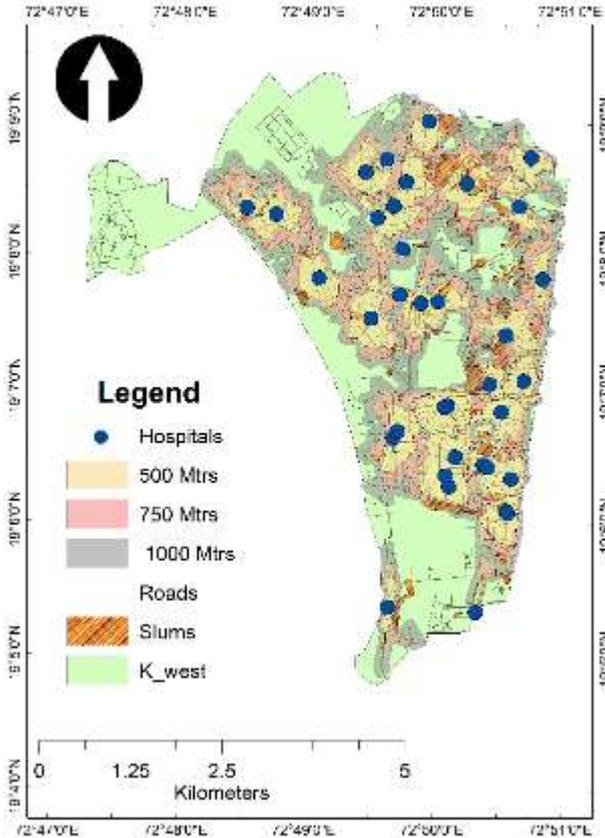

Figure 7: Buffer analysis for morning session

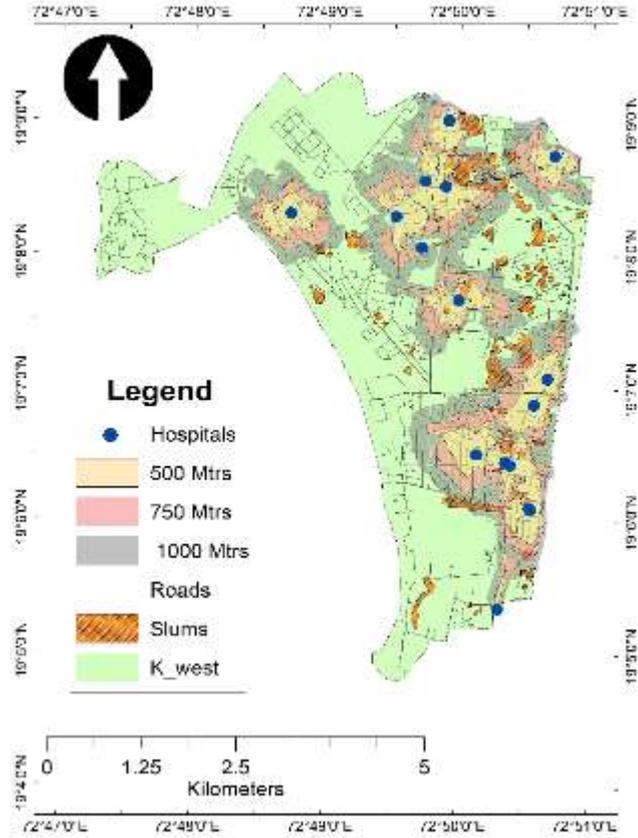

Figure 8: Buffer analysis for afternoon session

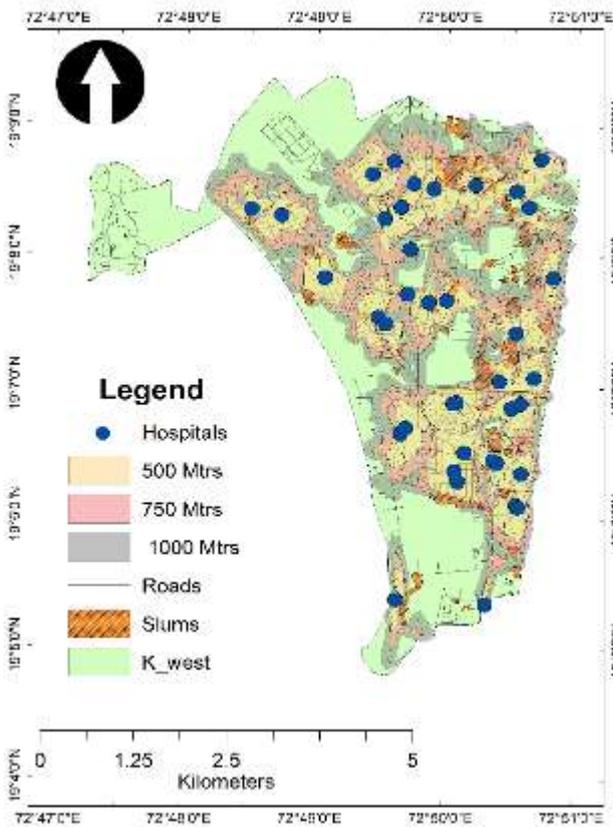

Figure 9: Buffer Analysis for evening hours

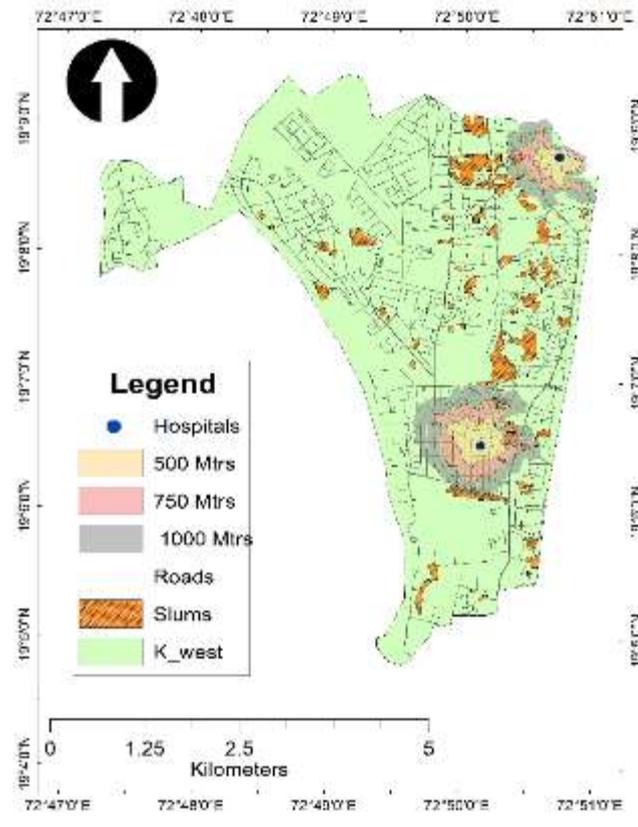

Figure 10: Buffer analysis for night hours

7 RESULTS & DISCUSSIONS

From spatial analysis, we can observed that a total of 179 HCFs are located in k-west ward of Mumbai, of which only two are govt. or municipal hospitals (one general hospital at cooper & one maternity hospital at Oshiwara), and the rest of 177 are private hospitals or clinics or medical centres (illustrated in Figure 3). The wide inequalities in different medical supply can be observed from the figure 4. Though the large number of hospitals located in K-west ward, but most of them are under private. Due to the cost of treatment is high in private hospitals urban poor can't access these facilities. From

figure 5, we can noticed that there are only limited speciality clinics or hospitals available in K-west ward. From figure 6, we can found that 122 HCFs operates for only 4-8 hours, 35 HCFs for 10-16 hours and 22 HCFs operates for 24 hours. This timing or operating hour based analysis was conducted further in deep, to observe the temporal variation of service or operation time of HCFs (Figures 7 to 10).

The spatial analysis showed that most of the HCFs are located near to the road network. So there are many areas which are still uncovered and majority of those portion belongs to the slum areas. The availability of HCFs might be good in a given study area in terms of volume. But, of which only few of the HCFs are affordable to the lower income group (LIG) and Middle Income Group (MIG) people. The access to these facilities further will be decreased if we consider time span of HCFs. For example, 24 hrs access to maternity hospitals is very important because of its emergency. But only one municipal maternity hospital and one general hospital operates 24 hours and remaining hospitals are private. These two hospitals will not be sufficient for all those lower-income people in K-west ward. The clinics, medical centres and pharmacies are well distributed, but multi-speciality hospitals are less in number. From the temporal analysis, we can found that better access to HCFs available during morning and evening hours. The access to HCFs is less during night hours, especially for the lower-income people because during this period only two public hospitals operates. As a result, LIG patient need to travel a long distance to get access to these facilities. There is need of providing sufficient number of public hospitals during the night hours also. Another important point is that most of the LIG people access to primary HCFs during evening hours to avoid the daily wage loss. But the public facilities operates only between 10:00 A.M to 5:00 P.M.

8 CONCLUSIONS

In this paper, we proposed a novel approach to assess the access to health services in urban areas. The developed methodology was applied in K-west ward of Mumbai. The analysis consist of two parts: spatial and temporal. The spatial analysis demonstrated the spatial distribution of HCFs with respect to land use, time span, ownership type and type of speciality. In addition, we also identified the areas which are medically underserved areas based on the above mentioned factors. For example, most of the lower-income neighbourhoods face lack of affordable HCFs especially public HCFs. The spatial analysis shows that of 179 HCFs, only few remains open for 24 hours, of which only two are govt. or municipal (or considered as affordable). It clearly shows that there is lack of HCFs especially during night time. The temporal analysis was performed based on operating time period i.e morning, afternoon, evening and night hours. This analysis revealed that there is variation in access to HCFs temporally. This analysis would help planners, medical practitioners and policy makers to make the necessary actions to improve the overall access to HCFs both spatially and temporally. Further, this analysis can be helpful in where to open new HF, how much should be its capacity, or what will be its operating time window. This similar type of analysis also can be conducted in case of other areas or locations where inadequate data is available. Despite the study has some advantages, it has limitations too. The main limitation of the study is we considered only private HCFs which were extracted from google earth. The other limitation is that instead of network distance or travel distance we can use the travel time for effective planning approach.

1784 GOVERNMENT OF INDIA'S ROLE AND RESPONSIBILITY IN CSR IMPLEMENTATION

Vishwanath B, Patnaik D, Laxmi N

ABSTRACT

CSR has become a priority issue on governments' agenda (Alberda, et al., 2007) and a partner (Marks 2013). It spans the entire spectrum of relationships between firms, states, civil society and markets (Dicken, 2007). CSR drivers are categorized as Business, Social and Government by Moon. Government drivers are seen as substitutes for government effort, complementarity issues government policies and fear of punishment for the irresponsibility of business and governance failures (Moon, 2004). Relationship between firms and society is symbiotic (Deegan et al., 2014) and so is the relationship between firms and government. Bell D V J (2002) identified five potential key roles of Governments in promoting corporate sustainability nationally and internationally: Vision/goal setter, Leader by example, Facilitator, Green Fiscal Authority and Innovator/Catalyst. In a globalized era, state remains a significant force in shaping the world economy and continues to play a fundamental role in the economic development of all countries; intervening in various degrees in the operation of the market (Dicken, 2007). India is not an advanced welfare state and there are many issues plaguing the nation. As quoted by Rossow (2015), India's development needs are immense and are host to some of the world's most striking social problems, often at massive scale though it is on a clear path of economic growth. India has changed its gear from voluntary to mandatory disclosures regarding Corporate Social Responsibility (CSR) reporting and spending. This paper outlines metamorphosis of CSR in India and role of Government. The purpose of this study is to find the extent of reporting done by selected companies operating in India. Understanding of companies in publishing their Business Responsibility Reports is studied. Top hundred companies in terms of market capitalization as on 1st April 2012 are considered as they are expected to publish the Business Responsibility Reports (BRR). Of these companies, it is noted that fifteen companies have not been given a score of zero: as reports are not in prescribed format, financial year followed is not 1st April to 31st March, incomplete reports and due to mergers and acquisitions. The BRRs of the selected companies of year 2015-16 is considered. The data of these reports is coded and analysed using multi-level content analysis for achieving purpose of this study.

Keywords: Government, Corporate Social Responsibility, Legislation, Business Responsibility Reporting

INTRODUCTION

In a globalized era, state remains a significant force in shaping the world economy and continues to play a fundamental role in the economic development of all countries; intervening in various degrees in the operation of the market (Dicken, 2007). Corporate Social Responsibility (CSR) aims to achieve sustainable economic, environment and social development. CSR enables business entities to contribute to the agenda of sustainability. CSR is understood as a part of a wider system of national societal governance incorporating government institutions, business organizations and non-governmental organizations (Moon, 2004).

CSR spans the entire spectrum of relationships between firms, states, civil society and markets (Dicken, 2007). Relationship between firms and society is symbiotic (Deegan et al., 2014) and so is the relationship between firms and government. In the last quarter of the 20th century UK Government realised the governance deficit and started encouraging CSR irrespective of political hue (Conservative as well as Labor). Business was encouraged to participate in formulation and enactment, or 'steering' and 'rowing', of community action (with non-profit organizations) and of public policy (with governmental organizations) (Moon, 2004). While Bell (2002) opines that Government's role is to steer society towards articulation of goals in public policy; business that propels a healthy economy, is best equipped to generate wealth by providing products and services. As increasing environmental and social standards in traditional public policy concerns, the spillover of CSR from business into government should not be a great surprise (Midttun et al., 2015).

CSR drivers are categorized as Business, Social and Government by Moon (2004). *Business drivers* include employee recruitment, motivation and retention; learning and innovation, reputation management; risk profile and risk management; competitiveness and market positioning; operational efficiency, investor relations and access to capital and license to operate (Deegan, 2014). Imperatives acting on companies from investors, suppliers, partners and customers as well as imperatives identified by corporations such as reputation, marketing, branding, employee relations and knowledge are mused as business drivers for enhanced CSR (Moon, 2004). *Social drivers* include demands from consumers, particular publics, organizations claiming to act on behalf of society and employees; *Government drivers* include - it can substitute for government effort, complement government effort and legitimize government policies and the fear that it will be punished for the irresponsibility of business and more widely for governance failures (Moon, 2004).

This study aims to study role of government in promoting CSR in general and particularly in India by focusing on Institutions and Ministries involved in formulating guidelines, trends in regulations, expansion of applicability, principles emphasized.

GOVERNMENT AND CSR

CSR has become a priority issue on governments' agenda (Alberda, et al., 2007) and a partner (Marks 2013). Governments at every level and in all regions of the world are beginning to recognize the importance of addressing the

challenge of sustainability (Bell, 2002). In addition to national governments, supra and intergovernmental organizations discuss CSR as well (Dentchev et al. 2015). Bell also stresses that government has an opportunity and a responsibility to take on a leadership role by creating a more suitable 'habitat' in which sustainable business can thrive. Government has an important role to promote the business case for CSR and to provide leadership by helping to achieve consensus on overall vision and priorities for action, whilst recognizing the very diverse interests of the companies involved. Governments are reviewing regulatory frameworks to integrate Corporate Social Responsibility into routine corporate disclosure regimes (Waheed, 2005) taking into account the diversity characterizing different national systems (Waagstein, 2011).

REVIEW OF LITERATURE

We will not arrive at more sustainable environmental performance (Deegan, 2014) and social performance unless there is a regulatory framework that guides the market. Deegan (2014) found that Social and Environmental organizations in Australia favor government's intervention in CSR. Governments often encourage CSR in order to manage an array of governance issues and in addressing public policy problems; in 1980s UK government focused to solve unemployment problem through CSR, in 1990s other countries followed the suit - Denmark : Unemployment and Social Inclusion, Australia : Social Problems, South Africa : Governance implications from Apartheid to Democracy and Sweden : Commitment to uphold relevant International standards.

Literature review reveals that focus area of research in the field of CSR and Government (including its agencies) has gained importance in the beginning of 21st century. Albareda et al., (2002) study focused on CSR public policies in EU-15, and proposed four ideal models viz. Partnership, Business in the Community, Sustainability & Citizenship and Agora. They contributed an analytical framework to analyze CSR public policies that provides relationships between governments, businesses and civil society stakeholders. Fox et al., (2002) analysed role of public sector agencies in providing an "enabling environment" for CSR and classifies public sector engagement along two axes namely roles and activities.

Bell D V J (2002) identified five potential key roles of Governments in promoting corporate sustainability nationally and internationally: Vision/goal setter, Leader by example, Facilitator, Green Fiscal Authority and Innovator/Catalyst. And has presented five policy levers that could be used by governments: Rebalancing the Roles of Government and Public Enterprise, Direct Regulation, Market Instruments and Economic/Fiscal Measures, Voluntary/Non Voluntary Initiatives and Education/Persuasion/information for Decision Making. Dentchev et al (2015) in their study on role of governments in CSR, approaches of CSR-Voluntarism vs. Regulation and limitations of public policy in CSR outlined how governments can support CSR, how CSR activities can support policy development; what will happen when business take over through their CSR activities what previously was considered as government roles and limitations of public policy in support of CSR. They present arguments that favor a contingency approach on the principle of voluntarism and secondly how governments are part of the CSR debate.

Much of the literature in the field of Government and CSR, focuses on individual nation state while Fox et al., (2002) focused on initiatives at national levels and came up with a two dimensional framework. They classified public sector engagement on dimensions of roles and activities that created an enabling environment for companies to carry on CSR; and found examples from developing countries that fit in this matrix. Roles considered include mandating, facilitating, partnering and endorsing while ten activities include: Setting and ensuring compliance with minimum standards, Public policy role of business, Corporate governance, Responsible investment, Philanthropy and community development, Stakeholder engagement and representation, Pro-CSR production and consumption, Pro-CSR certification, Pro-CSR reporting and transparency and Multilateral processes, guidelines and conventions.

Governments are complex and multileveled entities that have different responsibilities and powers depending on the level at which they operate and the geographical area with which they are concerned (Dentchev et al, 2015). As CSR is highly contextual not only in terms of its corporate environment but also in terms of its national environment (Moon, 2004), our focus is to analyse role of government in India in metamorphosis of CSR.

CASE OF INDIA

India is not an advanced welfare state and there are many issues plaguing the nation. As quoted by Rossow (2015), India's development needs are immense and are host to some of the world's most striking social problems, often at massive scale though it is on a clear path of economic growth. Over the past two decades, the issue for companies seems to be no longer about whether or not to engage in CSR, but rather on how to conduct CSR in a strategically and effectively planned manner with a clear and demonstrable narrative of its impact on company and Community (Wang, et. al., 2016).

Prior Acts in India since independence related to CSR:

Acts in independent India are galore in general and particularly in the broad field of environment and social, typically applicable to all companies. From late 1940s to mid70s, focus was on employees Acts include: Minimum Wages (1948), Employee Provident Fund (1952), Maternity Benefits (1961), Payment of Bonus (1965), Contract Labour (1970), Payment of Gratuity (1972) and Equal Remuneration (1976). Focus on natural resources and environment commenced with Wildlife Protection Act (1972) and followed by Water (1974, 77), amendment to Forest Act of 1927 in 1980, Air (1981), Environment Protection (1986), National Environment Tribunal (1995), National environmental Appellate Authority (1997), Biological Diversity (2002), Coastal Aquaculture Authority (2005). While there have been few Acts

that focused on social aspect - Essential Commodities (1955) and after half a century came the Right to Information Act in 2005.

With these acts in place and as companies have been carrying on CSR activities sometimes innovatively (for eg. ITC) and at other times experimenting - CSR is relatively mature in India. Government of India had a choice whether to regulate CSR or not, each of the option is constrained. As noted by Deegan (2014), in the presence of 'free-riders' market mechanisms fail to operate efficiently (see Cooper and Keim 1983), thereby necessitating the requirement for regulatory intervention. Total Environment Centre opines that regulation often creates a minimum standard, but rarely inhibits competition and innovations for those businesses willing and able to do better (see Deegan, 2014). Embedded in specific contexts, structures and places – and constrained by the knowledge and resources (Dicken, 2007); it has opted to regulate it in a *phased manner*.

Metamorphosis of CSR:

The series of Acts indicate that there has been an established approach to CSR. As recognized by Fox et al., (2002), many Acts and initiatives of Government of India, have not been expressly been promoted or recognized as part of the “enabling framework of CSR”. Development of CSR in India since 2009 indicates current enthusiasm of the Government. With an aim for wholesome & inclusive process of economic growth and for sustainable value creation, guidelines developed include inputs from diverse stakeholders. Guidelines formulated built on existing/prior initiatives and capacities of companies. Guidelines however voluntary in nature, in order to be responsible companies should adopt all principles in entirety or totality. In India, CSR metamorphosed with a succession of guidelines and regulations since 2009. Figure 1 depicts string of guidelines and regulations during 2009 and 2014. The metamorphosis can be perceived in three phases. The first outlines trend prior to transition, second presents quick transition from voluntary to mandatory (only for a class of companies) in a systematic and more encompassing nature. Third section presents in detail, mandatory Business Responsibility Framework for top hundred companies (in terms of market capitalization) which is extended to top 500 companies from 2016-17 and provides a detailed analysis of the Section 135 (CSR) of the Companies Act, 2013.

Prior to transition phase (before 2009): During this period there has been no particular guideline but companies have been carrying out activities related to environmental and social though sometimes under the name of CSR while most of the time not. Companies' response to environmental and social problems ranged a spectrum, while some were leading by investing in innovation, research and development and adopting to the new socio-economic-environment while others waited for the Government to push them. Crane et. al., (2014) notes corporations are actively entering social spaces that hitherto were the prerogative of (democratic) governments. Most of the companies practices of business responsibility varied in terms of amount spent and activities undertaken.

Transition phase (2009 to 2013):

Government has played an active role in encouraging corporations to voluntarily assume greater responsibility for the social and environmental impacts of their business policies and later on made mandatory to some select companies. Throughout this, period based on what companies have been doing prior to 2009, happenings in this field in different countries and intergovernmental bodies and organizations guidelines are formed and acts enacted. Government has aimed to steer the business community in a holistic approach in the field of CSR by providing a broad framework about procedure to be adopted, focus areas, what to report and frequency of reporting and where to report, personnel responsible for policy making, areas to be focused on and the like.

During this period following guidelines have been issued:

- i. Corporate Social Responsibility Voluntary Guidelines released by Ministry of Corporate Affairs in December, 2009. With a fundamental principle of formulating a CSR policy with an aim to guide in strategic planning and providing a roadmap for CSR initiatives. Core elements of this guideline included: Stakeholders, Ethical Functioning, Respect for Workers' rights and welfare, respect for human rights, respect for environment, along with activities for social and inclusive development.
- ii. National Voluntary Guidelines on Social, Environmental and Economic Responsibilities of Businesses published in July, 2011 by Ministry of Corporate Affairs is more encompassing; with nine principles with relevant core elements.
- iii. BRR Framework (2012): Vide a circular issued in August, 2012; Securities Exchange Board of India (SEBI), India's financial market regulator has made compulsory for top hundred listed companies (in terms of market capitalization) as on 31 March, 2012; listed on Bombay Stock Exchange and/or National Stock Exchange to include Business Responsibility Report in the annual reports of the company from 2012 onwards.

2013 and Beyond: Unlike many countries like Australia (Deegan, 2014), India has legislated CSR through Section 135 of Companies Action, 2013. In contrast to many governments that have chosen to draw businesses further into governance issues without actually mandating behaviour (Moon and Vogel, 2009), Government of India has mandated a class of companies, but without specifying any penalties for non-compliance of the same. Section 135 of Indian Companies Act, 2013 is not a strong regulation to control corporate conduct rather is more of hand holding and directing companies to focus on how much to spend, what to report, creation of a sub-system in companies for implementation of the policy/ies related to CSR. This Section has many elements both traditional and contemporary, traditional elements include

philanthropic (Moon, 2004) which is included in this Section - it is a must to contribute two percent of net profit by the selected class of companies. Contemporary elements include the following: i. Like *'how business is performed'* (Moon, 2004) thereby influencing core business activity; companies need to design products and services by incorporating social and environmental concerns that result in reduction of use of resources (energy, raw material and water) at different levels of procurement, operations, distribution and consumption. ii. Reporting.

Figure 1: Mandatory and Voluntary Guidelines for Public and Private Companies

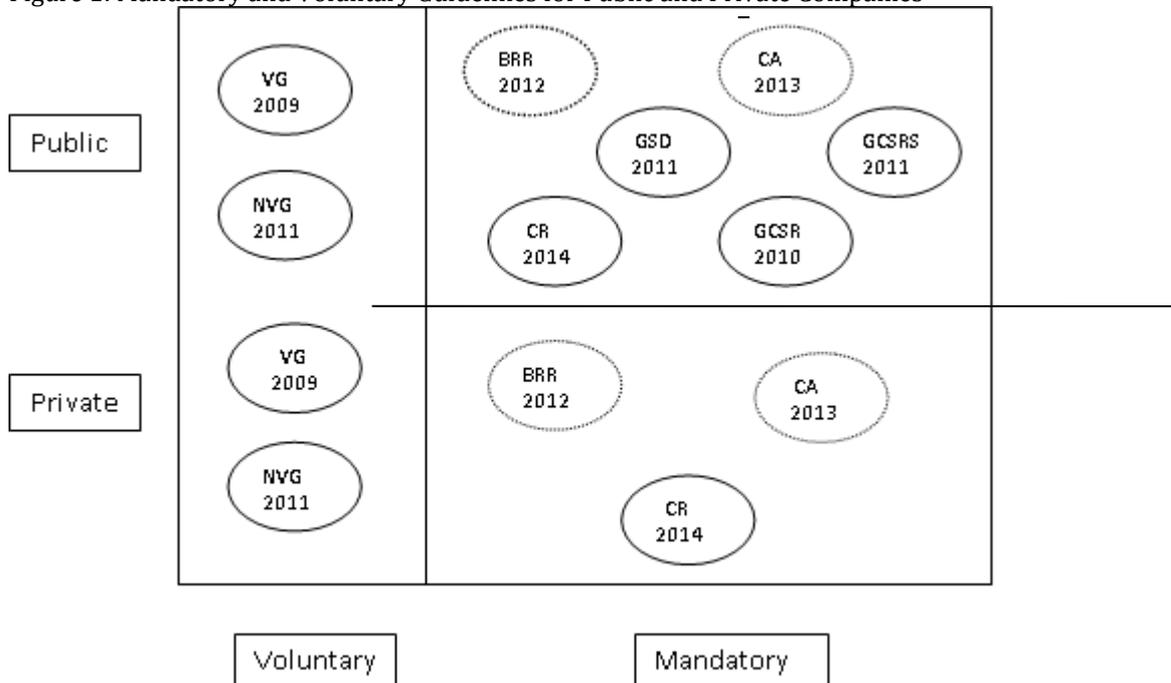

Figure 1 outlines various voluntary and mandatory guidelines to be adopted by Public and/or Private Companies. It is noted that voluntary guidelines remain the same for Public and Private but Mandatory guidelines are greater for Public Sector Enterprises, indicating that Government is keen to take up CSR initiatives and hence more mandatory guidelines. According to Jain et al., (2007) publicly listed companies are more likely to have greater pressure for accountability and thus more need for disclosures (quoted in Kansal, 2016). Prior to 2012 no mandatory guidelines were applicable to Private companies while Public Sector Companies had from 2010 onwards. CSR is deemed to have strategic importance to both public and private sectors of the Indian economy, as is evidenced by the GOI initiating the concept of mandatory corporate contributions towards social initiatives and activities (Kansal et. al., 2016).

RESEARCH METHODOLOGY

To understand how serious the mandatory guidelines are followed by Public and Private sector companies, researchers considered SEBI's 2012 Business Responsibility Reporting (BRR) mandatory. This mandatory reporting has five sections covering broad areas of i. General information about the company – Basic profile, sector in which the companies do business, their key products and services and also foot prints of the companies, whether they are local or global. Section ii. Financial details of the company – like paid up capital, turnover, profits earned and extent of CSR spending and also activities in which it is spent iii. Details related to subsidiary companies and also whether they participate in parent company's CSR initiatives iv. Business Responsibility information concerning Director/s responsible for implementation of BR policies, Company's policies related nine principles and governance related to BR v. Principle-wise performance of the companies' with respect to nine principles.

SAMPLE

The sample is comprised of all the hundred top companies (in terms of market capitalization) as on 31st March 2012 listed on Bombay Stock Exchange, oldest stock exchange in India. These companies have significant market share in more than a score of industries. Majority of the companies, sixty nine percent are private companies while rest are public sector enterprises.

DATA COLLECTION

This study considered Business Responsibility Reports which are part of the annual reports of the selected companies; according to Yuthas et al., (2002) Annual Reports is seen as 'legitimate and trustworthy'. These reports are independently audited and are presumed to have higher level of accessibility, consistency and timeliness on account of regulated financial disclosure requirements (Kansal et. al., 2016). The Business Responsibility Reports (BRRs) generally a part of Annual Report for the year 2015-16 are considered though it is mandatory for selected companies to publish the same from 2012-13 onwards; as by 2015-16, companies could have understood the reporting format.

DATE ANALYSES

Content analysis is used to empirically measure the extent of reporting done by the selected companies in Business Responsibility Reports. As quoted by Kansal et al., (2016) – Content analysis is a popular method of coding social and environment information from annual reports, and it has given empirically valid results in prior accounting research (Guthrie and Parker 1990). BRR format has five sections. Section A covers - a brief profile of the company, sectors engaged in, key products/services, geographical spread and markets covered; Section B covers – financial details, spending on CSR and CSR activities engaged in; Section C covers – details about subsidiary company/companies and their participation in business responsibility initiatives. Section D covers details of business responsibility director and head, governance related to business responsibility and nine principles. Section E covers detailed performance of companies with respect to nine principles. To measure extent of reporting, the BRR has been equated to 232 items, each company's extent of reporting is measured. This research relies on dichotomous scale (0 and 1) to measure the extent of disclosure made by companies. To measure extent of reporting, a score of 1 is given when companies report against each of the 232 items and a score of 0 when the company does not report. It is noted that there are certain items among 232 items that could not be applicable to some companies and hence each of the item has been given any one the following score of 0 or 1 or NA (Not Applicable). The overall score of each company is calculated using the following formula:

$$\text{BRR Score} = \frac{\text{Number of items with a score of 1}}{232 - \text{Number of items with NA}}$$

Section wise extent of disclosures of each of the company is calculated using the following formula:

$$\text{Section Score} = \frac{\text{(Number of items with a score of 1 in the Section)}}{\text{(Number of items in the Section - Number of items with NA in the Section)}}$$

ANALYSES AND DISCUSSION

This section presents extent of Business Responsibility Reporting of top one hundred listed companies (in terms of market capitalization) on Bombay Stock Exchange as on 31st March, 2012. This research aims to answer the following questions: First, what is the extent of business responsibility reporting done by top one hundred companies when it is mandatory? Second, what is the extent of reporting by public and private sector companies? Third, does the industry have impact on extent of reporting? Fourth, is the section wise score same in case of public and private sector companies?

With respect to first question, findings of the study indicate that level of disclosure made by companies is as low as zero in case of fifteen companies this could be due to non-penalisation; companies not complying need to only mention the reason for not doing the same. The extent of reporting done by rest of eighty five companies is presented in Table 1.

Table 1: BRR Scores of top one hundred companies

BRR Score	Frequency	Cumulative Frequency
Less than 10	17	17
10 to less than 20	1	18
20 to less than 30	0	18
30 to less than 40	2	20
40 to less than 50	0	20
50 to less than 60	7	27
60 to less than 70	12	39
70 to less than 80	16	55
80 to less than 90	37	92
90 to less than 100	8	100

From Table 1 it is noted that companies have taken BR reporting seriously as thirty-seven percent have scored between eighty and ninety; and eighty percent have scored more fifty percent. While seventeen percent of them scored below 10 percent, this could be because firms are not penalized for not reporting and an explanation suffices if they do not report.

With respect to second question, majority of the top one hundred companies in terms of market capitalization are private companies. Number of private companies (69) is more than public sector companies (31). The business responsibility reporting scores of public and private sector companies is presented in Table 2. It is noted from the table that private and public sector companies score similar on minimum and maximum values while average score of public sector companies is better than private sector companies. The variation in BRR scores is greater in case of private companies in comparison to public companies.

Table 2: BRR Scores of Private and Public Sector companies

S.No.	Particulars	Private companies	Public Companies	Selected Companies
1	Number of companies	69.00	31.00	100
2	Minimum BRR Score	0.00	0.00	0.00
3	Maximum BRR Score	95.54	94.67	95.54
4	Average BRR Score	61.38	70.03	64.06
5	Stdd. Deviation	32.41	29.15	31.55

With respect to the third question, the selected companies belong to thirty eight industries; companies are grouped in these industries based on BSE’s classification. Top three industries include Banks (12 companies), Electric Utilities (9) Pharmaceuticals (7); while Cement and Cement products and IT consulting and software (5 each) indicating that these six industries make up a majority in the selected companies. The BRR scores industry wise are presented in Table 3. Average scores of twenty three industries are greater than the average score of 64.06.

Table 3: Industry wise BRR Scores of companies

Industry	Min.	Max.	Average	Industry	Min.	Max.	Average
2/3 Wheelers - 2	8.19	56.64	32.41	Furniture Furnishing Paints - 1	68.89	68.89	68.89
Aluminium - 2	13.48	87.50	50.49	Heavy Electrical Equipment - 3	64.29	90.52	81.50
Auto Parts And Equipment - 2	66.52	82.27	74.40	Housing Finance - 2	0.00	77.72	38.86
Bank - 12	0.00	89.42	66.53	Industrial Machinery - 1	37.83	37.83	37.83
Breweries & Distilleries - 1	0.00	0.00	0.00	Integrated Oil & Gas - 1	85.33	85.33	85.33
Broadcasting And Cable Tv - 2	62.33	74.30	68.31	Iron & Steel/Interm. Products - 4	0.00	95.54	55.21
Cars And Utility Vehicles - 2	83.41	87.95	85.68	IT Consulting & Software - 5	0.00	89.45	58.78
Cement And Cement Products - 5	69.87	94.55	78.74	Marine Port And Services - 1	82.57	82.57	82.57
Cigarettes And Tobacco - 1	6.90	6.90	6.90	Mining - 1	87.00	87.00	87.00
Coal - 1	0.00	0.00	0.00	Oil Marketing And Distribution - 3	71.70	87.00	78.01
Comm. Trading And Distribution - 2	65.40	81.82	73.61	Other Apperals And Accessories - 1	0.00	0.00	0.00
Commercial Vehicles - 1	94.67	94.67	94.67	Packaged Foods - 2	91.28	91.82	91.55
Construction And Engineering - 2	64.89	66.82	65.85	Personal Products - 4	56.64	89.59	77.66
Copper - 2	0.00	88.64	44.32	Pharmaceuticals - 7	0.00	86.64	62.81
Defence - 1	87.00	87.00	87.00	Refineries/Petro Products - 2	80.00	83.48	81.74
Realty - 1	72.94	72.94	72.94	Telecom Services - 3	75.22	87.00	82.17
Electric Utilities - 9	0.00	89.04	58.59	Transport Related Service - 1	81.78	81.78	81.78
Exploration And Production - 3	0.00	81.70	27.23	Utilities Non Electric - 1	92.04	92.04	92.04
Finance (Including NBFC) - 3	57.87	89.14	77.23	Zinc - 2	0.00	94.62	47.31

With respect to Section wise score of private and public sector enterprises, the findings are presented in Table 4. As the BR reporting format has five sections, it is noted that BR average scores of public sector companies have scored better than private sector companies except in case of general information. The variation in BR scores measured by standard deviation is less in case of public sector companies in comparison to private sector companies. Based on average score and standard deviation, it is concluded that public sector companies are doing well.

Table 4: Section wise scores of public and private sector companies

Sector ↓	Particulars ↓/Section →	General Info.	Financials	Other details	Bus. Resp. Info.	Principle Info.
Private	Minimum	0.00	0.00	0.00	0.00	0.00
	Maximum	100.00	100.00	100.00	100.00	87.36
	Average	74.23	80.58	65.63	64.10	41.14
	Standard Deviation	34.82	37.73	38.24	35.58	30.55
Public	Minimum	0.00	0.00	0.00	0.00	0.00
	Maximum	100.00	100.00	100.00	100.00	78.13
	Average	73.93	83.87	77.90	70.49	52.50
	Standard Deviation	32.24	33.63	34.30	30.35	25.62

IMPLICATIONS

Government’s initiatives will incentivize companies to institutionalize their socially responsible actions, values, reporting (Moon, 2004), to build capability over time (Deegan, 2014) and environmental initiatives. Regulation often creates a minimum standard (Total Environment Centre) and a uniform approach will be of benefit to shareholders and stakeholders and ultimately to the reputation of company itself (Gippsland Community Legal Centre), as quoted by Deegan (2014)).

Implications to the Government:

Collaborating with companies, Government needs to plan the role of companies in achieving Sustainable Development Goals as the former’s potential capacity is enormous (Fox et. al., 2002). As no single government, or any other organization, can easily create economic, environmental and social value through policy changes or innovative practices if global drivers and reward systems are working in the opposite direction (Bell, 2002), so it has to network with other governments, regional bodies and intergovernmental organizations. As without enforcement, the higher norms of CSR and business ethics might remain underdeveloped (Dentchev, 2015) Government should ensure that companies follow rules of the land (the Section 135 of Companies Act) in word and spirit.

In selecting policy instruments to advance sustainable enterprise, it is important to recognize that businesses vary widely regarding their knowledge of, and commitment to, sustainability. Governments need to be aware of these differences and devise appropriate ways of dealing with businesses that are at different points along the curve (Bell, 2002), for example, the MSMEs and the informal sector need to be encouraged to adopt different means to achieve sustainability. According to Rossow (2015), central policymaking will have uneven application across states, policies at state and local level that can ensure MSMEs to contribute to economic, environment and social issues.

APPENDIX: LIST OF SELECTED TOP 100 COMPANIES IN TERMS OF MARKET CAPITALISATION

1	ABB LTD	51	JAIPRAKASH ASSOCIATES LTD
2	ACC LTD	52	JINDAL STEEL & POWER LTD
3	ADANI ENTERPRISES LTD	53	JSW STEEL LTD
4	ADANI PORTS AND SPECIAL ECONOMIC ZONE LTD	54	KOTAK MAHINDRA BANK LTD
5	ADANI POWER LTD	55	LARSEN & TOUBRO LTD
6	AMBUJA CEMENTS LTD	56	LIC HOUSING FINANCE LTD
7	ASIAN PAINTS (INDIA) LTD	57	LUPIN LTD
8	AXIS BANK LTD	58	MAHINDRA & MAHINDRA LTD
9	BAJAJ AUTO LTD	59	MANGALORE REFINERY & PETROCHEMICALS
10	BANK OF BARODA	60	MARUTI SUZUKI INDIA LTD
11	BANK OF INDIA	61	MMTC LTD
12	BHARAT ELECTRONICS LTD	62	NATIONAL ALUMINIUM CO. LTD
13	BHARAT HEAVY ELECTRICALS LTD	63	NESTLE INDIA LTD
14	BHARAT PETROLEUM CORPN. LTD	64	NEVELI LIGNITE CORPORATION LTD
15	BHARTI AIRTEL LTD	65	NHPC LTD
16	BOSCH LTD	66	NMDC LTD
17	CADILA HEALTHCARE LTD	67	NTPC LTD
18	CAIRN INDIA LTD	68	OIL AND NATURAL GAS CORPORATION LTD
19	CANARA BANK	69	OIL INDIA LTD
20	CASTROL INDIA LTD	70	ORACLE FINANCIAL SERVICES SOFTWARE LTD
21	CIPLA LTD	71	PETRONET LNG LTD
22	COAL INDIA LTD	72	POWER FINANCE CORPORATION LTD
23	COLGATE-PALMOLIVE (INDIA) LTD	73	POWER GRID CORPORATION OF INDIA LTD
24	CONTAINER CORPORATION OF INDIA LTD	74	PUNJAB NATIONAL BANK
25	CUMMINS INDIA LTD	75	RANBAXY LABORATORIES LTD
26	DABUR INDIA LTD	76	RELIANCE COMMUNICATIONS LTD
27	DLF LTD	77	RELIANCE INDUSTRIES LTD
28	DR. REDDY'S LABORATORIES LTD	78	RELIANCE INFRASTRUCTURE LTD
29	EXIDE INDUSTRIES LTD	79	RELIANCE POWER LTD
30	GAIL (INDIA) LTD	80	RURAL ELECTRIFICATION CORPORATION LTD
31	GLAXOSMITHKLINE CONSUMER HEALTHCARE LTD	81	SESA GOA LTD
32	GLAXOSMITHKLINE PHARMACEUTICALS LTD	82	SHREE CEMENTS LTD
33	GMR INFRASTRUCTURE LTD	83	SHRIRAM TRANSPORT FINANCE CO. LTD
34	GODREJ CONSUMER PRODUCTS LTD	84	SIEMENS LTD
35	GRASIM INDUSTRIES LTD	85	STATE BANK OF INDIA
36	HCL TECHNOLOGIES LTD	86	STEEL AUTHORITY OF INDIA LTD
37	HDFC BANK LTD	87	STERLITE INDUSTRIES (INDIA) LTD
38	HERO MOTOCORP LTD	88	SUN PHARMACEUTICAL INDUSTRIES LTD
39	HINDALCO INDUSTRIES LTD	89	SUN TV NETWORK LTD
40	HINDUSTAN COPPER LTD	90	TATA CONSULTANCY SERVICES LTD
41	HINDUSTAN UNILEVER LTD	91	TATA MOTORS LTD
42	HINDUSTAN ZINC LTD	92	TATA POWER CO. LTD
43	HOUSING DEVELOPMENT FINANCE CORP. LTD	93	TATA STEEL LTD
44	ICICI BANK LTD	94	TITAN INDUSTRIES LTD
45	IDEA CELLULAR LTD	95	ULTRATECH CEMENT LTD
46	IDFC LTD	96	UNION BANK OF INDIA
47	INDIAN OIL CORPORATION LTD	97	UNITED BREWERIES LTD
48	INDUSIND BANK LTD	98	WIPRO LTD
49	INFOSYS LTD	99	YES BANK LTD
50	ITC LTD	100	ZEE ENTERTAINMENT ENTERPRISES LTD

RS11.1. Regional Finance, Investment or Capital Markets

1028 PUBLIC DEBT AND REGIONAL INEQUALITY IN INDIA: AN EXPLORATORY SPATIAL DATA ANALYSIS

ABSTRACT

The Indian economy has shown a high rate of growth of gross domestic product of 7.56 percent during 2015-16 relative to 6.69 percent during 2011-12. In the post-liberalization economic era the size of fiscal debt has been sky rocketing as well. The fiscal debt is defined as the difference between total government expenditure and current revenue which has been escalating to an unsustainable level in recent periods. Maharashtra the most industrialized state in Western India has the largest debt followed by Uttar Pradesh and West Bengal in Central and Eastern India. Also, Tamil Nadu, Karnataka and Andhra Pradesh in the south have witnessed the maximum increase in debt during the past five years. Although Kaur et al. (2014) suggest that debt position of states at the aggregate level is sustainable. Gupta (2001) on the contrary opined unsustainability of debt at the state level. Government borrows debt to finance plan expenditure such as building roads, dams and airports and non-plan expenditure such as paying salaries or making interest payments. While West Bengal, showed a decline in debt to GSDP ratio, Andhra Pradesh showed no increase, and Maharashtra and Tamil Nadu showed a lower than national average ratio. Debt is not bad in itself provided states are growing at a rapid economic rate to service loans. This implies the interest payment to gross state domestic product (GSDP) ratio will be a better indicator of sustainability. Using these criteria it is observed that states from all corners in India i.e. Tamil Nadu, West Bengal, Gujarat and Punjab have been consistently paying huge amounts of servicing costs. Given this brief overview this research examines the temporal and spatial patterns of state debt in India during the period 2002-16. National and state level data are utilized to study the spatial analysis of state debt in India for 30 regions comprising 28 states and 2 territories i.e. National Capital Territory of Delhi and Puducherry. The following three overarching questions are addressed in this paper: (1) What are the trends in state level debt inequality during the period 2002-16 in India? (2) What are the characteristics of spatial temporal growth dynamics in India during various periods at spatial and temporal scales? (3) What mechanism explains the persistence, mobility, polarization and stratification if any in states across different periods? Several spatial analytical methods such as Gini Coefficient, Kernel density, Theil Entropy, Markov chain and spatial Markov chain are utilized to identify and describe trends and mobility patterns of state liability and its geographical dynamics in India. Data for analysis are obtained from Planning Commission and Reserve Bank of India.

1043 HOW DOES INSURANCE MARKET DEVELOPMENT AFFECT BANKING SECTOR DEVELOPMENT: EVIDENCE FROM GMM ESTIMATES

Rudra P. Pradhan¹, Saurav Dash¹, Manju Jayakumar¹, Dayal S. Prasad¹, Rana P. Maradana², Amrit V. Sabat¹

¹Vinod Gupta School of Management Indian Institute of Technology Kharagpur, India. e-mail: rudrap@vgsom.iitkgp.ernet.in, saurav.stat@gmail.com, manjujk@yahoo.com, d.prasad@tatasteel.com, amrits2012@gmail.com

²School of Management, KL University, Andhra Pradesh, India. e-mail: ranapratapmba@gmail.com

ABSTRACT

Using GMM estimation, this paper examines the impact of insurance market development (IMD) on banking sector development (BSD) in presence of the other BSD determinants like economic growth, foreign direct investment, trade openness, inflation rate, government consumption expenditure, gross capital formation, gross domestic saving, urban population growth, population growth, and young dependency population. The paper shows that IMD has a positive impact on BSD and hence, the study confirms that insurance market development plays an important role in achieving banking sector development.

Keywords- IMD, BSD, GMM

1 INTRODUCTION

Both banking sector development and insurance market development play an important role in economic growth (see, Pradhan et al., 2014). However, there is scarcity of research on the linkage between banking sector development and insurance market development. In fact, the relationship between the two has been the focus of academic and policy debate, particularly since global financial crisis of 2007-2008 (see, *inter alia*, Pradhan et al., 2016; Liu and Zhang, 2016; Liu et al., 2014; Lee, 2013; Pan et al., 2012). Theoretically, there exists some interaction between insurance market activities and banking sector activities (see, for instance, Lee, 2013; Haiss and Sumegi, 2008; Webb et al., 2005). The relationship between the two can be either complementary or competitive, depending upon the scenario of economic environment (Tennant et al., 2010; Allen and Santomero, 2001).

For instance, from the view of risk compensation and management, property insurance market can have significant effects on promoting the development of credit market (Liu and Lee, 2014). According to Grace and Rebello (1993), risk protection offered by insurance companies boosts bank borrowing due to falling companies' cost of capital. Similarly, Rule (2001) suggests that insurance market development stimulates the banking activities and their customers against a range of risks, underpinning bank lending by protecting customers against risks that might otherwise leave them unable to repay their debts. Equally, there are few other studies that substantiate the relationship between insurance market development and banking sector development (see, *inter alia*, Webb et al., 2005; Adams et al., 2006). The following cases are in line with complementary between banking sector activities and insurance market activities. In the similar line, we can also justify that there are ways where both banking sector activities and insurance market activities are competitive to each other. However, one of the controversies is that how insurance market development does affect banking sector development. Therefore, the main focus of this paper is to examine the impact of insurance market development on banking sector development.

The paper is arranged as follows. *Section II* describes our model and data. *Section III* describes the results. *Section IV* offers conclusion.

2 MODEL AND DATA

Following Blundell and Bond (1998), the study uses generalized methods of moments (GMM) to investigate the effect of insurance market development (IMD) on banking sector development (BSD). The study uses following econometric model for investigating the link between BSD and IMD.

$$BSD_{it} = \beta_0 + \beta_1 BSD_{it-1} + \beta_2 IMD_{it} + \sum_{j=1}^p \lambda_j X_{jit} + \varepsilon_{it} \quad [1]$$

where, $\varepsilon_{it} = \eta_i + \nu_t + \zeta_{it}$; η_i is country effect; ν_t is time effect and ζ_{it} is independent and identically distributed among countries ($i; i = 1, \dots, N$) and years ($t; t = 1, \dots, T$). BSD_{it} is banking sector development for country i over time t and is used as a proxy for LIQ, DCP, DCF, DCB, BDG, DMA, and PCO; BSD_{it-1} entails the lagged value of banking sector development for country i and time period $t-1$; IMD_{it} is insurance market development for country i and time period t ; Z_{jit} is the other banking sector development determinants included in the model for country i and time period t ; β_1 captures the lag of BSD, β_2 captures the effect of insurance market development on banking sector development; λ_j captures the impact of other BSD determinants, and ε_{it} is the error term. Table 1 highlights a detailed description of variables used in Eq. [1]. We expect that banking sector development has a complementary role in insurance market development.

The study uses a panel dataset covering the selected 19 Eurozone countries²⁷⁵ over the period 1980-2014.²⁷⁶ The countries included in this panel are Austria, Belgium, Cyprus, Estonia, Finland, France, Germany, Greece, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Portugal, Slovakia, Slovenia, and Spain. The data were obtained from World Development Indicators of the World Bank, Washington DC.

Note 1: LIQ is liquidity liabilities, DCP is domestic credit to private sector, DCF is domestic credit provided by financial sector, DCB is domestic credit provided by banking sector, BDG is banking deposits, DMA is deposit money bank's assets, PCO is private credit by deposit money banks and other financial institutions, TID is total insurance density, TIP is total insurance penetration, IMA is insurance market activities, PEG is economic growth, DCP is domestic credit to private sector and is used for banking sector development, FDI is foreign direct investment, OPE is trade openness, INF is inflation rate, GCE is government consumption expenditure, GCF is gross capital formation, GDS is gross domestic saving, URB is urbanization, PPG is population growth, and YDP is young dependent population.

Note 2: The reported figures are estimated coefficients, standard errors of estimates, and the t- statistics, respectively.

Note 3: *, ** and *** indicate the statistical significance 1%, 5%, and 10% levels, respectively.

Note 4: Some of the other variables are excluded due to lower sample size.

3 EMPIRICAL RESULTS

The estimated results are reported in Tables 1.1 and 1.2. We have two different descriptions, depending upon the deployment of two insurance market indicators such as life insurance density and life insurance premium. In each case, we have six models, depending upon the deployment of six banking sector development indicators. Table 1.1 is the case of insurance market density, while Table 1.2 represents the case for insurance market penetration.

From the estimated results, the study finds that the impact of insurance market development on banking sector development is positive and statistically significant, as expected, implying that higher level of insurance market development promotes banking sector development. For illustration, a 1% increase in insurance market activities bring about an adequate banking sector development of about 2.3- 24.22%. This finding is almost uniform for all the six models and for two different cases. The impact of economic growth on banking sector development is also statistically significant and positive, as expected, for the sample of these selected European countries and for all the six BSD indicators and two insurance market indicators. This implies that a higher level of economic growth promotes banking sector in the European countries. The lagged banking sector development is also having a significant positive impact on current banking sector is observed that a 1% increase in lagged BSD brings about a promotion of current banking sector development by about 6.9-27.4%.

The impact of other determinants, such as, *foreign direct investment, trade openness, government consumption expenditure, gross capital formation, gross domestic saving, urban population growth, population growth, young dependency population*, are more or less non-uniform and have both positive and negative impact on insurance market development. However, these are not statistically significant in all the situations in models 1-6. Their impact vary from model to model.

275 Note that a few of these countries are transcontinental.

276 Since data is not available for some of these countries over the entire sample period, our panels are unbalanced.

To summarize, the consistency of GMM outputs depends upon the soundness of instruments. This study employed three specification tests in order to validate the steadiness of system GMM estimations.

First, Hansen test is deployed to recognise the over-identifying restrictions that report the p-values for the null hypothesis of validity of instrument set used by the estimator. The null hypothesis of this test is not rejected for any of the three estimations.

Second, Sargan test to confirm independence between the instruments and the error term. The null hypothesis in this case is that the instruments and the error term are independent. Like the first case, the null hypothesis of this test is not rejected for any of the three estimations.

Third, Arellano-Bond test for serial correlations [i.e. the AR (2) test]. The null hypothesis of this test is that the errors in the first-difference regression reveal no second-order serial correlation. As anticipated, the values of the test of second-order correlation present no evidence of model misspecification, indicating the acceptance of the null hypothesis of serial correlation in the first-differenced errors at order 2. The failure to reject the null hypothesis of all tests provides an evidence in support of the fact that the instruments are indeed valid.

In short, the overall performance of these model outputs is robust and consistent in terms of validity of instruments and the coefficients of variables.

To sum up, the effect of insurance market development on banking sector development is positive and significant across the six selected BSD indicators, namely, LIQ, DCP, DCF, DCB, BDG, DMA, and PCO. Additionally, the regression coefficients of other variables are mostly consistent with the standard results in the existing literature. That means the findings are consistent with theoretical arguments and quite robust to different measures of both banking sector activities and insurance market activities including the country and year fixed effects.

4 CONCLUSION

The paper started with a conceptual question, “Does insurance market development affect banking sector development?” Our answer to this question is very much convinced, as it affects the banking sector development positively and is consistent with the earlier findings of [Pradhan et al., 2015; Liu and Lee, 2014; Webb et al., 2005]. This study has examined the effect of insurance market development on banking sector development, a subject that has largely been neglected in the financial development literature. The outcomes of this research can give some clarity in existing debate on the causality nexus between the two.

**1064 REGIONAL INEQUALITIES, PUBLIC INVESTMENT AND CONVERGENCE
ACROSS MAJOR INDIAN STATES**

ABSTRACT

Recent literature on regional inequalities is thwarted by increasingly complex regional economic changes. It has been observed that both in developed and developing countries, regional inequalities have widened over last couple of decades. Thus, it is imperative to investigate the factors that lead to region-specific economic growth and subsequently the impact of specific regional/spatial public investments towards reducing regional inequalities. The policy construct was based on the proposition that regional inequalities may decline as a result of a public investment, encouraging regional economic convergence. In Indian context there is a growing concern that the rapid economic growth since the initiation of reforms in India have been unequally distributed, as reflected by the increased growth difference and income disparity across various states. Number of studies had observed that growth across various states was not even and income was a critical contributor towards increasing regional inequalities in India. In other words, inequalities had widened and more so during the post reform period. This study intends to look for answers for the following questions: What are the major factors that drive high economic growth in certain states and certain states to lag behind? Are income levels across states converging or diverging after the reform process in India? Whether specific types of public investment (infrastructure or social investment) impacts income across states. Does public investment influence the productivity across states?

1259 MEASUREMENT POSSIBILITIES OF THE TYPES OF FINANCIAL DISTANCES - THEORIES AND THE EVIDENCES

ABSTRACT

The dual banking system – for example the Central and Eastern European countries’ banking sector – which can be characterized by the foreign banks’ dominance with less and small market weight of domestically owned local small banks, shows less lending propensity towards the SME sector and peripheral and rural areas. Dual banking system strengthens the process of financial exclusion, i.e. the exclusion of certain social groups (social exclusion) or areas (rural peripheries, small settlements, urban districts) from financial services. In these structures, the geographical diffusion of banking structures and instruments increased the operational (geographical) proximity between banks and borrowers, so the financial exclusion can decrease, but the concentration of bank decisional centres widened the functional distance between banks and local communities. Operational distance is a rate, what shows how many people served by a bank branch in a city or region, so this can be used the measurement of the degree of concentration of financial institutions or financial exclusion. However, the functional distance is a complex indicator of differences between the area of examined branches and their headquarters. For this, we can use three groups of data, firstly, the physical distance and the extension of branches, secondly, some economic indicator of relevant areas (distribution of economic activity, GDP, etc.) and thirdly we use some social data for example unemployment rate, social capital, and so on. Therefore, the main goal of this study is the examination of functional distance of the different types of the banks in Hungary. Our geographical focus is a multilevel approach, because we examined the county, regional and county levels of differences between the foreign and domestic commercial banks, and the cooperative savings banks. Our findings show that the financial exclusion is a real problem and the differences of financial distances of the analysed institutions is measurable in Hungary.

1740 PUBLIC DEBT. A TRAGEDY OF THE COMMONS FOR BORROWERS AND CREDITORS

ABSTRACT

Indebted entities and respective creditors are victims of a typical tragedy of the commons. On one side the credit is granted in excess to states with the price near to the discount rate. On the other hand, when the prospective of default appear, the spread raises to very high values because creditors try to save as much of the debt incurred before the collapse of the borrower. The result is bankrupt or dilapidated borrowers and partially reimbursed creditors. This paper addresses this problem with a simple model that relates, on the one hand, a borrower that evaluates and choses his investments in joint sets of minor investments. On the other hand, a number of creditors have that have free access to possible payments generated by the borrower. The debts models are reviewed and related to with open access models. Then a debt model is transformed into an open access model and used to understand the reality from this perspective. Finally some recommendations are derived based on the assumption that debt markets are open access markets.

1776 THE ECONOMIC IMPACT ON THE GREATER PEARL RIVER DELTA (GPRD) AREA OF THE HONGKONG-ZHUHAI-MACAO BRIDGE

ABSTRACT

Since the implementation of the Reform and Opening-up policy in mainland China, the Pearl River Delta (PRD) region has naturally enjoyed the first chance of economic development due to its predominantly location to Hong Kong. After decades of complementary cooperation and economic integration started in the 1980s, the regional agglomeration in the entire Pearl River Delta including Macau has witnessed a rapid development under the impetus of Hong Kong's inter-regional industrial transfer and export-oriented trade. However the development of the east and west banks of the Pearl River Estuary has always been in a state of imbalance due to the geographical advantage of the east bank which is connected to Hong Kong while the west bank is across the sea, and this has gradually become an obstacle to the balanced and integrated development of the PRD. With the expectation to promote the rebalancing of the east and west banks of the Pearl River, the construction and opening of the Hong Kong-Zhuhai-Macao Bridge is therefore become a strategic channel for GPRD areas to ease the traffic inconveniences. This paper attempts to capture and decompose the economic integration of the Bridge before and after its completion through building Multi-Regional Input-Output (MRIO) model for GPRD areas which including Hong Kong, Macau, the nine cities in PRD and the rest of China. With the tool of GIS network analysis on the true roads network, we respectively calculate the economic accessibility for each area in the MRIO table before and after the completion of the Bridge. Then based on gravity model, we use Poisson regression to estimate the parameter of the separation between any two areas in the MRIO table to interpret how the difficulty decreases along with the improvement of the economic accessibility. Lastly applying this parameter as the "accessibility adjustor" with holding price elasticity constant, the new MRIO is computable so to reflect the industries linkages after the accessibility improved. The preliminary results firstly show that the new IO multipliers of each region in GPRD get smaller while the total spillovers of each region do increase unanimously, and so do the total multipliers of each region. While the other major finding is a little contrary to the expectation of a large-scale regional economic take-off on the west of the Pearl River Estuary, as the finding shows Macau become the biggest trade import/inflow region with the principle and largest purchase from Hong Kong comparing to other cities locate in the west bank. Moreover, Hong Kong is still the leading economy in terms of its largest export earnings. The results also shows PRD would experience significant export growth to meet the demand from Macau and Hong Kong. Meanwhile, as the economy out of GPRD, the Rest of China is observed a trade surplus only with Macau. This could be interpreted that the general pattern of economic strength in the east bank dominated by Hong Kong will not change even after the connection of the Bridge, but the intensity of economic ties between the east and west of the Pearl

1783 ECONOMIC DETERMINANTS OF COUNTRY RISK IN SOUTH ASIAN COUNTRIES

Sudhir P R, Debasis Patnaik

ABSTRACT

The industries in the developing world are hugely diversified borrowers of funds. The growth of lending is accompanied by analytical methods to measure risk associated with such lending. These methods provide an indication of debt servicing difficulties associated with the borrowing nation. Meldrum defines country risk as 'risk involved in business transaction which are not present in domestic transactions'. Country risk ranking are an important factor in global asset allocation. Aspects of country are transfer risk and political risk. The indicators analyzed for assessment country risk are economic growth, inflation, foreign exchange reserves to GDP ratio, current account deficit relative to GDP, Exports, Imports, and foreign debt.

Key words: Country risk, Currency risk, South Asian countries, economic growth, Currency risk, Political risk and transfer risk

INTRODUCTION

The country risk rating is beneficial to borrowing countries and to the banks of lender countries and is also a challenging research area for institutions specializing in International finance and economics. Borrowing countries economic and political Indicators assumes greater significance in the decision making process of creditors [1]. The country risk encompasses the uncertainty of achieving expected financial results depending on factors unique to the project located in the target country [2]. Country risk analysis is based on the increasing imbalances in economic, social, or political factors which may increase the risk of negative return on an investment [3]. Meldrum defines country risk as 'additional risk not present in the domestic transactions. These additional risk arise from variety of national differences in economic structure, policies, socio political institutions, geography and currency' [3]. Country risk exists irrespective of the state of economic development even the most developed nation may generate a substantial degree of country risk [4].

In this paper we seek to calculate country risk of some of the south Asian nations and south eastern nations. The indicators used to arrive at the country risk of each country are economic growth, inflation, foreign exchange reserves to GDP ratio, current account deficit relative to GDP, Exports, Imports, and foreign debt. We analyze these factors based on their relevance and arrive at the country risk ranking of the respective countries. The paper consists of five sections. The section 2 provides a brief background to lending to developing countries and the country risk assessment system. Section 3 briefly reviews all relevant segments of the literature on country risk assessment. In section 4 the methodology followed and finally the presentation of results and conclusion in section 5.

BACKGROUND AND BEGININGS

Prior to oil price shock of 1973 the international lending to developing countries was in the form of long term project finance in a bilateral or multilateral arrangements [5]. External borrowing increases the rate of investment resulting into stronger economic growth in respect of the borrowing country. The pace of development depends on the size of capital inflow and the productivity of the capital [6]. The desirability to borrowing to accelerate economic development raised the concern to service this debt. The analysis identified short term and long term indicators. The short term indicators were (1) export growth rate (2) the ratio of debt to exports (3) lastly the ratio of foreign exchange reserves to imports. The long term indicators playing vital role in determining the economic growth which can provide for the servicing of external debt are (1) Growth rate of GDP (2) the ratio of investment to GDP (3) the ratio of exports to GDP, and (4) the rate of price increases [8].

The role of commercial bank lending to developing countries expanded rapidly to meet the increasing demands of developing countries. The sharp rise in commercial bank lending to developing countries led to formalization of procedures for monitoring, evaluation and assessment of risk [7]. In late 1980s the bank lending from OECD banks to East Asian countries tripled reflecting the initiatives by these countries to liberalise their banking sector. The increase in lending was in the shape of short term liabilities involving growth in trade financing and the creation of offshore banking centres [16]. Banks hold sovereign risk for variety of reasons such as diversified asset portfolios, as a collateral for interbank refinancing operations, as a means to generate liquidity or as due to moral suasion of governments [9].

LITERATURE REVIEW

Meldrum categorised country risk into six main categories of risks. They include Economic risk, Transfer risk, Exchange rate risk, location or neighbourhood risk and Political risk. Economic risk signifies change in the economic structure. Economic risk often overlaps with political risk. A growing current account deficit implies a greater need for foreign exchange to cover that gap. Exchange rate risk is an unexpected movement in the exchange rate. The country risk analysis rests on weighted index using the weighing scheme dictated by the relative importance of each risk category [3].

Country risk can be defined as the probability of particular future events with in a state that could have an adverse effect on the functioning of a given organisation, whether that organisation be a business, government agency or a non-governmental agency or other type of body. What is significant risk factor to one agency or business may be an

opportunity for another. This lack of specificity has posed to conceptualize and measure country risk both broadly as well as with respect to a specific organisation [10].

Oral et al, 1992, argued that G-LOGIT that is generalized logit model is a better performer for country risk analysis based on following indicators. The said indicators are reserves to import ratio, net foreign debt to exports ratio, GNP per capita, current account balance to GNP ratio, investment to GNP ratio, export variability, export growth rate, political insatiability and country group indicator [1].

Nunnenkamp et al, 1995, argued that debt overhang discouraged further lending and foreign investors were mainly concerned about the sovereign risk in host countries with restrictive FDI policies [11].

Quer et al, 2007, found that greater country risk and greater cultural distance reduce the likelihood of using higher commitment entry strategies. When faced with higher levels of risk and greater cultural distance, firms tend to choose entry modes with fewer committed resources [12].

The internalisation theory suggests that to internalise international transactions through FDI depends on the ratio between the profit obtained from minimising transaction costs and the actual cost generated by the internalisation process itself. The political risk and the uncertainty associated with foreign ownership are precisely some of the possible cost that will be assumed in the case of internalisation, foreign enterprise will be reluctant to commit many resources through FDI [13].

Meldrum contends that country specific country risk assessment should focus on the factors that produce the most uncertainty for the company's business [2].

Alan Shapiro investigated the role of currency and country risk in International banking. The exchange rate fluctuations affected the ability to service their debt to a large extent. The exchange risk on this debt transforms to credit risk. In his opinion the bank must identify the real cost of repayment of loan against the real wealth the nation has to draw on. Currency risk depends on exchange rate changes, which, affect the borrower's real cost and hence likelihood of servicing the debt. Country risk, the credit risk on government loans is dependent on nation's terms of trade its adaptability to adjust standard of living with respect to changing economic fortunes [14].

Claude B Erbe et al, 1995, analyzed the correlation between country risk and equity market indexes. A negative relation exists between currency returns and country rating because foreign currency changes are related to credit than with the underlying equity markets. Lower credit ratings are associated with higher average returns. The highest credit risk nations have high dividend yields and the lowest risk have the lowest dividend yields. There is a positive relation between credit risk rating and beta. Highest credit countries have lowest betas. The country risk rating has substantial predictive power in discriminating between high and low expected return countries. It is also successful in identifying high and low return portfolios. Adding emerging markets to a globally diversified portfolio reduces overall risk and increases expected return [15].

Siregar and Choy, 2010, examined the factors behind international lending to nine East Asian economies by private banks of seven OECD countries in the 1990 - 2004 periods. Their finding suggests that political instability and weaknesses in the legal, judicial and bureaucratic systems are responsible continued stagnation in the international lending. Institutional reforms are critical to successfully compete for international bank financing [16].

Longstaff et al, 2011, investigated the relation between sovereign credit risk and global macroeconomic factors. The sovereign credit risk appears to be strongly linked to global factors, risk premiums, and investment flows than by country specific fundamentals. There is a significant risk premium embedded in sovereign credit spreads. This risk premium represents about one- third of the total credit spread. Sovereign credit risk is much more correlated across countries than are equity index returns for the same countries [17]

Frank and Cline investigated the ability of eight indicators to identify debt servicing problems. The variables selected were, debt service ratio, index of export fluctuations, compressibility of imports, imports to GNP ratio, per capita GNP, and growth of exports [18].

DATA COLLECTION

Secondary data has been collected from the World Bank website. The pertaining to South Asian countries, Australia, Saudi Arabia and some Asean countries. The variation in countries is to carry out comparative analysis about the country risk of south Asian countries with other developed and developing countries.

1791 ANALYSIS OF INVESTMENT PATTERNS BASED ON SP/A THEORY

Tamanna Pahooja, Bhuvan Gupta, Debasis Patnaik

BITS Pilani K. K. Birla Goa Campus

ABSTRACT

This paper analyzes the risk appetite of investors by observing their behavior towards different options of lending and borrowing. The analysis, according to the responses received, has been done in four ways and focuses on diversification of portfolio, nature of assets and risks involved. The first analysis talks about how framing of questions affects the choices of investors. Second analysis is about the investment pattern and risk capacity according to demography. Third analysis studies the effect of the job type on shaping the ideology of the investor. Finally, the kind of employment and the associated risk appetite has been studied. Assets mainly considered for survey include stocks, bonds, derivatives, mutual funds and saving accounts.

1 INTRODUCTION

Behavioural portfolio theory (BPT) (Shefrin & Statman, 2000), provides an alternative to the assumption that the ultimate motivation for investors is the maximization of the value of their portfolios. It suggests that investors have varied aims and create an investment portfolio that meets a broad range of goals. The first part of Behavioural portfolio theory is the **Safety-First Portfolio Theory (SFPT)** which posits investor motivation to be to avoid ruin. An extension to SFPT was introduced in 1987 by Lola Lopes, named **SP/A Theory**. The letters in its title can be summarized:

S = security, a general concern about avoiding low levels of wealth

P = potential, reflects the general desire to maximize wealth

A = aspiration, the desire to reach a specific goal, such as achieving no less than the subsistence levels.

In Lopes' framework, risk-taking is balanced between **fear** and **hope**. Lopes posit that *fear* is such a strong factor because fearful people overweight the probability of the worst outcomes, underweight those for the best outcomes. This leads individuals to understate the probability of achieving the highest level of **expected wealth E(W)**. In other words, fearful individuals are pessimistic. *Hope* has the inverse effect on individuals – optimism causes hopeful investors to overstate the probability of achieving the highest level of expected wealth. Lopes contend that *fear* operates through an *overweighting of the probabilities attached to the worst outcomes*. (Lopez, 2013)

Therefore, risk aversion is motivated by a desire of security while risk seeking is rationalized by a desire to achieve maximum (He & Xun Yu Zhou, 2012)

The qualitative lesson from SP/A theory is that you should establish a portfolio in which you have reigned in your emotions of fear and hope, so that neither dominates.

2 METHODOLOGY

OBJECTIVES

1. Analyzing the effect of framing of questions and options on individual's choices
2. Analyzing the responses of the questionnaire by bifurcating them into the following three groups to reflect the key points of SP/A theory
 - i) On the basis of Demography
 - ii) On the basis of Type of Job (government / private)
 - iii) On the basis of Nature of Employment (full time/ part time)

Scope of the Study

- The research has been conducted on the people residing in India and investing in various financial instruments.
- This research involves people of all age groups above 15.
- The research involves people working across various domains like public sector, private sector and self-employed businessmen.
- Full time employed, part time employed as well as on call employed are covered under this study.

SUBJECTS

The subjects were 120 people of different age groups, having entirely different professions and having entirely different sources of income. The subjects included men as well as women, employed as well as unemployed people and people with prior knowledge about financial instruments as well as people who did not have knowledge about these financial instruments.

DATA COLLECTION

The study is based on Primary data. The main source of data used for this study is primary and it has been derived from a structured Questionnaire.

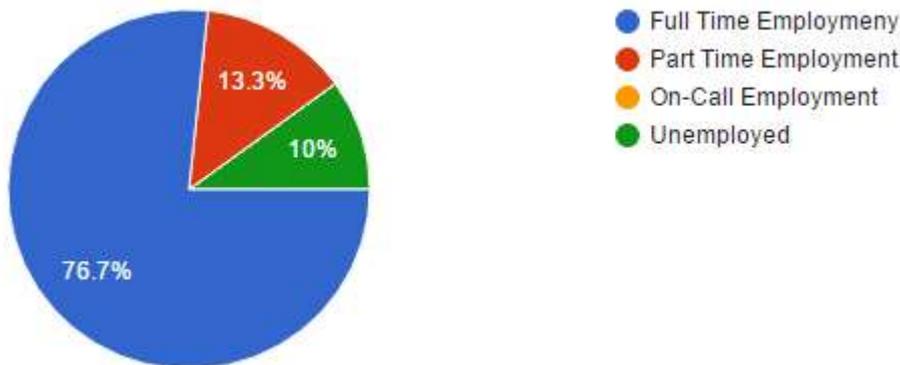

ANALYSIS TOOLS

The data has been collected via questionnaires and has then been plotted on pie charts and bar graphs which are subsequently analyzed

3 DATA ANALYSIS AND INTERPRETATION

3.1 Kind of Employment:

The Trend suggests 76.7% of the subjects were full time employed while 13.3% Part Time employed and only 10% Unemployed. The Part Time Employed were mainly the subjects of age bracket 15-25. This conforms to the ongoing scenario where a person works at multiple jobs at a time. Thus each one specialises in a particular aspect and is called upon to do that particular job. The entire business strategy is not disclosed to them and there’s a separate core team for all the business planning. The 25-40 age bracket subjects are all full time employed. This conforms to the old time scenario where an employee was considered as an asset by the firm and had to spend the full time in the office irrespective of the amount of work he had to perform.

3.2 Do you have a savings account?

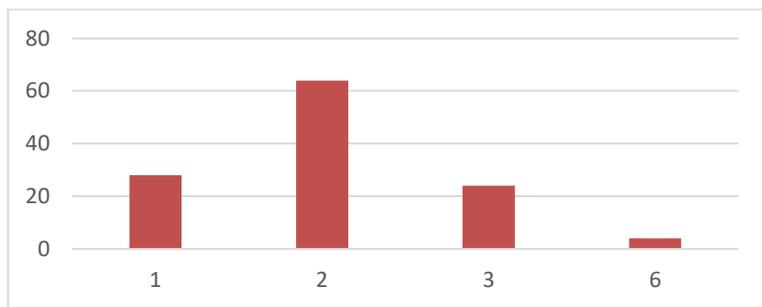

All the subjects have saving accounts in bank. This shows people trust banks and are risk averse as very less risk is involved when funds are invested in bank. Indians have trust in banks unlike Americans (Edelman Trust, 2015) where their banks have failed. This also reflects the response of Jan Dhan Yojana that was started by The Prime Minister Narendra Modi (Günther, 2017). Moreover, these days people have more awareness of banks rather than stocks, mutual funds, bonds and derivatives.

3.3 In how many banks do you have a savings account?

The majority of responses were recorded for 2 banks. This shows that the people do not completely trust a single bank. Another reason for such response may be due to the fact that most of the people put their money in public banks because it is less risky and in private banks because the facilities they provide is better than the public banks.

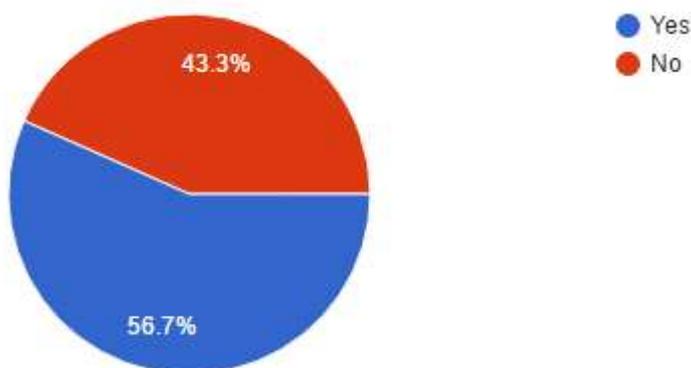

The response for 1 bank is just 23 % thus rest of the subjects keep their money in more than one bank which shows that people know the benefits of diversification. They know that if they will keep their money in one bank there is a higher risk as if that particular bank fails then they will lose their money. This shows that majority of the people are risk averse.

3.4 Have you ever taken a Loan?

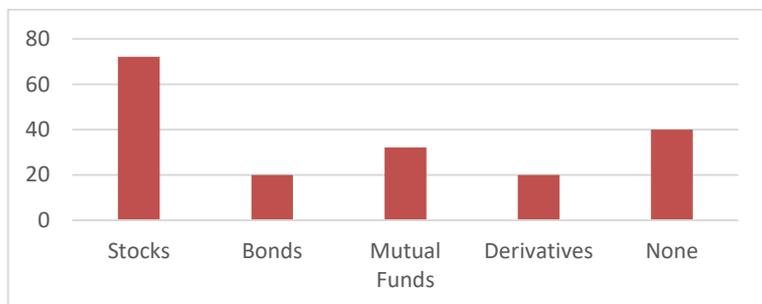

Only about 57% people said that they had at one point or the other taken a loan from the bank. This percentage is very low as compared to what we would expect in a developing country. The reason for not taking a loan could be many.

- a. People might be self-sufficient and hence do not require extra loans to be taken to fulfil their necessities or even their luxuries.
- b. Another reason can be that people still have less faith on banks and hence borrow money from their relatives only.
- c. Also, banks generally look at your previous financial record, whether you have a guarantee or not, whether you have something to be mortgaged or not. They also check your money inflow pattern is steady or not and whether you will be able to repay the loan or not (Chaplinska, 2012). Due to these reasons, many people are not given access to loans and hence they have never taken a loan.

3.5 What type of Securities have you invested in?

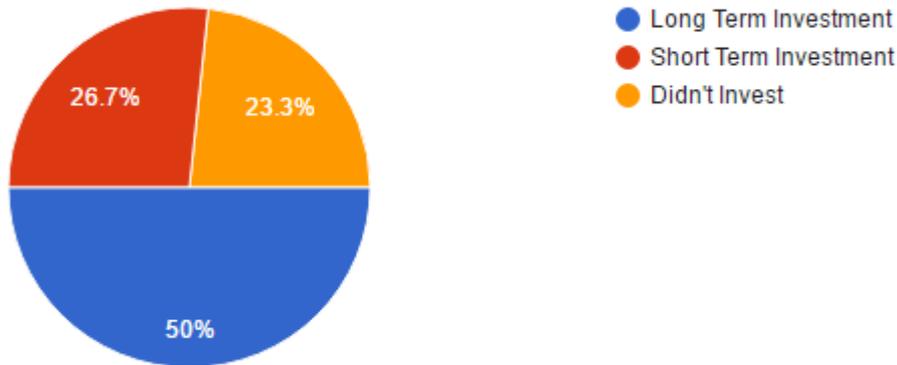

Majority of the subjects has invested in stocks followed by mutual funds. This reflects they have more risk appetite as stock market is high risk high return while Bonds are low risks low returns. Therefore, bonds are not much preferred. Risk appetite of investors gives an insight that most of them are in younger demographic group and thus seek risks while investing funds. Comparatively lower investment in Derivatives also suggests the lack of knowledge (Saroaha & Yadav, 2013) of these as Securities. People generally are unaware of these avenues and flock to stock markets, mutual funds or prefer investing in the real estate markets.

3.6 What is your investment pattern in the Stock Market?

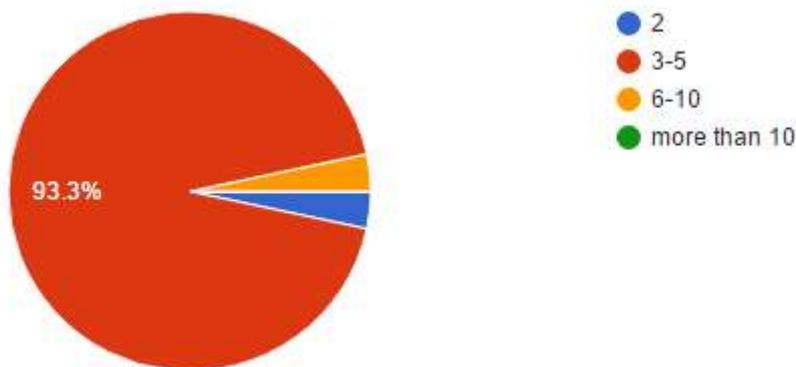

- d. The responses for long term investment is the highest (50%) which shows the risk averse nature of the people because if you do long term investment then you don't have to worry about the daily fluctuations in the stock market because the market recovers over the time.
- e. People invest less in short term investments (26.7%) because they are riskier than long term investment but the gains are higher than long term investments.

- f. Rest of the people do not invest in stock market may be because they don't have much knowledge about stocks or they don't want to risk their money.
- g. Overall this shows us that most of the people have risk averse natures but there are still certain sections which prefer higher returns over risk.

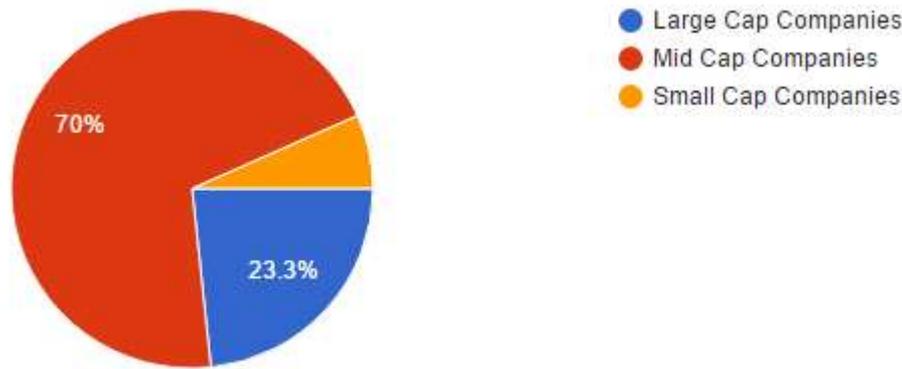

3.7 How many members are there in your family?

Approximately 93% people have 3-5 people in their family which means that nowadays more and more families are converting into nuclear families which might be because people have started understanding that money can be better managed if the number of people to feed are less.

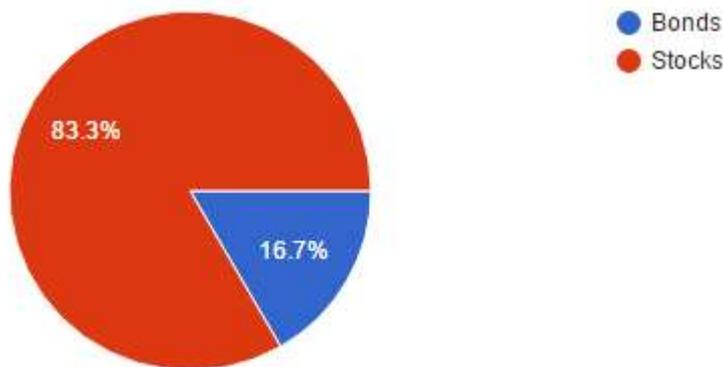

3.8 What kind of companies do you prefer holding stocks in?

- h. Large Cap Companies: Only 23.3% of the total subjects preferred holding stock in Large Cap Companies. The stocks of such companies are already appreciated a lot and a prospective investor doesn't expect much high returns from them. If a person invests in stocks for dividend yields, these are the companies he's looking for. On the other hand some people prefer investing in a big brand irrespective of the returns which the stock of that company has to offer.
- i. Mid Cap Companies: 70% of the investors preferred to invest in Mid Cap Companies. These companies are the ones that attract the maximum people and are the most traded (Tony Massena et al, 2015). The investor might gain much but at the same time might lose much as well.
- j. Small Cap Companies: Not much subject preferred to invest in Small Cap Companies. These also include the penny stocks which might die all out or might give a significant return if invested in heavily. This sector is the one which is easily manipulated by some big players.

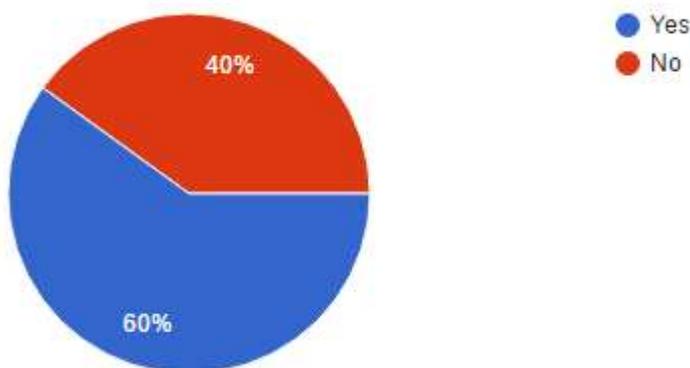

3.9 Do you prefer bonds or Stocks?

83.3% of the subjects prefer stocks over bonds. They expect better returns even if they have to take more risk. Aspirations of investors are high. Moreover, investing in bonds blocks the money for a certain time period and thus the liquidity decreases.

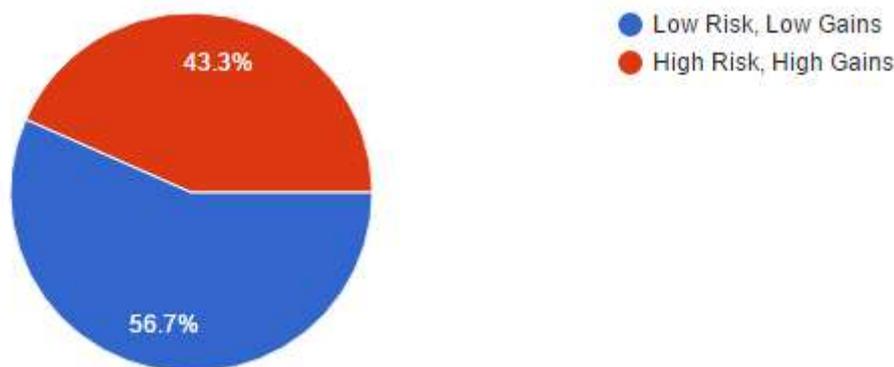

3.10 Did you have any prior knowledge related to investment in Banks, Stock Market or Corporate?

60% of the people agreed that they had prior knowledge about Banks, Stocks and Corporate. This may be due to the various initiatives taken by the government of India towards Financial inclusion (Günther, 2017). One such initiative is PRADHAN MANTRI JAN DHAN YOJNA which is a National Mission on Financial Inclusion which has an integrated approach to bring about comprehensive financial inclusion, provide banking services to all the households in the country, make them aware of the various schemes, banking facilities etc.

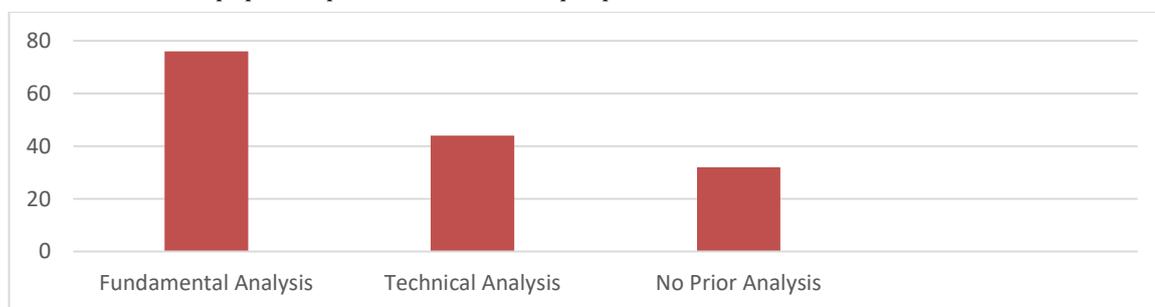

3.11 What would you prefer? Low Risk, Low gains or High Risk, High Gains?

Nearly equal percentages indicate that it generally differs from person to person and there is no generalized trend for the same.

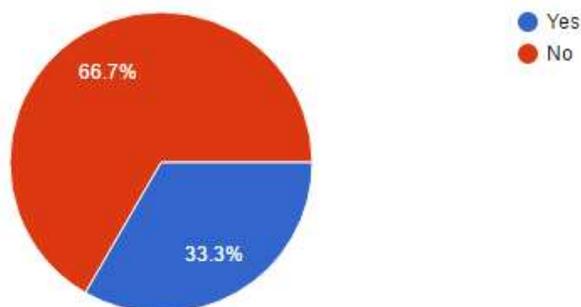

3.12 How do you analyse a stock before investing?

Mostly people prefer looking at the fundamentals of the company which include analysing the ratios, balance sheets, company's goals, vision etc. The ideology behind this is that if the fundamentals of a company are strong, one or the other day the share prices of company shall definitely rise one or the other day. With the availability of modern tools like charts, models etc. one can compare the performance of the company over a wide time range. This is called Technical analysis. Not much people prefer this. One must have a proper know how of the charts and techniques to use them properly. Thus this is not a much popular option with the older people.

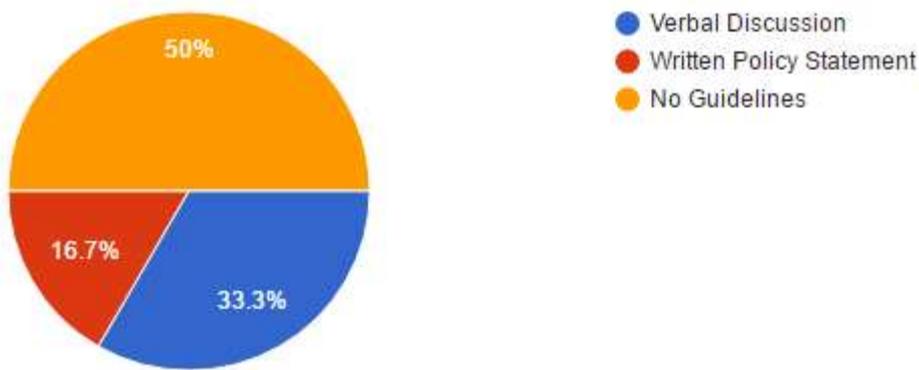

3.14 Do you hire a professional to manage your portfolio?

66.7% of the subjects do not hire manager for portfolio management. From this we can conclude that either they are well informed and updated regularly and know the investment procedure very well or people avoid risking their money at the hand of someone else.

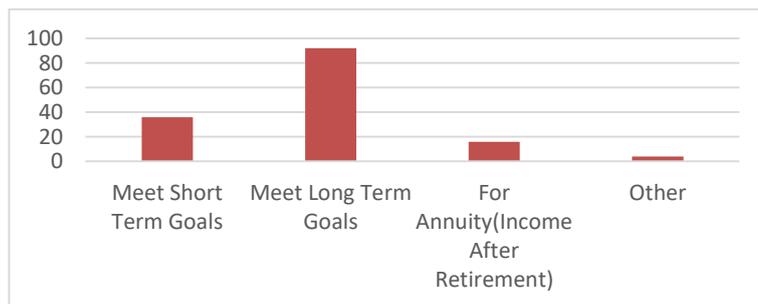

3.15 What kind of guidelines did you give to your Portfolio Manager?

Maximum response (50%) was recorded for no guidelines, which shows that either the people do not have any knowledge about investment and therefore they leave everything on their portfolio manager or people trust their portfolio manager more than themselves. This also depicts the carelessness of people depending only on the investor because without any guidelines, the investor cannot sue the manager for any losses. This shows that they want to take help of someone having more technical knowledge which is again a reflection of their risk averse nature. People prefer verbal discussions more than written policy statement which again shows their trust on their portfolio manager

3.16 What's your Investment Goal?

- k. Only 30% people invest for meeting short term goals. This means that there are very few people who do not keep in mind the future before investing. Short term goals are usually kept by people who are deeply engrossed in these financial instruments and can keep a check on how much they are gaining from them.
- l. Approximately 77% people invest for meeting long term goals is a clear indicator of the fact that people generally invest keeping in mind issues like education (especially children's higher education), health care, marriage, etc. Long Term investments also include the fact that people want to be ensured in case any unexpected problem comes up.
- m. Only 13 % people think about annuity. They would most probably be in a Gifting Stage of life (elderly people)

4 ANALYZING THE EFFECT OF FRAMING OF QUESTIONS AND OPTIONS ON INDIVIDUAL'S CHOICES

According to prospect theory, "risk attitudes change as a function of the valence or sign of outcomes. Risk aversion is shown towards gains and risk seeking tendency for losses.

There is a conflict between choices for subjects while setting their aspirations. A sure thing can be satisfactory for some while the same thing cannot be 'good enough' for another. Schneider explains the aspiration contingency with SP/A theory. "With the low aspiration levels postulated in the positive domain, both the need for security and the modest aspiration level can be satisfied by selecting a sure thing. With high aspiration levels in the negative domain, however, conflict ensues as security needs favor a risk-averse choice but the stringent aspiration level favors a risk-seeking choice" (Schneider, 1992).

According to the responses to the questionnaire, there are two instances where people have given contradictory responses to the same question framed in different ways:

1. 83.3% of the subjects preferred stocks over bonds. But when asked if they would prefer low risk, low returns or high risk, high return more than 50% of those subjects preferred low risk, low returns. This contradiction in response reflects how choice is dependent on the way question is framed. People don't feel the intensity of risk involved when the word 'stock' is mentioned but when asked directly, they exhibit risk averse behavior. In the second instance, two similar questions were posed: "What is your investment pattern in stock market?" and "What is your investment goal?" In both these scenarios, people had to choose if they prefer short term goals or long term goals. Responses show that 16.67% of the subjects shift from short term to long term goals if the framing of question avoids the term 'stock market'. This is a clear indication of the fact that people assume that the stock market is riskier and hence can fulfill only their short term goals.

Thus, it is evident from the two prior instances that people are sensitive to the way questions are framed and options are posed.

5 ANALYZING THE RESPONSES OF THE QUESTIONNAIRE BY BIFURCATING THEM INTO THE FOLLOWING THREE GROUPS TO REFLECT THE KEY POINTS OF SP/A THEORY

i. On the basis of Demography

- If we consider the **age group of 15-25**, there are 5 questions which give a striking result.
 1. The main striking similarity between people of age group 15-25 is that 44/44 people preferred stocks over bonds. This gives an insight about the fact that people in this age group are young and risk seeking. They prefer stocks because stocks are high risk high return instruments.
 2. Another striking answer is that 36/44 people responded that they had prior knowledge before investing in stocks. This means that people now-a-days are more acquainted with the stock market and other financial instruments and hence prefer investing on their own, rather than being dependent on someone else.
 3. On similar lines, out of 44 people in this age group 36 people responded that they do not hire a professional to manage their portfolio. This gets us inclined to the fact that people now-a-days are self-sufficient in knowledge and hence do not require a professional. Another reason is that people now-a-days do not want have faith in any other individual and hence want to work a way to invest on their own.
 4. For investing in stocks, 4/44 people use fundamental analysis or technical analysis, a wholly 40/44 people use both fundamental and technical analysis and only 4/44 people invest based on an expert's opinion. This means the younger generation believes that although fundamental or technical analysis cannot beat the market but it gives a picture of what is going and helps them to be prepared for the same (Suresh, 2013).
 5. To support the fact that people in this age group are more risk seeking, 28/44 people invest in mid cap companies as they have higher fluctuations which means higher returns.
- If we consider the **age group of 25-40**, there 4 questions which give a striking result.

NOTE: All 36 subjects under this category were full time employed.

1. 36/40 people in this age group invest in mid cap companies. These people are in the accumulation-spending stage of life. Hence they are risk seeking and want to grow as much as they can. Mid cap companies have more fluctuations in their stocks. Hence people in this phase prefer high risk high returns.
2. Another striking result is that people in this group are highly averse to technical analysis. 0/40 responses take into account technical analysis before investing in a stock which can be due to lack of knowledge or lack of belief in mathematical analysis.
3. The responses also show that due to less awareness among individuals, only 4/40 people give a written policy statement while hiring a professional for managing their portfolio. Rest of the subjects either gave no guidelines or gave guidelines only as a mode of verbal discussion.
4. Another feature is that subjects in this group fulfill to invest long term goals like buying a house, children's education, children's marriage, etc. Hence all 10 subjects said that they invest to fulfill long term goals.

- If we consider the **age group of 40-60**, there 2 questions which give a striking result.

NOTE: All 36 subjects under this category were full time employed.

1. 32/36 people in this age group preferred low gains, low risk over high gains high risk. This is because at this stage people are almost in the gifting stage of their life (Frank K. Reilly, Keith C. Brown) and hence do not want to risk losing the money that they earned by putting in a lot of hard work. Hence risk appetite of people in this age group is very small.
2. Another striking feature is that the investment goals of people in this age group are long term goals or investment for annuity. This phase of people is where they are stable and hence planning for the future. So, these responses are justified.

ii. On the basis of Type of Job (government / private)

- If we consider **private job**, there are 3 questions which give a striking result.
 1. 52/68 respondents preferred investing in a Mid Cap company while 16 chose to invest in a Large Cap Company and no one was keen on investing in Small Cap Companies. This reflects the prominent ideology of high riskiness of Small Cap Companies which may offer very good returns or be doomed thereby exposing to a greater risk than Mid Cap Companies. Investors seems to be aware with the rather steadiness of Mid Cap over Small Cap thereby offering still better returns but with relatively less risk. Large Cap are the most stable but don't have as high returns as the other two.
 2. 36/68 chose to invest in Securities and the rest chose not to invest in securities. This clearly shows the Risk Averse behavior of the subjects. When interviewed about the risk pattern. With a lot of pink slips being given nowadays and the instability of jobs seems to have influenced the investors to (Frank K. Reilly, Keith C. Brown n.d.)be rather Risk Averse.

3. 44/68 chose Long Term Investment over Short Term Investment. Private Jobs don't have the perks of the Government jobs like pensions etc. The subjects are wise enough to save for fulfilling their Long Term Goals and also to support them after retirement.
 - If we consider **government job**, there are 5 questions which give a striking result.
1. 20/24 people had invested in Stocks. This is because these people are relatively stable with secured and definite earnings and seek to make better returns on their Savings.
2. When interviewed about the preference over Stocks and Bonds. 20/24 people preferred Stocks over Bond. Because of stable earnings from job they chose better returns over total safety of money. The risk bearing attitude might also arise from the fact that if they bear a loss in Stocks, they'll still have their monthly salary to make up for it. (Market Capitalisation: Large Cap Mid Cap Small Cap, n.d.)
3. Though the subjects preferred bonds over stocks yet they stuck to the ideology of low risk low gains. They preferred to invest in a company with strong fundamentals (because they relied on Fundamental Analysis) and having a long term position in these industries thus enjoying on the dividends and reap the tax benefits on the proceeds of selling the stocks in the long run.
4. All the subjects had prior knowledge of investing in Securities. This shows that people now-a-days are more acquainted with the stock market and other financial instruments and hence prefer investing on their own, rather than being dependent on someone else (16/24 chose to rely on their own than hiring a professional to manage their portfolio).
5. All the subjects chose to invest for fulfilling Long Term Goals. They seek for a comfortable life post retirement and bridge the gap left by the Salary and the Pension Salary.
 - If we consider people having their own **business**, there are 3 questions which give a striking result.

Note: There were 8 subjects of this criterion, all in the age group 40-60 having a Savings Account

1. All the subjects preferred Stocks over Bonds. Thus indicating that though Stocks being a little risky over Bonds but offer a bit higher liquidity and better returns over Bonds is well perceived by these people. In Business cash crunch might arise at any point of time, thus an investment offering better liquidity was preferred.
2. All the subjects had no prior knowledge about the Analysis of Stocks. Therefore, half of them preferred investing in a mutual fund and relied on the technical analysis provided by the mutual fund company.
3. The investment pattern of the subjects is long term. This phase of people is where they are stable, probably well established and hence saving for the future.
 - If we consider **other types of jobs**, there are 4 questions which give a striking result.

Note: All the subjects were in the Age Group 15-25

1. The Investment pattern was strikingly different than those observed in other types of Employment. The subjects conform to the ideology of 'High Risk High Gains'. The subjects are still in the accumulation phase (Frank K. Reilly, Keith C. Brown) of their lives and have sufficient time ahead to help them recover from a major loss(if any).
2. All the Subjects preferred investing in stocks and relied on Fundamental Analysis as a mode of analysis to select a suitable company to invest in.
3. All the subjects had prior knowledge of investing in Securities. None of the subjects preferred hiring a Professional to manage their portfolio. They rather preferred relying on their own efforts to manage their portfolio. This clearly shows the growing awareness among individuals and an increasing want to understand these financial instruments thereby becoming self-reliant when coming to investments.
4. The subjects invested for meeting both their Short Term as well the Long Term Goals. This clearly shows the ideology of being self-reliant rather than relying on anyone for fulfillment of needs. By seeking to be able to satisfy their Short Term Goals the subjects want to be independent and not dependent on their families for their needs.

iii. On the basis of Nature of Employment (full time/ part time)

- If we consider **people who are unemployed**, there are 5 questions which give a striking result.

NOTE: 10% of the subjects are unemployed. The responses that we got from them are as follows:

1. All of them have a savings account which shows that the people are aware of the benefits of saving money in banks. 8/12 people who are unemployed have 2 savings bank account which shows that not only they know the benefits of saving money in a bank but also they know the benefits of diversification.
2. 8/12 of the subjects did not take any loan which may be due to the reason of lack of a fixed income.
3. All the subjects preferred high risks, high gain and if they are ready to invest they prefer to go for a long term investment. This shows that the firstly unemployed people are not ready to invest may be due to lack of money, however if they invest they prefer long term investment in order to meet their long term goals. This shows that

all the subjects have knowledge about the benefits and low risks related to long term investments and also shows that these people are security minded.

- If we consider **people who are part time employed**, there are 4 questions which give a striking result.
 1. All the part time employed subjects are paid on a monthly basis where 75% of them work in private sector and 25% work as a consultant. They all have a savings account and they all have account in more than one bank, this shows that these people are well aware of the benefits of saving money in a bank and diversification.
 2. None of the subject shave taken a loan which may be due to lack of a fixed source of income.75% of the subjects wanted to go for short term investment and only 25% for long term investment which may be due to the fact that 75% of the subjects have short term goals and since all the partly employed people belong to age category of 15-25 years their age might be a factor of their risk taking attitude.
 3. They all said that they have a prior knowledge of the market and therefore this might be the reason that none of them wants to hire a professional. It has been analyzed from the response of the partly employed people that those who want to go for high risks, high gain preferred both technical as well as fundamental analysis. This might be due to the higher risks involved, however those who are going for low risks, low gains preferred only fundamental analysis.
- If we consider **people who are full time employed**, there are 4 questions which give a striking result.
 1. 26% of the fully employed people have a government job, 4% have their own business while rest of them work in private sector. They all are paid on monthly basis and people of all age group are present in this category. They all have a savings account and most of them keep their money in more than one account. There are people in this category who have more than 2 bank accounts. Therefore, the people in this category know how to reap the benefits of diversification and saving money in a bank.
 2. 74% of the subject in this category have taken a loan, 17% of them have paid it earlier while the rest of them have paid it on time. None of them have delayed the payment which may be due to regular source of income.

6 CONCLUSION

Situational factors reflect the needs of an individual while making choices. Most of the investors are very sensitive about safety of their investment. They want more safety and reliability. Fearful investors are worried about *security* and hopeful investors are looking for maximum *potential* reflecting the relative strength of each. Further, *aspiration* levels are determined by keeping in mind that 'No Change' is the benchmark. People tend to be averse to the change pulling them out of their comfort zone.

APPENDIX

• Questionnaire

Securities & Aspiration

Your identity will not be captured and all the data will be confidential.

* Required

1. What is your Age Group *

- 15-25
- 25-40

- 40-60
- 60 above

2. Type of Job *

- Government Job
- Private Job
- Business
- Unemployed
- Other :

3. Source of Income *

- Paid on Daily Basis
- Monthly Pay
- Unemployed

4. Kind of Employment *

- Full Time Employment
- Part Time Employment
- On-Call Employment
- Unemployed

5. Do you have a Savings Account *

- Yes
- No

6. In how many Banks do you have a Savings A/c *

-

7. Have you ever taken a Loan? *

- Yes
- No

8. How fast did you repay the loan? *

- Prepaid the Entire Amount
- Paid as per the Schedule
- Extended the Loan Period
- Did not Take a loan

9. What type of Securities have you invested in?(More than one can be selected) *

- Stocks
- Bonds
- Mutual Funds
- Derivatives(Options, Futures)
- None

10. What is your investment pattern in the Stock Market? *

- Long Term Investment
- Short Term Investment
- Didn't Invest

11. How many members are there in your family? *

- 2
- 3-5
- 6-10
- more than 10

12. What kind of companies do you prefer holding Stocks in? *

- Large Cap Companies
- Mid Cap Companies
- Small Cap Companies

13. Do you prefer Bonds or Stocks? *

- Bonds
- Stocks

14. Did you have any prior knowledge related to investment in Banks, Stock Market or Corporates? *

- Yes
- No

15. What would you prefer? *

- Low Risk, Low Gains
- High Risk, High Gains

16. How do you analyse a Stock before investing?(More than one can be selected) *

- Fundamental Analysis
- Technical Analysis
- No prior Analysis (Invest as per the Expert Opinion)

17. Do you hire a Professional to manage your Portfolio? *

- Yes
- No

18. What kind of guidelines did you give to your Portfolio Manager? *

- Verbal Discussion
- Written Policy Statement
- No Guidelines

19. What's your Investment Goal?(More than one can be selected) *

- Meet Short Term Goal
- Meet Long Term Goals
- For Annuity (Income after Retirement)
- Other:

RS12.1. Rural Development

1142 AN IMPACT EVALUATION OF INDIRA AWAAS YOJANA (IAY) PROGRAMME INDUCED TRANSFORMATION OF RURAL DWELLING ATTRIBUTES UNDER SOUTH TRIPURA DISTRICT, TRIPURA

ABSTRACT

The study of settlement is basic to human Geography as the form of dwelling in any particular region not only reflects man’s response to his environment but also an asset which supports livelihood, symbolises social position and bears expression of cultural ethos of society. Indira Awaas Yojana (IAY), a flagship scheme of the Ministry of Rural Development has since inception provided assistance to BPL families who are either houseless or having inadequate housing facilities for constructing a safe and durable shelter. It is for all these reasons that a genuine effort has been made for empirical study of rural households through collection of primary data by structured schedule. During field survey using random sampling techniques, ten percent of households were visited and interviewed in order to gather knowledge about different dimensions of IAY homestead characteristics and investigate its impact in seven Autonomous District Council (ADC) administered villages and eight Non-ADC villages in South Tripura District. The analysis of data revealed that the quality of the house depends on the type of building materials used for the construction of the floor, wall and roof etc. In seven villages, use of thatch as roofing material for IAY dwellings is observed led by ADC villages of Paschim Takka Tulsi (34%) followed by Laxmichara (31%) and Tairumachara (18%) reflecting the survival of folk houses in the advent of cheap durable Tin. Under IAY developmental impact huge transformation is observed as folk huts with thatched roof are converted to metal Tin roof house due to its long durability and less maintenance cost. A cursory look at the IAY dwelling highlights the fact that out of 15 villages more than 60 per cent of household ownership is entitled to female members of the families reflecting change in socio-economic ethos of traditional societies in the rural human landscape of the study area providing sort of female empowerment. To sum up, the IAY as development scheme intended to providing housing to rural poor is not immune to the impact of physico-cultural setting and thus its implementation have given rise to varying distinguishable layout of IAY housing attributes in the study area.

1152 RURAL NON-FARM ECONOMY

ABSTRACT

India is still an agrarian nation, almost two-third of workforce are engaged in agricultural activity. Although there has been shift from agricultural activity to non agricultural activity especially into rural non-farm activity. It has resulted in degradation of agricultural activity in the country bringing negative and positive impacts on economies of nation. Rural non-farm activities has given some relief in providing the employment in rural areas as there is increase in percentage share of workers in rural non-farm activities from previous census years. So the farm and non-farm linkage is an important issue. Rural non-farm sectors have come up, especially in the regions where the agricultural activity has not been supportive enough for the economies of life. Making an inverse relation between agricultural and rural non-farm sectors. Whereas various literature talks about expansion of agricultural activity leading to demand of local inputs and thus better rural non-farm sectors. A large section of rural population has got indulged into the local non-farm activities. Working on the data of census and NSSO has given a vivid result and different perspective of rural non-farm economy (RNFE). There is a huge shift in the percentage share of workers both male and female in the rural non-farm activities from the previous census years. Composition of work force share has increased especially in the southern states. But the composition of workers in the agricultural activities have come to a stand-still indicating that agricultural activity has become stagnant. As many literature talks about shift of agricultural activity to rural non-farm economy (RNFE) through crop diversification and land convergence for better economy but when there is no accumulation of surplus in the country then what about better rural non-farm economy. Agricultural activity and rural non-farm economy are inter-related (backward and forward linkages) but in recent times agricultural activities is becoming stagnant then how can we talk about rural non-farm economy. Crop diversification lead to increase of rural non-farm economy but it has not proved to be fruitful considering the demand for food crops and herby raising question over food security in order of non generating surplus. As the literature argues that the expansion of agricultural activity leads better rural non-farm economy growth but an inverse relation has come between agricultural activity and rural non-farm economy.

1536 CHILD MALNUTRITION IN UGANDA: REGIONAL DISPARITIES AND SOCIO-ECONOMIC INEQUALITIES

ABSTRACT

While hospital records in Uganda do not show a significant reduction in the prevalence of nutrition related diseases, the lack of a comprehensive national survey since 2011 to measure child nutrition and household conditions poses a significant challenge in assessing the prevalence and determinants of child undernutrition. In this paper, we assess malnutrition prevalence in six districts of Uganda's Karamoja region using recent survey data for the year 2014. Variance analysis at different levels shows that there are significant differences between districts with respect to the prevalence of malnutrition. Gender-wise disparities in malnutrition exist where boys are in a disadvantaged position compared to girls. The variation in malnutrition can be attributed to the differences stemming from different regional characteristics at different levels (village, parish and subcounties). The finding of no variation attributable at the parish level for boys but for girls needs further investigation with regards to parish level characteristics that may affect malnutrition. However, the greatest variation is observed at the household level. We also find wealth related inequality in malnutrition where the poor are in a particularly disadvantaged position. Wealth-related inequality in malnutrition shows that malnutrition is concentrated highly among the poor with wasting showing greater inequality than stunting.

1559 MIGRATION INDUCED FEMINIZATION OF AGRICULTURE IN SELECTED AREAS OF INDIAN SUNDARBANS

ABSTRACT

The agrarian livelihoods pattern in Sundarbans has undergone various socioeconomic, political and environmental changes in recent times. An increasing trend of women’s involvement in agriculture, alongside their male counterparts, has become common in these regions and their critical role in agricultural development has also been recognised and documented. Women of rural households perform significant and diversified roles in agriculture such as farmers, co-farmers, family labours, and wage labours in spite of lower existing wage rates. The lack of wage employment opportunities from farming in rural areas in one hand and higher wage rate in cities and outside the country on the other, have influenced a major out flow of rural youth from rural areas. Despite of being an important livelihood strategy of rural households, labour migration has impacted agriculture in these areas especially in terms of women’s engagement as decision makers. The left behind women in rural areas now shoulder the added responsibilities of farming along with the archetypal gender roles in a traditionally male- dominant management of agriculture. This increasing dependency of agriculture on women is known as ‘feminization of agriculture’, which may either be manifested as the feminization of agricultural labour (labour feminization) or the feminization of farm management (managerial feminization). While labour feminisation often leads to increasing drudgery and vulnerability of the left behind women, managerial feminization tends to expanded participation of women in household as well as community decision making process. The present paper investigates the nature of migration and its impact on the ‘feminization of agriculture’ in selected areas of IndianSunderbans where prevalence of migration is reported to be high. This study employs a mixed method approach of data collection, using household survey followed by in-depth interview, key informant interview and gender analysis. Examining the data from both migrant and non-migrant households in terms of women’s engagement in farming activities and perceived drudgery, the paper tries to understand the nature and extent of feminization in agriculture and identify the factors associated with it. This study also explores the role of remittance in the feminization process and thus impacting women’s drudgery at origin. The study outcomes will be of particular use in formulating gender sensitive livelihood support programmes and agricultural research and extension strategies. : Migration, Livelihoods, Feminization of Agriculture

1584 SPATIAL SIGNIFICANCE OF MARKETS FOR RURAL DEVELOPMENT: AN INTRA- DISTRICT STUDY OF SANGLI

ABSTRACT

Regional disparities in development of a district are the outcome of discrepancy in socio- economic conditions. For the formulation of a development plan for a district with regional disparities, it would be necessary to make a critical assessment of present economic trends. Regional markets are one of the contributors to economic trends. Market is commonly viewed as a space for economic exchange of goods achieved by monetary transactions. Thus Market plays a progressive role in regional development especially ,in the rural areas where the location and spatial connectivity of the market institutes the overall impact on economy These exchanges in market not only influence the local economy but regional development as well for identifying spatial significance of markets in development. Sangli district is predominantly a rural area, an agricultural sector with more than seven hundred villages actively participating in weekly hats, monthly markets or agricultural market societies. The district is one of the significant regional market places in Maharashtra, where wholesaling and trading of agricultural goods take place such as Turmeric, Sugarcane, and grains like Jawar. Pomegranates and grapes produced in this district are exported to foreign markets as well. However inadequate rainfall of monsoon and frequent drought conditions hampered the development of agriculture, particularly in the drought prone areas of district. As a result economic activities and economic development are very unevenly distributed in the space economy of Sangli. Certain areas in district have relatively high levels of development while others have low levels of development or no development at all. The paper would inquire in the contribution of Sangli in development of economic space for development. The study would also highlight the role of markets as an indicator of development and the connectivity of markets as trading posts.

1572 EMPOWERING STAKEHOLDERS FOR IMPROVED WATER GOVERNANCE: A STUDY OF WEST BENGAL, INDIA

ABSTRACT

The world is facing a global water crisis challenged by increased demand, pollution of water resources and poor water management. Many districts in West Bengal, India including South 24 Parganas and Birbhum, are affected by diminishing water reserves and exposure to contaminants like arsenic, salinity and fluoride in the groundwater system. While the Public Health Engineering Department, Central Ground Water Board, United Nations Children’s Fund are already working on improving the condition, it is important that the community and stakeholders take up the responsibility of accessing safe drinking water. Stakeholder empowerment and risk communication are essential for successful participatory water governance. It dates back to the Dublin Principle at the International Conference on Water and the Environment, 1992 and stakeholder engagement preserved in the concept of integrated water resources management. The prerequisites towards effective stakeholder empowerment include stakeholder mapping, risk communication and information sharing. Governments, citizens, end users, private actors, donors and financial institutions, as well as infrastructure and service providers, all have a stake in the outcome of water policy and projects. Because of the highly fragmented nature of the water sector, the role of water governance and stakeholder engagement in formulating and implementing solutions to the world’s criticalwater challenges is receiving increasing attention. The objectives of this research include creating awareness about the spatial dimensions of water insecurity, both qualitative as well as quantitative, stakeholder mapping to identify core stakeholder functions, information sharing amongst all stakeholders, designing solutions involving the local communities and the local governance to resolve water issues. The methodology consists of questionnaire survey in sample households to assess water problems, enlisting water sources and water quality parameters, information sharing, focus group discussion involving various stakeholders to design and develop solutions to resolve water issues. The paper would thus highlight the importance and scope of stakeholder empowerment for effective water governance.

1649 PARTICIPATION OF TRIBAL WOMEN IN SELF HELP GROUPS FOR THEIR SOCIO-ECONOMIC DEVELOPMENT AND WOMEN EMPOWERMENT IN HEZAMARA R.D.BLOCK OF WEST TRIPURA DISTRICT: A GEOGRAPHICAL ANALYSIS

ABSTRACT

Self-Help Groups (SHGs) under Swarnjayanti Gram Swarozgar Yojana (SGSY) is one of the important poverty suppression programmes in India. It helps the women to realize and exercise their inner strength as well as to directly address rural poverty. Basically in tribal community the poverty level is too high than the other community. Tripura is a tiny and hilly state in the North-East India with an area of 10,491.69 sq.km of land. The total population of the State of Tripura is 36, 71,032 as per 2011. About 31.1 percent of the total population of the state belonged to tribal population as per 2011 census. Diverse 19 (nineteen) ethnic groups have been residing in the State of Tripura. Recently the tribal population of the state were engaged in economic activities by forming SHGs in Tripura. The present study tries to find out the impact of tribal women participation in Self Help Group (SHGs) with empowerment indicators i.e. economical, social and cultural aspect. The study has been conducted in Hezamara R.D. block selected in West Tripura District. A Random sampling techniques have been used for the study. A total of 558 members from 55 SHGs 10 Per cent have been randomly selected for this purpose. From the study it was found that participation of tribal women in SHGs directly help in their socio-economic development and also enhanced empowerment in all respects.

1647 EMPOWERMENT OF POOR RURAL TRIBAL WOMEN THROUGH SELF- HELP GROUPS: AN APPRAISAL OF MANDWI RURAL DEVELOPMENT BLOCK, TRIPURA, INDIA

ABSTRACT

Achieving equal participation of Women in the national development is not merely a question of providing some special concessions or launching of some special programmes for them, rather facilitating their collective action on issues of relevance for their empowerment is sought to be the key factor around which every women movement and empowerment practice has to be organized and directed. In this context SHG as a strategy has been proved to be an effective alternative not only to facilitate women to realize and exercise their inner strength but also to directly address rural poverty. The group serves as a basis of mutual help, cooperation and joint action. The members, gradually, in the process of SHG’s functioning, gain confidence to turn their group strength into individual strength to deal with their marginalization and vulnerability. Present study would highlight the structure, functions and activities of SHGs as an instrument of women empowerment operating in tribal poor women of Mandwi block and at the same time the socioeconomic background of the members of SHGs and the impact of SHGs on the member’s life. The present study followed both exploratory and descriptive research method. The unit of analysis for the present study is the women members of SHGs. The method adopted for data collection is interview method and tools adopted are Interview schedule was used for primary data collection from members of the SHGs. Access to credit can help in expansion of material base of women by enabling them to start and expand small businesses, often accompanied by market access; the women also experienced ‘Power within’: feelings of freedom, strength, self identity and increases in levels of confidence and self-esteem.

1194 STUDY ON THE BARRIERS AND CHALLENGES FACING THE MOST VULNERABLE PEOPLE INCLUDING ETHNIC MINORITIES TO ACCESS SSNPS IN BANGLADESH

ABSTRACT

Social Safety Net Programmes (SSNPs) are defined as non-contributory cash and in-kind transfers that aim to reduce and prevent vulnerabilities of the poor people. SSNPs are recognized as an important tool for reducing extreme poverty and vulnerability in Bangladesh. SSNP beneficiaries are mainly the poor segments. The nine SSNPs i.e. Old Age Allowance (OAA), Allowances for Financially Insolvent Disabled (AFID), Allowances for Widowed, Deserted and Destitute (AWDD), Vulnerable Group Development (VGD), Vulnerable Group Feeding (VGF), Food-for-work (FFW), Monthly Allowance for Poor Lactating Mothers (MAPLM), Primary Education Stipend Project (PSEP) and Female Secondary School Allowance Programme (FSSAP) are very important in Bangladesh. Social Protection is a constitutional obligation for Bangladesh. As the constitution illustrate it shall be a fundamental responsibility of the state to attain the basic necessities of life including food, clothing, shelter, education and medical care (Article 15 [a]). But a significant number of poor citizens are still facing troubles to access the SSNPs. So, for better management of SSNPs in Bangladesh, an in-depth investigation about the barriers and challenges facing the most vulnerable people including ethnic minorities to access SSNPs in Bangladesh is needed. Considering these circumstances a study was conducted at the Bangladesh-India border district Dinajpur and Joypurhat during January to April 2017. The major objectives of the study were - to identify the gaps in and barriers which vulnerable people face in accessing the selected SSNPs due to systems, structures, and practices; to formulate the recommendations for reducing or removing the barriers. Therefore, to meet the objectives of the study both qualitative and quantitative methods were used for data and information collection. The broadly used methodologies were included: (i) comprehensive literature review of all relevant documents and policies; ii). Focus Group Discussions (FGD), iii). Key Informant Interview (KII), and iv) Case studies. The study conducted 32 KII, 20 FGD with 200 adults and collected 5 case stories. The study exposed that the status of accessing SSNP supports by the poor indigenous communities of the study areas is not reasonable up to now. Poor people, especially those, belong to the indigenous communities were still facing huge problems in getting enrolled in the SSNP schemes. The challenge lies in the targeting and selection of the beneficiaries, participation of the indigenous communities in the overall SSNP process, and budget allocation. The lack of appropriate policy and rules for the indigenous community in accessing SSNPs along with the role of the duty bearer in-terms of accountability and transparency were also considered as the important determinant in this regard. The SSNP services should be implemented at field appropriately following the guidance of policies, involving the representative from CSOs, NGOs, Ethnic group and beneficiaries. The selection process should be transparent and target people should be well informed timely. The SSNP services should have free from any political influences and nepotisms. Considering market price and demand, the rate of allowances should be increased. Moreover, Government of Bangladesh should properly follow National Social Security Strategy 2015 for ensuring the social security of vulnerable peoples.

1195 SPATIAL PATTERNS OF HOUSEHOLD ENERGY POVERTY DYNAMICS IN MOZAMBIQUE, 2002-2015

ABSTRACT

We analyze the spatial evolution of household energy consumption patterns in Mozambique, a typical low-income, high-growth country in Africa. To this aim, we use 3 extensive household surveys, covering about 7.500-10.000 households over the period 2002 – 2015, to describe changes in energy consumption behavior under influence of income growth, electrification and urbanization. In addition, we use newly collected micro data for 2015, covering almost 1000 households across 19 neighborhoods within the Maputo metropolitan area, to analyze with more detail the dynamics of energy consumption, including the role of urban mobility in energy poverty incidence. We provide descriptive statistics to describe the evolution of energy poverty in relation to income poverty, we analyze spatial patterns of energy poverty and we identify the role of urbanization in the observed trends. We develop poverty lines based on the energy expenditure share, energy consumption in physical quantities and share of modern energy fuels. We calculate poverty incidence curves (i.e. cumulative distribution functions) for each of these poverty lines, while distinguishing between urban and rural areas. We calculate the degree of energy poverty inequality across the country by means of Gini and MLD coefficients. Furthermore, we calculate the evolution of spatial variation in energy poverty incidence over time by means of a sigma-convergence analysis. We use regression analysis to explain (changes in) energy poverty incidence across space by exploring spatial variation in household income (expenditures), population density and distance to larger cities, roads and the coast. We find that, in general, energy poverty incidence levels are lower for energy poverty than for income poverty, except for energy poverty measured in terms of modern energy, which is still extremely high in Mozambique. Over time, energy poverty is decreasing when measured in terms of energy consumption and modern energy share, but increasing in terms of energy expenditure shares. The latter is especially manifest in rural areas. Comparison of the results based on national data and with own survey for Maputo, reveals that the national households surveys grossly underestimate urban energy poverty incidence by largely ignoring the substantial role of fuel consumption for urban transport in energy poverty incidence rates. Finally, we find that spatial variation in energy poverty is larger than in income poverty, and that spatial variation in energy poverty is higher across urban than across rural areas. Spatial variation in both energy and income poverty increases over time, except for energy poverty in terms of expenditure shares. The decrease in spatial variation of energy poverty in terms of expenditure shares is especially strong across rural areas. Key words: Energy poverty, residential energy use, spatial patterns, developing countries, urbanization.

1268A SPATIAL PERSPECTIVE ON INCOME INEQUALITY DYNAMICS IN DECENTRALIZING INDONESIA

ABSTRACT

This paper studies income inequality dynamics in Indonesia since 1960, with a focus on the period 1987-2015. We do so at different levels of spatial aggregation: i) national level (in international perspective); ii) regional level (islands and provinces); iii) individual level (income classes). Our analysis at the (cross-)country level and province level covers the period 1961–2015, while our analysis for income classes is based on micro data (Susenas) for the period 1987-2015. This approach allows us to present new insights into the story of inequality dynamics in Indonesia. Indonesia is the 4th most populous country in the world and currently undergoes rapid socio-economic changes. In recent years, economic development in Indonesia is characterized by high economic growth and a rapid increase of overall income inequality. However, we show that from an international perspective, inequality in Indonesia – as measured by the Gini ratio – used to be exceptionally low and relatively stable for a long period of time, until about the year 2001. Also, we show that in terms of the Gini index, the degree of inequality in Indonesia still is much lower than the leading ASEAN countries, emerging countries and African countries. We argue that this historical low level of inequality is (partly) caused by government interventions in the economy, which continued until at least the liberalization era of the early 1980s. Meanwhile, we find that Indonesia is catching up to ASEAN and emerging countries in terms of per capita GDP. From a regional perspective, we measure income inequality in terms of expenditure per capita, expenditure for food per capita and expenditure for non-food per capita using four indicators: Gini index, Theil index, Ratio P90/P10 and Decile Dispersion Ratio. Interestingly, we find that – despite the increasing inequality at the national level – the spatial variation of inequality across provinces is persistently decreasing over time. In contrast, variation in income inequality across Indonesia’s islands is increasing over the last decade – suggesting the existence of increasing spatial disparities along a geographical dimension. From the individual perspective, we find that the rapidly increasing interpersonal inequality in Indonesia is mainly driven by strong income growth at the top of the income distribution – and this is true for all provinces and islands. In other words, we find that the rich, rather than the middle class, gained most from globalization and decentralization processes in Indonesia during the observed period of 1987 to 2015. The middle class grew only relative fast during 2005–2015, while the poor are persistently left behind in terms of income growth. We also find that the highest income classes in the relative poor provinces experienced a substantial higher income growth than the lowest income classes in the relative rich provinces. Together, these trends lead to the conclusion that on average the relative poor provinces catch up to the relative rich provinces, while at the same time interpersonal inequality in Indonesia is rising at all levels of spatial aggregation – with individual income growth being strongly positively correlated to individual income level.

1315 SHARING ECONOMY, HOUSING RIGHTS AND SUSTAINABLE DEVELOPMENT

ABSTRACT

Sharing economy platforms like AirBnB have caused an enormous shift in tourist habits as well as in housing prices in some cities. The impact of house sharing in housing rights because of the rise of rental prices in tourist places has moved several cities to find solutions that try to balance the potential of peer-to-peer economy with urban planning to preserve housing rights, urban mobility and social integration. The technological and transnational dimension of sharing platforms call for new approaches to urban planning capable for dealing with the issues that arise. Also differences in the type of offers (individual or multiple owners, occasional or professional operators...) require different approaches. Some cities are starting to study and plan how to deal with gentrification and housing rights, specially those of vulnerable groups (elderly, low income...), facing with an exponential increase of houses used for tourist purposes that change neighbourhoods and economic activities expelling traditional dwellers. This paper tries to identify the problems for urban planning that come from house sharing and how legal changes have to be put in place in order to balance the different stakeholders. Cities are looking for innovative solutions to the challenging triple-crisis of economy, social division, and environment and an insight in the benefits and difficulties of some of the proposed measures will be given (registration, limitation in the number/days of offer, taxing...).

1166 INTEGRATING RURAL WOMEN THROUGH SELF HELP GROUPS IN ASSAM

Tejaswita Duarah

Research Scholar, Centre for the Study of Regional Development, Jawaharlal Nehru University, New Delhi-110067

ABSTRACT

Self Help Groups have emerged as a significant collective microfinance unit of economic production in rural areas. It has been seen as a common source of economic stability for rural women across the state of Assam, India. With changing socio-economic systems women tend to lose their traditional economic role in the agriculture and other handicrafts and handloom production in the neo-liberal market. An effort has been created for collective assistance to promote traditional and rural based products to balance economic prosperity and environmental sustainability. Through the initiatives of the state, micro-financing through self help groups has gained a momentum in securing the lives of rural women and integrating her into the contemporary economic system. The paper is an attempt to observe micro-financing rural economic activities of women through self help groups and its effects in creating better socio-economic and political conditions for rural women. The study examines the access to the financial benefits provided by the state through self help groups by women and its utilization on economic liabilities and assets. It surveys the engagement of rural women into various activities like handloom and food processing and acquiring material assets for living. The study observes the process of rural women creating her identity as an economic asset and also a political significance to the society.

Key words: Self help groups, rural women, microfinance, economic stability, identity, integration, liabilities and assets.

INTRODUCTION

Rural women in Assam have been traditionally engaged in both household activities and agricultural activities (Saikia, Gogoi & Lekharu, 1986, pp.12-13). These include domestic chores like cooking, cleaning and washing to working in the fields. The productive significance of an Assamese rural woman is seen in both non-economic (domestic chores) and economic activities, which not only comprise of being an agricultural labour but in various other activities like weaving, sericulture, food processing, liquor processing and other allied agricultural and animal husbandry activities. However, there has been a transformation in these roles played by the rural women with changes in the market systems, including education levels, socio-economic levels and technology (Baruah, 1992, pp.22). There is constant effort hence to provide a platform to enhance traditional rural activities and empower rural women into the contemporary economic system.

The role of Self Help Group (SHG) comes here as a boost to the rural economy empowering especially women through the help of micro-financing or a small credit based system. This concept of small credit to tackle poverty especially in the rural areas was first introduced by Prof. Md. Yunus who pioneered the first Grameen Bank in Bangladesh. The effect of SHGs on women has been seen throughout Bangladesh in examples like the Jobra Mahila Samity, a cooperative effort through which banks provided reasonable credit and further providing assistance in organizational framework for collective action and self realization (Chowdhury, 1989, pp.147). Another such credit distribution was seen in Jamalpur Women’s Programme which gave small credits and necessary training to the disadvantaged landless women to become economically self-reliant and socially stable (Chowdhury, 1989, pp.98). A similar structure of microfinance was adopted in India too to reduce poverty and to mobilize women to achieve self reliance. In the case of Assam this movement observed a trace in the group approaches like the Development of Women and Children in Rural Areas (DWCRA), Integrated Rural Development Programme (IRDP) and most importantly the initiatives of National Bank for Rural Development (Devi & Upadhyay, 2008, pp.825). NABARD was set up as a development bank under the Md. Yunus Model to tackle rural poverty (Shandilya and Kumar, 2012, pp.22).

Micro-financing in India had a variety of government and non government organizations practicing micro finance schemes and in spite of all failures and success stories the main objective of empowering the poor and mainstream into development has grown significantly (Shandilya and Kumar, 2012, pp.5). The NABARD was formed to refinance rural financial institutions for promoting rural economic activities and in 1992 it further launched the active partnership of SHG-Bank Linkage Programme with the help of RBI (Chauhan, 2004, pp.14). This saw major rise in number of SHGs nationwide (Selvam, 2005, pp.113). Although, the SHG-Bank linkage models are broadly of three types, i.e. NGO based SHG model, the Bank-NGO based SHG model and the Bank based SHG model (Chauhan, 2004, pp.34); the study area comprised only of the third category.

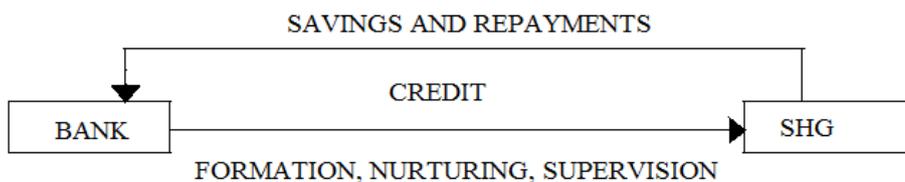

Figure 1: Bank based SHG model (Chauhan, 2004, pp.34)

A self help group has been defined as a small and informal association of poor having preferably similar socio-economic back ground and who have come together to realize some common goals based on principles of self help and collective responsibility. There are two major roles of a SHG. These are firstly to establish credit worthiness by poor especially women and secondly the ability and potential to empower the women members (Shandilya and Kumar, 2012, pp.39-40).

OBJECTIVES OF THE STUDY

To analyze the existing poverty through the socio-economic conditions of the women in Self Help Groups (SHGs) and their consequent pattern in the credit and repayment of loans through micro-finance.

To observe the growth in empowerment of women through economic stability and further promoting social and political participation.

STUDY AREA

The study was undertaken in two villages namely Duliajan village and Joypur village located in Dibrugarh district of Assam, India. These villages were chosen due to their locational value of Duliajan village to be in the periphery of Duliajan OIL Town, a growing industrial area and Joypur village in Naharkatiya which is 13kms away from Duliajan. Both the villages are 42kms and 58kms from Dibrugarh town which is the second largest town in Assam.

DEMOGRAPHIC INDICATORS	DULIAJAN	JOYPUR
Total Population	2529	3833
Sex Ratio	964	932
Total Literacy	86.11%	89.24%
Female Literacy	81.39%	84.85%
Female Work Participation	13.59%	16.03%

Figure 2: Demographic Indicators of Duliajan village and Joypur Village (Census, 2011).

METHODOLOGY

A purposive random sampling was used to collect responses from members of women SHGs in both the villages. The study sample targeted all rural women who were an active member of any SHG for a period of at least 5 years. In Duliajan village from a total of 10 SHGs, catering to 148 women a total sample of 75 was collected. Whereas, in Joypur village out of a total of 7 SHGs, catering to 83 women a total sample of 42 was collected. Thus, the sample had a total of 117 responses.

The study was collected through a prepared questionnaire which was held on the months of Dec’17 to Jan’18. The responses were collected from door to door and at monthly meetings all SHGs of the village which was held on the 8th of Jan in Duliajan village and 16th of Jan in Joypur village. Attending weekly gatherings and conducting participatory rural appraisal (PRA) on Wednesdays and Saturdays gave more insights on the daily activities of the groups.

ANALYSIS AND FINDINGS

Socio-Economic Profile of women in SHGs

The study observed a difference in socio-economic conditions prevailing in Duliajan and Joypur villages, which was perceived by taking selective indicators of housing (building materials), land owned (in husband’s name), monthly income of the respondent, monthly income of the family, level of education and health status in the past one month. These indicators were selected and modified from the study taken by Frances Sinha’s poverty assessment (Sinha, 2009, pp.9). The poverty assessment from these indicators showed that women under SHGs in Joypur village lived in more poverty than Duliajan village. There was significantly higher percentage of women living in very poor, poor and marginal groups in Joypur, compared to Duliajan. However, Duliajan had more women in the group of “not poor”.

POVERTY CONDITIONS	1. VERY POOR		2. POOR		3. MARGINAL		4. NOT POOR	
	DULIAJAN	JOYPUR	DULIAJAN	JOYPUR	DULIAJAN	JOYPUR	DULIAJAN	JOYPUR
HOUSING	Mud walls, mud floors, thatched roof		Mud wall, concrete floor, tin roof		Semi pucca wall, concrete floor, tin roof.		Pucca House	
	14 (18.67%)	8 (19.05%)	6 (8%)	7 (16.67%)	10 (13.33%)	12 (28.57%)	45 (60%)	15 (35.71%)
LAND (husband owned)	Landless		1-2 bigha		2-5 bigha		More than 5 bigha	
	8 (10.67%)	10 (23.81%)	21 (28%)	21 (50%)	12 (16%)	8 (19.05%)	34 (45.33%)	3 (7.14%)
SELF INCOME (Rs per month)	No Income Or upto 500		500- 1000		1000-5000		more than 5000	
	37 (49.33%)	10 (23.81%)	22 (29.33%)	15 (35.71%)	14 (18.67%)	17 (40.48%)	2 (2.67%)	0 (0%)
FAMILY INCOME (Rs per month)	Less than 5000		5000-10000		10000-20000		more than 20000	
	6 (8%)	9 (21.43%)	15 (20%)	12 (28.57%)	26 (34.67)	16 (38.18%)	28 (37.33%)	5 (11.90%)

HEALTH (last one month)	Any birth diformity or disorder		More than 7 days illness or fever		1-2 days Chronic fever, flu, etc		No illness	
	0 (0%)	0 (0%)	9 (12%)	12 (28.57%)	20 (26.67%)	12 (28.57%)	45 (61.33%)	18 (42.86%)

Figure 3: Poverty conditions of women in SHGs of Duliajan village and Joypur village by their socio-economic profile.

The housing conditions of Duliajan village and Joypur village was observed by the building materials of the walls, floors and the roof. Although, this may not directly reflect on the poverty conditions of the woman, but it gives an idea of the family’s living infrastructure. It was observed that household usually tend to concretize their floors first and then proceed to build concrete walls, thus the classification of poor and marginal housing conditions have been categorize accordingly. Thus, it was seen that houses in Dualiajan had a slightly skewed difference of pucca houses (60 per cent) and poor mud houses (18.67 per cent). This was however not the case in Joypur village as the houses fairly distributed among the categories , with only 35.75 per cent with pucca houses, 28.57 per cent in marginal semi pucca houses having concrete floors and 19.05 per cent in mud houses. The housing condition in Joypur village was more homogeneous than the skewed differences in Duliajan village, where many had build pucca houses. This difference can also be observed in case of land

ownership. But, since no women had land in their own name, the study took the amount of land owned by her husband or her father. Land ownership in a village is an important economic condition as villages mostly indulge in agriculture. A similar skewness was observed in Duliajan village indicating better economic conditions of the people here. Landlessness was observed to be 23.81 per cent in Joypur and households here concentrated at 28 per cent having 1-2 bighas of land. While, households in Duliajan face 10.67 per cent landlessness there is a striking concentration of 45.33 per cent which owned more than 5 bighas.

The economic stand of these household could be measured by the income of the family and also the individual's income which shows her own economic significance in the household. Interestingly, women in Duliajan were majorly (49.33 per cent) not involved in any economic activity, 5000/ per month, but with a mere 2.67 per cent even earning more than Rs5000/ per month. But in case of Joypur women were 40.48 per cent were involved with some kind of activity earning between Rs1000/- Rs5000/ and another 35.75 per cent between Rs500- Rs1000/ per month. However, there was not a single case earning over 5000/ and 23.81 per cent wasn't involved with any economic activity. Nevertheless, it was observed that the same household income varied when it came to family income as a whole. Here, 8 per cent and 21.43 per cent households earned less than Rs 5000/ in Duliajan and Joypur respectively, with 37.33 per cent and 11.9 per cent earning more than 20000/ per month and falling in the non poor category. Though, a significant number of 34.67 per cent and 38.18 per cent households were observed in the marginal category respectively.

Educational level of women in both villages seems to have only a negligible difference in all categories, with a major population of women studying up to secondary level of education. This comprised 50.67 per cent and 57.14 per cent in Duliajan and Joypur respectively. In the rest of the categories of educational level Duliajan fares slightly better results. It was seen that in spite of a very few women completing their higher education, neither of them were illiterate and at least had some kind of primary education. The health conditions of all women surveyed majorly had no illness in the last one month, which are seen to be 61.33 per cent in Duliajan and 42.86 per cent in Joypur. Also, neither case had any kind of birth deformity or disorder. However, the conditions of women in Joypur had a poorer health in comparison in all categories.

Thus, it can be said that socio-economic conditions of women in SHGs of Duliajan village was much better in comparison to Joypur village. Accordingly, a poverty index is calculated from the z-scores of all six indicators the scenario to see these differences more clearly. Here, it shows a high of 30.97 of Duliajan village as not poor, with Joypur village only 5.43. Both the villages have significant and almost equivalent scores in poor and marginal category. Joypur village has its highest of 19.02 in poor category. However, in the category of very poor conditions Duliajan village has a slightly higher score of 6.56 than 5.72 of Joypur village.

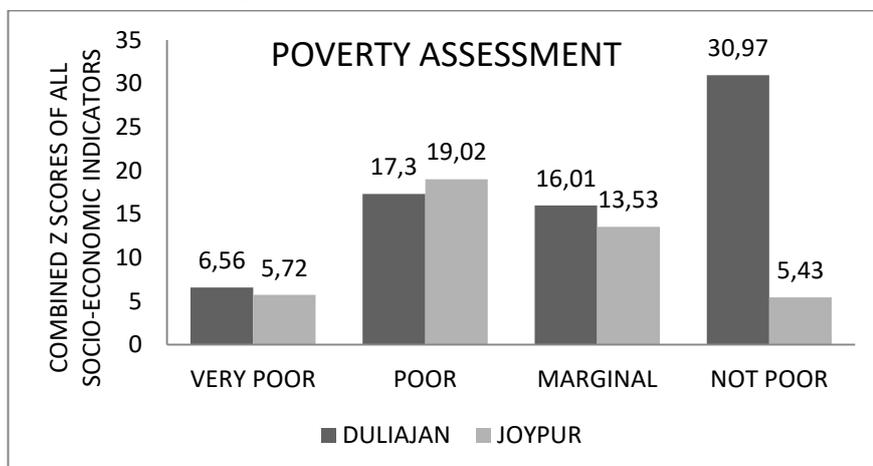

Figure 4: Poverty Assessment of women in SHGs of Duliajan village and Joypur village by calculated z-scores of all socio-economic indicators.

Reasons for credit and Repayment of Loans

The role of SHGs is to forward small amount of credit to needy borrowers, here women members of SHGs. These women form groups of 5 to even 30 members to accumulate some kind of wealth and use to lend to each other. Since, all the SHGs in the study follows the Bank based SHG model, here the SHG themselves conduct regular and orderly meetings where views are represented, decisions are taken for mechanism of financial and social discipline and implementation of the decisions made (Chauhan, 2004, pp.35). This involves the amount of loan, savings and interest of the money dealt among them. In the case of loan repayment there are two ways or stages of the SHG- internal borrowing (within the group members) and external borrowings (loan from banks) (Sinha, 2009, pp.119). External borrowings are often received as micro finance credits through banks under the supervision of NABARD, when the SHG reaches a self sustaining level or point. These borrowings by the SHG women are mostly (95 per cent) repaid on time as per NABARD annual reports (Sinha, 2009, pp.121).

With rise in micro-financing women have been encouraged to take loans in small amount and repay in time with minimum interest values (Premchander, 2003). Hence, all women surveyed during the study had once or the other taken some kind of loan after becoming a member of some SHG. However, this study puts focus on the reasons for taking this

credit, i.e. where is it invested or used. The responses varied vastly across village economic activities, some non-traditional activities and some even for emergency or personal development. The study identifies these reasons for credit into two categories namely investment in assets and investment in liabilities. Credit used for investing in something or some purpose which shall generate income or maximize the credit value to gain profit output may be termed here as assets, while investing in those activities which has no output and may burden the individual under debt maybe considered as liabilities. Nevertheless, not all investment in economic activity or assets may necessarily increase income (Mayoux, 2003, pp.31). Assets included investment in poultry, animal husbandry, buying seeds/ plant saplings for cultivation, buying sewing/weaving products, learning and setting up beauty parlours and also inputs in some kind of trade. Liabilities included repayment of former loans, paying bills, education fees of children, any health crisis, building house, buying household goods and conducting any ceremonies or rituals.

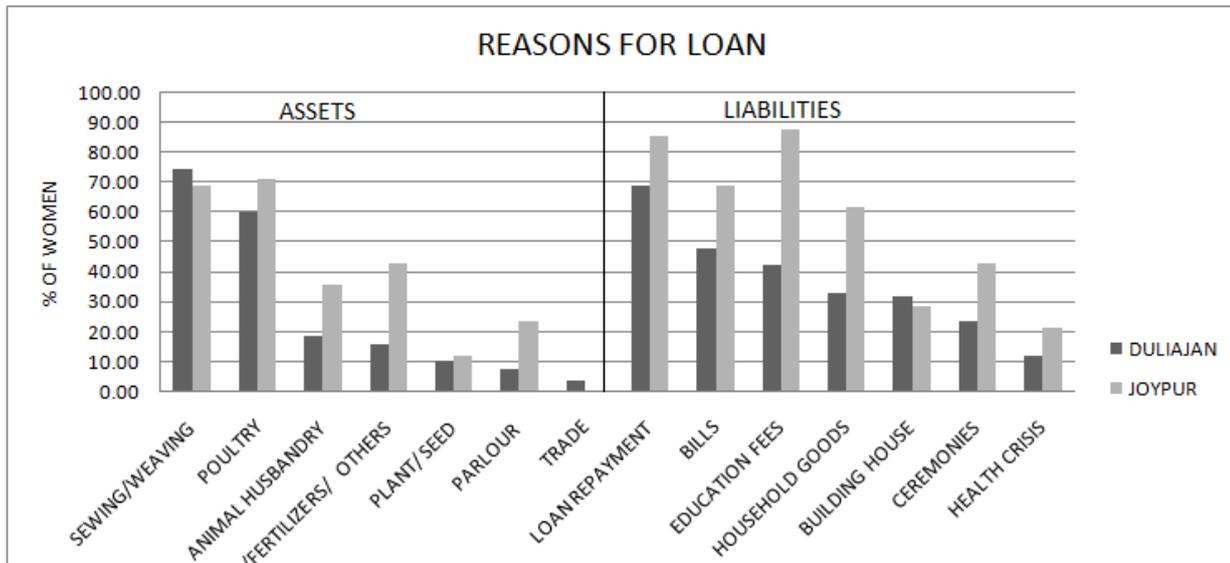

Figure 5: Reasons for Loan taken by women in SHGs of Duliajan village and Joypur village.

It is observed that more number of women especially in Joypur village was using their loan money in liabilities like education fees of children, repaying former loans from bank or other informal sources, electricity and water bills and other daily uses. In Duliajan women were comparatively using less of their loan money in these activities of which repaying loans was the highest and similarly other uses too. However, in case of building houses women here was somewhat utilizing her loan money more than in Joypur village. Nevertheless, in case of asset investment the engagement of women in weaving and sewing, poultry farming and animal husbandry was significantly high in both the villages. More so, women in Joypur village invested more in assets too. As economy here is more traditional and rural based women are significantly engaged in investing in agricultural inputs like pesticides and fertilizers and also animal husbandry than in Duliajan village. However, in case of Duliajan investment was prominent in weaving, which was observed to be more professional and practiced in collective way. Due to the potential urban market for traditional clothing women of the neighboring Duliajan village has managed their weaving activities for commercial gain and enjoy better profits. However, an overall observation shows that loan credited is significantly higher in Joypur, both for utilization in assets and liabilities.

The purpose of credit taken may directly affect the existing poverty level of the women or it can also be a result of the level of poverty she is already in for which she has taken credit from the institution. However, regression values for showing dependence of the amount of loan taken to the income of the family may be positive yet with a little significance. In the case of Duliajan the amount of loan taken by women in last 6 months had a positive relation of 0.35, while in the case of Joypur it had a poorer relation of 0.29.

Credit taken from any institution which can be from SHGs collection or directly through bank (SHG-Bank linkage) must be repaid with minimum interest in some given time which usually ranges from three month to twelve months according to the amount of loan take. These can be paid through installments or whole. Portfolio At Risk (PRA) is the standard measure indicating risk of default (Sinha, 2009, pp.135). The observed PRAs were not more than two month for all the cases. Out of 5 defaulters 2 in Duliajan village had said the delay was caused as their houses were being constructed. These two women were building pucca houses and had a month family income of more than Rs15000/-. Their husbands were employed in the neighboring Oil India Limited. However, the other 6 defaulters including the 3 from Joypur village were unable to pay as they had taken the loans to cover a medical emergency or a pending loan repayment. These women belong to families of agricultural labourers, small farmers and construction labourers. Thus, there are those that willfully default and those that find it difficult to repay due to poverty (Sinha, 2009, pp.121). As most of the respondents agreed to have paid all their loans and some were due and delayed to pay in time, the study put focus on the source of repayments of loans. This way it could observed economic expansion of wealth and reduction of poverty of the respondent.

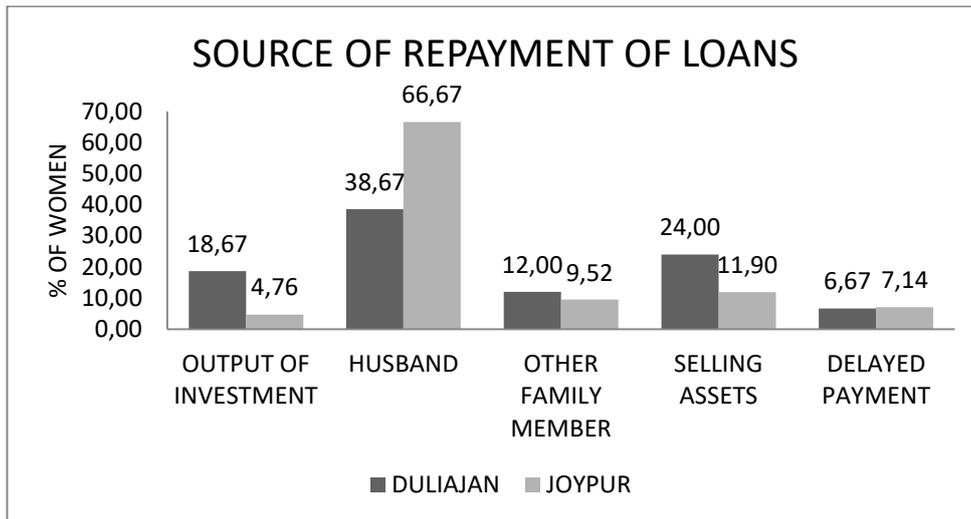

Figure 6: Source of repayment of loans by women in SHGs of Duliajan and Joypur villages.

Source of repayment of loans were identified as repayment from the output of investment, borrowed from husband, borrowed from other family members or relatives and friends, selling assets and the rest had delays in their payment. It was clearly observed that a majority of the women had repaid their loans by borrowing money from their husbands which was 38.67 per cent in Duliajan and a very high of 66.67 per cent women in Joypur. Meanwhile, repayment through output of investment was only 18.67 per cent in Duliajan village and 4.76 per cent in Joypur village. A 24 per cent and 11.9 per cent women from the villages accordingly sold off their acquired assets to pay off the SHG loan.

This suggested that loans taken were not being able to generate wealth among women those had taken loan under SHGs. They had to rely upon their husbands or any other relative or friends for repaying any of these loans. There is a heightened stress among women resulting to turn to assistance from husbands (Kabeer, 2010, pp.223). Retrospective of the earlier finding that many of the women had invested their credit loans to spend on liabilities, it is answerable that money taken as loan is utilized to cover for earlier debts and day to day spending. And at the time of repayment these borrowers rely on others especially husbands to repay their debts. This should further suggest the dominance of the husband upon the wife due to her economic dependence, but observations spoke of a mutual economic understanding between the husband-wife and the economic significance of the women with rest of the family. Loans granted to the women was used to fulfill the current needs of the household which included a vast array of day to day necessities from household goods to paying bills and fees and to contribute in building a house for the family. In many cases where the family income may not be stable or fluctuate due to delay of wages and salary, loans generated through SHGs have kept families surviving even in the worst situations. Thus, wealth flow to run the household is not just brought in by the male head but also the earlier dependent women who were not incurring any income into the family. As a result, there are many families where the male heads have encouraged the women of their household to join SHGs. The women may not be a direct generator of wealth in the family, but through SHGs she has integrated herself to the economy of the contemporary market and elevated her economic significance in both family and society.

Another observation projects those women in collective effort of commercializing their activity here 20 women involved weaving and 10 women selling momos in Duliajan had agreed to have repaying their debts through profit maximization. Therefore, collective efforts were seen to have fared better economic expansion than individual undertakings. Thus, according to Chauhan SHGs in a collaborative effort can be more sustainable and successful than those formed for shorter gains or here individual uses (Chauhan, 2004, pp.25and65).

Empowerment through Self Help Groups

The question of empowerment can be a debatable issue depending on the definition used. Women empowerment is defined as “a bottom-up process of transforming gender power relations, through individuals or groups developing awareness of women’s subordination and building their capacity to challenge it” (Reeves and Baden, 2000, pp.35). As per the Beijing declaration, “women empowerment and their full participation on the basis of equality in all spheres of society, including participation in the decision making process and access to power are fundamental for the achievement of equality, development and peace”. It is seen that empowering rural women is frequently generalized with poverty alleviation, while gender issues are overlooked as mere cultural (Mayoux, 2003, pp.13-14). Accessing micro-finance by rural women contributes to the household by adopting an economic activity or by becoming a financial channel for her household, which signifies her increased role in decision making.

However, empowerment in patriarchal rural circumstances would mean women hardly have any control over deciding and directing the loans she obtains and its purpose, which only enhance individual economic position over those dictated by familial requirements. The goal of SHGs in enhancing credit access and savings among rural women have not necessarily resulted in wealth expansion, but have provided her to take up day to day household economic activities and subsequently economic significance in the household. At times of need her credit money acts as a current monetary backup to tackle daily financial crisis. Thus, repayment by her husband’s or other family member’s money is a circulation finance within the household. Even though, micro-financing through SHGs have mainly taken care of the practical need

and not strategic needs; women have gain a significant productive status within the household but not necessarily empowerment (Shandilya and Kumar, 2012, pp.194). Moreover, increased income not necessarily empower women but may simply add more hours of work to her already burdensome domestic work and also have no control over her earnings (Dixon-Mueller, 2013, pp.5). Thus, the status of women is elusive in nature and can be defined as women’s access and control over material resources of food, income, land, wealth and also social resources like knowledge, power and prestige (Dixon-Mueller, 2013, pp.194) within family and society.

The study asked the following question to get a brief idea of the empowerment that women in SHGs had in the two villages. The following questions were answered in Yes or No.

- i. Does your husband or any other family member give you suggestion or decide upon the usage of your loan credited?
- ii. Have you taken loan on the say of your husband or any other family member?
- iii. Does your family encourage your involvement in SHG?
- iv. Does your family give you time for attending SHG meetings and activities?
- v. Does your family give you time for attending any training programmes?
- vi. Do you sell your product by yourself?
- vii. Have you/ do you plan to take part in political activities- like village panchayats and women’s organizations?
- viii. Does your family support your involvement in politics?

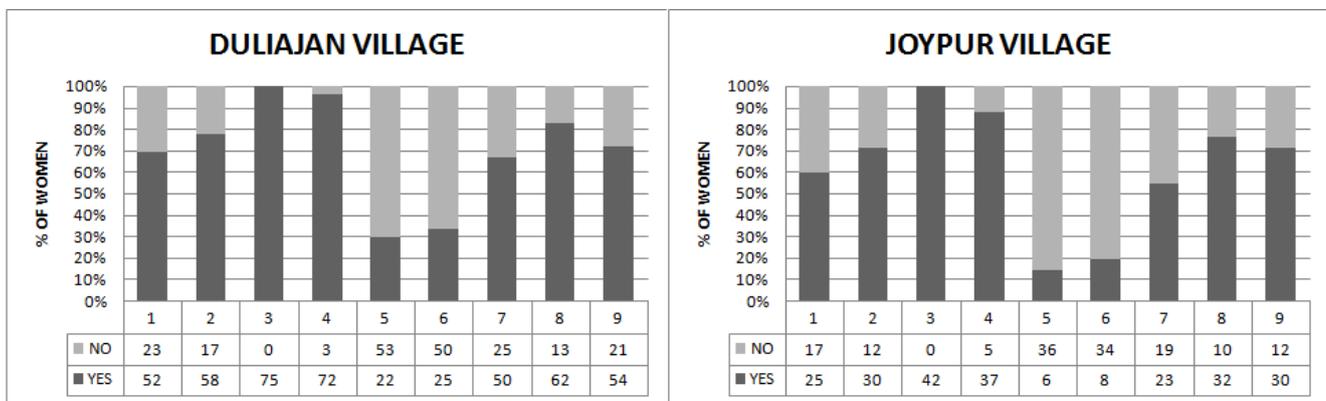

Figure 7: Responses to empowerment by women in SHGs in Duliajan village and Joypur village.

Both villages show a similar pattern overall with marginal differences. 69.33 per cent and 59.52 per cent of women in Duliajan village and Joypur village take opinion of their husbands and other family member for the purpose of utilization of loans given to her and more over 77.33 per cent and 71.43 per cent women in each of these villages are insisted to take loans from SHGs. They are persuaded by other members of the family to access these benefits given through SHGs. So is the case that everyone of the respondents were encouraged by their family members to be actively involved in the activities of the SHG like weekly meetings, gatherings, etc. and a major of 96 per cent and 88 per cent families of the women had given the time to participate in them. However, when asked about the time given by the family to be involved in training activities, they were considered unnecessary and time consuming. In Duliajan village only 29.33 per cent had allowed their women to attend training programmes, including 33.3 per cent had some form of training. This was poorer in Joypur village with only 14.29 per cent women allowed for training programmes including just 19 per cent with some training. Further, it is observed that all women may not be involved in selling their own produce that she has generated by SHG activities. The sale of products like milk, eggs, meat or cloth involves taking them to market or negotiating with buyers. Even though, a 66.67 per cent in Duliajan and 54.76 per cent women in Joypur village have been selling their own product, but the rest still relies on the male members of the family to do the negotiations especially in activities like selling woven clothes and seasonal food processing. The role of SHGs is not just to make a woman economically and socially stable but further promotes political status. Thus, a good number of women- 82.6 per cent and 76.19 per cent in Duliajan and Joypur village accordingly have shown some interest or actively participating in political activities of the village panchayats or other women’s organizations. However, only 72 per cent and 71.43 per cent women in these villages have the support of their family members to be involved in any kind of political activities.

According to Amartya Sen “Women are less likely to secure favourable outcomes for themselves in household decision making process. They feel that their long term security lies in subordinating their well being to that of male authority figures” (Shandilya and Kumar, 2012, pp.128). The observations show that women have been greatly encouraged by members of her household to be involved in SHG activities. But autonomy of the woman may not prevail as the access and purpose of utilization of the loans are often decided or influenced by the male members of the family, especially the husband. The support to women in SHGs may only be for financial gains for current monetary help for household or expand wealth which is too controlled not by the women but by her husband/ male family member. This is evident by the sale of produce by them and as found earlier in the utilization of credit in household activities and liabilities. Mayoux in her study too observes that even those who have profited out of their invested activity were not necessarily actual users of loans accessed in their names (Selvam, 2005, pp.128). If encouraging women in SHG was done for empowering women’s

capabilities than they would have also supported and promoted some form of training programmes for more efficiency. Studies explain that entrepreneurial skills achieved from skill training and counseling input promotes progress and success (Chauhan, 2004, pp.10). However, the study area showed poor interests in any such kind of training for women.

Thus, empowering women in a patriarchal society is of greater challenge than simply giving financial aids. In the process of change towards women empowerment there is a need for participatory process of not just women but the support of men too in ensuring flexibility for women's aspirations and loosen the constraints of contextual and organizational processes (Mayoux, 2005). The first priority must now be more on to bring women out of the vicious cycle of poverty or more specifically put forward by Mona Khare as "vicious cycle of economic status"(Shandilya and Kumar, 2012, pp.217) of Low income generation to Low savings to Low Investment Capacity to again Low income generation. SHGs have been in a way helping women to be engaged in daily financial struggles, but through proper management, training and education of both men and women the goal of empowering women shall be fulfilled.

CONCLUSION

Rural women have always been a part of the village economy, but recognizing and valuing their work in economic terms has become difficult in the contemporary market system. SHGs have now attempted to capture these activities and channelize them into economic strength of these women and integrating into the system as well. This is through micro-financing with other self managerial ability to be an independent as well as a collective economic unit. However, there are various disparities formed in this process by the existing economic status within these women and differential pattern in integration is thus observed.

The poverty assessment of the two villages shows that poverty level of Joypur village was higher than Duliajan village. Duliajan village which lie in the periphery of an industrial town gets the benefits of urbanization, with many of residents employed in the town. There is a rapid construction of houses and a flourishing market for home produce. However, there is an observation of increasing disparity in poverty levels with many women either falling in the "not poor" category and others in "very poor" category. This is not in case of Joypur village though, as women have been more or less equally distributed in the three poor categories and very few only being "not poor". Women in SHGs here have seen a boost in weaving in a collective and commercial arrangement. Weaving is also popular among women in Joypur village, but have not been managed efficiently to gain proper returns. This results from the poor training experience achieved by the SHG women as these may hamper their time for other household chores. Even though women have been encouraged to be involved in SHGs they are not provided the time needed for professional caring out of activities. Training opportunity gives women a secondary chance to complete their education or knowledge (Kabeer, 2010, pp.78). Those few women who have organized themselves and are caring out professional weaving have received training to do so and they basically come from "not poor" category of Duliajan.

Furthermore, loan utilization in assets and liabilities also decides growth of wealth. As a majority of women use their loan money in household financial necessities like education fees of children, bills and earlier loan repayments, the loaned money doesn't grow with profit. Although, women tend to invest loaned money into assets and profit expansion activities, the money used for liabilities exceeds the wealth growth in most cases. And these cases often live in the vicious cycle of poverty. With no profit, repayment of loans are repaid by husband's/ other family member's money or by selling assets. Moreover, many a times these loans are taken in the suggestion of the husband/ other. The flexibility in autonomy of the woman is lost in control over loan and its repayment. Yet still empowerment can be accounted in the emergence of the woman being a significant mode to access finance to run the household. Even if so she is not fully empowered to have total autonomy, she is an economic asset to the household. There is first a need to bring women out of the vicious cycle of poverty to enable her to become economically viable.

Integrating rural women would necessitate her to establish her importance in her household and then in the market. SHGs have enabled women to provide the current money to afford the emergency needs or investing in small scale economic activities. They are assisted by their male members of the family for overall household gains, but the need to expand for profit would need training and management. Due to lack of time for such training programmes women usually lack the skill to carry out these activities. Household support only for monetary gains hampers women's empowerment to access these skills. She is burdened by chores and with no support these economic activities would only add to her work hours. Thus, integrating women through SHGs would require the cooperation of both men and women. Micro-financing women through SHGs is gradual but effective process, as there are different women in different economic categories and each need to be addressed separately to nurture them for growth and empowerment.

1369 URBANIZATION AND FEMALE WORKFORCE PARTICIPATION RELATIONSHIPS IN INDIA

ABSTRACT

Introduction: The process of urbanization can be termed as the process of transforming agricultural economy into non-agricultural economy as well as transformation of rural cultural setup to urban cultural setup. This transformation effects different group of people differently. Traditionally females are backward in terms of social freedom and employment. As economic freedom and social freedom are deeply interconnected thus participation of females in economic activities is important for their social status. **Need for the study:** In India, studies analysing the census data conclude that female workforce participation in urban areas is lower than in rural areas but theoretically it should be opposite one. The studies which correlates the urbanization rates to female work participation rates lack in two more ways: one, they do not show the variability of female work participation rates given the same amount of urbanization at different regions and secondly, what are the different variables that explain this variability. Our study will try to fill up this knowledge gap. One aim of the study is to develop new statistical techniques of measurements to analysis such datasets. The study combines a spatial dimension to the demographic analysis by showing spatial distributions of the facts. **Objectives:** Three objectives have been chosen and they are; first, to study the correlation between urbanization and female workforce participation at different states; second, to identify the impacts of some factors (regarding female demographic characteristics) which may have played some role on the extent of female participation in urban workforce thirdly, the spatial distribution of the above mentioned factors. **Data base:** The study has been done at national level taking district as study unit. Districts have been taken for the study based on the same amount of increase in urbanization from census 2001 to census 2011 (within 99% confidence interval). **Methodology:** In the first stage, Correlations between temporal increase in urbanization and temporal increase in female workforce participation for each study unit have been calculated. This shows: 1% increase in urbanization in a particular district is associated with how much amount of change in female workforce participation within that district. In the second stage, it was tried to analyse the different levels of change in female workforce participation rates (given the same amount of change in urbanization rate) with the help of four factors namely, sex ratio (a crude indicator of female status in society), female literacy rate, marital status and fertility rate. Correlations will be calculated between female work participation rate on the one hand and sex ratio, female literacy rate, marital status and fertility rate on the other hand respectively. In the third stage, Spatial distribution of all the above results was plotted on maps to observe spatial pattern of distribution. **Findings:** The conclusion is that the levels of female work participation increase with the same amount of urbanisation increase can be explained by other female demographic variables. But the impacts of different demographic variables on work participation rate given the same amount of urbanization are not same all over India.

ABSTRACT

To map and augment the liveability of urban spaces, different sets of judgment parameters have been identified and applied since the history of urban planning initiated. Since 5th century BCE, applied by Hippodamus, diverse pool of elements have been identified to augment the liveability of urban spaces. These spaces have been examined, organized and reorganized in the works of F.L Wright, Ebenezer Howard, Fredrick Olmsted, and in the early 20th century, all the ideas culminated in the Work-Folk-Place triad of Sir Patrick Geddes. But till date, very few researches have been done in tapping Indian context of urbanization and liveability. India, as the fastest urbanizing country, need to have identified parameters of judgment, corresponding to the urban context of developing countries. Thus, contextualizing recipes of happiness as per the urban scenarios of Indian cities can help to tap the current scenarios and also enables to come up with the prospects to augment urban spaces. Moderation of 6 recipes of happiness, namely, **Joy** can be explained as the basic ability to survive delightfully, **Health** as the ability to live based on sustained survival, **Freedom** as the ability to exercise self-autonomy and self-respect. As the cumulative result of the first three elements can help to achieve the fourth parameter **Resilience** which denotes the ability to reach a higher threshold of self-security and to move further, thus, paved the way for implementation of the fifth element called **Equity**, which denotes the ability of the society itself to realize and co-share self-esteem. Securing all these five elements leads to the final stage of social connection, which promotes to establish transparent networking and enhanced **social connectivity**. The first three elements Joy, Health, and Freedom act as a tool to secure the basics of survival and advances towards securing liveability. Finally, a livable resilient urban space can march towards enhancing livelihood through the rhythm of equity and transparent networking.

Key words: Liveability, Parameters of Judgement, Urban Happiness, Urban space

1 INTRODUCTION

21st century witnesses the wave of urbanization in developing countries of the third world. Rapidly urbanizing countries like India witnesses spreading of the cities in the form of conurbation, organic and hardly planned development. Gradually, protruding city sphere encroaches lands towards the village areas. Expansion of the city sphere attracts human resources migrating towards the CBD and increasing population pressure on urban space became the reason behind the haphazard growth of the city or vice-versa. Discrepancies in managing the growth of the urban sphere further acts to hinder the development of the emerging societies. These rapidly emerging urban areas receives minimal attention to its physical and social infrastructure and also in maintaining the livelihood. In developing countries like India a very brief study has been done on maintaining the liveability of the chosen city sphere that reflects directly on the emerging urban spaces.

Thus to tap the liveability conditions of these rapidly expanding cities, this paper revisits different concepts of urban planners elucidated and sieved through the urban scenario of India. The exploration of ideas, started from the grid city planning of Greek city Miletus by Hippodamus, through various proliferations like the ideologies of 'form follows functionality' of F.L. Wright, concept of 'Garden city' of Ebenzer Howard, Frederick Olmsted's 'Ecosystem planning' and all these ideas matures in the hands of Sir Patrick Geddes's 'Work-Folk-Place' triad. Finally, in case of judging contemporary urban spaces and the liveability parameters of rapidly growing and transforming cities, 6 principles of urban happiness by Charles Montgomery has been moderated as per the context of Indian cities. Hence, this paper will evaluate the existing urban planning concepts and parameters and therefore moderated the 6 recipes of happiness to best fit to explore the liveability conditions of Indian cities.

2 LITERATURE REVIEW (CONCEPT OF LIVEABILITY AND URBAN SPACE THROUGH THE AGES)

In literature review, planning and mapping for liveability concepts are revisited and elucidated as per the contemporary context. To reach the ideology of recipes of urban happiness, varied earlier approaches are probed into depth to find the solution for the contemporary urban spaces. Since history of urban dwelling and planning has developed, western countries shows their inclination towards approaching their space in a more scientific and organized manner. Managing of urban space in order to optimize locational facilities like solar power, wind power, optimization of connectivity as per the best purview of geo-terrestrial positions put forth for implementation.

2.1 Hippodamus (Greece)

The very first instance of urban planning in order to secure the liveability and happiness of the citizens found in the city Greece.

Hippodamus arranged the buildings and the streets of Miletus around 450 BC such that the winds from the mountains and the sea close to Miletus could flow optimal through the city and provide a cooling during the hot summer (refer figure 1). Hippodamus first applied the grid plan which he had developed on inspiration from geometrically designed settlements, and that later many cities were laid out according to this plan. Miletus, is a fine example of the grid plan, comprises houses on blocks created by streets and side streets crossing at right angles, with public buildings in the city center, This plan retained in the Hellenistic period, however in the Roman period it began to deteriorate gradually and inevitably (Lahanas, 2002).

Figure 1. Grid plan of the city Miletus conceptualized by Hippodamus

2.2 F.L Wright

Initiated in 450 BCE, urban planning has matured in pre-modern and modern period in the ideologies of Frank Lloyd Wright, Fredrick Olmsted, and Ebenezer Howard. All these ideas promote the relationship between urban spaces, man and nature has reached its zenith in the ideas of Patrick Geddes. Concepts of nature into design and considering man nature and their economic activity in nurturing urban space design was addressed by Geddes. F.L Wright's idea of sustainable urban design has initiated the idea of incorporating nature into urban design.

F.L. Wright's concept of sustainable design starts with revisiting the idea or the philosophy of Organic Architecture, which maintains that 'the building must develop out of its surroundings and blends well in the environment.' The philosophy emerges from Sullivan's believe 'form follows function'. He tried to integrate space into a unified whole (Jain, 2012). He believed that, – association with nature aided to personal, spiritual and even physical well-being. Described as having an intuitive understanding of social and human needs; designed to human scale. He put forth nine principles of architectural design (New Architecture: Principles) for sustainability and livelihood that consists of nature, organism, forms and functionality, beauty, tradition, ornamentation spirit etc.

Nature is the first component towards building a happy urban space. Here, nature not only means –landscape clouds, trees, storms, the terrain and animal life, but refers to their nature as to the nature of materials or the –nature of a plan, a sentiment, or a tool. A man or anything concerning him, from within (Kimberly Elman).

Organic refers to entity, integrated to the natural inlay of the space itself and thus entity reflects through organic components indigenous to the space Organism further promotes the forms to follow functions to make the space pulsating and dynamic.

The component **beauty**, refers to a quality. Organic architecture sees actuality as the intrinsic romance of human creation or sees essential romance as actual in creation. So romance is the new reality. Creativity divines this.

Different trajectories of tradition proceed to retain a sense of socio-cultural continuity. It bears the creative capacity as tradition is derivative of the first and original style.

Ornament as an integral element of architecture efflorescence of a tree or plant is to its structure. It binds the emotionality and if ornament is well-conceived the character of structure can be revealed and enhanced.

Combination of all the above elements invokes spirit to the concrete. Spirit is used in reference to the inner not the outer substance. Hence, created lively, pulsating, acceptable and sustainable spaces.

2.3 Ebenezer Howard

Ebenezer Howard came up with the idea of Garden cities in 19th century London (and other cities) which bears the marks of industrialization, and the cities were exerting massive forces on the labour markets of the time. Massive immigration from the countryside to the cities was taking place with London compared to "a tumor, an elephantiasis sucking into a

gorged system[s] half the life and blood and the bone of the rural districts" (Lord Rosebery). Thus, Howard...sought "how best to provide the proper antidote against the greatest danger of modern existence" (St. James's Gazette, 1892).

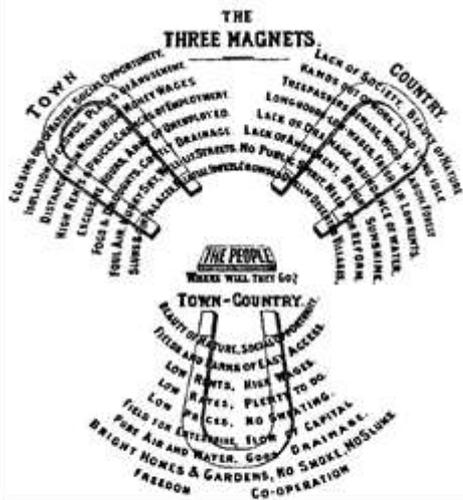

Figure 2. Concept of three magnets Town, Country, and town-country of Howard

His idea of The Three Magnets compares the 'town and country magnets' as shown in figure 2, but decided that neither were suitable attractors for his utopian vision. Instead he believed that "Human society and the beauty of nature are meant to be enjoyed together" – his solution "the two magnets must be made one."

He believed that "Human society and the beauty of nature are meant to be enjoyed together" – his solution "the two magnets must be made one." His idea of de-centralization promotes the principle of "always preserving a belt of country". Hence a city has reached capacity a new one must be founded outside the agricultural belt. The off-shoot city would grow organically, a ward at a time. Eventually there a central city (of perhaps 58,000 inhabitants) would be surrounded by a number of smaller off-shoot cities, connected by railroad and canal infrastructure.

2.4 Fredrick Olmsted

On the other, to illustrate the points Olmsted's belief, three points can be mentioned, namely,

- A. Contemporary green infrastructure theory and practice: ecosystem services and human well-being;
- B. Environmental restoration
- C. Comprehensive planning.

Identified by the President's Council on Sustainable Development as one of the five strategic areas providing a comprehensive approach to sustainable community development, green infrastructure encompasses both natural and engineered green space across spatial scales (Dunn, 2010)

Sustainable urban space design demands green infrastructure encompassing both natural and engineered green space, resulting in "an interconnected network of natural areas and other open spaces that conserves natural ecosystem values and functions, sustains clean air and water, and provides a wide array of benefits to people and wildlife . . . in short, our natural life-support system." The idea of green infrastructure networks are natural, social, cultural elements that juxtaposed to ensure the comprehensive ecosystem services, which also ensures support, regulation, and cultural benefits to people.

2.5 Patrick Geddes

Patrick Geddes promotes the ideology of combining work, folk and place (refer figure 3) to assure successful integration of man, nature and ways and means of their livelihood closely knitted to that particular space. Patrick Geddes explained an organism's relationship to its environment as follows:

"The environment acts, through function, upon the organism and conversely the organism acts, through function, upon the environment." (Cities in Evolution, 1915). In human terms this can be understood as a place acting through climatic and geographic processes upon people and thus shaping them. At the same time people act, through economic processes such as farming and construction, on a place and thus shape it. Thus both place and folk are linked and through work are in constant transition. He adopted Spencer's theory that the concept of biological evolution could be applied to explain the evolution of society, and drew on Le Play's analysis of the key units of society as constituting "Lieu, Travail, Famille" ("Place, Work, Family"), but changed the last from "family" to "folk". In this theory, the family is viewed as the central "biological unit of human society" from which all else develops.

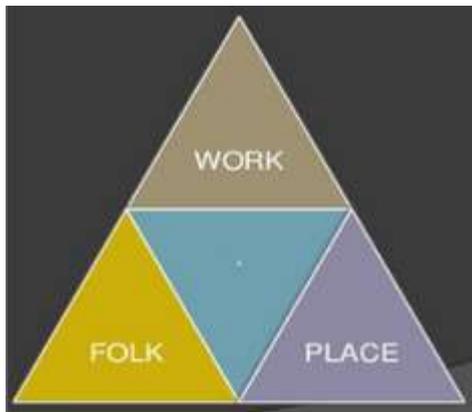

Figure 3. Work-Folk-Place triad of Patrick Geddes

According to Geddes, it is from “*stable, healthy homes*” providing the necessary conditions for mental and moral development that come beautiful and healthy children who are able “*to fully participate in life*”. Assuring the presence of all the three elements promotes space a plot to synthesize human aspirations, his activities to maintain livelihood by retaining the originality of the space.

3 LIVEABILITY AND URBAN SPACE DESIGN IN DEVELOPING COUNTRIES

Considering all the philosophical notions, proliferated and implemented to some extent to make a space better for the stakeholders and to enhance the liveability of urban space mostly done considering the context of the developed countries. To deal with the rapid urbanization of the third world developing countries like India, the present imageability, background and regulations needs to be studied in light of their socio-cultural and economic set-up. Only a proper involvement with the current scenario will enable to moderate the ideas of urban planners to mitigate urban dichotomies.

To cope with the growing urban issues The Government of India along with the various State and Local Governments is implementing several flagship Urban Missions. An overarching goal of the various missions and schemes is to make Indian cities more ‘Liveable’. As can be seen in figure 4 that the Ministry of Urban Development (MoUD) has developed a set of ‘Liveability Standards in Cities’ to generate a Liveability Index and rate cities. Figure 4 shows the index where liveability standards are bifurcated into four pillars, namely, Institutional, Social, Economic and Physical, which shares the weightage of 25%, 25%, 5% and 45% accordingly.

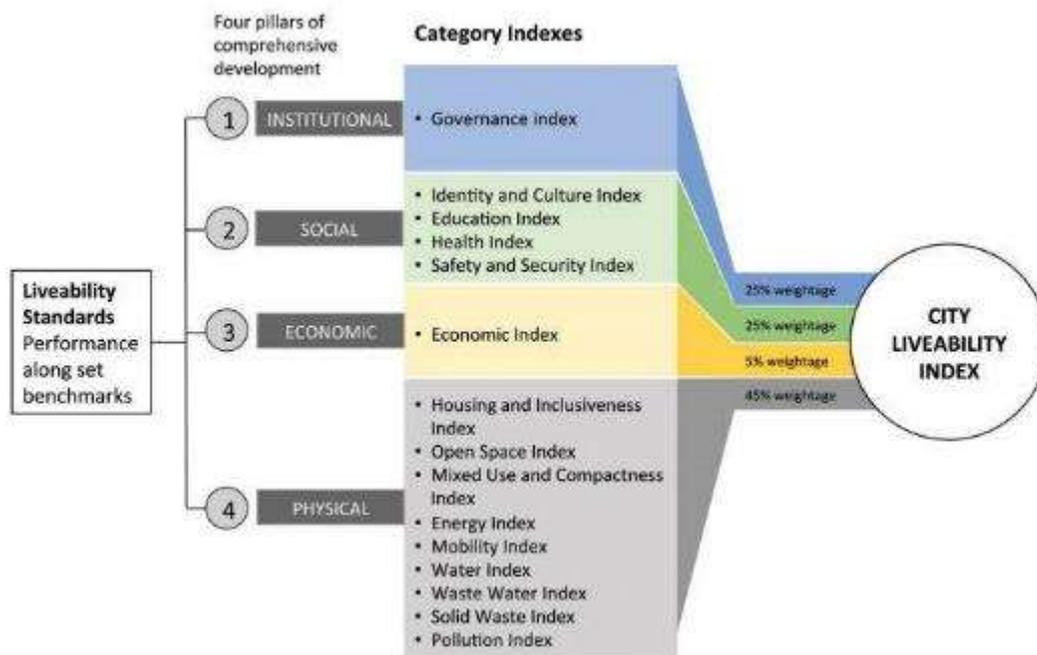

Figure 4. Liveability pillars and category Index

According to Ministry of Urban Development (MoUD) cities are comprised of more than just buildings and people. The most “liveable” cities in the developed countries are now concentrating on conforming green zones, water bodies, and public spaces as the parameters of urban design – and to preserve and promote their culture. As the world’s cities continue to grow, continuing to value green space in cities is vital: but is also a challenge, particularly in developing nations where there is pressure for space, resources and development. Therefore, a set of categories have been identified under the four pillars of Institutional, social, economic, physical levels of comprehensive development to address all the spheres of urban development.

As the physical infrastructural pillar in India has received the highest weightage of 45%, it also assures the most affectability on judging the liveability of a space. Various steps can be taken to enhance the physical indicators that directly affects imageability. Hence, restoration and reuse of historic buildings, promoting and maintaining ecologically important areas, availability of green spaces, availability of public and recreational places, share of mixed land use area in overall city land use, density of the place defines the liveability of the space.

4 URBAN SPACE AND LIVEABILITY IN INDIA: PROBLEM IDENTIFICATION

Rapid and haphazard growth of most of the Indian cities destabilized the bearing capacity of urban areas and created the problem like space crunch and influx of huge population and thus, social-cultural-infrastructural collapse.

Studies been done on the major problems of rapidly increasing Indian cities identifies the critical areas that demands immediate consideration. It aims to focus on some critical areas which have a close connection with the concepts of inclusion, indigenoussness, resilience and authenticity of the city. Physical infrastructural issues have consistently been of concern to policymakers (e.g. urban housing, services and transport), as well as issues which have recently emerged (or, re-emerged) and captured the imagination of urban stakeholders (e.g. revitalization of historic districts within cities, security and social inclusion). The major concerns of present urban places of developing countries like India includes the problems with urban infrastructure, urban housing, inadequate transport system and retaining the historic connection and tradition of the places.

Urban housing, infrastructure and service delivery report says, over 80 million poor people live in the cities and towns of India. This is mainly a result of heavily distorted land markets and an exclusionary regulatory system that fails to accommodate the needs of the poor, or adequately address the challenges of slums, informal settlements and pavement dwellings.

Next, mobility is a serious challenge in most Indian cities and towns, mainly due to inadequate transport infrastructure, and an unbalanced economic structure aided private transport to grow, and little integration between land use and transport planning. However, public transport is increasingly coming into focus, with a range of options being tried, from improved and environment-friendly bus services, introduction of bus rapid transit, and the development of metro rail systems. National Urban Transport Policy adopted in 2006 has focused on the integration of transport and land use planning and Transit-Oriented Development is slowly becoming a strategic focus in several key cities, such as Delhi.

Pressure of urbanization on urban land and services, also has a significant bearing on the older/historic areas within cities, often leading to deterioration and decay, as well as the loss of harmony and a sense of place. Unfortunately, this dimension of live ability is frequently neglected by Policy-makers as developments in the countries of the third world only concentrates on monuments, or remains of monuments, or at the most, sites or complexes containing a number of monuments or other historic structures (Steinberg 1996).

5 PARAMETERS TO JUDGE LIVEABILITY AND URBAN HAPPINESS

To judge the liveability and condition of urban happiness a set of parameters can be identified through investigation of its social, cultural, physical and institutional sphere. A happy place is a space that can transmit a feeling of happiness to anyone who uses it. Both tangible and intangible characters of the place can make a place liveable and happy to the stakeholders. Physical and socio-cultural rootedness of a space have created its tangible and intangible characters accordingly and both of these are equally important to retain the sense of place. The identity of a place means – as defined by Kevin Lynch – a set of characteristics that make the place unique and recognizable. The uniqueness of an urban space and architectonic elements are attributed by – namely tangible – and by elements connected to the perceptions.

- i. It is important to be a space 'age-friendly', encourage the use of the place by people of different age groups.
- ii. A public space should allow and encourage different types of functions (games, breaks, walking, etc.). A particular area can be designated for such activities.
- iii. The possibility of performing actions that normally are not permitted, such as walking barefoot in the water or in designated public areas, creates a feeling of freedom and joy.
- iv. The composite elements of the space should have an appropriate balance between the elements of nature, landscape and equipment.
- v. The presence of water in different shapes (e.g. fountains) promotes the vitality and create emotions in a place.
- vi. The presence of art in its different forms is desirable. Art constitutes a factor that is able to cause emotions favoring a condition of happiness.
- vii. A public space should have natural lighting during the day and artificial at other times, it is associated with different actions and allow a condition of safety.
- viii. An adequate state of cleanliness and maintenance must be maintained
- ix. A public space has to give a sense of security and safety to those who walk in it.
- x. The possibility of perceiving naturally occurring smells – e.g. wood, grass, sea – provides a feeling of happiness. Beyond the sound and visual perceptions, the ones of smell also are important for urban happiness.
- xi. The possibility of using the space in different seasons and weather conditions improves its liveability and increases willingness to contribute to its good state of maintenance.

xii. The possibility of using new technology to increase the knowledge about its intangible values and history can offer a more profound experience of the place. The new technologies for Internet constitute adding value to support the knowledge about a place and its use.

6 CONTEXTUALIZATION OF RECIPES OF HAPPINESS

Considering the parameters of livability and happiness in the earlier discussion, contemporary urban spaces can be tapped for betterment of imageability of the spaces. To identify, to promote and to secure happiness, Charles Montgomery's idea of 6 recipes of urban happiness, elucidated in the book called "Happy City" (2013) can be moderated as per the Indian context. Therefore the paper attempts to present the 6 recipes as the parameters to secure and judge the liveability of urban spaces. Montgomery, in his book "Happy City" (2013) explains 6 elements, namely, Joy, Health, Freedom, Resilience, Equity and Social Connection.

Joy is the first elementary variable to initiate the journey from dystopia or sorrow to achieve Happiness. Urban happiness is a concept which can be defined through the observation both of many tangible and intangible aspects of a place and the activities carried out by the people who live and use it. The intangible qualities of a place consist of all the elements that can be perceived by the senses – smell and noise, but also sensations of Visual sight and taste, of its memory, cultural tradition, etc. The tangible elements are related to the urban fabric and a series of morphological, natural, and historical invariants as, colours, shapes and materials become an inseparable part of any one spot in the city, and thus components of the urban happiness.

Health is the element of happiness can be defined as an artificial body of Man, as they no longer use their legs, enclosed in automobiles, perched on escalators. Therefore, Human being as a component of urban space and environment as the larger paradigm need to secure its health. To assure an overall well-being, as psychological, physical, economic development is needed, art is equally a necessity for mental health.

The third element Freedom indicates freedom of choice and the power of control have a deep psychological rootedness in predicting happiness. An empirical investigation that covers over 260,000 individuals from 84 countries during a period of 25 years finds evidence in support of this hypothesis. Democracy and the freedom to choice is important for securing happiness. This freedom can be achieved only if the first two recipes, i.e. Joy and Health is secured.

Combination of the first three elements lead to achieve the fourth parameter called urban resilience. It has conventionally been defined as the "*capability to prepare for, respond to, and recover from significant multi-hazard threats with minimum damage to public safety and health, the economy, and security*" (Wilbanks, T. 2007), or the environmental hazards. Thus, only when the first three Elements of Happiness are achieved, i.e. Joy, Health and Freedom, then only planning for resilience can be successful, as it includes the component of human capability as the core. According to figure 5, individual human capability leads to community resilience and aided to curb vulnerability of a space.

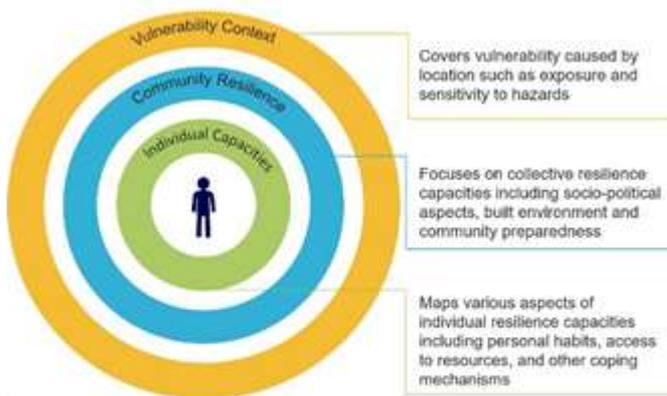

Figure 5. Layers of resilience, from individual, community and vulnerability context

The fifth element, Equity has become an indispensable element of the environmental movement. It helps cities spur development that meets the economic, health, and transportation needs of low-income communities (Martin, Amanda W. 2011). Equity in democracy ensures choice of people, and the major scope to secure the needs.

Finally, humans are social creatures who require connections with other humans in order to thrive. Social connections, such as friendships, relationships with family members and closeness to community, are so closely related to well-being and personal happiness the two can practically be equated.

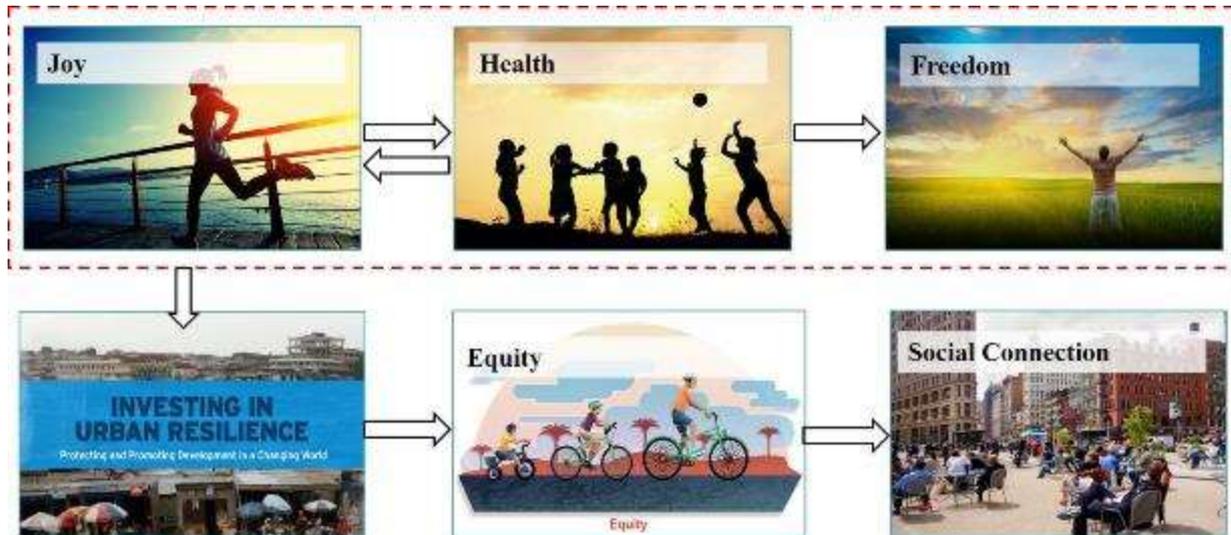

Figure 6. Journey of the six recipes to secure liveability and urban happiness

Thus, contextualizing recipes of happiness as per the urban scenarios of Indian cities can help to tap the current scenarios and also enables to come up with the prospects to augment urban spaces. Moderation of 6 recipes of happiness, namely, **Joy** can be explained as the basic ability to survive delightfully, **Health** as the ability to live based on sustained survival, **Freedom** as the ability to exercise self-autonomy and self-respect. As can be seen in figure 6, the cumulative result of the first three elements can help to achieve the fourth parameter **Resilience** which denotes the ability to reach a higher threshold of self-security and to move further, thus, paved the way for implementation of the fifth element called **Equity**, which denotes the ability of the society itself to realize and co-share self-esteem. Securing all these five elements leads to the final stage of social connection, which promotes to establish transparent networking and enhanced **social connections**. The first three elements Joy, Health, and Freedom act as a tool to secure the basics of survival and advances towards securing liveability. Finally, a livable resilient urban space can march towards enhancing livelihood through the rhythm of equity and transparent networking.

7 CONCLUSION

Despite different positive impacts like, growth, opportunities, job etc. urbanization often brings challenges like infrastructural, operational, maintenance and security. In India, like many other countries, the most obvious one is the increasing vulnerability of urban areas. To cope with the increasing crumbling scenarios, different approaches can be implemented, especially fusing nature into design, introducing green belt, public spaces and by endorsing local socio-cultural phenomena. Publicizing tradition and culture imbue social solidarity to the place and its people, hence, helps to reflect its indigenous character. Therefore to make urban spaces livable and happy presence of visual aesthetics, such as, sculptures, games, or other elements and amenities can be promoted that bring smile to a person's face promotes and indicates the state of happiness. The use urban sculpture in its value for socialization, favors the atmosphere of happiness of the place. The possibility of having direct contact with natural materials, preferably local, used in the design of the space gives a sense of well-being. The possibility of doing actions – such as walking, watching, etc. with a moderate or slow pace promotes opportunities to take breaks in the space. The feeling of being able to contribute to the life of that place increases the sense of belonging. Community activities can be encouraged that allow to vitalize the place and people mutually, creating a perception of happiness and well-being in people who perform the activity as well as in those who observe it.

Place of happiness is sustainable and is not used for the sole purpose of rapid consumption of cultural resources. The principles should not be considered static, but dynamic, in keeping with the increasingly rapid rates of change in a place, which leads to a continually expanding concept of happiness. Public places need to be flexible for adaptation, alteration as per the opinions of the stakeholders, practitioners and administrators to guide the creation or enhancement of happy and sustainable places.

1715 SOCIAL INTEGRATION AND SUSTAINABLE REGIONAL DEVELOPMENT THROUGH DESIGN

Ana Moreira da Silva

CIAUD, Lisbon School of Architecture, Universidade de Lisboa, Portugal; CITAD, Universidade Lusíada de Lisboa, Portugal

ABSTRACT

Throughout this paper we try to understand the way how Design, as a meta-discipline with transdisciplinary skills, may become a useful instrument in the creation and promotion of new practices based on craftsmen and industrial workers skills, achieving design sustainability, social integration and regional development.

We analyze two examples of design practice in Portugal from the seventies to the present, in industrial and handcraft areas. Projects that focus on sustainability with fixation of the local population and even constitute a form of local attraction with the ability to give visibility to the distinctive values of the territory.

Perhaps we do not need special technological know-how to achieve sustainable design, we just need to look at ways that have worked in the past and adapt them to current needs and conditions. We can apply successful examples that can socially and economically transform people, adapting them to other regions or realities.

We can conclude that we need to cross over the new ideas that designers can bring to the skills of workers and craftsmen and find new forms of sustainable design artifacts. The goal is to contribute for the construction of a partnership model between Design, Handcraft Skills and Industrial Techniques that may lead to an increase in the value of local identities, achieving sustainability, social integration and regional development.

Keywords: Design, Sustainability, Social Integration, Regional Development.

INRODUCTION

As Design is about solving problems of different nature, designers can take advantage of the cross-over between "thinking" and "doing", between their design ideas and the skills of artisans and industrial workers. Integrating knowledge of materials from their own experience, approaching vernacular design to material use without nostalgia, creating a sustainable future. In the examples we focus on this paper, designers are finding ways of crossing-over new ideas with old skills and making the best of it: achieving sustainability, social integration and regional development.

Nowadays we speak of cultural diversity and not of globalization when we want to define authentic and non-standardized material culture as being constituted by the dynamics of traditional and popular cultures, erudite and non-erudite, contemporary or vernacular, constantly mobile and cross fertilized. As if we all have a unique and specific contribution to a global culture, to a collective imaginary that does not necessarily want to be 'modernized'.

The following examples of design practice in Portugal go from the seventies to the present, both in industrial and handicraft areas. This projects are based on sustainability with fixation of the local population and some even constitute a form of local attraction with the ability to give visibility to the distinctive values of the territory.

LONGRA INDUSTRY: A SUSTAINABLE ACHIEVEMENT BY DACIANO DA COSTA

We can't speak about Portuguese Design without referring Daciano da Costa (1930-2005). Daciano conceived numerous interior and product design projects of outstanding quality from the early 60's onwards until 2003. His work made him one of the most relevant figures of the twentieth century Portuguese Design. Daciano's interior design and equipment projects already followed sustainability values anticipating one of the main transversal aspect of nowadays design: sustainability.

He has played a pioneer role on design's theory fundamentals in Portugal and an important pedagogic role as teacher. In those days, Daciano brought innovation to the practice and teaching: a modernization of processes, a new perspective on the emerging themes of design such as social commitment and sustainability.

Daciano da Costa believed that designing was providing a service to the community and so designers should assume new social roles towards a sustainable development. On his own practice and teaching he implemented a design process which deals with sustainability and social commitment, searching for simple long-term solutions that could last and fulfil human needs, causing minimum material waste.

Design projects developed by Daciano da Costa can prove that the real dimension of his work greatly exceeds its strict physical function as objects and they take on an eminently social dimension implementing interaction between the interests of the industry and his workers needs and skills, but also with the local resources in a sustainable way. His design thinking successfully operates the mediation between the designer, the industry and the society. Since the early sixties he always tried to develop a close relationship between human systems integration and production systems engineering when dealing with the Portuguese industry.

We can considerer Daciano's working solutions for Longra Industry as 'sustainable' achievement (we must point out that in the sixties this concept was not yet established and meaningful), an innovation anticipating one of the main transversal aspect of nowadays design: sustainability.

Daciano da Costa considered that one of the goals of the designers' practice was to design and produce products that would last in time both for the durability of their materials and for their formal characteristics.

In the example of Longra we can also find its concern with social sustainability through the creation of a new line of furniture that allowed to keep the jobs, thus avoiding the unemployment of many workers by the closure of a section of this factory. Metalúrgica da Longra (1919-1995) was a Portuguese company located in Longra, Felgueiras region, which produced hospital and office equipment. In the 1970s, this industry became a pioneer in the application and development of industrial design in Portugal, a fact that is not unrelated to the close collaboration of designer Daciano Costa (Lage, 2007). For Longra, Daciano was able to develop a production of furniture for domestic consumption, avoiding imports and using local resources that combined durable natural materials with Portuguese technology and traditional craftsmanship. He was able to avoid the unemployment of nearly 100 workers by reusing local technology for new furniture projects by combining durable natural materials with the steel structures that this steel industry normally produced, taking economic advantage and social gains from the human capabilities and local resources that they could have been wasted. Despite being a serial industrial production, he incorporated the Portuguese identity through the use of local long-lived materials, local human resources and technology in a search of what it considered to be the true concept of sustainable social and regional development.

His intervention at Metalúrgica da Longra was decisive to achieve these goals, resulting in the famous line of Cortez furniture and other innovative pieces such as a series of upholstered chairs metal, widely used in audiences of theater and cinema.

At a time when the supply of Portuguese industry was limited and undefined, there was so much to be done. These particular circumstances produced the need for opportunity to design a global project of great coherence: an integral relationship between the nature of production (the deadlines, the means and the processes associated with it) and the cultural, economic and social context. Daciano believed that Design should be set up as the construction of a relationship with users, with those who commissioned it, and even with those who produced it. (Martins and Spencer, 2009)

The commitment to industry was evidenced in the creation of office furniture systems, with the choice of durable materials and the rationalization of industrial production, allowing the reuse of old machines and methods. Daciano's options led to the production of furniture still in use today, due to its simple and timeless forms and the quality of the materials in which they were manufactured.

Figure 1. Daciano da Costa (1970) office chairs produced by Longra.

In the early seventies, Victor Papanek in his book "Design for the Real World, Human Ecology and Social Change", challenged designers to work on social responsibility and that they should propose simple solutions to be used by the whole community. (Papanek, 1972)

Designers need to recognize and play new roles based on the world rapid changes and in the artifacts that are massively produced. Daciano showed an early interest in the rationality and functionality values, which he intended to incorporate in their work, in line with what was happening with other pioneers of modern design abroad (Neves, 2009).

Daciano was involved in the process of understanding the need for a comprehensive integration of human capabilities, social needs and local resources into the design process. He has developed his creative process to reconcile the ingenuity of the designer with the needs of the producer and with the capacities of the workers, but also with the local resources and with durable materials and forms.

We can consider Daciano's working solutions for Longra Industry as 'sustainable achievement' (we must point out that in the seventies this concept was not yet established and meaningful), an innovation anticipating one of the main transversal aspect of nowadays design: sustainability.

Since the early sixties, when dealing with the Portuguese industry, he have always tried to develop a close relationship between the integration of engineering production system with human principles. (Martins e Spencer, 2009).

For several decades, Daciano was a striking figure in the development of a Design Culture, not only because of his project work, but also because of his influence as a teacher and as a promoter of the new project thinking ruled by the principles of Sustainable Design. He criticized the desperate quest for originality and repudiated the effect of immediate culture and "high-pressure success" that encourages useless production and "visual waste" (Costa, 1998). The products he has created maintain the sense of synthesis where complexity is simplified, where tradition is integrated into the contemporaneity within the process of industrial design.

He maintained the desire to adopt the processes of systematic thought and production rationalization. Since the early 1960s, when dealing with Portuguese industry, he has always tried to develop a close relationship between the integration of human principles and the production systems engineering. (Martins and Spencer, 2009)

The design developed by Daciano demonstrates a high technical and methodological control of the industrial product and a distinctive ecological and social awareness, in the sense of an accurate design thinking that operates the mediation between the designer, industry and society.

We can consider Daciano's working solutions for Longra Industry as 'sustainable achievement' (we must point out that in the seventies this concept was not yet established and meaningful), an innovation anticipating one of the main transversal aspect of nowadays design: sustainability.

Figure 2. Longra's stand in Lisbon International Fair (1971)

BUREL FACTORY: SUSTAINABILITY BY THE RE-SIGNIFICATION OF CRAFT TECHNIQUES

Design for sustainability requires generating solutions that are equally beneficial to the society in general and to the communities around us, to the natural environment, and to the global, but especially to the local, economic systems. (Vezzoli e Manzini, 2008; Vezzoli, Kohtala & Srinivasan, 2014)

The *Burel Factory*, a textile industry design project in which Cláudia Albino was involved can be part of this basic principles. Cláudia Albino is a senior designer and assistant professor at Universidade de Aveiro, committed with social Integration and sustainable regional development. She is involved in several projects about this issues, through partnership models between design and handcraft techniques. Her work is based in searching to understand the way how Design, as a meta-discipline with transdisciplinary skills, may become a useful instrument in the creation and promotion of new practices with the ability to give visibility to the distinctive values of the territory.

One of the projects takes place in Manteigas, a region located in the inner center of Portugal near Estrela Mountain. By the end of the first decade of the 21st century, many people in this region were in economic difficulties because they had stopped working on woolen manufactures once they had shut down. The *Penhas Douradas Fashion* project, created by Isabel Costa and João Tomás was undertaken under the motto "Re-creating the past, making it present forever and now". This idea allowed that the old knowledge and the how-to-do of the people of Manteigas could find new applications for their skills, integrating them into a new agglutination project. The main purposes of this project were: to value the skills of the inhabitants of Manteigas, who have lost their jobs in large numbers due to the closure of wool mills, which have always characterized this region. And also, through the collaboration of several designers, to value the raw material of burel, pure and resistant wool, traditionally used in confection of the covers used by shepherds of the mountain. (Albino, 2014)

Burel is a Portuguese handcrafted fabric, with 100% wool, high durability and resistance, which has always accompanied the life in the mountains. Each family produced their pieces for their own use, and the article that acquired greater cultural expression was the cover used by the shepherds. Today it is intended to bring this unique heritage, reinvented to the measure of the present so that it is not only remembered as a handcrafted fabric of the past. By the combination between passion, dedication and commitment of those who work this ancient handcraft skill to an innovative, relevant and surprising design, it seeks to provide new memories with new meanings, dimensions and values. (www.burelfactory.com, 2014)

In 2011, *Lanifícios do Império* was an old textile factory dealing with a process of insolvency and, in order to keep the jobs for the 30 people who worked in it, *Saberes e Fazeres da Vila* rented this factory, managing to ensure the required orders avoiding the factory closure.

That same year a new use for the burel fabric produced by *Burel Factory* was tried, as an interior finishing material in architecture. Specifically, burel was used as the lining of the interior walls of the *Microsoft Lx* headquarters building in Lisbon. This work has led to new orders in burel fabric for the new use in wall surfaces lining in several parts of the world, already representing this type of orders, a significant part of the turnover of *Burel Factory*.

Figure 3. Burel fabric on the interior walls of the Microsoft Lx headquarters building in Lisbon

Nowadays *Burel Factory* manufactures burel fabrics, with new weavers, carders and dressmakers. The majority of the workers in the factory are from this region and holders of the ancestral knowledge in the production of the burel fabric.

The artisans work in partnership with several designers integrated in the project, in an open outsourcing system, producing burel products both for home and clothing.

Guided visits to this factory are taking place, with many foreigners visiting it, so that the use of English language is fundamental. All this implied to involve in the project also other people efficient in other skills like project management and communication, not endemic in the territory.

Currently this company has its products presented in an exclusive packaging, for sale in more than 40 stores in Portugal. This brand products are also communicated through the company website, increasing more and more the number of orders that are carried out in this way. E-commerce also allows the possibility of buying products online.

Figure 4. Burel Factory products.

Burel Factory brand sales for the international market represent a high percentage of total turnover. Currently the company sells, in addition to Portugal, to Finland, Germany, Belgium, the Netherlands, France, the United States of America and Japan. Being Japan its main international market. The company is even working with a design office in Tokyo to implement burel products more associated to the needs of Japanese tastes and needs

This project, in accordance with its objectives of rescue and translation of the diversity of the knowledge and practices of this region, presents itself as an effective initiative to develop a local culture through Design. It involves local communities, contributing for the territorial and human development. It has been a project able to give new meanings to traditional techniques, creating new experiences in the region promoting the artifacts and the territory of origin both locally and globally.

Portuguese design in its relationship with handcraft techniques, thus updates its knowledge vocation through artefacts of sustainable value in harmony with diversity, providing social and environmental quality, redesigning possibilities for partnership, valuing local values while incorporating artisans, as an effective partner of processes and projects, in a collaborative way. In this context, design is the communication interface between the inherited past and a desired future. (Providência, F. in Albino et al. 2011)

From her experience in several projects in this areas, Cláudia Albino concluded that in projects where there is a high material and immaterial involvement of the actors that promote their likelihood of success is significantly higher than in cases where these commitments are not made by the agents involved and the promoters of the projects. (Albino, 2014)

CONCLUSIONS

Throughout this research we understood that design, being a meta-discipline with transdisciplinary skills, may become a useful instrument in the creation and promotion of new practices with the ability to enhance the distinctive values of the territory.

Usually we do not need special technological know-how to achieve sustainable design, we just need to look at ways that have worked in the past and adapt them to current needs and conditions. We can apply successful examples that can socially and economically transform people, adapting them to other regions or realities.

From the initial phases of this research, we can conclude that it is important to cross over the new ideas that designers can bring to the skills of workers and craftsmen and find new forms of sustainable design artifacts. The main issue is to contribute for the construction of a partnership model between Design, Handcraft Skills and Industrial Techniques that may lead to an increase in the value of local identities, achieving sustainability, social integration and regional development.

We can also conclude that in projects where there is a high material and immaterial involvement of the actors promoting them, the probability of success is significantly higher than in cases where these commitments are not verified by the agents involved and the promoters of the projects.

1192 HOW PLACE BRANDING CREATES AND BENEFITS FROM SOCIAL CAPITAL

ABSTRACT

The success of place branding is judged by the economic prosperity the branding creates. When implemented successfully place branding has a positive economic effect on the community by accomplishing the goals for which it was crafted. These goals can include increasing tourism, attracting new businesses, or revitalizing a downtown. All achieved through governments and private organizations (local development groups, chambers of commerce, not for profits, resident associations, etc.) working under the same overarching message. The most successful branding campaigns have a very high level of cooperation and high levels of social capital. Social capital holds the organizations together and keeps them focused. The purpose of this paper is to show how place-branding strategies can both build social capital and benefit from existing stocks of social capital within a community. In the former case, this formation of social capital can come as an unintended consequence of the branding process. Section one provides a brief overview of social capital and defines the term for use in this paper. It describes how bridging and bonding aspects are fundamental in understanding social capital formation. Section two describes the fundamentals of place branding. It identifies three key principles present in successful place branding campaigns. Section three offers examples of how place branding campaigns created social capital within a region’s economic development community. It describes how the increase in social capital is an unintended consequence in many place branding campaigns. Section 4 describes how existing social capital that exists within an industry can be leveraged to assist in the branding process.

1655 SOCIAL INTEGRATION OF THE UTHULIS AND CHUKANIS INTO THE CHARLAND COMMUNITIES IN BANGLADESH

ABSTRACT

The paper is wedded to explore the social integration of the uthuli and chukani riverbank erosion displacees into the charland communities on the Jamuna riverine ecosystem of Bangladesh. The livelihood of charland people of Char Chhinna in the Jamuna riverbed is desolated annually by the riverbank erosion displacement and they are impelled to leave their places of origin. This alarming situation seizes their own dwelling environment and pushes them to find shelters under their neighbor’s and/or relative’s houses and/or other places. The uthulis are not able to pay for such shelter. But the chukanis have to pay annual rent for that. In reducing their vulnerability to displacement and/or mitigating the erosion hazards, the uthuli and chukani households use their social capital and connectedness, e.g., kinship, neighborhood, samaj membership, patron-client relationship, etc. It increases their trust and ability to cooperate before and during the riverbank erosion displacement. The paper is primarily based on the data gathered through direct interviewing with the randomly chosen uthuli and chukani household heads of the study village, observation, focus group discussions (FGDs), case studies, and informal interviews with some stakeholders. Both the qualitative interpretation and quantitative measurement of social reality are considered to be reciprocally focused here. For analysing the unit of this study, the primary and empirical sources of data are exclusively utilized. In the time of riverbank erosion displacement uthuli and chukani households help each other to transfer all dismantled materials from their place of origin to safer places. Their relatives and/or neighbors also extend their hands in sheltering the displacees in the time of crisis. As it is not adequate, they have to take a local loan (haolat) from their samaj members, neighbors and/or relatives without interest. The uthuli and chukani riverbank erosion displacees are impelled to secure supports and cooperation of the non-displacee charland people, and other stakeholders in confronting with the adverse livelihood and in securing social integration into the charland communities so that they can continue their familial survival. A number of suggestive policy measures for sustainable rural development are formulated based on findings as the final job of this research.

1786 KNOWLEDGE DISCOVERY BASED INTERACTIVE DECISION SUPPORT SYSTEM FOR IDENTIFYING ASSOCIATIONS AMONG CHILDHOOD HEALTHCARE INTERVENTIONS AND HEALTH SYSTEM BUILDING BLOCKS

ABSTRACT

Maternal and Child Healthcare (MCH) has always been regarded as one of the important issues globally. There are various priority interventions for adolescent females, pregnant mothers, infants, and children. These interventions get circulated among society through different healthcare service facilities like hospitals, primary health centres, sub centres, community health workers, etc. To improve healthcare condition of any region, all MCH interventions and healthcare service elements should perform synergistically. A knowledge discovery based interactive Decision Support System (DSS) has been developed with five different modules. Among them, one module has been developed for identifying frequently occurring healthcare service elements along with infant and childhood healthcare interventions. This module extracts healthcare service elements which have frequently occurred along with a healthcare intervention when coverage of the intervention was either poor or moderate or good. For development of this DSS, Shiny app under R software has been used. This specific module has been prepared by incorporating Association Rule Mining (ARM) technique, which is a very renowned unsupervised data mining technique, with the system. An interactive Graphical User Interface (GUI) has also been developed so that policy makers can generate different scenarios very easily by using this sophisticated data mining technique just by clicking some widgets. Data of around 14 infant and childhood healthcare interventions and 40 healthcare services from 600 Indian districts have been utilized to check efficiency of the module. All data used in the system are secondary data, collected from Districts Level Household Survey Phase three. Results are showing that presence of healthcare committees like health and sanitation committees, Rogi Kalyan Samity were comparatively higher at districts where coverage of adolescent interventions was higher and on contrary influence of ASHA workers was comparatively more at districts with low interventions coverage rate. Among SC level services, there were few services which have frequently occurred along with childhood interventions and availability of these services have increased as coverage rates of interventions got enhanced. Those services were male healthcare workers at SCs, availability of auto disposable syringes, IFA tablets, and ORS at SCs, communication facility at SCs, and SCs located at government buildings. By utilizing the system, frequently occurring healthcare services have been found out separately for all 14 interventions. By exploring differences in healthcare service elements, users would be able to gather knowledge about different behavior patterns of healthcare service elements at good performing MCH regions and poor performing regions.

1787 A QUASI-EXPERIMENTAL CASE STUDY OF ESTIMATING THE EFFECTS OF PROGRAM DESIGN AND IMPLEMENTATION ASPECTS ON PROGRAM OUTCOMES IN NATIONAL HEALTH MISSION

ABSTRACT

Background: India’s National Health Mission (NHM) was launched in 2005 to strengthen the primary healthcare system, and to encourage pregnant women to use institutional healthcare. A notable program design feature of NHM is its ‘Janani Suraksha Yojana’ component (a cash-transfer program) that provides cash incentive to pregnant women to use institutional delivery. But, until the year 2010, this cash incentive was not linked to the uptake of ante-natal care (ANC), which might differentially impact program outcomes. Objective: This study measured the extent to which program design and implementation aspects reflect on two major program outcomes of NHM: uptake of institutional delivery and ANC. Methods: Data from District Level Household and Facility Surveys (DLHS) Rounds 1 (1995–99) and 2 (2000–04) from the pre-NRHM period, and Round 3 (2007–08) and Round 4 (2011–12) from post-NHM period were used. A quasi-experimental study design was applied. Wealth-related and education-related relative indexes of inequality, and adjusted pre-post difference-in-differences regression models were estimated. Results and Conclusion: The study found that the program design and implementation aspects differentially and adversely affected the program outcomes. No positive impact on the uptake of ANC was found in the early post-NHM period 2007–08. However, there was considerable increase in the uptake of, and decline in inequity, in ANC in the late post-NHM period 2011–12 (the period when ANC was included in the cash-transfer program). On the other hand, inequities in institutional delivery declined steeply in both the early post-NHM period 2007–08 and the late post-NHM period 2011–12, but with larger equity impacts in the late post-NHM period 2011–12. These study findings highlight the importance of effectively designing public programs and targeting the deprived populations in the early stage of the program for better program outcomes.

RS14.1. Spatial Planning

1556 URBAN PLANNING IN BANGLADESH: ISSUES AND CHALLENGES

ABSTRACT

At present urban planning has become an important issue all over the world including Bangladesh due to the huge growth of population and their effective management in urban settings by systematic techniques and policies. Bangladesh has highest population density in the world. More than 30% of its people live in urban areas which will be around 50% by 2050. Now, the development of any country depends on the planning of its urban sector as the country is shaping its urban face day by day. Although the urbanization in third world countries is full of socioeconomic, political, cultural and may other problems, it has become inevitable process in the present era. The Vision 2021 and the Perspective Plan 2010-2021 have set development targets for Bangladesh by the end of 2021. Those targets if achieved will alter the socio-economic environment of Bangladesh from a low income economy to the first stages of a middle income one. Those development priorities include ensuring broad-based growth and reducing poverty; ensuring effective governance, sound institutions, creating a caring society; addressing globalization and regional cooperation; providing energy security for development and welfare; building a sound infrastructure and managing the urban challenge; mitigating the impacts of climate change; and promoting innovation in a knowledge-based society. An attempt has been made in this study to find out the issues and challenges of urban planning in Bangladesh. The study identified that the present trend of urbanization is the causes of pollution, joblessness, criminal activities, poverty, deplorable condition of slums, corruption, inefficiency in service delivery, weak governance etc. It has also explored that the challenges of urban planning in Bangladesh are enormous. That is, poor management, inefficiency and lack of coordination among implementing agencies, insufficient financial resources, individual control of land, arbitrary political boundary, irregularity of environmental site; difficulties in breaking down past heritage, anticipation of future change etc. The study is mainly based on secondary data which have been collected from different published materials and processed manually in order to make the study more informative, analytical and useful for the readers. It may help to the academicians, policy makers, urban development practitioners and researchers to do more and more empirical research on urban planning to explore the real issues and challenges with a view to ensuring sustainable urban planning and development. Finally a number of recommendations have been put forward to meet the issues and face the challenges of urban planning in Bangladesh.

1223 HOW DIVERSE ARE THE NEIGHBOURHOODS? A DIVERSITY INDEX TO ASSESS LAND USE MIX THROUGH OPEN SOURCE AND ONLINE DATASETS**Deepank Verma²⁷⁷, Arnab Jana, Krithi Ramamritham**Indian Institute of Technology Bombay, Mumbai, India, Email: deepankverma1@gmail.com, arnab.jana@iitb.ac.in, krithi@iitb.ac.in**ABSTRACT**

Land use mix has been studied as a phenomenon as well as the part of policy initiatives towards the creation of vibrant neighbourhoods. It has also been viewed in different perspectives by researchers primarily in economic terms where the presence of complementary land uses supports Transit Oriented Development, Public transportation, encourages street activity and businesses. Mixed-use development promotes urban diversity and vibrancy by increasing the attractiveness of the area. However, due to lack of credible datasets, it becomes infeasible to quantify the diversity in urban areas. We demonstrate an approach using open source databases and datasets to measure aggregated land use and typology diversity mix at a detailed spatial scale. With the availability of large geographic databases, POI's have become primary option to extract the information about urban land use types and its functions. We collected Points of Interests (POI) information and performed Local Climate Zone (LCZ) classification for the city of Mumbai. We further used standard diversity indices such as Richness, Entropy and Simpson Index to measure degrees in mixed land use and built typologies. The POI an LCZ calculation helped in providing a greater understanding of the inherent structure of the city when viewed from the perspective of diversity. This process facilitated the creation of diversity maps which might be helpful in monitoring dynamics in housing, transportation, public health, urban planning and design. Although analysis of the results is still limited in the paper, it still provides the methodology to recreate such work in various cities.

Keywords: Google Places API, Wikimapia, OpenStreetMap, POI, LCZ, Mixed Land Use**1 INTRODUCTION**

Land use mix has always been counted towards the strategic urban planning and design. Mixed land use has been one of the major proponents of activism held by Jane Jacobs for American Cities. Since then, it has been viewed in different perspectives by researchers primarily in economic terms such as in Multifunctional (Batty, Besussi, Maat, & Harts, 2003; Rodenburg & Nijkamp, 2004; Vreeker, de Groot, & Verhoef, 2004) cities, and Multiple Land use theory (Louw & Bruinsma, 2006). Mixing land use has a literal meaning of mixing functional uses horizontally, among the different parcels of land or vertically, among the various floors of a building (Montgomery, 1998). According to (Louw & Bruinsma, 2006), Mixed-use development promotes urban diversity and vitality by increasing the attractiveness of the area to the people and other businesses. It further creates a dense mix of these activities which are alive during most of the hours in a day. Apart from advocating interaction between different people, businesses, and environment, it creates a vibrant neighbourhood, creates a place for various activities which in turn provides a better quality of life. The diversity of the area explains the importance of one land use for the sustenance of others by showing the dependence of people, public amenities and other businesses towards each other.

Land use mix as a policy has been widely researched and considered as a great urban planning tool for optimising usage of urban resources while keeping neighbourhoods safe, vibrant and lively. However, large-scale studies with empirical analyses are still non-existent owing to lack of credible datasets which are open to the research community. Furthermore, there is no particular methodology to ascertain the approach with which any of the studies in measuring land use mix should proceed. This particular study is focused towards the creation of a method to select and identify the most diverse areas in the city of Mumbai. Jane Jacobs (Jane, 1961) in her book "The life and death of great American cities" identifies four elements which induce diversity such as a mix primary land use, intensity, permeability of urban form, and the mix of building typology (Montgomery, 1998). This study undertakes two of the elements such as the land use and built typology to study the diverseness across all the sub-wards in the city. Points of Interests (POI) is taken as a proxy indicator of the existence of various land uses. Diverseness in Urban area can be measured via analysing different indicators such as economic prospects, demographical aspects, and infrastructure. It can vary in scale and depend upon the choice of domain. It is challenging to understand the intricate relationship between different variables and actors. Higher Diversity across one domain might be low in other (Choi & Sayyar, 2011). Mix use diversity has been found to provide lively, secure and stimulating public realm while balancing workspaces, businesses and living spaces (Jacobs, in (Louw & Bruinsma, 2006)). This study deals with the formulation of methodology to calculate the diversity indices for cities at fine administrative scale. In particular, the city of Mumbai is considered in this study as an example to portray the methods. Diversity indices for each block are calculated from the POI datasets collected from online databases and Built typology extracted from Satellite imagery available widely on open repositories.

2 RELATED WORK

(Montgomery, 1998) gives an account of the creation of healthy and active cities, which are a balance of ordered form and structured complexity. He further advocates the role of diversity in mixed-use for the creation of dynamic cities. Creation of mixed-use diversity is a two-step process, one, the creation of primary land uses which are people attractors such as offices, schools, shops, recreation places. Second, land uses including businesses and services which grow in response to primary land uses (Jane, 1961). Empirical studies have linked land use diversity to the availability of

²⁷⁷ Corresponding Author

employment (Malizia & Motoyama, 2016), use of public transportation and reduction of travel times (Cervero, 1988; Holian, Kahn, & others, 2012), ease of setting up of businesses (Quigley, 1998), the low cost of housing (Song & Knaap, 2004). Regardless of the existence of vast literature in understanding Mixed use, there has been a crunch on methods and datasets to calculate and represent diversity. (Batty et al., 2003) Introduced techniques to represent multifunctionality by visualising diversity and density through data sources in GIS. (Choi & Sayyar, 2011) studied how land use mix affects the walking behaviour of people, where people travel less in areas with high mix land use diversity. (Hao, Geertman, Hooimeijer, & Sliuzas, 2012) explained of land use diversity through statistical models in which the results revealed the relation of land use diversity with the proximity to industries and city centres. (Song & Knaap, 2004) developed several quantitative methods to measure mixed land uses in various neighbourhoods.

Until now the research in understanding the relationships between land use diversity and behaviour was quite limited due to the unavailability of large datasets. Recently, Volunteer Geographic Information (VGI's) is increasingly being used to explore and understand places and cities. VGI datasets such as Foursquare, Facebook places, OpenStreetMap have become increasingly popular among the researchers as they provide access to well maintained and up to date databases. (Jiang, Alves, Rodrigues, Ferreira, & Pereira, 2015) used VGI information from Foursquare and Facebook places to prepare disaggregated land use of Boston. Similarly, (Jayanetti, Meedeniya, Dilini, Wickramapala, & Madushanka, 2017) created enhanced land use information generation through foursquare datasets for the city of Colombo. Google API has been used to explore the empirical laws governing the colocation of businesses and amenities within a neighbourhood using the location of amenities. (Casta, Hidalgo, & Castañer, 2015) Created an Amenity-space where connections between different businesses which are likely to co-locate are marked. The likeliness of occurrence of the businesses is then statistically calculated. Google POI has also been used for transportation research mainly in trip prediction problems (Ermagun, Fan, Wolfson, Adomavicius, & Das, 2017). The POI's information from Google API is not exhaustive at any level and mostly focused on targeting businesses. However, among all the online managed databases, it is the most reliable and managed online places database. Also, most of the other online databases have limited coverage in the cities. To create more rigorous and exhaustive data collection tool, we considered including Wikimapia and OpenStreetMap databases as well.

We performed Supervised classification task in satellite imagery to classify and extract these typologies. LCZ classification technique is followed, which is highly documented and researched in studies related to Urban Climate Zones demarcation. LCZ classification approach has predefined classes and step by step procedure to create climate zone maps for any city. Here, this technique is utilised to delineate various types of land typology present in the city. We extended the classification approach by using different methods and datasets to arrive at better classification accuracy than vanilla procedure. In this study. The diversity of POI and land typology together help explain the concentration of particular land uses over specific typologies. The usage of one diversity measure over the other has been a highly debatable topic in ecology and economics (Baumgärtner, 2005; Magurran, 1988). Diversity metrics such as Atkinson index, Simpson index, Balance index, Herfindahl index, etc. (more on (Song & Knaap, 2004)) have been used to compare and differentiate between different areas. Among such metrics, Hill numbers have been utilised in the calculation of diversity in this study. Hill (Hill, 1972) unified the measures of diversity into the quantitative framework, which provides species abundance distributions in the form of richness, Shannon entropy and Simpson measures; also called Hill numbers (Jost, 2006; Yue et al., 2016). The hill numbers notation can be given as:

$$q_D = (\sum_{i=1}^s p_i^q)^{1/(1-q)}$$

where, D: Diversity, p: Proportion of the abundance of the species; s: the total no. of species and q is the order of the diversity.

- a) q = 0: Richness: Richness of the individual sub-wards is higher where more significant number of classes are detected. Richness does not depend on the frequency of elements in the class. The richness component of the diversity provides the information on the unique types of POI and Built typology present in each of the wards.
- b) q = 1: Exponential of Shannon entropy index: Shannon entropy considers every class according to its number of the elements present. It does not provide more weight to the abundant classes. High Entropy values indicate randomness while the lower shows order. Among all of the orders of diversity, Shannon entropy is widely used in other domains.
- c) q = 2: Inverse of Simpson concentration index: Simpson Index is more sensitive towards more dominant classes in a ward. The calculation includes the sum of squares of the proportion of classes which for lower value becomes insignificant; therefore, higher value dominates. "It is a measure of dominance concentration" (Hill, 1972).

3 STUDY AREA AND DATA COLLECTION

Methods of Dividing the area into smaller parts to apply diversity metrics may result in complications in the usage of self-defined shapes and sizes giving rise to Modifiable Areal Unit Problem (MAUP) (Dark & Bram, 2007). The concept of Ecological Fallacy has been widely discussed in the research circles involving spatial aggregation tasks. However, no particular solution is available to check this problem. For this study, rather than sub-dividing the area into a grid, we utilised Election sub-ward boundaries of Mumbai city. The boundaries are obtained from the Mumbai municipal election board which constituted 228 sub-wards (Fig. 3) divided from 22 wards. The POI information present in the databases is usually

in the form of geolocation, name and types of their functional uses. We developed a programming script to fetch a wide range of information on diversity indices from these POI sources when provided with the shapefile of each of the sub-ward boundary (fig. 1 A).

The Google Places API provides access to the POI database through different search options such as radar search and radial search. Radar search is useful when ranking the POI's based on the distance to the queried location, whereas radial search provides an output on a comprehensive list of POIs within that queried radius. We developed custom search based on above two methods which recursively fetch information on POI given the shapefile (boundary) of the queried ward. The places in Google database are categorised into 96 different types including specifics of sub-types of establishments, which is massive from the analysis point of view. We aggregated 96 categories into 16 classes (Ermagun et al., 2017) relevant to our study (Table. 1). The data from Wikimapia is gathered through Wikimapia API. Unlike Google Places, Wikimapia provides access to POI's through different options such as search by area, by place id and bounding box. The results also provide the vector files of POI's polygons, where present. Wikimapia has no fixed set of categories. Moreover, quite a few places are also tagged in different languages. Similarly, OpenStreetMap provides the data in the form of points, polygons and annotations to describe the place of interest. It provides the detailed description of the different types of tags by which places are marked. The data can be queried from the custom-made script and is also available for download as a shapefile for the city from the companion website *Geofabrik*²⁷⁸. The labels of POI obtained from OpenStreetMap and Wikimapia are then grouped into 16 classes.

Table 24: Categorization of various POI labels.

S.no.	Group	POI
1.	Vehicle repair/services	car repair, carwash, gas station
2.	Night Life	bar, nightclub
3.	Personal Care	beauty salon, haircare, spa
4.	Administrative offices	courthouse, lawyer, police, fire station, city hall, embassy, local government
5.	Educational Institutions	library, school, university
6.	Food	bakery, cafe, food, meal takeaway, restaurant, meal delivery
7.	General stores and establishments	miscellaneous stores
8.	Medical Services	dentist, doctor, health, hospital, pharmacy, physiotherapist, veterinary care
9.	Services	electrician, locksmith, moving company, painter, plumber, real-estate agency, travel agency, general contractor, roofing contractor, insurance agency, laundry, storage
10.	Recreational	amusement park, aquarium, art gallery, casino, bowling alley, gym, movie rental, movie theatre, museum, park, stadium, zoo
11.	Hotels	Rv park, lodging, campground
12.	Religion	cemetery, church, funeral home, Hindu temple, mosque, place of worship, synagogue
13.	Financial	accounting, atms, finance, bank, post office
14.	Specialised Stores	bicycle store, bookstore, clothing store, convenience store, department store, electronics store, florist, furniture store, grocery, supermarket, hardware store, home goods store, jewellery store, liquor store, pet store, shoe store, shopping mall, car dealer
15.	Transportation	bus station, subway station, train station, taxi stand, parking, car rental
16.	General Establishments	Miscellaneous

We followed Local climate zones (LCZ) classification (Bechtel et al., 2015) approach to categorise different built and natural typologies in the city. LCZ classification was initially studied as an attempt to gather details about the morphological aspects of the cities for the climate studies. It provides a framework named WUDAPT²⁷⁹ for the classification of different climatic zones using readily available remote sensing techniques without the use of proprietary software and databases. The process includes usage of widely available free satellite imagery from Landsat, Google Earth Platform and SAGA GIS software. This technique classifies the urban areas into 17 classes, in which 10 represent built-up areas and remaining, the natural areas. This process is feasible for the analysis of city-wide area expanding to regions, however, does not provide satisfactory results at the building structure level. The output is an aggregation of the typological details of the surroundings.

4 ANALYSIS OF THE DATA

However easier is the availability of these datasets, the information is far from being error-free. Points gathered with the help of API's are not tagged with the correct label; most of the points in Wikimapia are tagged without any labels. There are large number of POI classes listed in Wikimapia and OpenStreetMap, but only a few are actively used by the users while tagging the information. Fortunately, names of the places in the POI provides a hint to the type of the establishment. To solve the issue of missing classes information in POI, we created a bag of words (BOW) (fig. 1B) which included common names of various establishments such as eateries, housing societies and general stores from the correctly labelled POI.

278 <http://download.geofabrik.de/>
 279 <http://www.wudapt.org>

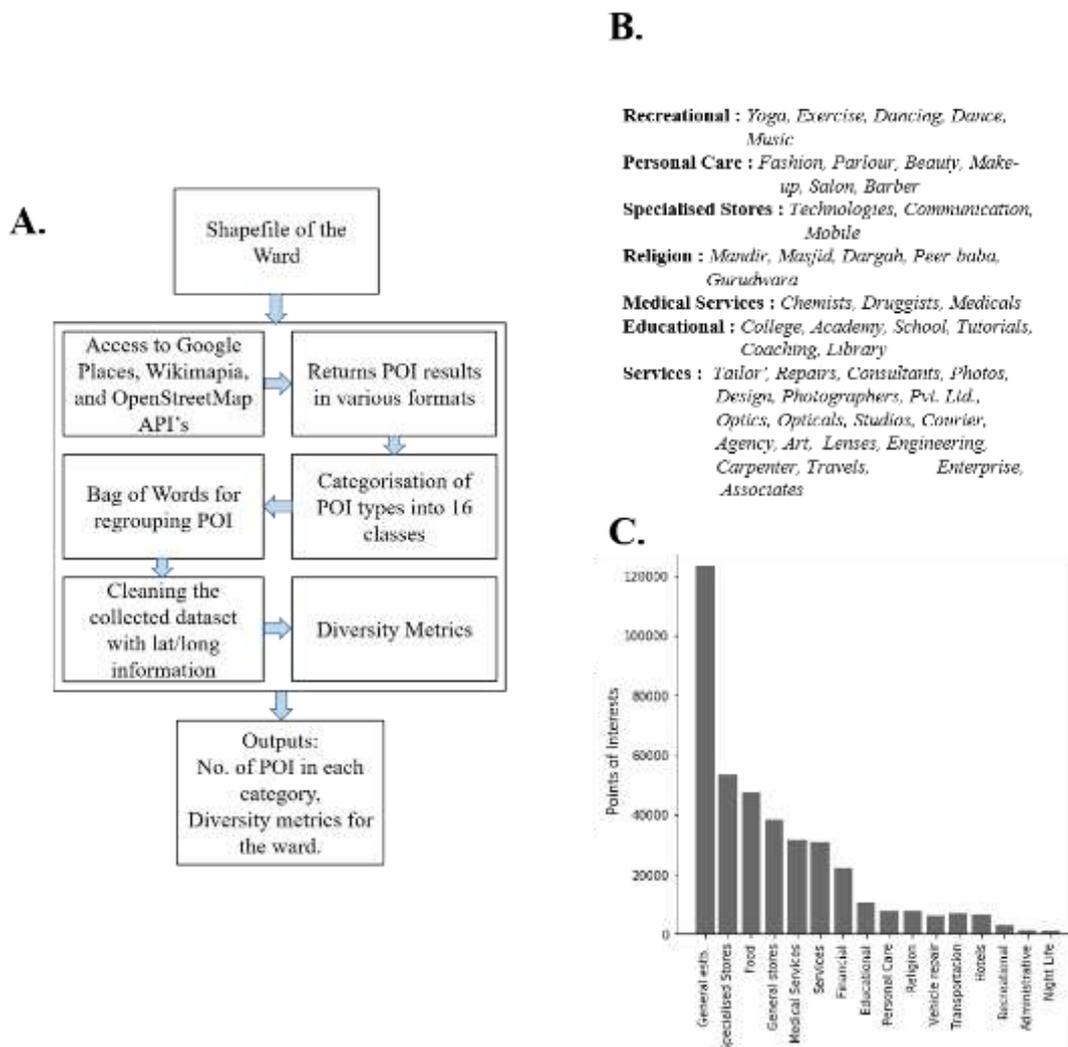

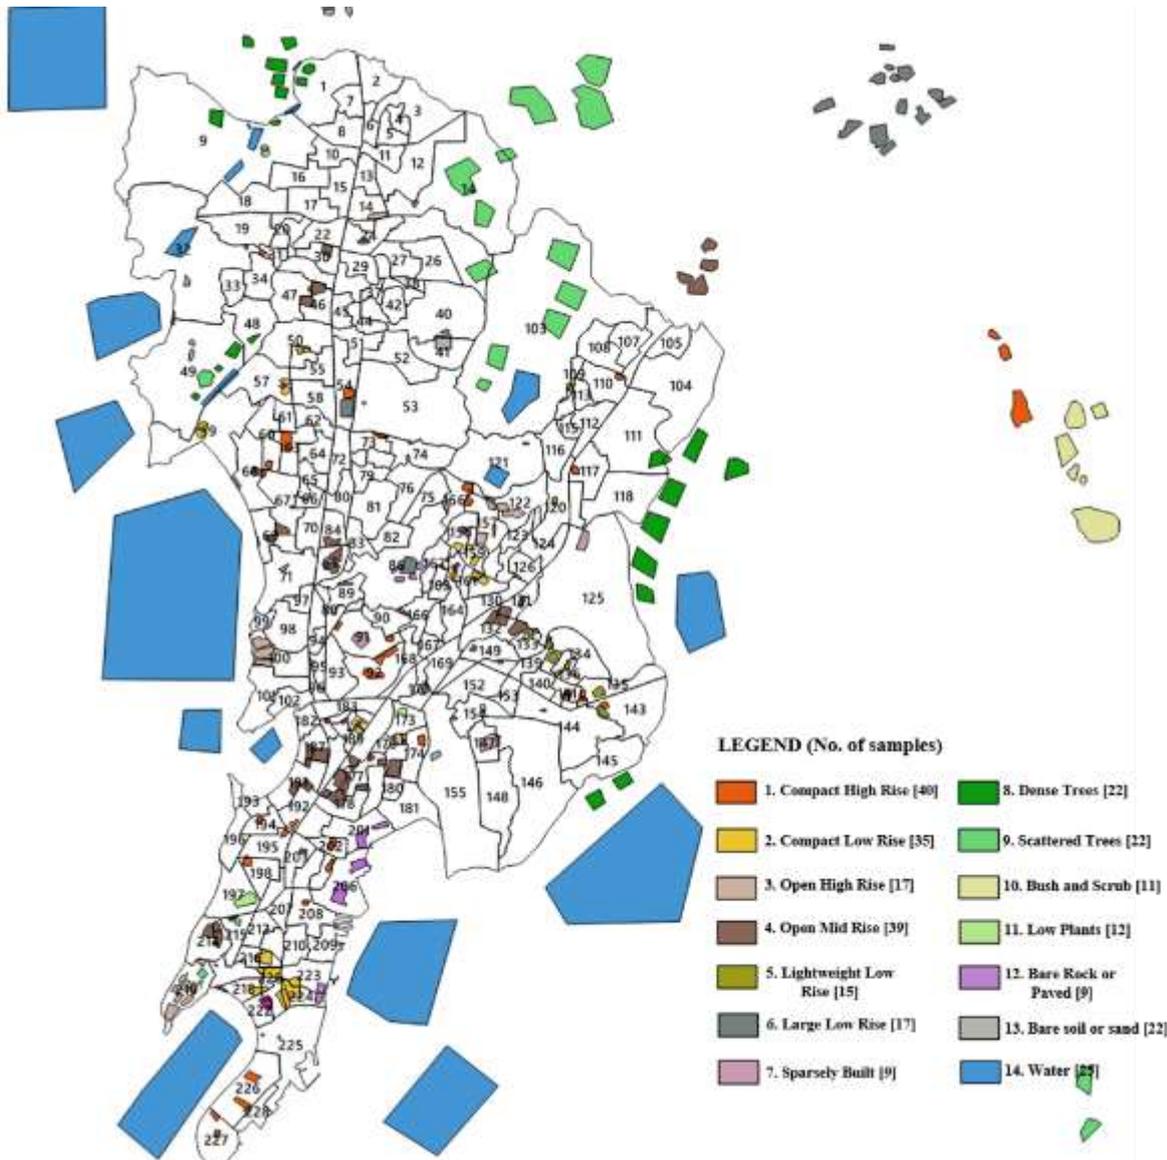

Figure 62: Workflow of POI data collection and Outputs (A). An example of Bag of Words (BOW) to classify labels (B). The total number of POIs gathered through three API's. (C)

The uncategorised POIs are then classified by matching the part or the portion of the name with the words in created BOW. However, the creation of BOW is not fit for use in different areas due to the prevalence of a different set of naming conventions being followed by people from different regions in branding their establishments. We discarded the Places which do not provide sufficient information about the names or the labels. The POIs with residences category are removed from the calculation of entropy due to the fact that all of the wards have almost an equal number of households since we used administrative, electoral wards. Collection of data from various sources have high chances of duplicity and the inadvertent inclusion of rogue POIs. The Wikimapia is a most accessible website to masses and provides an easy interface for drawing and locating POI. However, it has no control over moderation or to filter out the vandalism in updating POI information by the website users. Hence it consists of significantly more corrupt dataset amongst the three sources. However, easy access to the website helps in the inclusion of local information by the users which might not be present in other managed databases. For example, the location of weekly markets and local small shops are present in Wikimapia but absent in OpenStreetMap and Google Places databases. The duplicity in the data is removed using the combination of the latitude-longitude pair and the name of the establishment. A radius of 10m is selected around each existing points to filter out the similar named POIs inside the radius. The output of the script provides the diversity metrics which can be plotted and represented in GIS map. The developed script takes the input as a shapefile and returns the output as a diversity metrics utilising every process we discussed (fig. 1A).

Figure 63: Type of LCZ classes prominent in city of Mumbai.

The WUDAPT classification is well documented and straightforward technique to classify urban morphology of any city. We followed a similar process as described in the documentation²⁸⁰ with slight modifications where required. Landsat images of the area are downloaded for two seasons (October 2016 and May 2017) and stored after clipping the extent to the city region. The resulting images are then subsampled to 100m resolution, down from the original spatial resolution of 30m. 300 Training samples for the 14 classes are manually digitised with the help of Google Earth (fig. 3). We kept aside 75 samples for determining classification accuracy.

²⁸⁰ <http://www.wudapt.org/create-lcz-training-areas/>

Figure 64: Map showing training samples of LCZ.

The samples for all the 17 classes as described in WUDAPT are not present in the city of Mumbai. The classes such as compact mid-rise and open low-rise have negligible existence in the city, therefore are not considered in this study. However, we removed the samples of the "Heavy Industry" class although it has distinct presence due to its close resemblance to other built and natural classes. We performed Random Forests Supervised classification technique to identify different clusters. It has been found that the vanilla approach towards classification does not always provide results with sufficient accuracy. The reason for this is overlapping built typologies especially in cities of developing nations, where the compact high-rise, mid-rise, open high-rise and mid-rise are jointly present in a neighbourhood (Kotharkar & Bagade, 2017). The classifier produces a large number of false-positives due to such occurrences. Many studies (Xu, Ren, Cai, Edward, & Wu, 2017) have dealt with this situation by utilising alternative processes to classify images such as through modified supervised classification techniques. Taking a hint from such studies, we extended this approach by using data and image processing solutions such as PCA (Principal Component Analysis) and GLCM (Grey Level Co-occurrence Matrix).

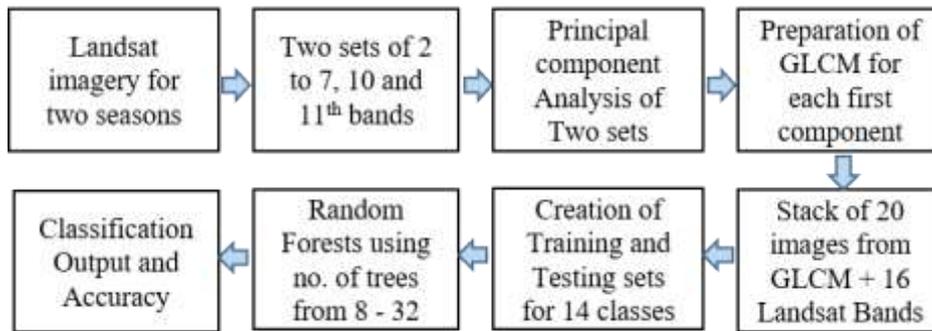

Figure 65: Flowchart describing process of LCZ classification.

With 16 individual bands of Landsat imagery for two different seasons (Bands 2 to 7, 10 and 11 of each imagery), we performed Principal Component Analysis for each set of bands. PCA is dimensionality reduction technique which lay emphasis on variation present in the dataset and generates patterns. It transforms the set of correlated values to produce set of uncorrelated variables, also known as principal components. In satellite image, the set of correlated values are the pixel values present in each band. PCA transforms the values from 8 bands to produce principal components which show their contribution to understanding the variation in brightness values of pixels. In the individual set of bands, the first, second and third components explained around 85, 11 and 3 percent of the variance among the pixels, respectively. GLCM is a measure of textures present in satellite imagery. GLCM is useful in the images where the differences between the brightness values in different classes are smaller. According to (Haralick & Shanmugam, 1973), "This matrix is a two-dimensional histogram of grey levels for a pair of pixels which are separated by a fixed spatial relationship." The matrix estimates the joint probability distribution of a pair of pixels. GLCM provides 10 different texture measures such contrast, dissimilarity, homogeneity, angular second moment, energy, max. Probability, entropy, mean, variance and correlation in the form of imagery. GLCM is calculated for the first PCA component of both the sets with the help of SNAP²⁸¹ software by ESA. The process resulted in the creation of 10 images explaining GLCM textures for each first components in both sets.

The Image classification task included 16 Landsat bands from two different seasons and 20 images computed from GLCM resulting in 36 images. The classification task was performed in SAGA GIS software using random forests. We experimented with a different number of trees from 8 to 64. The classification accuracy increases with the numbers of trees and plateaus after 24 trees. In the study, we are more interested in the diversity of the built typology. Therefore, we bundled the other natural classes into single Natural class. A total of 8 classes (7 Built + 1 Natural) are used to calculate classification accuracy (Table. 2). The classification accuracy is calculated as a fraction of total correctly predicted pixels and the total number of pixels classified which gave 85% accuracy. Fig. 4 shows the flowchart of the process of LCZ classification.

²⁸¹ <http://step.esa.int/main/toolboxes/snap/>

5 RESULTS

The number of points in each of the POI classes and the number of classified pixels of each LCZ class were used to calculate hill numbers as diversity metrics for each sub-ward. The results of which can be understood with the help of various data representation techniques such as choropleth maps and scatter plots. Throughout the study, we assumed the total number of POIs captured by custom-made scripts is consistent with the actual number of POIs present in each ward. It is to note that the actual Points of interests and establishments would be much higher than what is being reflected in Online databases. We assume that collected POI is the representative sample of the diverse Places present in each ward. Similarly, The LCZ technique to identify the urban typology within 8 classes is only accurate to 85 percent, which is a satisfactory figure in terms of the WUDAPT classification technique, however false-positive pixels in classification may produce different diversity values in each ward. However, this error in classification is not localised and affect the complete area. Therefore, a comparison between different areas regarding diversity metrics can still be conducted without significant consequences.

We compare the LCZ and POI Shannon entropy maps (fig. 6) to find out the consistency between the clustering pattern between the two. It is evident from the maps that POI entropy does not form any specific clusters as in LCZ. Also, there is less variation between the POI entropy values than LCZ. A trend of wards with high POI diversity can be seen along the major roads of the city. The reason can be cited to the establishment of the variety of the businesses due to the presence of major roads for quick access to other parts of the city. LCZ on the other hand show clustering pattern. Wards in South Bombay (A), North (B), and Central (C) are more diverse which is due to the inclusion of different built typologies such as High, Mid and Low rise (slums) and Water due to streams and coast; dedicated Green spaces and presence of small forests.

The wards which share the city boundary usually are larger and include coastal areas, forests and mangroves. The diversity in Land typology is, therefore, higher for such wards. Interestingly, such wards also account for relatively higher diversity in POI which might be the reason due to the onset of various businesses in the periphery of the city. South Bombay (A) is considered as a business and cultural hotspot due to the presence of heritage monuments, offices of multinational companies, restaurants and recreational places. This can be reflected in the comparison indices for both the maps. The scatter plot (fig. 7) shows the diversity values with respect to each ward. Interestingly, the wards in south Bombay (173- 228) are present in both ends of the spectrum. Quite of few have rich diversity in businesses, and others have diversity in land typology. Together, such wards provide an interesting mix of establishments and natural spaces.

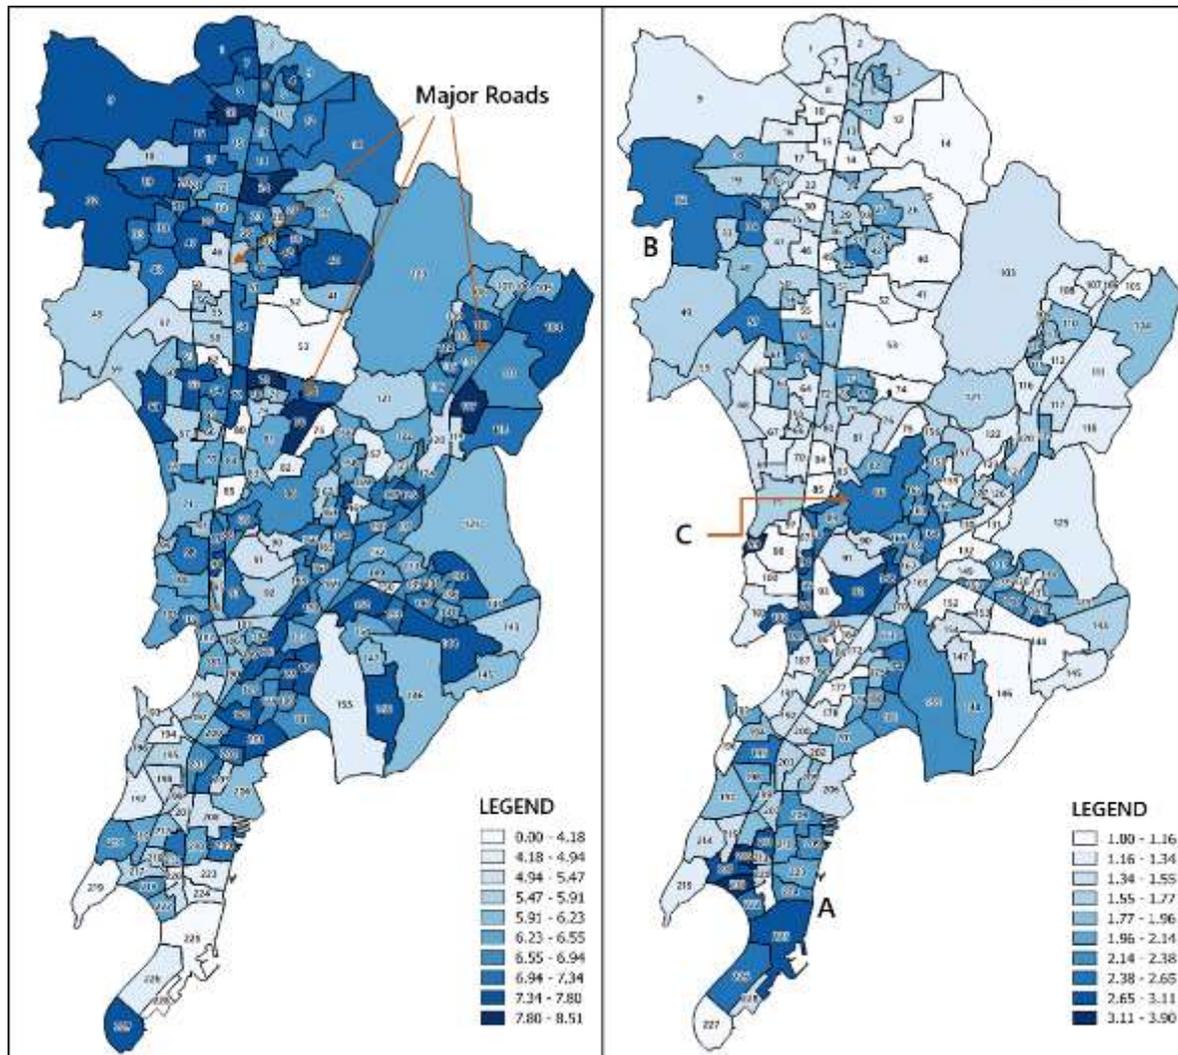

Figure 6: Comparison of Shannon Entropy results between POI (Left) and LCZ (Right) maps.

Cities have been the product of advances humankind has made over the years in technology and innovation. In recent years, due to rapid and haphazard growth, neighbourhoods have started to become vastly similar and unrecognisable. Monotony in visual appearances and built typology have started becoming apparent which is altering inherent diversities present in the cities. Research in understanding form and function at a large scale have been quite scarce owing to the absence of large datasets and the techniques to calculate the assorted variety in the cities. This study is aimed towards the creation of methodology where the diversity patterns can be studied. Although diversity of neighbourhoods depends on various factors and domains taken into consideration, we made use of the data which is widely available and can be used to determine the micro relationships between form and function in a detailed manner. Such process can be reiterated in different cities to compare and relate the localised diversity in terms of built typology, land uses and businesses. This study provides the overview of the results based on aggregated statistics of the presence of individual Points of Interest and Built typology. Such study if focused on investigating few wards in close comparison may outline significant details about the relationship between the occurrence of specific POIs at specific typologies. Future studies might use Land uses, demographic statistics to gain detailed insights into urban character and can monitor dynamic nature of cities.

The tendency of a diverse set of POI's being clustered in few wards is possible due to the existence of major or local economic hub of the city. We relate the spatial extent of each ward with the Shannon entropy values of POI to comment on the possibility of the existence of such districts and hubs. The area statistics of 228 wards varies from 31 sq. km to 0.23 sq.km. Fig.8 shows the scatter plot of ward area and the amount of POI present in the city of Mumbai. The scatter plot presents only the top and bottom 50 wards with respect to the area. The Colorbar and the radius represent the typology diversity (LCZ diversity) for each ward. It can be seen in the graphs that POI entropy in wards with lesser area tends to vary when compared to the larger ones. Only 10 of the bottom 50 wards in the 2nd figure have entropy less than 6 which is considerably lesser than 25 wards being under 6 in the first figure. Further, comparatively larger and brighter data points suggest high diversity values in typology in the 2nd figure. Smaller wards therefore are more diverse in terms of POIs and typology than the larger ones.

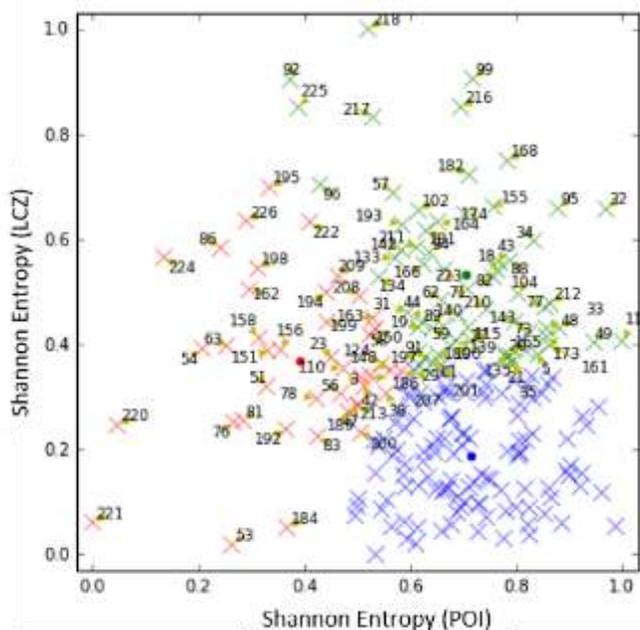

Figure 7: Scatter plot of sub-wards displaying relationship between POI and LCZ diversity values.

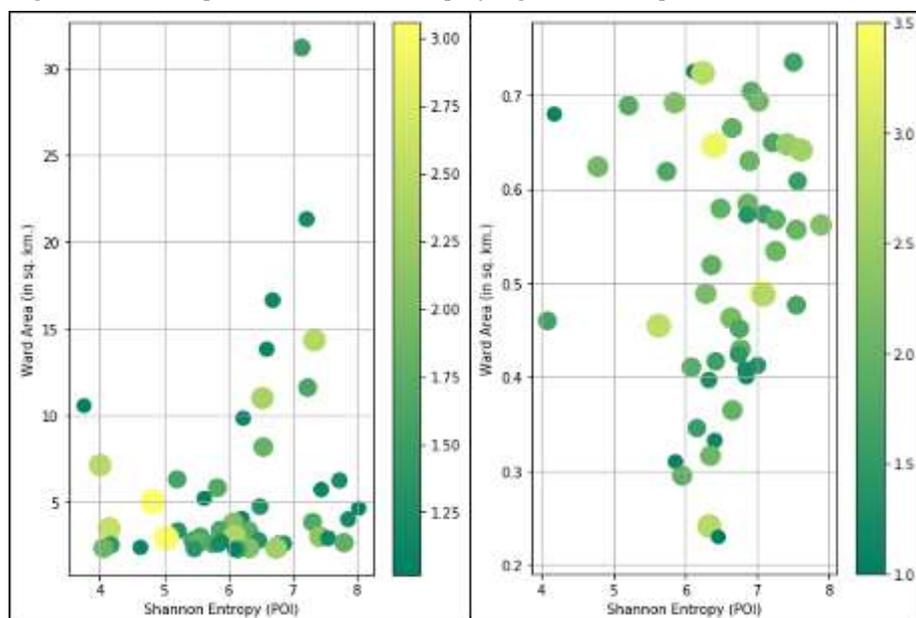

Figure 8: Comparison of Diversity between larger and Smaller wards.

6 CONCLUSION

Cities have been the product of advances humankind has made over the years in technology and innovation. In recent years, due to rapid and haphazard growth, neighbourhoods have started to become vastly similar and unrecognisable. Monotony in visual appearances and built typology have started becoming apparent which is altering inherent diversities present in the cities. Research in understanding form and function at a large scale have been quite scarce owing to the absence of large datasets and the techniques to calculate the assorted variety in the cities. This study is aimed towards the creation of methodology where the diversity patterns can be studied. Although the diversity of neighbourhoods depends on various factors and domains taken into consideration, we made use of the data which is widely available and can be used to determine the micro relationships between form and function in a detailed manner. Such process can be reiterated in different cities to compare and relate the localised diversity regarding built typology, land uses and businesses. This study provides the overview of the results based on aggregated statistics on the presence of Points of Interests and Built typology. Studies like these, if focused on investigating few wards in close comparison may outline significant details about the relationship between the occurrence of specific POIs at particular typologies. Future studies might use Land uses and demographic statistics to gain detailed insights into dynamic nature of cities.

ACKNOWLEDGEMENT

The authors would like to thank Ministry of Human Resource Development (MHRD), India and Industrial Research and Consultancy Centre (IRCC), IIT Bombay for funding this study under the grant titled Frontier Areas of Science and Technology (FAST), Centre of Excellence in Urban Science and Engineering, (grant number 14MHRD005).

1506 SPATIAL & TEMPORAL ASSESSMENT OF HEALTHCARE FACILITIES IN MUMBAI: K-WEST WARD

ABSTRACT

There is a necessity of healthcare facilities (HFs) to perpetuate human life from various kind of diseases. The demand is growing briskly day by day with the growing population in urban areas, which generates some questions like, are the HFs well distributed over the area based on their speciality, affordability and service timing, if so then, how much area can be served by the existing HFs, if so then, are they able to provide 24 hour service, if not then, which areas are underserved or health facilities shortage areas and in which time window, and which are the probable areas to place a new HFs. This paper analysed the current situation of HFs both spatially and temporarily in k-westward of Mumbai as a study area. The spatial analysis demonstrates the spatial inequality in terms availability and accessibility of HF's. From the results, it was found out that most of the unserved areas are low-income neighbourhoods and they are lack of affordable HFs (i.e. public). The spatial inequality of various healthcare services was computed using the network analysis with different catchment areas. The temporal analysis considers different time frames of service timing of HFs like morning, afternoon, evening and midnight. The result shows that only a few out of 179 HFs provide 24hrs services, of which only two are public HFs that means lack of public HFs, especially in night hours. This spatial and temporal analysis will give an idea to health managers, policy makers and planners where to open new HFs, or what will be its operating time window. This methodology can be applied to other geographic areas.

1109 LAND USE/COVER CHANGE AND URBAN GROWTH IN AGARTALA CITY, TRIPURA, INDIA

ABSTRACT

Agartala is one of the fastest growing City among North-Eastern states of India with a population over four lakhs. Being a capital city of India, Tripura it is experiencing multi-dimensional problems such as over population, traffic congestion, water logging, inadequate solid waste disposal system and tiltation of buildings. The present study illustrates an integrated approach of Remote Sensing and GIS (Geographical Information System), i.e., Geospatial techniques for assessment of urbanisation, urban growth and land use/land cover dynamics of Agartala city. Landsat Satellite imageries of two different time period, i.e., Landsat Thematic Mapper (TM) of 1991 and Enhance Thematic Mapper (ETM) 2015 were acquired from USGS Earth Explorer/GLCF and quantified the land use/land cover changes in Agartala City during 1991 to 2015. The images of the study area were categorised into five different classes, viz. built-up area, water bodies, open space, vegetation and agricultural land. The remotely detect land use/cover change during 1991 to 2015 shows that Agartala is gradually changing as vegetative cover and open space have been renovate into built up areas. Low-lying marshy land and water bodies have been also transformed into built up areas. The study reveals that the city is expanding maximum towards the north-south direction due to presence of an airport in north and National Highway-8 along the periphery of the city in the south. The paper also highlights the importance of digital change detection technique for nature and location of change of Agartala city area. And it will contribute to both the development of sustainable urban land use planning decisions and also for forecasting possible future changes in growth patterns of the city. : Land use/cover, Urbanisation, Urban growth, Geo spatial technique.

1565 REJUVENATING AN ABANDONED TOWN: THE CASE OF DHANUSKODI ISLAND, INDIA

ABSTRACT

Cities or towns that were previously functional but have been abandoned at some stage, represent an instance of unprecedented urban decaying. The revival of such towns get interlinked with the concept of urban renewal and redevelopment. This study revolves around Dhanuskodi, the end point located in the eastern part of Pambam Island, that was abandoned after the devastating impact of the cyclone and coastal disaster that took place in December 1964. Since colonial period Dhanushkodi was famous for trade and commerce. During mid of 20th century it was established as a modern market due to availability of good and transport facility. Due to the geographical location and its economic richness it was known as “Singapore of the South”. The most severe cyclonic storm which struck the town on 22-23 December 1964 and it lost its importance and abundance with the storms immediate effect. The cyclone devastated the entire town, washing away the railway track along with the last stream engine Pamban-Dhanushkodi passenger train that once connect Rameshwaram with Dhanushkodi and the entire villages swept away. This tip of southern part of Dhanushkodi island was destroyed and it is the same location that underwent subsidence under the Neo-tectonic activity in the mid of century and a subsequent emergence during the 2004 tectonic activity and tsunami. Presently Dhanushkodi island consists a small fishermen community that has been struggling in isolation since 1964. The local and state govt has proposed such kind of plans for rejuvenating the township. For the development of coastal tourism in TamilNadu the Ministry of Tourism, Tamil Nadu has launched “Swadesh Darshan Scheme” in 2016. Local, State and Central government has been proposing initiation of several scheme to redevelop towns infrastructural, communicational and other purpose has been needed. This study is an attempt to review the situation, attempt to draw up a framework for its revival with proper conservational measures coupled with renovation and restructuring so as to preserve its previous historic and mythological significance. This study analyses the evolution of the island, and assesses the present situation of existing dwellers of that island and subsequently proceeds to draw up the development issues, in the context of the proposed railway link with the mainland. The objective is to envisage the future possibilities of Dhanushkodi to be established again as an integrated region Southern India. The study will be based on qualitative survey aimed at an attempt to undertake a SWOT Analysis.

1648 IMPACT OF URBAN CENTRES ON REGIONAL DEVELOPMENT: A CASE STUDY OF UTTAR PRADESH

ABSTRACT

Regional development is the outcome of territorial, economic and social integration. Urban centres act as an engine of growth of a region due to its multifunctional role in its internal and external relations with the human settlements and its environs. In 21st century, 'changing mode of production' and rapidly growing population leads to urbanization in developing countries. Urban population and urban centres are increasing rapidly in India as well as in Uttar Pradesh. According to census of India 2011, Uttar Pradesh has 22.28 percent urban population with 915 urban centres. But inter-regional variation of urbanization is very high in the state, census of 2011 shows that the Western Uttar Pradesh has most urbanization and Eastern Uttar Pradesh has least, 32.45 percent and 13.40 percent respectively. This paper is based on secondary data collected from Census of India, National Sample Survey Organisation (NSSO) and etc. Correlation, Nearest Neighbour Method for statistical analysis and cartographic representation are used to show the distribution of urban centres and regional development in different parts of Uttar Pradesh. This paper focuses on the regional distribution of class-wise urban centres and share of statutory towns and census towns in total urban population of Uttar Pradesh. It also tries to shed light on the connectivity among different urban centres and district headquarters and how they could help in planning and regional development of the region. The study found that number of urban centres has direct impact on the level of regional development, the western part of the state is more developed than the eastern part of the state. Most of the part of Bundelkhand and Tarai region has least number of urban centres and both come in the most backward regions of Uttar Pradesh. The results depict that small urban centres play a major role to provide services and markets to rural economy and it has positive impacts on regional development. Key words- urbanization, urban centres, regional development, planning, region

1728 PLANNING SCHOOL NETWORKS IN DECLINING TERRITORIES: AN ANALYSIS AT THE LOCAL SCALE²⁸²**J. Wolf*, J.L. Marques, E. Castro**

Department of Department of Social, Political and Territorial Sciences (DCSPT), University of Aveiro, 3810-193, Aveiro, Portugal.

*Corresponding author: E-mail: jwolf@ua.pt**ABSTRACT**

Demographic change, and in particular phenomena such as ageing, shrinkage and depopulation, have a prominent place on the agenda of many European countries. But, even if they can be understood as general European problems, different regions and countries have different trends. Portugal, which has currently one of the lowest fertility rates in the world, has witnessed a particularly intense demographic decline, aggravated by the fact that the negative natural growth rates have not been compensated by a significant influx of migrants (as has occurred in other EU countries). The highly asymmetrical spatial layout of the country also means that this demographic challenge affects regions very differently, with some regions still growing, while others are already declining for decades. Notwithstanding the broad scientific discussion of this topic, local planning policies have struggled to address the challenges that arise from a contracting population on a broad scale. In fact, planning instruments are often based on the assumption of economic and demographic growth, to which they respond with urbanization and the provision of services and infrastructures, and not set to assume shrinkage as a permanent, or at least long-term, reality. Further, service provision to a shrinking population rises a particular set of problems that are inherently difficult to address such as; shrinking revenue; underused and overstretched infrastructures; the need to justify increased spending for adapting these infrastructures in declining territories; or guaranteeing service provision and quality to small and decreasing population pockets. This article will discuss the planning of public services in a context of shrinkage, by focusing the planning of primary schools in Portuguese municipalities. Six municipalities, which have witnessed significant restructuring of their schooling network in the last decade, and a varying degree of population decline, will be analysed. This analysis will focus on: i) the criteria underlying the used planning instruments; ii) the spatial layouts that are the outcome of applying these criteria; iii) the way in which (or whether) the planning of the schooling networks took into account the significant changes in the quantity and age structure of the population.

Keywords: Shrinkage; demographic change; public services; spatial planning**INTRODUCTION**

Territorial decline has been a frequent subject of urban and rural development literature in the last decade. Regarding rural areas, their decline has already been analyzed by many authors in the context of the urbanization processes and the concentration of industrial and tertiary activities of the late nineteenth and early twentieth century (see, for example, Carver, 1927 or Longstaff, 1893). But the decline of rural areas continues to be a relevant subject in many European territories, including issues such as: rural ageing (Burholt & Dobbs, 2012); the abandonment of remote agricultural or low density areas (MacDonald, Crabtree, & Wiesinger, 2000; Strijker, 2005); or the process of decline and its relation to cultural marginalization (Bryant, Paniagua, & Kizos, 2011).

Urban decline is also, by no means, a recent scientific subject. Decline has, for example, been considered by the cyclical models that, since the 1970, have tried to apprehend urban transformation through several phases: growth, suburbanization, decline and (eventually) reurbanization (Champion, 2001; Hall, 1971; van den Berg, Drewett, Klaasen, Rossi, & Vijverberg, 1982). In these models decline can be understood as response to saturation of some urban areas, which leads to people and firms favouring less densely populated areas which have lower agglomeration costs and provide more access to urban amenities (in particular space). Decline is therefore assumed to affect major urban areas as well as city centres, as a consequence of suburbanization or relocation of employment. Other early authors focusing on decline, noting the difficulty in apprehending it through a single conceptual framework, note the coexistence of different trends in different regions and at different scales (Morrill & Symons, 1977; Bourne, 1980).

Notwithstanding these analyses, the last decades saw an increased interest in this phenomenon, as can be seen by the proliferation of literature centred on the concept of *urban shrinkage* (Großmann, Bontje, Haase, & Mykhnenko, 2013; D. Haase, Haase, & Rink, 2014; Lang, 2012; Reis, Silva, & Pinho, 2015; Wiechmann & Pallagst, 2012). This conceptual shift – from decline to shrinkage – can be linked to changes in decline patterns, namely the low fertility rates of many European countries and the broad political and socioeconomic restructuring processes in Eastern Europe, as well as broad changes in urban systems, where broad polarization trends have led to the marginalization of many urban areas. But, coexisting with urban decline and shrinkage, other areas continue to grow and expand (Turok & Mykhnenko, 2007), highlighting the complexity of urban transformation processes, which comes from: i) the uncertain number of factors that influence urban development, ii) their unpredictable behaviour, iii) interactions at different scales, and its variability over time (Cheng & Masser, 2003). Therefore, urban change has been highly differentiated and dependent on concrete spatial context, with their specific spatial, economic and demographic layouts.

²⁸² This work was financially supported by the research unit on Governance, Competitiveness and Public Policy (POCI-01-0145-FEDER-008540) and it was developed in the context of the research project P-RIDE, Project Portugal: Regional Integration of Demography and Economy (POCI-01-0145-FEDER-016868), both funded by FEDER funds through COMPETE 2020 - Programa Operacional Competitividade e Internacionalização (POCI) – and by national funds through FCT - Fundação para a Ciência e a Tecnologia.

This complexity of urban transformation processes makes it difficult to devise planning approaches that deal with the multiple dimensions of shrinkage, while also addressing the specific challenges that are associated with it. It has, in this regard, often been noted that current planning instruments are essentially growth oriented and therefore ill-suited to shrinkage (G.-J. Hospers, 2014; Johnson, Hollander, & Hallulli, 2014; Sousa & Pinho, 2015). But the analysis of concrete spatial planning instruments and the way in which (or whether) they address shrinkage/decline is still scarce. This article will contribute to this discussion by analyzing the planning of school facilities in six municipalities in Portugal, which have gone through varying degrees of decline, as well as restructuring of their school networks. It is divided into three sections: the first one analysis of shrinking, with a focus on Portugal; the second one briefly reviews the planning challenges coming from shrinkage; the third one analysis the case studies.

DEMOGRAPHIC CHANGE: SHRINKING REGIONS IN PORTUGAL

As noted in the introduction, decline and abandonment are an essential part of any urban transformation process. The main causes associated with it – economic, politic, demographic or spatial – have also already been discusses since the 1980 (see for example Bourne, 1980)²⁸³. What is new about current shrinkage is the importance of each of these dimensions and their specific role. Three aspects in particular should be highlighted: urban sprawl; economic change; demographic decline (A. Haase, Bernt, Grossmann, Mykhnenko, & Rink, 2013).

In this sense decline, or shrinkage, are multidimensional concepts, whose precise definition is subject to a broad scientific debate. While not intending to contribute to this debate, this conceptual ambiguity makes it useful to shortly clarify what is understood by each one: shrinkage is essentially a process of sustained population loss that leads to a decrease of the urban (or artificial) land uses; decline mostly entails population loss. Both terms – decline and shrinkage – will here be used interchangeably. In fact, possibly the most important dimension of shrinkage is demographic decline. This is not only because population decline tends to be the starting point of any analysis of shrinkage (Hospers, 2014, p. 1508), but because demographic changes are often the underlying cause of this phenomenon. Currently, ageing, population decline and the depopulation of some of the more remote areas are occurring at a large scale in many European countries, as well as other developed countries in the world. These trends can be linked what some authors considered to be a second demographic transition (Kaa, 2002; R Lesthaeghe & Neels, 2002), where fertility rates became structurally lower than replacement levels, linked to a maslovian change in preferences (Ron Lesthaeghe, 2010).

But urban shrinkage also reflects a growing polarization and fragmentation of urban development. In the last decades, a global network of urban places emerged, accompanied by a disconnection from their regional or national contexts – in a trend towards “deregionalizing” urban development (Stratmann, 2011). This global network, shaped by a global system of communications and led by global capitalist socio-economic forces, has been witnessing two main processes: i) specialization – which promotes the differentiation of urban landscapes according to their role in the global hierarchy; and ii) homogenization – mainly related to sharing, across the globe, tastes, living patterns or fashion – which results in what Koolhaas calls the emergence of the generic city (REM Koolhaas, 1995). Both mechanisms lead to a polarization of the urban system where the more dynamic and central urban areas develop into large socio-economic agglomerations and important nodes on the global urban network, in a metropolisation process analysed by many authors (Borja & Castells, 1997; Frey & Zimmer, 2001; Peter Hall and Kathy Pain, 2006; Stratmann, 2011). These urban areas also concentrate a growing share of economic activities, namely the ones related to innovation and knowledge, industrial and tertiary alike (Krätke, 2007).

At the European level, this metropolisation process has led to the growth of the large urban areas and conurbations that are located in the pentagon formed by London, Paris, Milan, Munich and Hamburg, which are complemented by a second layer of cities, such as Barcelona, Rome or Berlin, or cities with a national or regional relevance (Peter Hall and Kathy Pain, 2006). In parallel to the growth of large metropolises, many of the more peripheral areas are stagnating or declining. This decline affects many of the old industrial cities but also cities in shrinking regions, namely in eastern Europe (Turok & Mykhnenko, 2007): the majority of the eastern European cities has witnessed population loss in recent years, even if capital cities and more centrally located cities are excluded from this trend (Scott & Kühn, 2012).

The polarization of the urban system is also very visible in the Portugal, which has a very hierarchical urban systems and lacks medium-sized cities. In fact, the two largest functional urban areas (the metropolitan Areas of Lisbon and Porto) concentrate around 40% of the population (according to the urban audit) and have been growing above the national average since the 1950 (Marques, 2003).

²⁸³ According to this author, decline can be understood as a consequence of: 1) structural economic changes; 2) the movement of people according to job opportunities, amenities, social attributes or cultural preferences; 3) the unplanned outcome of public policies; 4) the systemic exploitation which is inherent to capitalist systems; 5) the complexity of social systems, with their significant randomness.

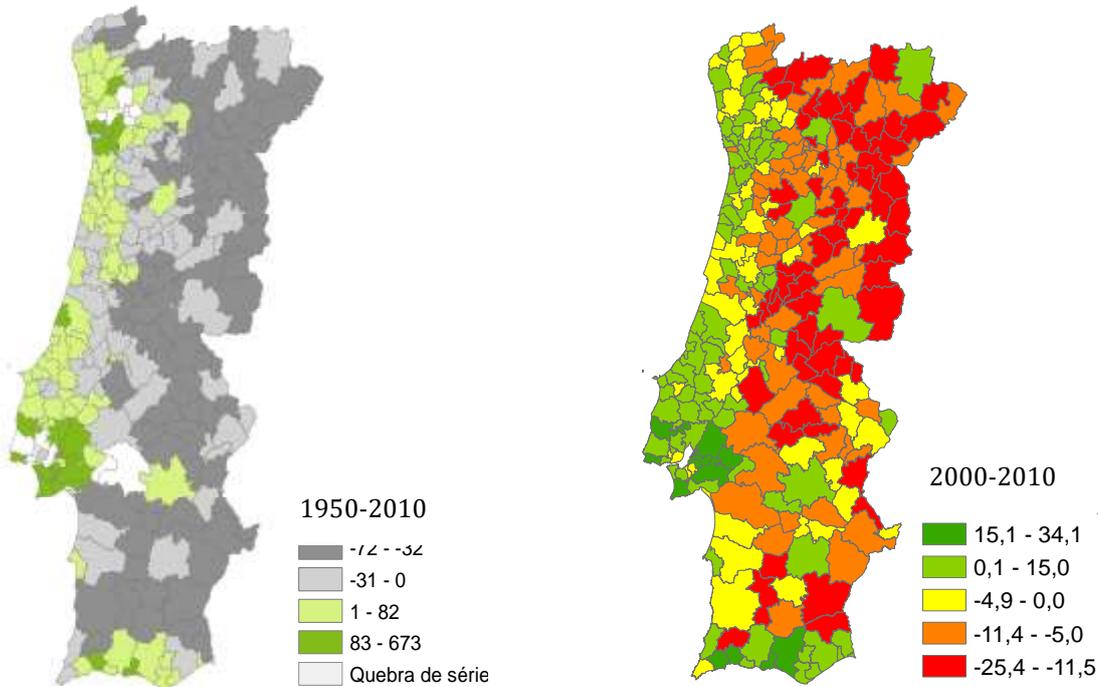

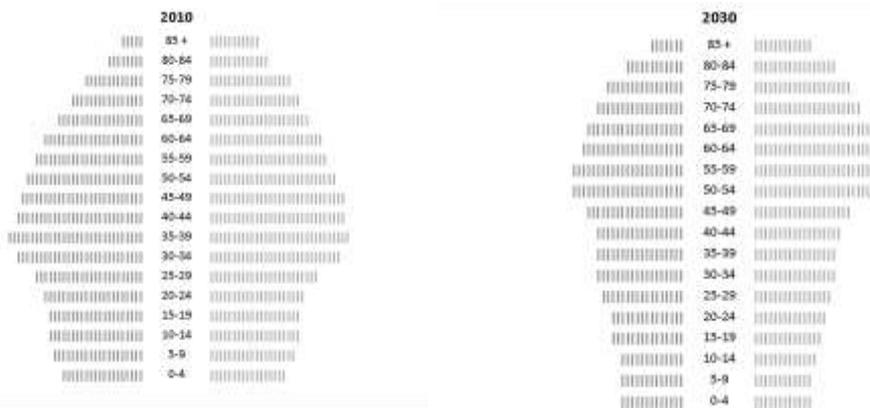

Figure 67: Growth rates in Portuguese Municipalities (%)

Much of the territory outside of the influence of the two largest urban areas has been witnessing very low growth rates, or decline, in particular the inland areas. This divide between coastal and inland areas is central to the territorial layout of the country, and can be observed since the nineteenth century, when the inland districts began to witness growth rates below the national average (Mourão, 2006). This trend has been accelerated throughout the twentieth century and, in the last decade, only a small share of non-coastal municipalities has been growing (see figure 1). But when looking at the medium-term trends the decline has even been more accentuated, with a smaller share of municipalities concentrating the population growth.

Source: Demospin Project (the projection is made considering a closed population)

Figure 68: Current and projected age structure of the Portuguese population

This trend is expected to continue, or even accentuate. In fact, given the age-structure, and its expected evolution if considering current fertility trends, population decline can be assumed for the next decades. And, considering current polarization trends and the fact that the general level of urbanization of Portugal is still below EU averages (the ESPON 1.3.4. project, for example, shows that in 2006 73,5% of the Portuguese population lives in functional urban areas, comparing to 83,7% in Spain or 77% in France), there is still room for further concentration of the population and for a sharper decline in much of the territory.

PLANNING SERVICES IN SHRINKING REGIONS

As was discussed in the previous section, the causes for shrinkage are manifold and include structural issues – such as demographic trends, global economic linkages, technological development or cultural preferences – with more localized ones – which are concerned with the spatial characteristics of a given territory or its position in the broader urban context. As noted by Martinez-Fernandez *et al.* (2016), this makes shrinkage an essentially glocal issue, meaning that it depends on local responses to broader societal trends. Shrinkage is, thus, a complex and highly differentiated phenomenon, which is difficult to address through local planning policies, not only given its multidimensionality and the complex causal relations which lead to it, but also because many of the explaining factors are out of reach to local policy makers.

From a service provision perspective, population decline poses specific challenges such as: shrinking revenue; underused and overstretched infrastructures; the need to justify increased spending for adapting these infrastructures in declining territories; or guaranteeing service provision and quality to small and decreasing population pockets. However, service provision should not only be understood as a reaction to population decline: it is, in itself, a factor that contributes to shape shrinkage. The planning of public service regarding decline can, thus, be made from two perspectives: i) as part of policies to counter it; ii) as a way to mitigate its negative consequences.

Regarding the first (i), the most frequently considered strategies for countering decline are not directly related to service provision. In fact, given that local development prospects dependent more on attracting and retaining population (and not on stimulating natural growth), many local policy-makers have focused on developing strategies aimed at stimulating the local economies or place-making. These policies range from providing favorable fiscal regimes (this was used, for example in Sosnowiec – Bernt *et al.*, 2012), to promoting urban regeneration or tourism through place marketing. The main goal of these approaches is to create a favourable image and put the place on the map, through marketing strategies (Hospers 2011, p. 370). But the practical impact of these measures is often questionable. Not only because territories are multi-dimensional and complex and are therefore difficult to ‘sell’ (Kavaratzis & Ashworth, 2005), but also because the broad use of these strategies can lead to a highly competitive environment and zero-sum games (G.-J. Hospers, 2014).

Another frequently adopted strategy for countering decline is the provision of amenities (which include services). The literature has shown they concur with labor-market opportunities in explaining attractiveness of a given place, in particular in the USA (Chen & Rosenthal, 2008; Clark & Hunter, 1992; Ferguson, Ali, Olfert, & Partridge, 2007; Gustafson, Hammer, Radeloff, & Potts, 2005) but also, to a lesser degree, in Europe (Biagi, Faggian, & McCann, 2011; Cheshire & Magrini, 2006; Rodríguez-Pose & Ketterer, 2012; Sarra & Del Signore, 2010). In Portugal this relation was analysed, in an exploratory fashion, by Barreira, S. Ramalho, Panagopoulos, & Guimarães (2017). But, even if the importance of the provision of amenities for the attractiveness of a territory is broadly recognized, there is scarce empirical prove of the success of measures that are based on this approach in dealing with decline. In Germany, for example, many municipalities have developed child-care services or the provision of affordable housing, without a clear contribution for mitigating or countering decline (Küpper, 2011). In Portugal, many of the less developed territories have also tried this type of approach and tend to have a better coverage of social services for children or the elderly, without a clear impact on their demographic prospects.

Strategies for mitigating decline and adapting to it (ii), on their turn, tend to focus on resizing and repurposing. One of the most debated case is, in this context, the urban strategy applied to eastern German cities – the *Stadtumbau Ost* (Deutscher Bundestag, 2012) – which namely included the demolition of a very significant amount of housing (see, for example, Bontje, 2004; Wiechmann & Pallagst, 2012; Wiechmann, 2009; Pallagst, 2008). Another strategy is to deal with shrinkage through a smart decline approach, such as using vacant urban land to provide green areas (D. Haase et al., 2014), involving citizens in its management or on sharing the provision of functions between different local authorities (Popper & Popper, 2002). Nonetheless, the adoption of this kind of approach is challenging, since it implies assuming decline as a long-term reality which, as was noted, is not something planning systems are well adjusted to. Further, given the impact physical decline and population loss have on the image and identity of a region, assuming shrinkage can even contribute to accelerate it (G.-J. Hospers, 2014) or become a self-fulfilling prophecy. This means that most strategies for addressing decline are based on revitalization or stabilization (Johnson, Hollander, & Hallulli, 2014, p. 151).

PLANNING SCHOOL FACILITIES IN PORTUGAL

Although often considered bureaucratic and centralized, education in Portugal has been subject to several policies, programmes and measures that embody a gradual shift towards decentralization and territorial contextualization (Alves, 1996: 1169; Formosinho, 2000; Machado, 2014). Decentralization essentially means shifting competences from the central state to local or regional bodies, in particular municipalities. In Portugal, decentralization in education has been advancing since the 1980 and, while initially comprising mainly complementary tasks – e.g. transport or social services (Neto-Mendes, 2007), gradually moved to include more essential issues, such as non-teaching staff management or the definition of extra-curricular activities. The territorialisation, while overlapping with decentralization in some aspects, can be understood as a step further in rethinking the regulation in educational matters. It implies a greater autonomy for the schools in defining local educational projects (assumed by the Decreto-Lei nº 553/80, de 21 de novembro), as well as the involvement of a broader set of agents and the acceptance of the diversity of processes, solutions and decision centres, without losing national coherence and equity (Barroso, 2013: 22).

In many ways the decentralization and territorialisation of educational policies reverberate with the broader debate on the role the state and different local and regional agents have in policy formulation and implementation, expressed in the governance literature of authors such as Kooiman, (2003, 2008) or Rhodes (1996, 2007). For this paper, two aspects become crucial. The first one is the way in which state control is being eroded and substituted by the rise of networked coordination, where the boundaries between “state, market, and community” are blurred or even dissolved (Rhodes, 1996). In the planning field, this new understanding of the role of different agent in the policy process can be associated with collaborative planning approaches, which emphasize deliberation, communication (Healey, 1990, 2003) and consensus seeking (Innes, 1996), and tend to assume the establishment of a varying set of partnerships or collaborations between different stakeholders as a key way of functioning (Healey, 1998: 1533). The second one is a change in scale in the predominant institutional arrangements between stakeholders. This change implies a downward shift, towards more localized and place-based approaches (Oliveira & Breda-Vazquez, 2010). But, in the European context, it also implies and

upwards shift, where competences and decision-making are assumed by the different EU wide bodies (Papadopoulos, 2010). This means that policy decisions, even at the local scale, increasingly depend on the institutional arrangements that are established along different layers of agents and on their position and bargaining power in these shifting policy arenas – leading some authors to classify this new context as a multilevel governance system (Kokx & van Kempen, 2010).

But, while these trends can be associated with more participated policy processes, an increased autonomy of local stakeholders or even the (co)production of public services by local communities (Gofen, 2013; Ostrom, 2010), they have also been subject to criticism. The governance discourse, and the horizontal, collaborative, policy practices which are associated with it, are often considered a way to promote a neoliberal appropriation of state functions (Swyngedouw, 2005), or at least to provide legitimacy to a neoliberal supporting state (Gunder, 2010; Purcell, 2009). In fact, the substitution of the rational, bureaucratic, administration of public services by more flexible post-modern forms of coordination often favours the capture of processes by more powerful and organized interest groups as well as the application of performance and output-oriented approaches. Further, it has also been pointed out that central states continue to play a crucial role in defining public policies (Kokx & van Kempen, 2010; Marinetto, 2003), given their capacity to define funding mechanisms, to establish bureaucratic procedures or simply because, even if they would start as an equal partner in a collaborative governance approach, they have greater access to each of the sources of power identified by Purdy (2012) as being fundamental in this kind of process – authority, resources, legitimacy.

The inherent complexity of most modern public policy issues also means that they are not easily addressed through a loosely formulated set of procedures that is defined by a varying network of public and private agents. Therefore, more than witnessing a shift towards networks of horizontally linked public and private agents, modern states combine bureaucratic organizations, networks and markets, which form contending and cooperating institutions (Olsen, 2006).

Given this context, planning processes in education should be understood as the outcome of central state regulation, as well as the way in which local agents articulate themselves in institutional and governance arrangements. These two levels correspond, broadly, to what Barroso (2006: 51) called the “institutional regulation” and “local microregulation” of educational matters. The institutional regulation refers to the way in which the State and its administration coordinate, control and influence the context in which local decisions are made. The local micro-regulation highlights the horizontal coordination of institutional and non-institutional agents that share a space of interdependencies and interests. Both dimensions are fundamental for analysing the way in which local planning instruments face decline. In fact, the criteria and strategies for dealing with population decline in planning school facilities are very depend on the interplay that different agents and institutional frameworks in these different governance layers, as well as the assumptions regarding the role these facilities have in declining territories.

The responsibility for constructing, equipping and maintaining of primary school facilities was passed from the central State to the municipalities in 2003 (Decreto-Lei n.º 7/2003, de 15 de janeiro, revised by the Decreto-Lei n.º 72/2015, de 11 de maio). This law also assumed that planning this type of facilities would be done by the municipalities, by establishing a local planning instrument – ‘school charts’. These instruments are assumed to make a “prospective planning” of education facilities for the medium/long term, according to the offer that best serves the demographic and socioeconomic context of the municipality and the principles of rationality and complementarity. The municipalities are responsible for developing the charts, following technical criteria established by the Central State (for sizes, for the integration of different study cycles in one facility, etc.) and premises regarding the goals of these charts – such as reducing the isolation of students, promoting equal opportunities, meeting demand and articulating itself with the urban policy of the municipality. These charts are thus marked by a decentralized approach, where territorial contexts are taken into consideration and local bodies are given responsibilities but are also supposed to follow general goals and technical guidelines. In addressing decline, this integrated approach means that, besides adapting to the broader demographic, economic and social development trends, local education projects must also be understood as a central part of a territorial vision, given their role in any conceivable strategy to counter or mitigate shrinkage.

REORGANIZING THE PRIMARY SCHOOL NETWORK: FROM DISCOURSE TO PRACTICE

In this paper, the planning of primary school facilities in six different of the Centre Region of Portugal is analyzed in an exploratory way. The municipalities were selected given the role the authors had in devising local planning instruments related to education, including the revision of school charts or the development of strategic plans, which allowed to gather information as well as insights into the planning praxis that dominated these matters. The focus on primary education is justified by the changes these facilities have witnessed and, also, because they must guarantee spatial coverages which are not expected for other cycles. The depth of the analysis changes, according to the amount of information that is available for each case.

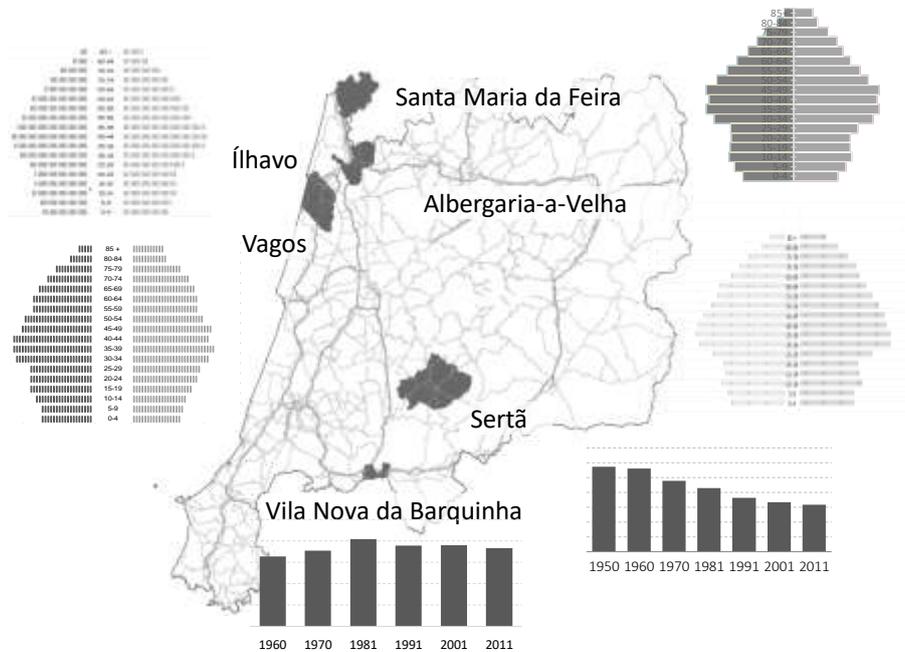

Figure 69: Municipalities considered in the analysis

As can be seen by Figure 69, the considered municipalities face very different demographic challenges. The two municipalities which are further from the coast have already witnessed a declining population in the last decades, while the other four have witnessed small increases, although their current age-structures are barrel shaped. Given these age-structures, population decline is almost inevitable in all the considered municipalities, in the medium or long-run. This decline can, essentially be understood as a consequence of persistently low fertility rates, which have led to a small amount of women in fertile age-groups, generating a negative momentum of demographic growth, which is affecting most of the European countries (Davoudi, Wishardt, & Strange, 2010). As noted by Castro, Martins, & Silva (2015), in most Portuguese regions this ageing process has reached a point where even an abrupt rise of fertility rates would not have a very significant contribution to countering decline, which would imply a very significant and constant influx of migrants in the next decades. Given that the migration rates in the analyzed municipalities are generally negative for young cohorts (and positive of old ones), further ageing and population decline can safely be assumed for all of them. This shift in the size and age-structure of the population, as well as the spatial asymmetries they tend to assume (with the more remote and less populated areas of these municipalities facing a much stronger decline), poses a considerable challenge to planning school facilities, which has led to very different policy responses in the six municipalities.

THE “RATIONALITY” OF THE SCHOOL NETWORKS

The reorganization of the school network has been one of the major planning challenges in Portugal and a paradigmatic one in dealing with decline. In fact, given the shrinking student population, there has been a continuous closing of school facilities and, since 2000 more than half of the national primary schools closed. Simultaneously, there was also a significant modernization of the school network, with the construction of many new buildings and the requalification of old ones: as noted by Martins (2014), the last decade witnessed a major renewal in school facilities, many of which were still from the first major expansion of the network in 1950-1970.

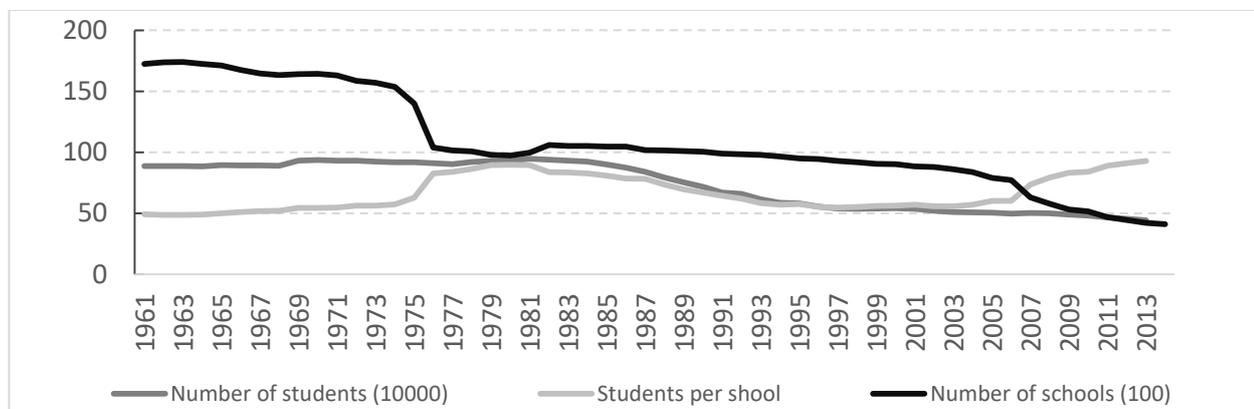

Figure 70: Number of primary schools and students (1961-2012)

This way in which these changes in the school network were done, while being a consequence of a decreasing student population, also expresses broad pedagogic assumptions. As becomes clear from Figure 70, primary school closures do not only reflect changes in the number of students, since the average size of schools has been changing significantly; they also reflect the type of school that is considered desirable. In the last decade there has, for example, been a push towards

larger school facilities that can provide the necessary amenities as well as a scale which is supposed to be more adequate for the socialization of student and the establishing of a teaching to advance their training.

In this regard, in 2010 the Government established as the criteria for primary schools to function a minimum of 21 students as well as amenities such as libraries or sport facilities (Resolução do Conselho de Ministros n.º 44/2010), following the goal for “rationalizing” the school network, established in 2005 by the second revision of the basic law for education. According to the dominant paradigm of school facility planning, this “rationality” essentially entails the closure of facilities that served small and shrinking population, mostly in rural areas, and their progressive concentration in new, much larger facilities. The rationalizing discourse has also, by a large degree, been adopted by the local planning instruments. In fact, the need to introduce “rationality” into the local school networks is stressed by five of the six school charts, which assume the need to counter the “isolation” of some of the student population.

THE PROSPECTIVE APPROACH OF THE SCHOOL CHARTS

Given this overall reduction in the quantity of primary schools it is interesting to analyse the way in which local planning instruments struggle to define a strategy for dealing with decline. In fact, the schooling charts of two of the municipalities did not include any projection for the student population but only the general population. And the projections that were made, had a very short time-span: taking into consideration that a school facility should be planned for a time-span of about 50 years, one school chart made projections for only 4 years and the longest time span was 13. But, most importantly, the estimations were overly optimistic. The two cases were only the evolution of the general population was projected, for example, assumed a growth rate which was much higher than the one that actually occurred. The projected number of students in the other school charts where also well above the real growth in the student population in all municipalities, except one. It should, nonetheless, be taken into consideration that the extension of the compulsory education until 18 years old or the finishing secondary education in 2007/2008 unexpectedly rose the number of students, which made the projections more accurate. For primary education, where the level of enrolment is much more stable, the projected number of students was, for example, much further from the actual evolution.

Municipality	Year of the school chart	Total student population					Primary schools	
		Last year of the projection	Projected student population	Projected growth rate	Actual student population	Actual growth rate	Projected student population	Actual student population
Sertã	2005	2011	2.372	-6.9	2 721	6.1	669	568
Vagos	2006	2016	3692	-2.5	3572	-4.9	1009	796
Ílhavo	2007	2011	6293	5.3	5705	-4.6	1880	1547
St M ^a da Feira	2005	2011	-	-	-	-	-	-
Vila N. da Barquinha	2005	2015	1074	17.0	896	-2.9	252	246
Albergaria-a-Velha	2007	2020	-	-	-	-	-	-

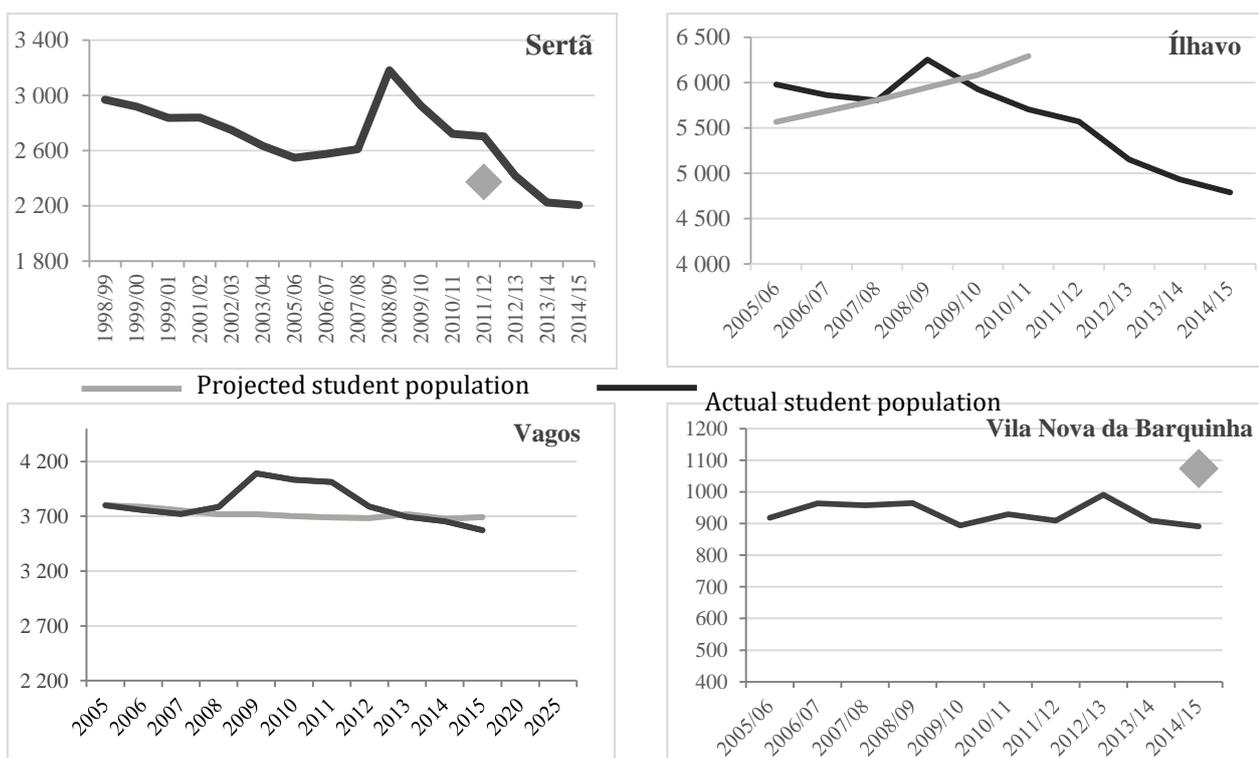

Figure 71: Projected vs actual change in student population

This difficulty in assuming decline can be explained by the applied methodologies, which often assumed the continuity of past trends, and the factors mentioned in the literature review – a growth-oriented planning system and the negative image that is generally associated with decline. But, as became clear by interacting with local policy-makers, it also expresses a very mundane issue: the difficulty in justifying the application for funding interventions in local facilities for a shrinking population. It can this be associated, to a certain degree, with the constraints of a multilevel governance structure where the definition of local planning strategies depends on the (perceived) rationales of external funding mechanisms.

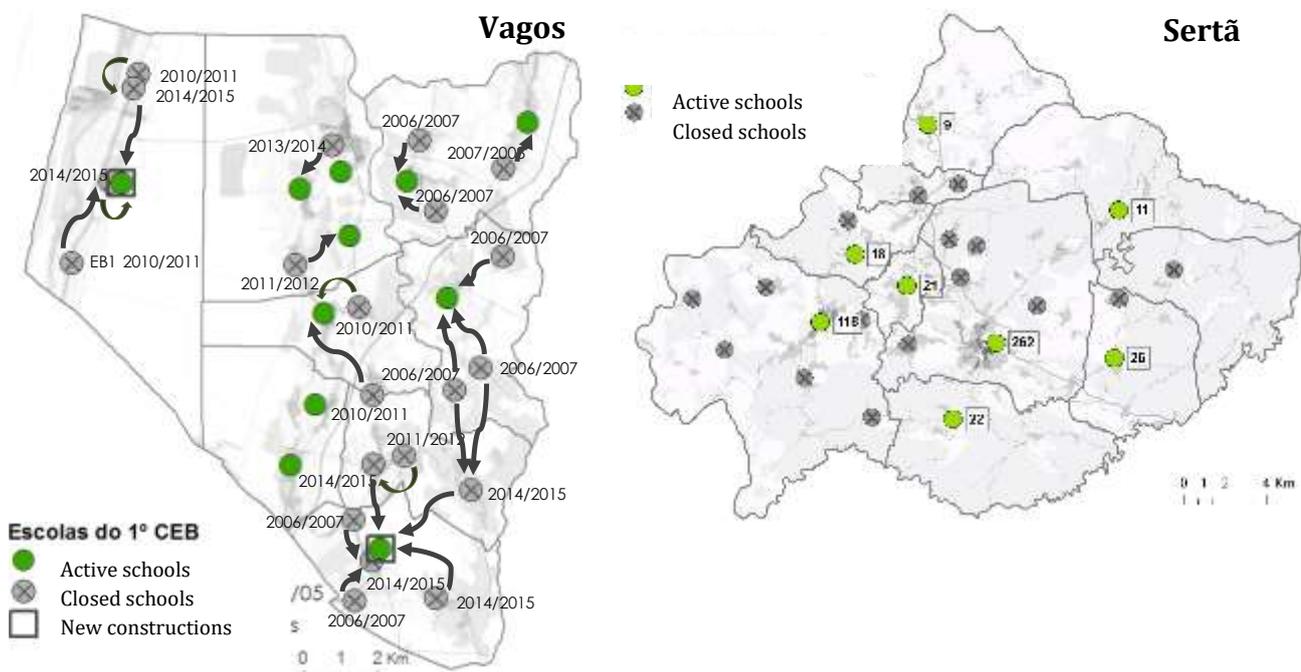

PLANNING THE DECLINE?

These multilevel governance structures are also fundamental in defining the way in the institutional regulation of the education system is translated into concrete spatial layouts. Cordeiro & Martins (2012), analysing the reorganization of school networks in 12 municipalities in Portugal, identify three different strategies at the local scale: (i) “reconfiguration by decree”, where national criteria for the functioning of schools are completely applied at the local scales; (ii) “reconfiguration by conciliation”, where criteria established by the central state are harmonized with the ones established by the municipalities; and (iii) “communitarian reconfiguration”, where the criteria established by the central state are largely ignored and closure of schools and the construction of new ones is subject to significant bargaining between local stakeholders and between those and central state actors.

When analysing the practical outcomes of implementing the school charts in four of the six considered municipalities, these different strategies become apparent. As can be seen in table 1, all the municipalities closed some school facilities, but the share differs significantly: from reducing the amount of schools by more than two thirds to reducing the amount by only one. Since the overall capacity in the school building rose in this last municipality, this meant that average occupancy rates fell, leading to an underused infrastructure.

Table 26: Reorganization of the primary school network in 4 municipalities

	Before the school chart					After the school chart				
	Year	Students	Schools	Average Size	Occupancy rates	Year	Students	Schools	Average Size	Occupancy rates
Ílhavo	2005	1706	20	85	77%	2012	1594	19	84	70%
Vagos	2004	1057	28	38	70%	2011	863	11	78	86%
Sertã	2004	651	29	22	45%	2011	487	8	61	68%
A-a-Velha	2005	1287	30	43	51%	2015	998	14	71	89%

The strategy regarding the new construction was also very different in the municipalities. In one municipality (Sertã), for example, no new facilities were constructed and the progressive closure of schools simply led to the already existing facilities absorbing the remaining students. In another one (Vagos), the strategy was mixed, with two new large buildings absorbing the student population from some of the small ones that closed, while in the rest of the territory there was a strategy of progressively closing facilities and transferring students to the remaining ones.

DISCUSSION

This analysis of the way in which local school planning instruments dealt with decline, while exploratory, allowed to get some interesting insights. The first one regards the difficulty in assuming decline. This can be seen by the tendency for overestimating the number of students, as well as by the absence of a declared strategy in addressing decline, even when it is expected. Essentially, decline is addressed through denial or passive adaptation, with a complete absence of more

proactive strategies, that could either aim at countering decline or managing it. The former strategies are further hindered by the sectoral and narrow planning approaches that predominates educational planning instruments, revealed by the complete absence of broader urban planning considerations in the reconfiguration envisaged in the analyzed schooling charts.

The second one concerns the way in which the reconfiguration of local school networks allow to understand many defining aspects of a multilevel governance system. As noted by Baixinho (2011), much of the decentralization push in educational matters has been led by rationalization discourse, where the planning and strategic allocation of resources remains centralized, while the operational decisions are decentralized. The definition of guidelines for the functioning of schools by the central state, and also the way in which local planning instruments adopt these guidelines (or even the discourse of these national policy directives), is a good example of this approach. It also highlights, in a more general way, the coexistence of central steering (or institutional regulation) in a context where local micro-regulation is supposed to be the privileged approach.

But the different approach to reconfiguration of the schooling system is also an example of the way in which central state guidelines are adapted to fit different local policy approaches. This is most evident in the varying degree to which the municipalities adopted the “rationalization” of the schooling system by simply maintaining many small facilities. But it can also be seen by small steps that are, ultimately, used to increase the reach of local decision-making. The denial (or limited assumption) of decline can even, in itself, be understood as a part of this strategy, by not providing the justification for a more radical reconfiguration of the school network and also by making it easier to apply to external funding mechanisms for rehabilitating existing school facilities.

RS16.1. Tourism

1417 ON THE SPATIAL ASPECTS OF DOMESTIC TOURISM IN INDIA: ROLE OF LANGUAGE, CULTURAL AND REGIONAL DEPENDENCE

ABSTRACT

India is seventh largest country by area and second largest country by population with diversity in terms of geographical terrains (from cold deserts of Ladakh to dry deserts of Thar, to Himalayas, tropical forests of Kerala and Nilgiris). This diversity is not limited to geography but of languages, cultural, societal and historical heritage as well. This diversity makes India one of the most popular destinations for tourists from all over the world and has been explored in the context of travel and tourism literature. One aspect that not received due attention in the context of India and other developing countries is the role and scope of domestic tourism. In this paper, we intend to explore the extent of domestic tourism using a novel dataset. We use data from National Sample Survey Organization’s sample survey on domestic tourism in India conducted from July 2014 to June 2015. This survey captured information on domestic tourism, household, visitors, and trips undertaken. The scale of the survey covered a representative sample from the whole of India, covering 8,001 villages and 6,061 urban blocks, with total number of households at 79,497 and 60,191 in rural and urban India respectively. For a job-starved country like India, tourism is a great hope sector. It is expected to grow at 11.2% CAGR in next few years, supported by penetration of digital technologies (Chowdhury, 2017). The relevance of the tourism sector for Indian economy and the growth numbers aside, the tourism sector in India is not well-explored in academic research. As a consequence, the sector grows organically without much policy understanding or interventions. We aim to plug this gap by exploring the behavioral pattern of domestic tourists in India. Specifically, we explore the tourist profile for socio-economic strata, purpose, duration, pattern of expenses, and place of choice to understand the facilitators and inhibitors of such choices. One of the key research question, we intend to answer relates to the spatial aspects of the domestic tourism. Drawing insights from the literature on international trade and gravity models of trade, we explore whether regional proximity is important for regional/spatial pattern of domestic tourism in terms of origin and destination. The regional proximity can be in terms of multiple aspects: a) physical proximity, b) lingual proximity, c) cultural and historical proximity. We intend to analyse the separate effect in determining the flow of domestic tourism and its implications for local employment and growth opportunity and spatial dependence in mobility for tourism. We use social network analysis and empirical gravity model from trade to analyse the regional patterns of domestic tourism and factors affecting these flows. Using the social network analysis, we intend to identify the clusters of local tourism which can be identified based on homophily in the network based on regional proximity defined above. A gravity model analyzes the role of size of a region, its economic prosperity, population size to explain and predict the flow of domestic tourism.

1440 TOURISM BELIEFS, CONSERVATION PREFERENCES, AND SUPPORT FOR TOURISM DEVELOPMENT IN AN EMERGENT RURAL DESTINATION

ABSTRACT

In the last 25 years a vast literature on attitudes of host communities regarding tourism development has been produced, usually modelling support for further tourism development after residents’ beliefs about economic, social, and environmental benefits and costs of tourism. This paper aims contributing to the literature over two different grounds: on one hand, it includes expectations about affective outcomes of tourism, along with cognitive beliefs, to better explain overall attitude towards tourism; on the other hand, it assesses how conservation-related values do influence support for tourism. Based on literature gaps, a model was designed integrating two central features: (i) an overall evaluative attitude mediating the relationship between affective and cognitive belief composites and support for tourism; (ii) a measure of preferences regarding municipal conservation policies moderating the relationship between attitude and support. It was assessed from data collected in a quota sample of 349 residents in a municipality of North Portugal largely covered by a natural park with some natural and rural attractions. Quotas were defined proportionally according to the population distribution in typology of place (town versus villages) and in three demographic characteristics: sex, age, and education. Measures’ reliability and validity and paths between variables are estimated by SmartPLS software. Results show that both positive and negative affective changes are expected, but only the positive expectations contribute to explain overall attitude. As to cognitive beliefs, most residents see no significant impacts or they are moderately optimistic regarding economic and environmental effects of tourism. A noteworthy result is that the global evaluative attitude towards tourism is much more dependent on the positive affective outcomes from tourism than on the instrumental outcomes. The overall attitude has a positive effect on support, fully mediating the contribution of beliefs to explain support. On the other hand, leaning for conservation policies negatively affects support for tourism development. There is an additional positive interaction effect between attitude towards tourism and preference for conservation, meaning that people who strongly want the municipal government body to have conservation policies tend to be less supportive for tourism development, but more responsive to the effect of attitudes. On the opposite, people who want the municipal government to be less focussed on conservation, tend to be firm supporters of tourism, so their support is less dependent on the attitude. Both business and academic discourse tend to emphasise that rural destinations’ development benefits from the preservation of central features from rural physiography and culture in order to keep their attractiveness and competitiveness. However, this paper’s results suggest that, at least in this particular emergent rural destination, a conflict is apparent between residents’ conservation concerns and their support for tourism. We then interpret the overall favourable attitude and warm support as a manifestation of low concern with rural conservation and with potential negative impacts from tourism.

1590 SUSTAINABLE TOURISM AN APPROACH THROUGH RURAL-URBAN DICHOTOMY

Maria da Graça Moreira

Assistant Professor, GEU, CIAUD, Faculdade de Arquitetura, Universidade de Lisboa, Portugal gmoreira@fa.ulisboa.pt

ABSTRACT

The areas of low population density that characterize many of the rural areas have tourism as an opportunity for economic growth but also as a critical factor for the preservation of heritage. Sustainable tourism, whether environmental, social or cultural, can be an important element in the valorisation of these territories, keeping them part of the national productive sector. The demographic decline in rural areas endangers the tangible and intangible heritage produced by the rural society, that created them in past centuries. The study is carried out in one of the municipalities with the greatest aging and abandonment population in Portugal, and where since the 1950s the process of social desertification has had the greatest impact. With the disappearance of the rural society that created it, this architectural heritage is threatened by an urban society that presents other aesthetic values and use. The identity of the remaining populations is threatened by the devaluation they feel of the dominant social groups in relation to their heritage. The current appropriation of buildings, especially public ones, with the change of their initial functions and the de-characterization of the villages as a socio-economic centre, leads their experience to an evident post-ruralism. This paper analyzes, at the level of the parishes, the functional transformation, which occurred during the second half of the XXth century, in the municipality of Idanha-a-Nova in Portugal and the public policies developed by the local administration to promote tourism.

1 INTRODUCTION

The demographic and economic decline in rural areas, that are by definition areas with low density, puts in danger to maintain the tangible and intangible heritage produced by the rural society that created them, in past centuries.

With the disappearance of rural society, the material heritage is threatened by an urban society that presents other aesthetic values and usage; the architectural characteristics is often neglected by the need of reuse of buildings as public as private ones.

The identity of the rural populations, that still remain in these territories, is threatened by the devaluation that they feel, on the part of the dominant social groups, with respect to their heritage.

Tourism can be the factor that counteract or not, a tendency that has been reflected in the destruction of the landscape of the small settlements of the territory.

The sustainable tourism can be an option to increase economically these areas by its defence of natural conditions and built heritage.

In Europe, in general, what is called natural landscape had always a human hand, since the density of occupation of the territory, the dispersion of the population, and the millennia that was occupied, do not leave much opportunity for a pristine nature, so the natural heritage is also a cultural one.

2 GOALS AND FRAMEWORK

This paper intends to analyse the actual situation of rural territories of the interior of Portugal and the importance of the heritage to make them reborn economically.

It is studied the functional and organizational changes and, or appropriation of the territory in the context of demographic desertification and disappearance of the traditional economic structure between 1960 and today.

The focus is put on the importance of the development of new and old local festivities to increase the local economy of the villages profiting from their heritage and the opportunity to participate in this new dynamic that the residents can have.

These transformations are evaluated in the trends of evolution in a context of economic transformation of the territory "desruralised" which means a territory that has lost many of its rural characteristics and has urban functions or at least complementary to these ones as a landscape for the use of the urban population.

To connect the preservation of the popular architecture with the tangible and intangible heritage of the region with tourism activity in special the sustainable ones.

Analyze the municipal policies with the objective of to promote a sustainable tourism in the region, valorising the natural landscape namely the geological characteristics and the cultural heritage.

3 LOW DENSITY AREAS IN PORTUGAL

In the 1950s, a process of abandonment of rural areas began in Portugal, reflected in the demographic data of 1960, and has not yet ended using new local festivities to increase the visibility of the local communities.

The rural settlements had a sediment and varied functional and spatial organization, suitable for rural life.

Rapid urbanization and the process of economic globalization have affected the organization of rural areas. With demographic desertification and the technological changes of the second half of the 20th century, the economic and social structure began to disintegrate.

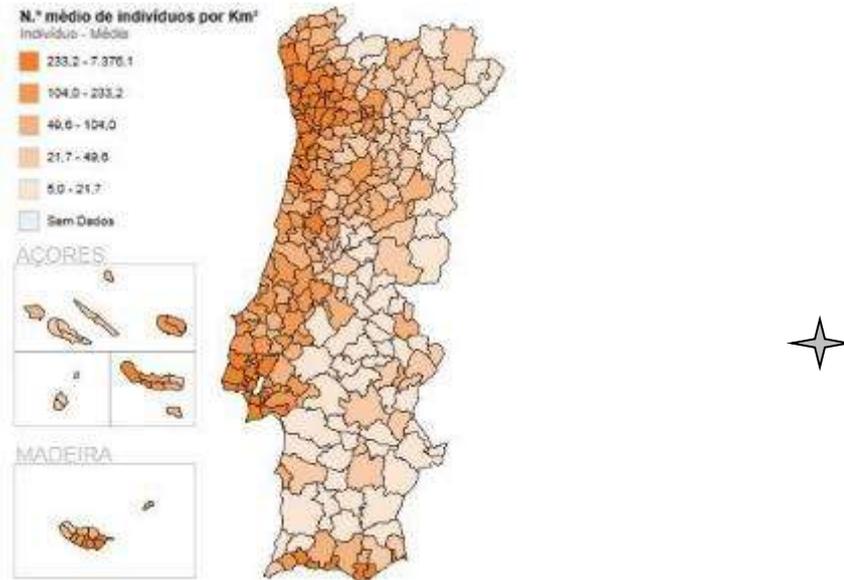

The public and private tertiary sector no longer provide part of the services; which culminated in an administrative reorganization of the parishes around the country, in 2012, which merged several local administrations and the change of place the local civil servants.

Traditional agriculture and livestock farming are in decline, the traditional landscape is in danger and some botanical species became rare by the abandonment of the fields.

Socio-economic changes from last decades endanger the tangible and intangible heritage of the villages.

This is a recurrent situation in the largest part of the country, with the exception of some towns and cities.

The territory chosen to be studied is representative of a low density area with a majority of old population, a traditional rural economy in decline and an peripheral accessibility in the east border (fig 1).

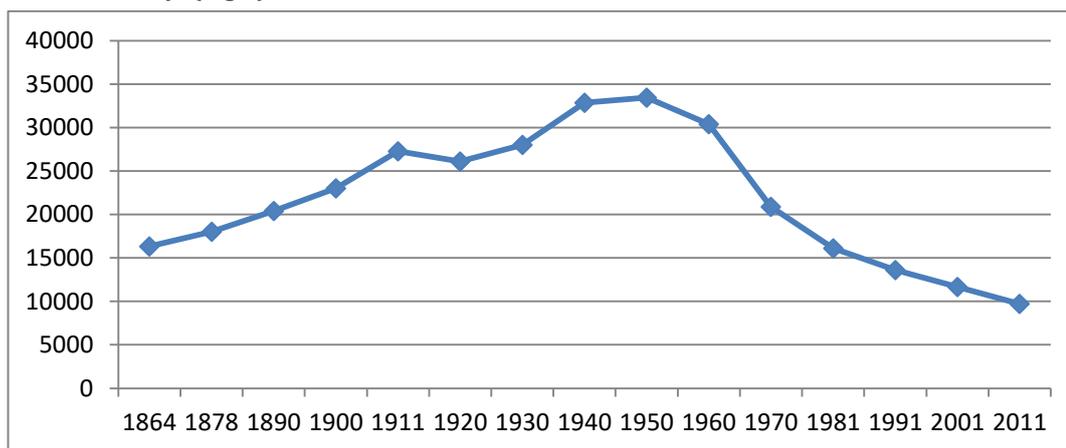

Source: INE, PORDATA

Figure 1 - Map of population density in Portugal 2011

3.1 The case of Idanha -a - Nova

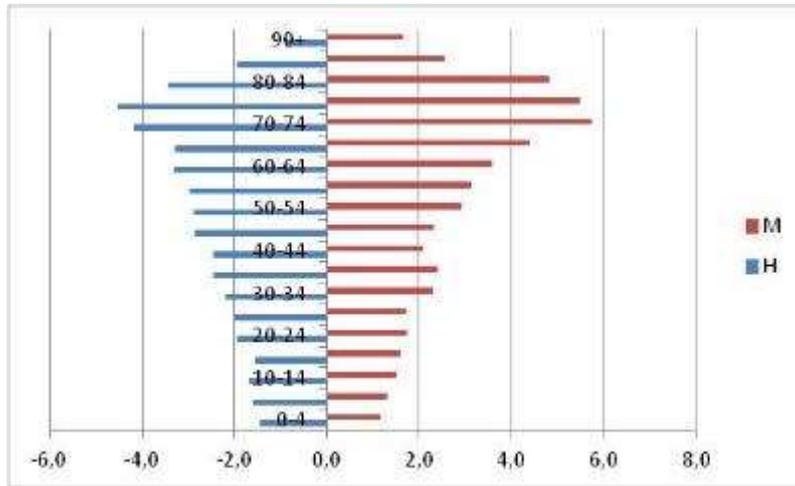

The municipality of Idanha-a-Nova as 1416 km², is the 4th largest in the country; it is also one of the municipalities with the highest aging population in 2011 (40.8% in 1960 and 49.2.8% in 2011). In 2011 has less population then in the middle of 19th century. (Fig 2)

Source: INE

Figure 2 - Evolution of the population in Idanha-a-Nova (1864/2011)

Analysing some other demographic index the elderly dependency rate was 16% in 1960 and is 88.7% in 2011, the 4th highest in Continental Portugal. The demographic pyramid (Fig.3) shows the imbalance of the municipality's age structure, with a dangerously irreversible aging.

Source: INE

Figure 3 - Demographic Pyramid of Idanha-a-Nova in 2011

With low population density: 21.5 inhab / km² in 1960 and 6.9 inhab / km² in 2011, the 3rd less dense municipality of mainland Portugal.

Table 1 - Situation of open public services in 2017

Parishes/villages (2011)	public schools	parish services
Alcafozes		
Aldeia de Santa Margarida		✓
Idanha-a-Nova	✓	✓
Idanha-a-Velha		
Ladoeiro	✓	✓
Medlim		✓
Monfortinho	✓	✓
Monsanto	✓	✓
Oledo		✓
Penha Garcia		✓
Proença-a-Velha	✓	✓
Rosmaninhal	✓	✓
Salvaterra do Extremo		
São Miguel de Acha		✓
Segura		
Toulões		✓
Zebreira	✓	✓

It was administratively organized, till 2012, in 17 parishes that all had public schools and parish administrative services, but in 2017 many of them lost the public primary school and some were merged in, so now only 7 has primary school and 4 lose the administrative services (see table 1).

The closure of these services and equipment raises the problem of the re-use of buildings and their potential abandonment. Some built heritage is in danger of ruin.

4 HERITAGE IN IDANHA-A-NOVA

The municipality has a very rich heritage related with his long history, since the built heritage such as the Visigoth Basilica of Idanha-a-Velha (Sec. VI) or the built characteristics of the village of Monsanto located in a granitic inselberg that is, in itself, an important geological heritage (natural heritage).

Figure 4 - Built heritage: Visigoth Basilica of Idanha a Velha and village of Monsanto

The Intangible heritage has been less valued but it is necessary to mention the use of “*adufe*” as a percussion instrument of Arabic origin used in local music. The religious manifestations such as the feast of “*Senhora do Almortão*”, which also has a movable heritage component for existing pieces.

Figure 5 - Intangible heritage: Bodo de Salvaterra do Extremo and to play the Adufe

The Gastronomic manifestations like the “*Bodo de Salvaterra do Extremo*” a community meal offered for free to everyone who comes.

5 MUNICIPAL POLICIES FOR THE TOURISM DEVELOPMENT

The municipality developed since 2008 with a study about the development of the territory (IPI, 2008) a new approach to the importance of tourism as a economic value.

The importance of "natural and historical-cultural heritage with with great tourism potential"(IPI, 2009) is a main impacts of municipal government action linked with the strategy for sustainability.

In this decade, the cultural and natural heritage has gained importance and visibility by the way the Municipality has increased and promoted some periodic activities around the territory in partnership with parish authorities.

The development of new periodic festivities and activities to promote local specificities at natural and heritage level in all villages that, till 2013, were parishes is very important to call people to visit them.

The events can be organised in cultural, related with social or religious cultural heritage, and natural ones, these related with the geological or botanical heritage.

Table 2 - Typology of events in the villages (parishes 2011) in 2017

Parishes/villages (2011)	Cultural Events	Nature events
Alcafozes	religious	natural products
Aldeia de Santa Margarida		nature
Idanha-a-Nova		
Idanha-a-Velha	gastronomy	
Ladoeiro	gastronomy	agricultural production
Medelim	built heritage	
Monfortinho		nature/hunting
Monsanto	historic performance	
Oledo	traditional music	
Penha Garcia	historic performance	
Proença-a-Velha	gastronomy	
Rosmanhal		nature
Salvaterra do Extremo	gastronomy/music	
São Miguel de Acha		
Segura		nature
Toulões		nature
Zebreira		nature

A important marketing of all the events in the villages, namely in outdoors around the municipality but also in newspapers and social networks gave a much bigger visibility and increases new visitors from the neighbourhood namely from Spain..

Figure 6 - Some advertisement of the events promoted by the municipality

Another interesting project that was, in first hand, related with the social support to the elder people of the municipality is the creation of a Senior University. This kind of organizations reflects the urbanization of the population who lives now in this territory. The rural population even when is at retirement age continues with the everyday life but the urban one when returns to the villages needs a different kind of leisure activities.

One of the most interesting cases is the development of the Senior University of Idanha-a-Nova (USIN), created in 2015 and headquartered at the town and with four poles in the villages: Medelim, Penha Garcia, Toulões and São Miguel de Acha; is the emergence of choral groups of traditional music, who perform in some events.

6 CONCLUSION

The situation studied is common to a large part of the rural territory of Portugal.

The municipality has developed a policy of activities, complementary each other, to increase sustainable tourism in all villages.

Both cultural heritage and traditional landscape are promoted with some success in the events with broad participation of the population.

The Senior University can be an asset for the preservation of the intangible cultural heritage and for the active aging of the population.

The popular domestic architecture is being appropriated by the urban population originating from these parishes, for seasonal use.

1796 ISSUES & APPROACH FOR PREPARATION OF TOURISM MASTER PLAN FOR VARKALA AND ITS SURROUNDING 7 PANCHAYAT AREA IN THIRUVANANTHAPURAM, KERALA

Utpal Sharma, Peeyush Purohit

Director, Institute of Architecture and Planning, NIRMA UNIVERSITY, Ahmedabad (Gujarat) INDIA

Senior Urban Planner & Geographer, MaRS Planning & Engineering Services Pvt. Ltd. Ahmedabad (Gujarat) INDIA

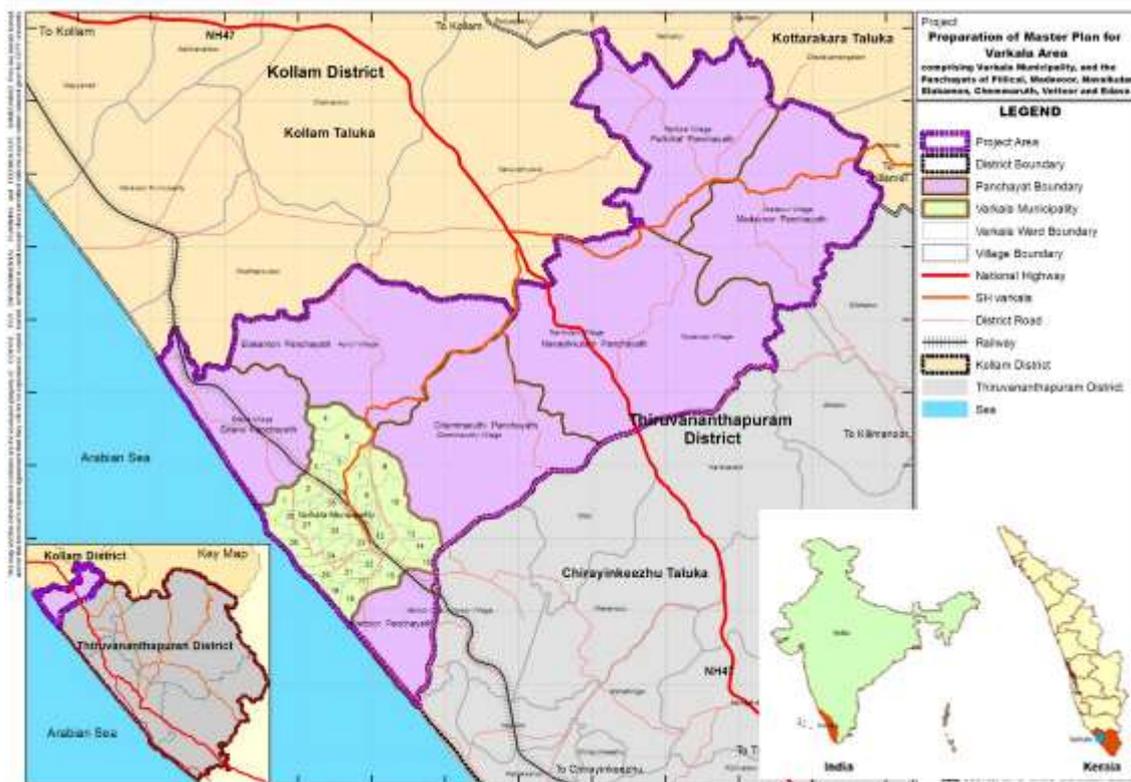

A. INTRODUCTION

Varkala Town and its surrounding 7 panchayat area is one of the preferred and eco-friendly tourist destinations in Kerala the local area plan focus on integrating it with needs of community, local tourism economy, improving quality of life and providing employment opportunities with least interference in the natural environment. Minimum Intervention in local environment & maximum output through participatory process of planning is the desired goal of the proje

Varkala, located north of Thiruvananthapuram, is one of the important religious tourist destinations in Kerala. It is visited by hundreds of thousands pilgrims regularly as well as during the special occasions throughout the year, tourist both from India and abroad. In view of Varkala's enormous tourism potential, Government of Kerala has initiated the process of preparing Master Plan-2041 for integrated development of this area through a number of infrastructure development projects to make Varkala a tourists' paradise, both for the domestic and foreign tourists.

1. Study Area

Varkala Municipality and seven Panchayats namely; Pallickal, Madavoor, Navaikulam, Elakamon, Chemmaruthy, Vettoor and Edava constitute the study area. It is part of the Chirayinkeezhu taluka of Thiruvananthapuram district and has a population of nearly 2.22 lakhs (Census 2011). it has an area of about 142.58 sq.km. This is the first planning effort of developing the project area comprising Municipal and Panchayat areas through a regional planning framework.

Figure 1: Administrative Boundaries

2. Demographic Structure

The total population of the project area in 2011 was around 2.22 lakh persons which was around 1.77 lakh in 1981 and 1.99 lakhs in year 1991 and 2.17 in 2001. The decadal growth rate of population has shown a decline trends during the decades 1991-2001 and 2001-2011. The average population density is around 17.1 person per hectare, which is quite low as compared to the district density (49 person per hectare) and the State average of 65.4 person per hectare (Census 2011). The average household size is 3.8 persons in the project area (Census 2011). The workforce participation rate in the project area is around 34% (Census 2011), of which nearly 25% are Main Workers and the remaining 9% are the Marginal Workers.

3. Existing Land Use of Study Area

The project area is well connected by roads, railways and the airways. The National Highway NH-66 connecting Kollam to Kanyakumari passes through it. Rail connectivity is provided by Southern Railways in this region. The international airport of Thiruvananthapuram is only 55 km which is linked by NH-66.

The existing land use study shows that nearly 7.06 sq.km (5.4%) of the total project area is under Residential (Built) category, while about 0.43 sq.km (0.3%) and 0.11 sq.km (0.1%) is under Commercial (Built) category and Industrial (Built) category, respectively. The combined area covered under land use categories namely Vacant Open Area and Vacant Vegetal Area measures about 63.85 sq.km (49%), while under Plantation and Agriculture it is about 38.41 sq. km. (29.4%)

Main Features & Land use details

i. **Residential (Built):**

The major concentrations of activities under this category are around Varkala Municipality (22.3%) followed by Chemmaruthy (15.9%) and Navaikulam (14.4%) and the least is in Pallickal (6.9%).

ii. **Commercial (Built):**

The major concentrations of activities under this category are around Varkala Municipality (45.8%) followed by Navaikulam (15.1%) and the least is in Chemmaruthy (3.9%).

iii. **Industrial (Built):**

The area under this category is primarily concentrated in Navaikulam (30.9%) followed by Chemmaruthy (18.0%) while the least concentration is in Edava (2.8%) and Vettoor (3.2%).

iv. **Institutional Area:**

The major concentrations of activities under this category are in Varkala Municipality (33.5%) followed by Elakamon (26.4%) and the least is in Madavoor (2.7%) and Pallickal (2.7%).

Utility Area:

The major concentrations of activities under this category are in Varkala Municipality (55.8%) followed by Chemmaruthy (26.2%) and the least is in Madavoor, Pallickal and Navaikulam with almost nil area in each.

v. **Recreational Area:**

The major concentrations of activities under this category are in Varkala Municipality (75.1%) followed by Elakamon (10.2%) while the least is in Madavoor and Pallickal with almost nil area in each.

vi. **Vacant Open Area:**

The area under this category is primarily concentrated in Navaikulam (27.2%) followed by Varkala Municipality (23.5%) and the least is in Pallickal with almost nil (0.8%) area.

vii. **Paddy Area:**

The major concentrations of activities under this category are in Madavoor (24.2%), Navaikulam (20.6%), Chemmaruthy (20.2%), and Pallickal (18.1%) while the least is in Vettoor (0.3%).

viii. **Plantation and Agriculture Area:**

The area under this category is primarily concentrated in Madavoor (33.6%) followed by Pallickal (33.1%) and Navaikulam (26.1%) while the least is in Vettoor and Edava with very less area.

ix. **Vacant Vegetated Area:**

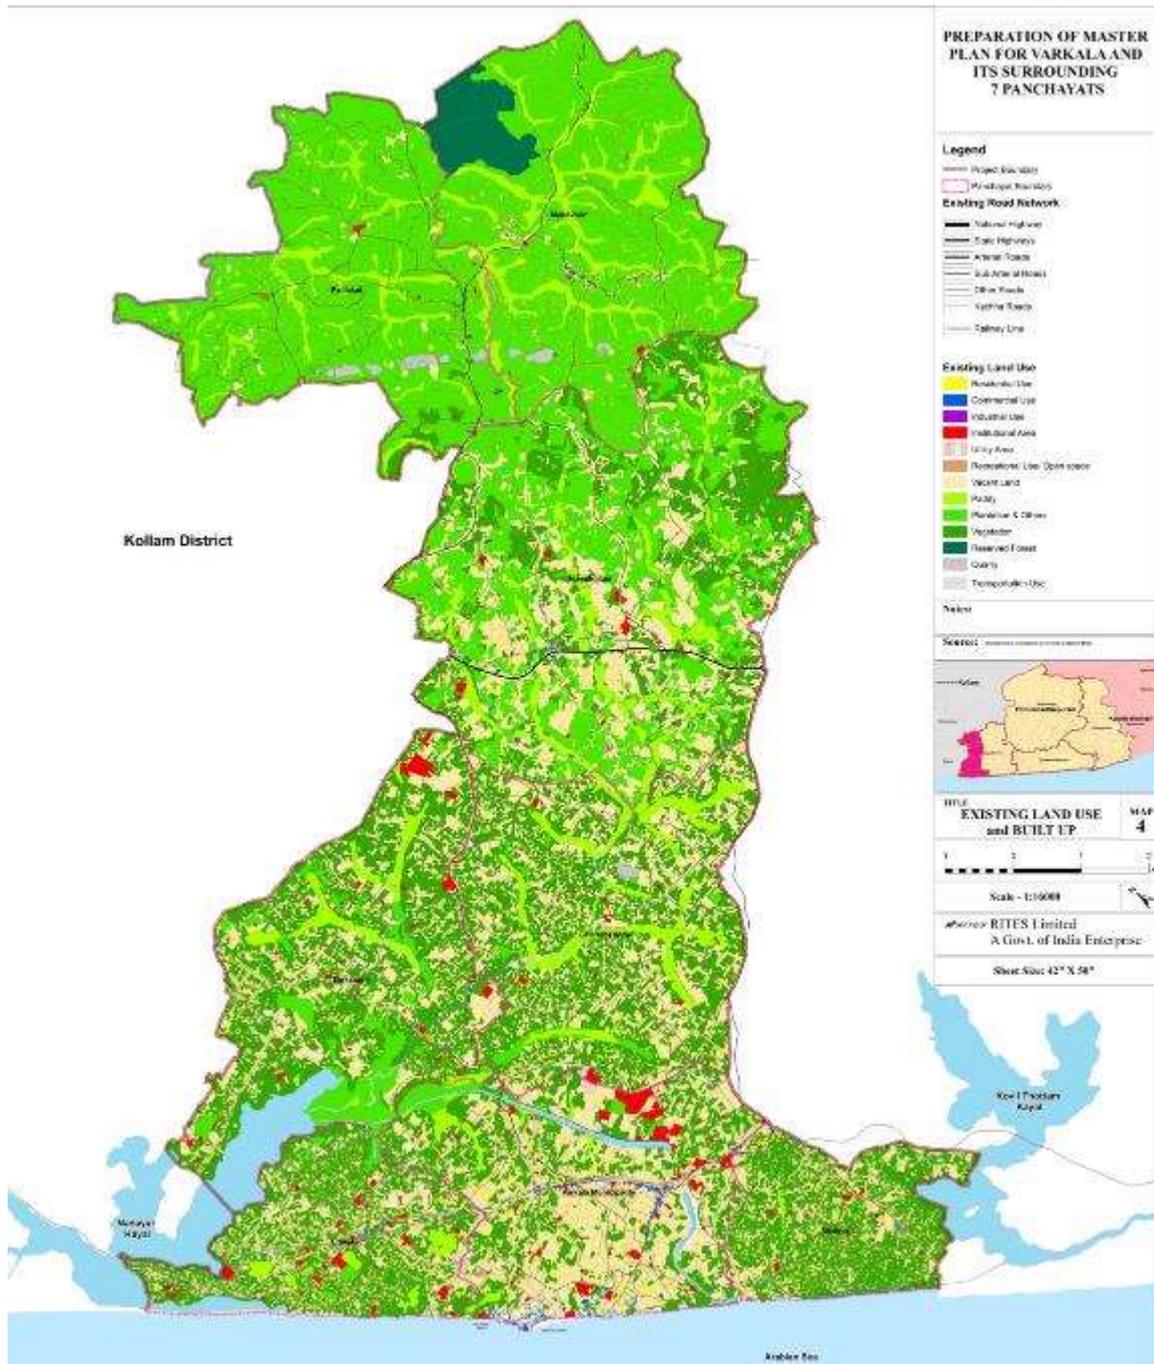

The major concentration of activities under this category is in Elakamon (22.6%), Chemmaruthy (21.3%) and Navaikulam (18.3%) while the least is in Madavoor (0.7%) and Pallickal (0.8%)

x. **Forest:**

The area under this category is only in Madavoor (100%).

xi. **Water Body:**

The water bodies cover in (61.5%) area of Elakamon, 13.8% of Varkala Municipality and 10.8% of Edava while the water bodies comparatively have less area in Madavoor, Vettoor, and Chemmaruthy ranging between 1 to 1.2%.

Source: Land Use Survey carried out for tourism master plan
Figure 2: Existing Land Use Pattern

4. Major Concerns

The major concerns are of local employment and local participation for the long term sustainability and the broad measures that emerged -

a. Ownership Pattern-

- Most of the owners of establishment whether resorts/hotels or home stays were local people from Varkala (63%) and Kerala (33%) while only 4% of the owners were from outside of the State.
- Most of the accommodation establishments were either fully or partly owned comprising nearly 74% of the total establishments surveyed. About 20% of the establishments were fully or partly leased while about 6% were run on contract basis either fully or partly.

b. Employment Pattern-

- In the surveyed accommodation units, almost half (50%) of the staff (other than restaurant staff) working in facilities during peak season was from Kerala while that from Varkala was 34% and from outside Kerala was only 16%. On the other side, during the off season, the share of staff (other than restaurant staff) working was 44% from Kerala, which was marginally higher than that from Varkala at

40%. The percentage of worker staff (other than restaurant staff) from outside Kerala remained constant at 16% during off season.

- In the surveyed accommodation units, restaurant staff during peak season was highest from Kerala at 41% while that from Varkala was least at 23% and from outside Kerala was 36%. On the other side, during the off season, the share of restaurant staff working was 45% from Kerala, which was quite higher than that from Varkala at 30%. The percentage of restaurant staff from outside Kerala declined to 25% during off season.

c. Tourist accommodation and Social Facilities-

- Most of the accommodation facilities (82%) were operational for the whole year while about 4% of the facilities were operational only up to 3 months in a year. Nearly 11% of the facilities were operational for nearly 6 months while about 4% of the facilities were operational up to 9 months within a year.
- As regards the foods and beverage facilities available in the establishment nearly 34% had restaurants and 24% had cafeteria. The other foods and beverage facilities included bakery and bar which was observed in 5% & 4% respectively of the total sample surveyed.
- With reference to business related facilities nearly 15% had conference facility and about 13% said to have information / travel desk. With reference to fitness and yoga centre, nearly 23% of the establishments had ayurvedic centre, 7% had yoga centre while only 1% had saloon facility.
- Less than half of the accommodation facilities (55%) surveyed did not have any restaurant facility in the premises.
- Nearly 38% of the restaurants served vegetarian food while 37% of the restaurants served non vegetarian food. Sea food was served in the highest number of restaurants (40%) while Continental food was served in the least number of restaurants (23%).

d. Inadequate Infrastructure Services-

- Nearly 33% of the accommodation facilities had source of only tap water and other sources, about 87% of the accommodation facilities had source of only ground water and other sources, and nearly 11% of the accommodation facilities had source of tanker water supply.
- Of the total surveyed accommodation units more than 92% of the units had the water storage capacity of more than 1,000 litres while the remaining 8% had capacity of less than 1,000 litres. Only about 3% of the accommodation units surveyed had more than 5,000 litres water storage capacity.
- Only 1% of the total accommodation units surveyed had piped sewerage network facility while majority of the units (79%) had either septic tank or soak pit facility.
- It was observed that on an average the distance of procurement of raw material ingredients like vegetables, fish, food grain, etc was 3-4 km for the hotels/accommodation units in Varkala.
- When inquired about the environmental awareness practiced in the establishments, nearly 52% of the establishments introduced solar energy as a part of the green energy initiative in their premises. Nearly 24% practiced rain water harvesting and 7% practiced water recycling in their premises. About 13% segregated the solid waste and nearly 16% of the establishments generated energy from waste.

B. MAJOR ISSUES OF THE STUDY AREA

In order to make tourism development sustainable in Varkala, an integrated development strategy is essential formulation of the Master Plan. The major concerns identified in the study related to environment, economy and socio-cultural aspects mentioned as follows.

• **Environmental Issues -**

- Violation of Coastal Regulation Zone
- Pollution of water bodies and beaches
- Cliff erosion
- Destruction of the natural environment (fauna and flora)
- Reduction in tree cover due to uncontrolled development

• **Economic Issues -**

- Lower level of local participation in tourism and related activities in terms of employment, entrepreneurship and informal activities
- Marginal jobs/low wages from tourism sector for local people
- Lower economic benefits to local people in spite of increasing tourist inflow to the region

• **Socio-Cultural Issues -**

- Exclusion of local community from beaches/tourism spots

- Commoditization of culture and art forms
- New building styles/westernization of styles among people
- Low level of interest/involvement in tourism
- **Traffic and Transportation Issues –**
 - Signage's plays a very important role to reach the tourist destination, which is lacking in town.
 - Safety and security is very important in tourist areas. On the cliff at places railings are missing, streets lights are not adequate. So it very unsafe to walk on the cliff in the night time. There should security staff members on the cliff and near the beach.
 - Road network capacity is not adequate in the Varkala as the available right of way (ROW) of roads is very limited at most of the network and thus roads cannot be widened adequately.
 - Considering limited road capacity there is need to optimize the use of available infrastructure by adopting traffic management measures wherever possible.
 - Planned roads need to be provided with adequately wide right of way to meet the requirement of future traffic.
 - In Varkala out of seven railways crossing only one has been grade separated and remaining area road level. About 72 trains are passing on these crossing every day. This problem needs to be addressed on priority.
 - Absence of footpaths on the entire road network.
 - Out of total person trips the share of walk trips is about 35%. Walk trips as feeder to buses and other modes are additional. There is high pedestrian traffic on Varkala Beach and in Varkala Town area and some other areas in Varkala. Footpath facilities are almost absent; therefore provision of footpath facilities is very important. Share of cycle traffic is as low as 2%. This mode of transport needs to be promoted by providing cycle tracks along the roads.
 - Parking of vehicles is assuming critical dimension in Varkala. Limited off-street parking lots encourage on street parking in the core areas and Varkala Beach resulting in reduced capacity of the road system. Parking facilities need to be augmented substantially.
 - Poor geometrics at the junctions. Geometrics of the junctions need to be improved. Grade separation required wherever necessary.
 - Varkala Tunnel was a popular tourist highlight. With the advent of advanced transportation methods through road, rail and sky, the transportation through Varkala tunnel has stopped. The canal and the tunnel have gone into disuse and heavy silt accumulation and vegetative growth has taken place. It is recommended to revive the canal and tunnel for tourist activates
 - Outer cordon surveys indicate significant through traffic to the city. This point to the need of road bypasses to the city.
 - At present, modal split in favor of public transport is about 65% of total motorised person trips. As the income levels increase, car ownerships would also increase. This would lead to increased use of cars and share of public transport would fall. In order to arrest this shift, it is very important that fast, reliable, frequent and comfortable mass transit system is planned for the city.
- **Overexploitation of coastal natural resources and unchecked construction activities–**
 - Concentration of tourism activities near the helipad and the north cliff, without any development in other area have resulted in over exploitation of resources at one place thus posing major threat to the sustainability of the tourism activity,
 - Over exploitation of coastal natural resources for tourism development is a major concern. Unchecked construction activity is constantly spoiling the pristine beauty of these areas.

C. DESIGN APPROACH & PLANNING PRINCIPLES

For the purpose of formulating the Varkala Master Plan-2041, the approach adopted to mitigate local & Tourism issues.

- Assessing existing demographic and infrastructural scenario in the project area,
- Assessing the existing tourism scenario of Varkala and the surrounding area,
- Impact of tourism on environment and the culture of the project area,
- Identification of major issues confronted in Varkala with reference to tourism,
- SWOT Analyses
- Vision, Objectives and Strategies for increasing tourism potential of the region and overall development,
- Planning Proposals, Land Use Zoning and framing the Development Control Regulations considering the existing situation and envisaged future developments,

- Estimates on requirement of physical and social infrastructure to cater to the growing needs of the Study Area by 2041,
- Strategies for protection of environmentally and culturally sensitive areas,
- Master Plan implementation strategy

The **broad principles** has been formulated are as follows:

- **Multiple Nuclei Concept**

Multiple-Nuclei development approach shall be adopted for creating more places of investment opportunities. This nuclei approach will be ideal since each component of project area will have development opportunities as per their potentials. The concept will also help in creating equitable development across the Study area guided by the dominant existing land use. The model will also help in effective utilization of natural resources by spreading activities at different nodes thus avoiding overutilization of natural resources and also minimizing congestions at a one place.

- **Decentralized Development**

Decentralization of tourism activities will help in developing the planning area for reducing pressure on particular area and also safeguarding the cliff from construction activities. Decentralization can be supported by incentives (special packages, etc) and promoting thematic tourism activities (monsoon tourism, winter tourism, water sports etc.) to promote tourism at multiple locations - distributive tourism.

- **Low-Rise and Low-Density Built Form**

Considering the existing development pattern within the State and especially in Varkala, wherein the conditions for low-rise and low-density development is favorable, it is suggested to continue the same principle for future development in the Study area unless a project has specific height requirements. For an area like Varkala, where overall population density is quite low and population growth is also low the development has to be in sync with the surroundings. As a broad thumb rule, no building should be taller than the height of the local trees within the area, to ensure that buildings do not dominate the natural landscape.

- **Promotion of Public-Private Partnerships**

In Varkala, public-private partnership is needed for infrastructure development including development of accommodation, transportation, site development, other amenities, waste management, etc.

- **Local People's Participation**

Local people's participation is important for the development of the area since it provides them an opportunity of feeling pride and belongingness. Local people's participation will retain the ownership. The participation can be ensured through measures/strategies suggested as under:

- Capacity building through workshops/seminars in various fields like hospitality services, foods and beverage segment, etc.,
- Promoting Employment of local human resource in all developmental activities through policies/incentives,
- Promoting local handicrafts by providing a platform for display and marketing the products through creation of artisans' village, artisans' market, weekly market, etc.
- Promoting eating joints of local food and beverage products and cuisines,
- Integration of ongoing tourism schemes of the Government like "My Village, a Tourism Friendly Village" can be effectively implemented in areas of Edava and Vettoor Panchayats to being with.

- **Promotion of Home Stay**

Home stay tourism is an evolving branch in tourism industry. By drafting proper guidelines, the concept of the home stays by involving local people can be promoted in Varkala. The vernacular architecture of the home stay, offers tourists the experience of lifestyle of the local people and the authentic local food at a competitive pricing. It will also generate employment and finally arrest the outmigration.

- **Promotion of Tourist Circuit**

The following works may be taken up under the scheme:

Improvement of the surrounding of the destination this would include activities like landscaping, development of parks, fencing, compound wall etc.

- Enhance connectivity of tourist destination
- Providing for improvement in solid waste management and sewerage management
- Construction of budget accommodation, wayside amenities
- Procurement of equipment directly related to tourism, like water sports, adventure sports, eco-friendly modes of transport for moving within the tourism zone
- Refurbishment of the monuments

- Interpretive Signage's, directional signage, information boards, track heads etc
- Tourist arrival center/reception centers/interpretation centers/tourist information center
- To enhance the major road loop connecting all destinations can be proposed along with the major transition nodes

D. CONCEPTUAL TOURISM MASTER PLAN

1. Vision

“Developing Varkala as the one of the most preferred and eco-friendly tourist destinations and integrating it with needs of local community, improving quality of life and providing more employment opportunities with least interference in the natural environment”.

The mission set forth for realizing the vision requires a definitive approach. For this purpose, the entire project area has been divided into two zones described as under;

- i. Urbanization Area-1 (UA-1), is the area that will have comparatively high intensity of development i.e. higher FSI and developmental permission charges and the development permissions linked with the hierarchy of roads as specified in the Development Control Regulations,
- ii. Urbanization Area-2 (UA-2), is the area that will have lower intensity of development i.e. lower FSI and developmental charges than the UA-1.

It is the typical character of the project area that demands this type of approach. Since this is the first planning effort of developing the project area comprising Municipal and Panchayat areas, the development agency requires flexibility of attracting the investments at places with a few restrictions specified in the Development Control Regulations. It is the foremost requirement of the private investor, because the first choice of investor is to develop the area where land is accessible, cheaper and has the marketing potentials. Such flexibilities are not available in the strict land use zones.

Since the Zonation is based on the existing potentials to attract the investment, equally important is attaining the balanced growth and development of the project area. For this purpose, the project area within the two zones, has been designated for polycentric development as nodes of investments listed as under:

- i. Commercial hubs in Varkala, Chemmaruthy, Edava and Navaikulam,
- ii. Cultural Hub between Varkala, Chemmaruthy and Edava,
- iii. Health and Education hub in Navaikulam,
- iv. Technology Parks (IT and Other Technologies) in Madavoor, Pallickal and Navaikulam,
- v. Sports and Leisure/recreational Hub in Varkala, Edava and Elakamon,
- vi. Agro based Industry in Vettoor,
- vii. Transportation Hub in Navaikulam

2. Population, Tourist & Employment Projections

2.1 Population projection

The population of the project area comprising Varkala and other constituent Panchayats reached 222,154 in 2011 from 177,443 in 1981. During the decade 1981-91 the growth rate was 12.59% which decreased to 9.01% during 1991-2001 and further decreased to 2.01% during the decade 2001-11 suggesting a steady out migration from Varkala.

To carry out the population projection for the project area three different scenarios were considered namely

- (i) Existing decadal growth rate,
- (ii) Moderate decadal growth rate, and
- (iii) Optimistic decadal growth rate. Envisioning the type and the scale of investments that are likely to come in the project area, Scenario-3 which is Optimistic DGR of 31% has been considered for future population projections. The total population under this scenario would be around 5 lakh persons by 2041.

Table 1: Projected Population and Population Density

S. No.	Project (Municipality / Panchayat)	Area (sq.km)	Population		Projected Population Density (persons / sq.km)	
			2011	2041*	2011	2041*
1	Varkala (M)	15.33	40,048	90,032	2,612	5,873
2	Edava	9.22	25,994	58,437	2,819	6,338
3	Elakamon	17.81	25,307	56,892	1,421	3,194
4	Chemmaruthy	17.59	32,444	72,937	1,844	4,147
5	Navaikulam	28.46	40,702	91,502	1,430	3,215
6	Pallickal	16.34	16,873	37,932	1,033	2,321
7	Madavoor	18.64	21,118	47,475	1,133	2,547
8	Vettoor	7.04	19,668	44,215	2,794	6,281

Total	130.43	222,154	499,422	1,703	3,829
Existing Population Source: Census of India * Forecasted Population					

2.2 Tourist Inflow Projection and Demand Assessment

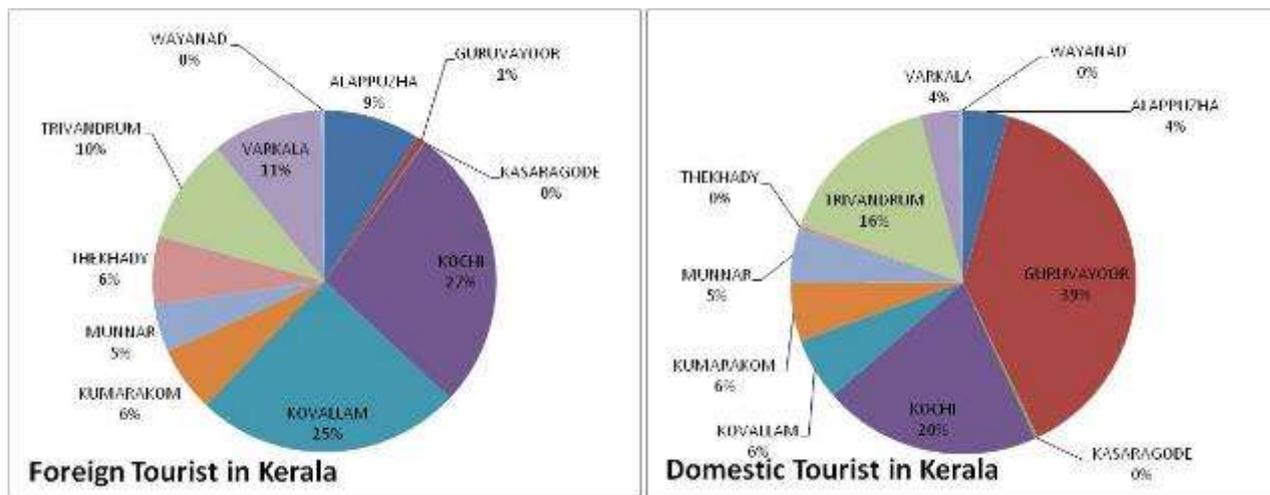

Considering the existing situation and the growing trends of tourist inflow, it was estimated that the total tourists visiting Varkala by the year 2021 would be around 4.5 lakhs (2.5%); by year 2031, would be around 8.4 lakhs (3%) and by 2041, would be around 14.8 lakhs (3.5%). During the same period the total tourists visiting Kerala would be around 164 lakhs by year 2021, around 250 lakhs by 2031 and around 380 lakhs by year 2041.

The accommodation unit requirements in Varkala by the year 2041 have been calculated considering the inflow of tourists during weekdays and weekends, both during peak and lean seasons, which comes to around 8,000 rooms by 2041. Apart from these, there will be day time tourists and pilgrims that shall be visiting the place during festivals or religious occasions.

Table 2: Projected Tourists Inflow to Varkala

S. No	Year	Tourists Inflow to Kerala			Tourists Inflow to Varkala					Decadal Growth Rate		
		Total Tourists	Foreign Tourists (FT)	Domestic Tourists (DT)	Assuming % share of Varkala in Kerala (FT)	Tourist Visiting Varkala (FT)	Assuming % share of Varkala in Kerala (DT)	Tourist Visiting Varkala (DT)	Tourist Visiting Varkala (Total Tourists)	Foreign Tourists (FT)	Domestic Tourists (DT)	Total Tourists
1	2010	9,254,340	659,265	8,595,075		45,545		160,238	205,783			
2*	2021	16,476,298	1,465,970	15,010,328	5.5%	80,628	2.5%	375,258	455,887	77%	134%	121%
3*	2031	25,007,641	2,492,149	22,515,492	6.5%	161,990	3.0%	675,465	837,454	100%	80%	83%
4*	2041	38,009,891	4,236,653	33,773,238	7.0%	296,566	3.5%	1,182,063	1,478,629	83%	75%	76%

Source: Kerala tourism statistics 2010

Figure 3: Tourist Arrival in Kerala & Varkala

Varkala stands 3rd popular place in Kerala for foreign tourist visit.

Varkala stands 7th place in Kerala for Domestic tourist visits.

Source: Kerala tourism statistics 2010
Figure 4: Month Wise Tourist Arrival in Varkala

2.3 Projected Employment Structure

Assuming the average employee-to-room ratio of 1.6 for all categories of hotels and home stays in Varkala, the total employment in Varkala would be around 25,600+ jobs in the next 30 years i.e. by year 2041 in the tourism industry.

Table 3: Employment Projection (Year 2041)

S. No.	Description	Population
1	Projected Population	499,422
2	Assuming, WFPR	40%
A	Total Jobs Created	199,769
1	Total Number of Rooms required by Year 2041	8,000
2	Assuming, Employee-to-Room Ratio	1.6
B	Jobs Created in Hotels	12,800
C	Total jobs in Tourism Sector including Hotels	25,600
A-C	Jobs Creation in Other than Tourism Sector by Year 2041	174,169

3. Proposed Land use Pattern

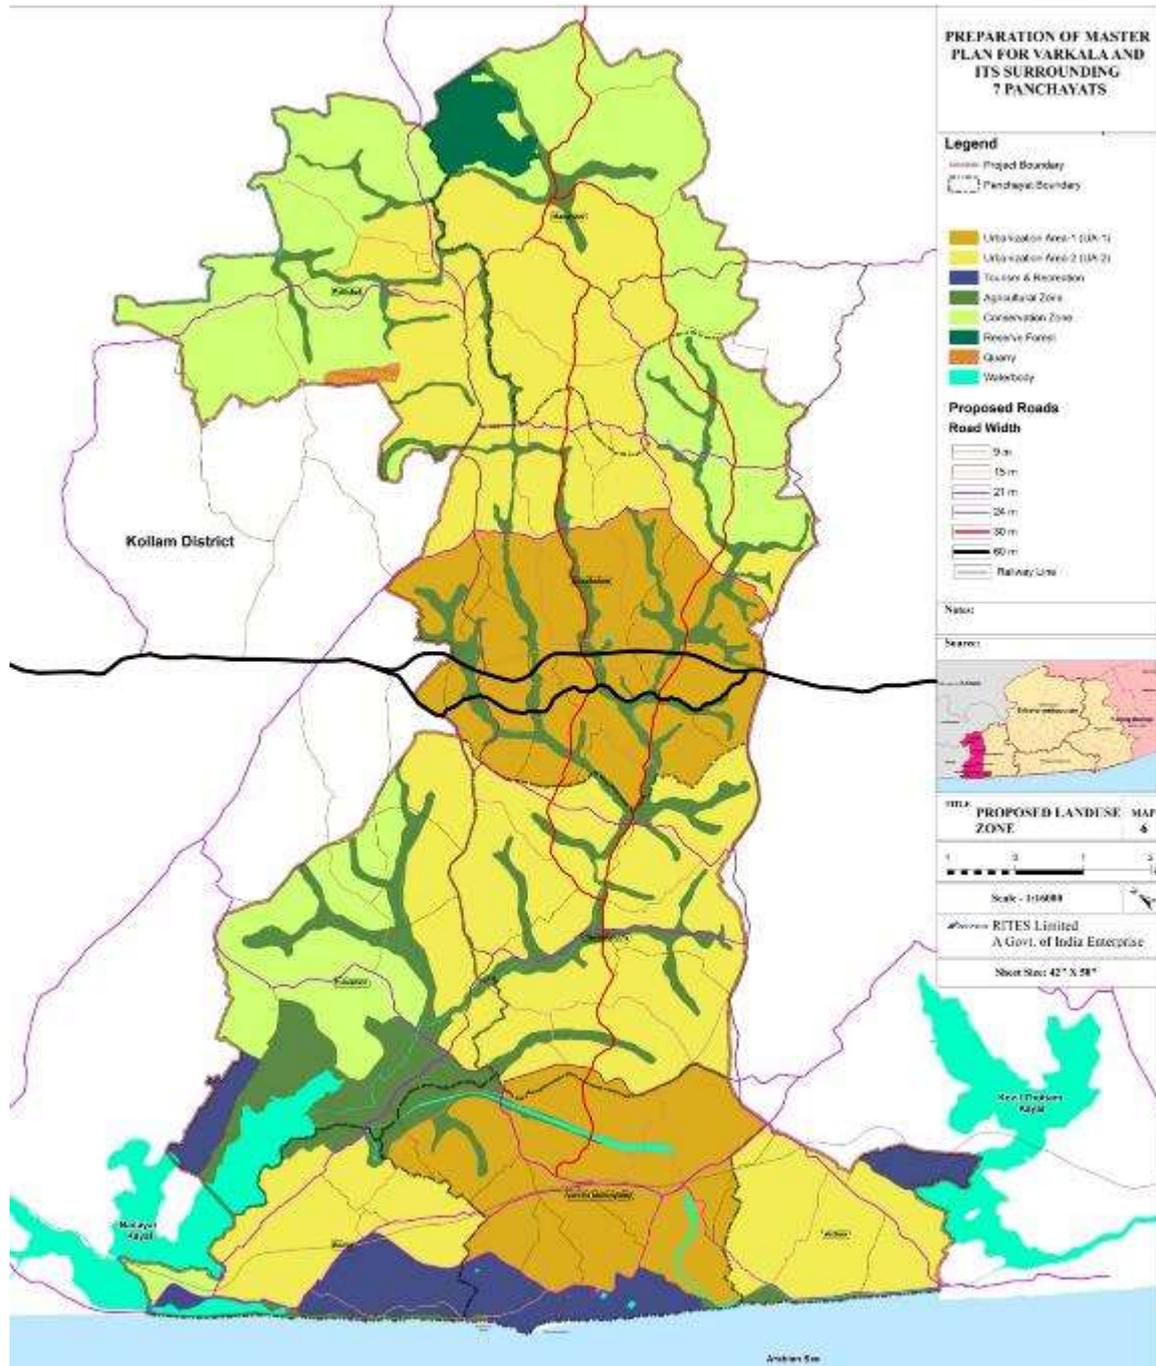

The Urbanization Area of 71.06 sq.km (54.5%) has been categorised into two zones namely Urbanization Area-1 having area of 24.51 sq.km (18.8%) and Urbanization Area-2 having area of 46.55 sq.km (35.7%). Considering the importance of the ecosystem, around 27.87 km (21.4%) area has been identified as conservation area. The tourism and recreation area has been kept around 5.71 sq. km (4.4%) and the area under agriculture is around 16.05 sq. km (12.3%) of the total project area.

Table 4: Proposed Land Use in the Project Area

S.No.	Proposed Land Use	Varkala (M)	Edava	Madavoor	Vettoor	Elakamon	Chemmaruthy	Navaikulam	Pallickal	Total
		sq.km	sq.km	sq.km	sq.km	sq.km	sq.km	sq.km	sq.km	sq.km
		% to total	% to total	% to total	% to total	% to total	% to total	% to total	% to total	% to total
1	Agriculture Zone	1.00	0.87	0.87	0.24	5.13	2.62	4.01	1.48	16.22

The zone wise concentration of activities is as follows:

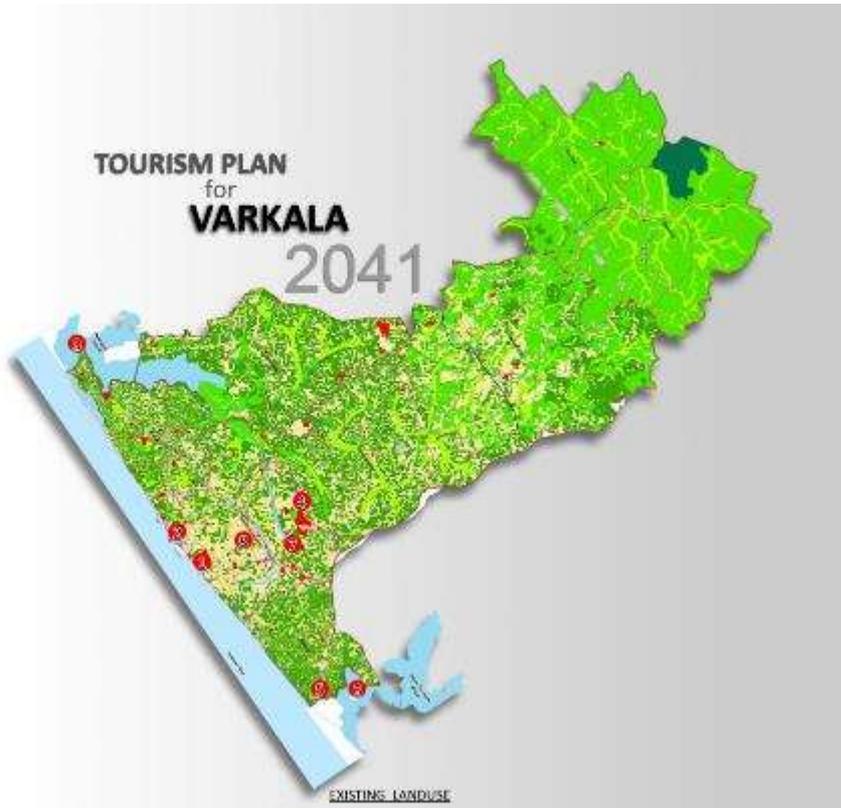

- i. **Urbanisable Area-1:** This zone comprises existing predominantly built / developed areas of Varkala Municipality and covers part of Varkala Municipality and Navaikulam. The existing developments and developing areas around the National Highway are covered under this zone. This zone shall have mixed use developments and shall accommodate the expansion of built / developed areas while at the same time focusing on the on densification of the existing developed areas. The higher order development activities shall be limited to roads of higher hierarchy i.e. more than 15 m road width. This zone comprises Varkala Municipality (46.4%) and adjoining Navaikulam (52.1%) and Chemmaruthy (1.5%).
- ii. **Urbanisable Area-2:** This zone shall act as an intermediate zone between the Urbanization Area-1 and the vernacular rural settings, ecological and natural areas. The main focus is on densification of existing developed areas and development of new areas. Mixed land use along with various service and cottage industries shall be allowed in this zone. Higher order activities shall be allowed only on the roads with road width higher than 21 m. This zone shall have various development nodes as identified in the Master Plan which shall have agro based industries, sports and recreation, IT/ITES and other technology based establishments. This zone comprises the areas of Navaikulam (11.6%), Chemmaruthy (29.3%), Madavoor (17.7%), Edava (11.5%), Vettoor (12.4%), Elakamon (7.7%) and Pallickal (9.9%).
- iii. **Tourism and Recreational Zone:** This zone covers existing areas of hotels, resorts; home stays concentrations, and such other tourism related activities. The main purpose of this zone is to promote tourism related activities within the project area while at the same time controlling and regularizing such activities within the eco-sensitive areas (cliffs). This zone shall have various activities like art centres, museums, theme parks, fair grounds, etc. That shall help in promotion of tourism in the project area. The tourism and recreation zone is concentrated in primarily four areas viz. Varkala Municipality (37.4%), Edava (33.8%), Elakamon (15.3%) and Vettoor (13.5%).
- iv. **Agricultural Zone:** This zone comprises area of existing paddy fields which are primarily low lying areas and valley areas. Various activities related to agriculture, paddy, horticulture, seed farms, dairy farms, fishing, etc have been envisaged in the zone. The major agricultural lands are in Navaikulam (24.7%), Chemmaruthy (16.2%), Elakamon (31.6%) and Pallickal (9.1%), Madavoor (5.4%), Edava (5.4%) and Varkala Municipality (6.2%).
- v. **Conservation Zone:** This zone has been provided where the development is sparse and where the large tracts of vacant land and incidental agriculture activities with the main purpose to conserve the vernacular rural settings within the project area. Residential developments with low rise and low density and passive tourism activities like home stays and lower order of commercial activities are permitted in this zone. The conservation zone is mainly in Pallickal (33.8%) Madavoor (26.3%), Elakamon (22.6%), Navaikulam (15.7%) and Edava (1.6%).
- vi. **Water Bodies:** The area under water bodies is mainly concentrated in Elakamon (61.9%), Varkala Municipality (14.4%), Edava (10.9%) and Pallickal (8.6%).

 Figure 5: Proposed Land Use Zone

4. Identified Projects for Tourism Promotion

Various tourist attractions like North Cliff, Papanasam Beach and Janardhan Swami Temple have high tourist activities and it lacks required tourism infrastructure facilities that needs to be upgraded and/or provided to attract tourists to this place. The major projects and the conceptual design for the development and/or up-gradation of the same have been highlighted ahead:

Source: Land Use Survey

Figure 6: Location map of Major Tourism promotion spots

4.1 Papanasam Beach

a. About the Site

Papanasam is one of the main beaches here and it is not only an important tourist spot but it also has religious significance. It is believed that a dip in the waters here can wash away all the sins (papam) and hence the beach obtained its name. Hindus find it a very auspicious place and ashes collected from the cremation grounds are immersed at the sea here. They believe that the sins of the deceased will be washed away and the soul gets *moksha* or *eternal salvation* through this ritual.

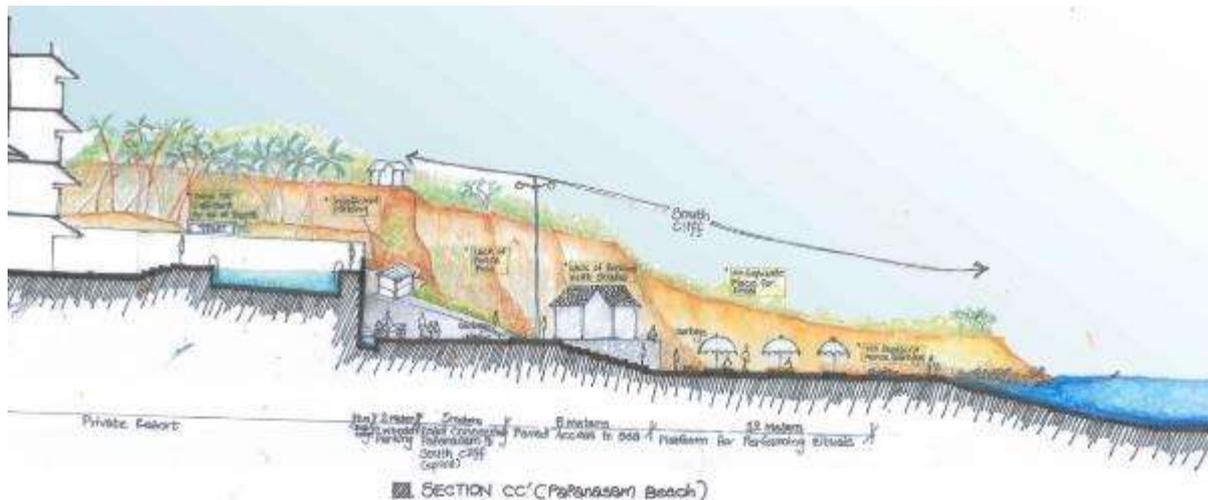

Figure 7: Section Showing Papanasam Beach

b. Approach and Access to the Site

The main junction of the Janardhan Swamy temple has the better connectivity to the Papanasam beach where bali rituals are performed. Papanasam beach is well connected by secondary streets forming a loop and which is connected to the major temple road. The access from the temple road to Papanasam through south cliff has major concentration of resorts and hotels with home stays.

c. Existing Land Use around the Site

The majority of the land use around the Papanasam beach is Hotels. The major street connecting Papanasam and Janardhan Swamy temple has more of congestion due to overlapping of religious and other commercial activity. Land use along the Papanasam and South Cliff includes majority of hotels, home stays, resorts, studios etc. Public spaces need to

be developed by providing necessary street furniture by giving better connectivity for pedestrians along the south to north cliff.

d. Major Issues

The major issues of the area:

- It lacks the proper connectivity with Informative signages along the major roads connecting the attraction and the Information center at tourist attraction
- Parking facilities are not sufficient for tourist visiting Papanasam beach, parking lots should be proposed along the major road for better connectivity and accessibility while reducing resultant congestion along road side parking
- Lots of visitor visits the Papanasam beach to perform the bali ritual and contrary it lacks the basic infrastructure to perform the rituals which results in the chaos while polluting the beach area by dumping garbage along the sea
- In spite of lots of tourist visiting the Papanasam beach it lacks the basic amenities like toilets, changing room, shading area/benches etc and basic street furniture like streetlights, benches, dustbins, railing etc. along the beach area
- Safety and security is also very important aspects near the beach area, however it lacks the security during night hours and it also becomes inaccessible due to lack of streetlights

e. Proposal

Thousands of people offered `bali` to propitiate their forefathers on the occasion of `Karkidakavavu` which seems one of the important rituals and due to these there is a heavy rush of devotees at Papanasam beach, Janardhana swamy temple at the peak seasons and also during major festivals. The proposal aims to provide the proper connection from the major temple road to the secondary streets with street furniture and easily approachable parking areas along the secondary streets and to encourage the pedestrian activity by reducing the resultant congestion due to overlapping of different activities.

Figure 8: Proposed Amenities around the Papanasam Beach

Secondary Street connecting Janardhan swamy temple and the papanasam beach should be developed by providing footpaths, streetlights and dustbins proper infrastructure to perform the bali rituals. Tourist information center should be upgraded with the better amenities and facilities, which will help tourist to gain the knowledge of the particular. It should be placed along the street at a distance of 4 meters. However, the pedestrian connection from helipad to papanasam beach area should be strengthen by providing street lights, dustbins and benches to make it more accessible during night hours.

4.2 North Cliff

a. About the Site

These cliffs, termed as Varkala Formation, that are found adjacent to the Arabian Sea are declared as geological monuments by the Geological Survey of India.

Figure 9: View of the North Cliff

b. Approach and Access to the Site

The secondary street evolving from the major temple road connects the north cliff at different points. The street connecting perpendicular to the secondary streets are the tertiary streets connecting inner cliff part. Pedestrian walkway connects the north cliff from one end to the other but due to landslides and other extreme weather the cliff has fallen at certain areas and resultant the walkway is not continuous. However at certain distance where the beach is approachable the staircase are connected to the beach.

c. Existing Land Use around the Site

The major land use around the North cliff comprises hotels, restaurants and resorts, while the cliff edge caters the major commercial activities. According to the CRZ guidelines up to 100 meter from the cliff's edge permanent construction activities are not permitted but the existing shows large number of illegal permanent constructions. During the peak season, the walkway along the cliff becomes congested due to overlapping of different activities. Public spaces are lacking and need to be developed by providing necessary street furniture by giving better connectivity for pedestrians along the south to north cliff.

d. Major Issues

The major issues of the area:

- Public Parking facilities are not available at north cliff area, parking lots should be proposed along the secondary streets and the major road for better tourist connectivity and accessibility while reducing resultant congestion along road side parking
- North cliff being one of the famous spot at Varkala many tourists choose to accommodate themselves from the stretch of helipad to black beach, which has given rise to the large number of commercial activities along the cliff's edge. Due to lack of proper waste disposal facility, the area gets flooded with garbage from restaurants as well as tourist areas.
- The cliff edge becomes a major issue for pedestrians during the nighttime since it is not demarcated properly with some kind of fencing
- Safety and security are also very important aspects near the cliff area, however it lacks the security during night hours and it also becomes inaccessible due to lack of streetlights

e. Proposal

The proposal aims to provide the proper connectivity from the major temple road and also widened the inner roads of north cliff area. Since there is lack of parking spaces on the north cliff a proper parking spaces will be marked and vehicles will be allowed to a certain point and the streets will be made pedestrianized.

Due to certain landslides on the cliff the paved walkway has been damages at certain areas with no demarcated cliff's edge, hence firstly the proper cliff's edge needs to be protected by making bio fencing and by leaving a wide paved footpath with buffer of open space before commercial activities.

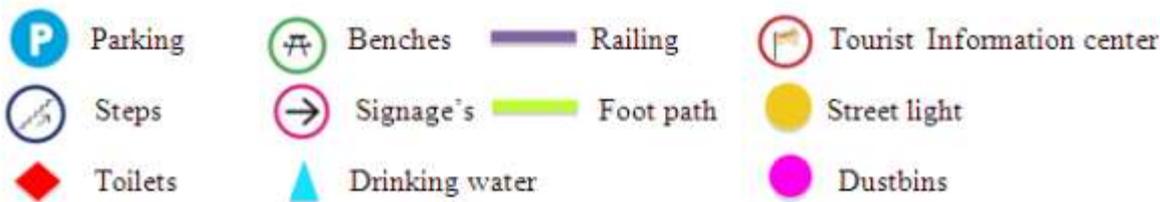

Figure 10: Proposed Amenities around the North Cliff

Tourist information center should be upgraded with the better amenities and facilities, which will help tourist to gain the knowledge of the particular attraction in and around the north cliff. Secondary Street connecting inner cliff area should be developed by providing footpaths, streetlights, benches and dustbins. It should be placed along the street at a distance of 4 meters. However the pedestrian connection from helipad to black beach should be strengthened by providing street lights, dustbins and benches to make it more accessible during night hours.

4.3 Development around Kappil Lake

a. About the Site

Kappil Lake is the north-west border town of Thiruvananthapuram district. It is located in Edava Panchayat, near Varkala. Flanked by the coconut plantations and paddy fields, Kappil backwaters attract a large number of domestic and foreign tourists.

Kappil is also famous for Kappil Bhagavathy temple and a tourist spot during the festival season. Recently DTPC has provided boating facilities in the backwaters. The boat club offers Safari boat, speed boat, pedal boats and rowing boats to the tourists at moderate rates. Communication facilities, parking and refreshment facilities are inadequate for the current level of tourist flow itself. Kappil beach is the meeting point of Kappil Lake and Arabian Sea. It is secluded, rocky stretch facing the Sea.

b. Major Issues

The major issues of the area:

- No bus or auto stands near the lake
- Lack of basic tourist oriented infrastructure
- In day time the region is deserted, there is no police booth.
- Lack of awareness among the tourist

c. Potential for Development

The place has high potential for development for the following reasons:

- Scenic beauty and backwaters
- Estuary – a place where backwater and sea meets
- Seasonally the character of the place changes i.e. in high tide the backwater and the sea meets, while in low tide the same place is accessible for beach
- Pleasant climate around the beach, sea breeze
- The area around the lake has potential area for development of tourist related activities

d. Proposal

The orange color in the map shows the potential area for tourism related development. Various viewing points have been created, which act as an independent nodes for development of various activities. The activities which are proposed in

these nodes are fishing areas, boating facilities, high end resorts, home stays etc. There is proposed pedestrian bridge connecting view point-3 and view point-2. Each of these nodes has viewing towers. Various other proposed activities have also been listed. This lake is also a major connectivity to the waterways proposed. The lake has potential for development of Dolphin Park.

Figure 11: Proposed Development around Kappil Lake

- i) There is no bus/auto stand within 2 km area of the Kappil Lake and hence it has been proposed
- ii) Tourist information centre & police booth service has been proposed for awareness of locations around the Kappil Lake and for assuring safety of tourists especially during the morning and afternoon time
- iii) Provision of water booth & public toilet near the beach area

4.4 Anjengo Fort

a. About the Site

This monument has been declared to be of national importance under the ancient monuments and archaeological sites and remains act 1958. It was one of the important forts of East India Company in Kerala. It was also served as a first signaling station for ships arriving from England and as a depot for military stores during Carnatic war. Fort is square on plan with 4 bastions with high laterite walls. Two of them face on sea side and other two on the land side. The fort campus also has two Tombstones of the Commodore of Anjengo.

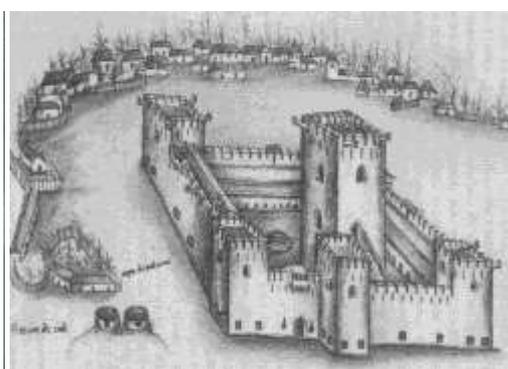

Figure 12: Aerial View of Anjengo Fort

Located about 36 km North of Thiruvananthapuram, near the famed beach of Varkala, and lying on the seacoast is Anjengo or Anjuthengu, meaning five coconut trees, 14 km away from the Helipad, Varkala.

b. Major Issues

The major issues of the area:

- Lack of maintenance at the fort
- The fort has no proper connectivity of roads

- There is Lack of awareness to the surrounding and local people
- The fort has no attraction point and has no signage to it
- There is no parking space provided and hence cars are parked on the roads at the entrance
- Big colonies of fishermen houses are built between the fort and the beach

c. Potential for Development

The fort is located right next to the beach giving it a beautiful view and location. Moreover the fort is also of great historic importance.

d. Proposal

Proper connectivity should be provided giving proper access from the beach. The condition of roads should be improved and roads should be widened. Proper signage should be provided for better direction. Proper maintenance should be done for the whole infrastructure. Sound and light show (case study: Golconda fort and Udaipur palace) should be organized for more attraction of the fort. Parking areas should be allotted and proper organized parking facilities should be provided.

ASI should organize awareness campaigns for the fort. Tourist attracting activities water sports, camels riding etc. have also been provided. The green blocks are the rehabilitee housing property comprising 60-70 (kachha pakka) houses for the betterment and development of the fort area as it positively results in the local body economy due to increase in local commercial and other activities which can greatly promote localization and economy as a whole.

Figure 13: Proposed Development at Anjengo Fort

4.5 Janardhan Swamy Temple

a. About the Site

The 2000-year old Sree Janardhan Swamy where Hindu pilgrim flocks to perform the final ritual for the deceased is the one the main attraction among the devotees. The temple precincts comprises of Temple Street, temple pond, library, Temple food court, administrative block, prayer hall etc.

Figure 14: Section Showing Janardhan Temple Precincts

b. Approach and Access to the Site

The Janardhan Swamy temple can be reached through three secondary temple streets connected by major temple road in north, east and west. It also has three access routes from which one is the main access connected by the major temple street which is in west direction and other has a direct access to the temple pond in north.

c. Existing Land Use around the Site

The majority of the land use around the Janardhan swamy temple is residential. The major node of the Janardhan Swamy temple has more of commercial activity with other religious activity throughout the day. The institutions like schools, administrative unit, library etc. is in the precincts of temple complex due to which the activities overlap and resultant congestion during peak hours. Land use along the papanasam and south cliff includes majority of hotels, home stays, resorts, studios etc. Public spaces need to be developed connecting the different building within the temple complex with a better accessibility.

d. Major Issues

The major issues of the area:

- Lack of proper connectivity and insufficient parking facilities
- Lack of basic infrastructure facilities like toilets, resting space, etc
- The water of the Temple pond needs to be treated and maintained
- Lack of basic street furniture like streetlights, benches, dustbins, railing along the temple pond etc.
- Tourist information centre in Varkala and the road side signages highlighting the important locations need to be provided

e. Proposal

The Conservation and the Revitalizing the heritage temple complex is a vital issue to be looked upon. The proposal aims to provide the proper connection from the major temple road to the secondary streets with street furniture and easily approachable parking areas to reduce the congestion during the peak hours and festival season like karkidavavubali.

However the temple pond and the Access staircase of the temple should be well connected. Public spaces in and around the temple complex needs to be renovated with proposed ramps for physically challenged devotees along with the toilet and changing room facilities

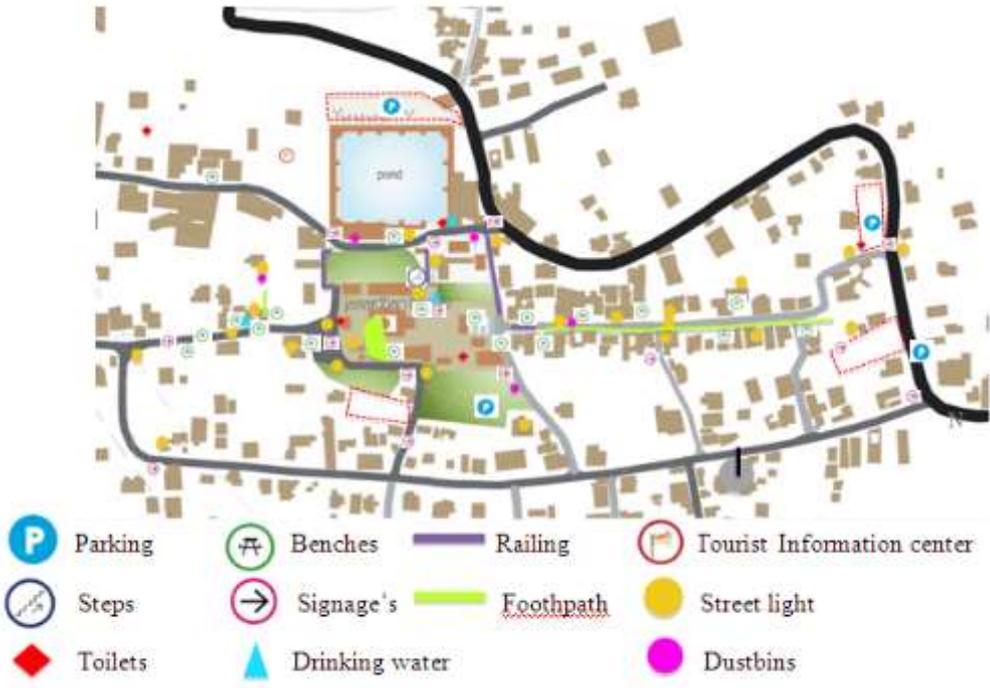

Figure 15: Proposed Amenities around the Janardhan Swamy Temple

4.6 Renovation of Varkala Tunnel

To tap the potential of backwater tourism and to meet the foreign travelers demand it is necessary to make the Varkala tunnel navigable.

Figure 72: Canal and Other Water Bodies in Varkala

Canals are waterways that are sheeted to provide a new path of travel to vessel (as opposed to improving a national water ways along its current course)

A Varkala Tunnel waterway is an aqueducts type of canal that may be used for the conveyance and delivery of portable water for human use municipal uses and agriculture irrigations.

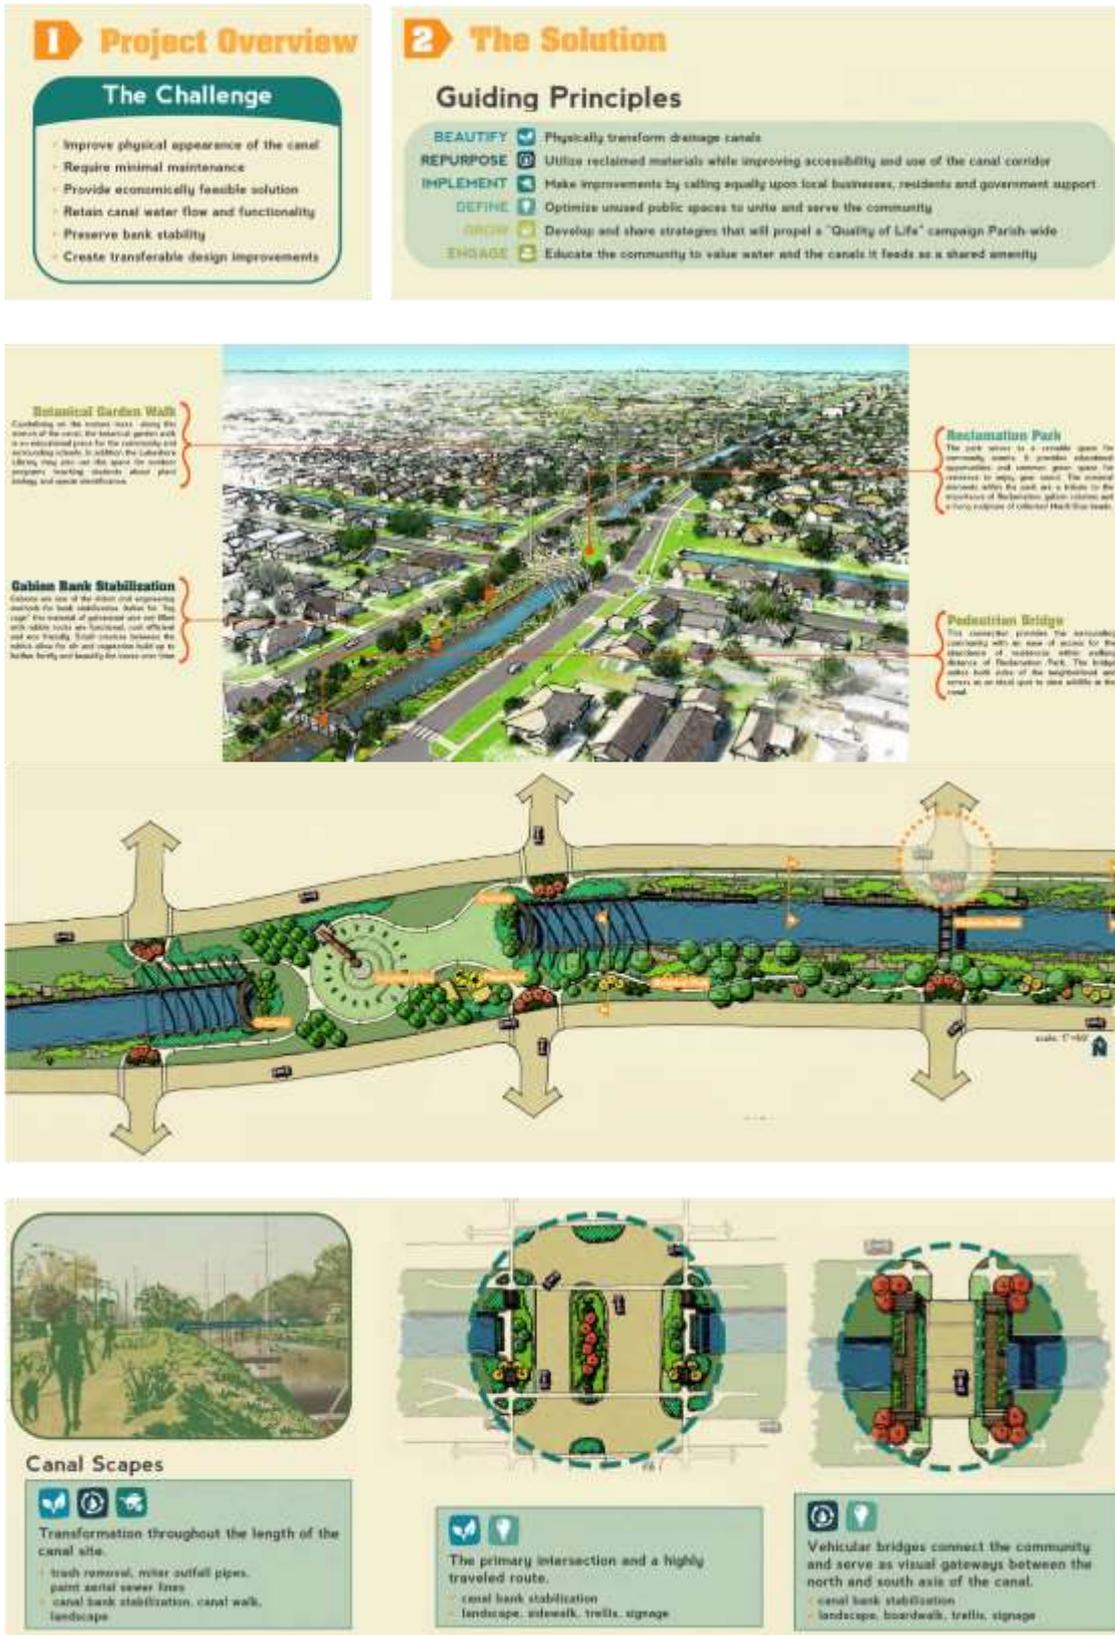

Figure 73: Conceptual Development along T.S. Canal

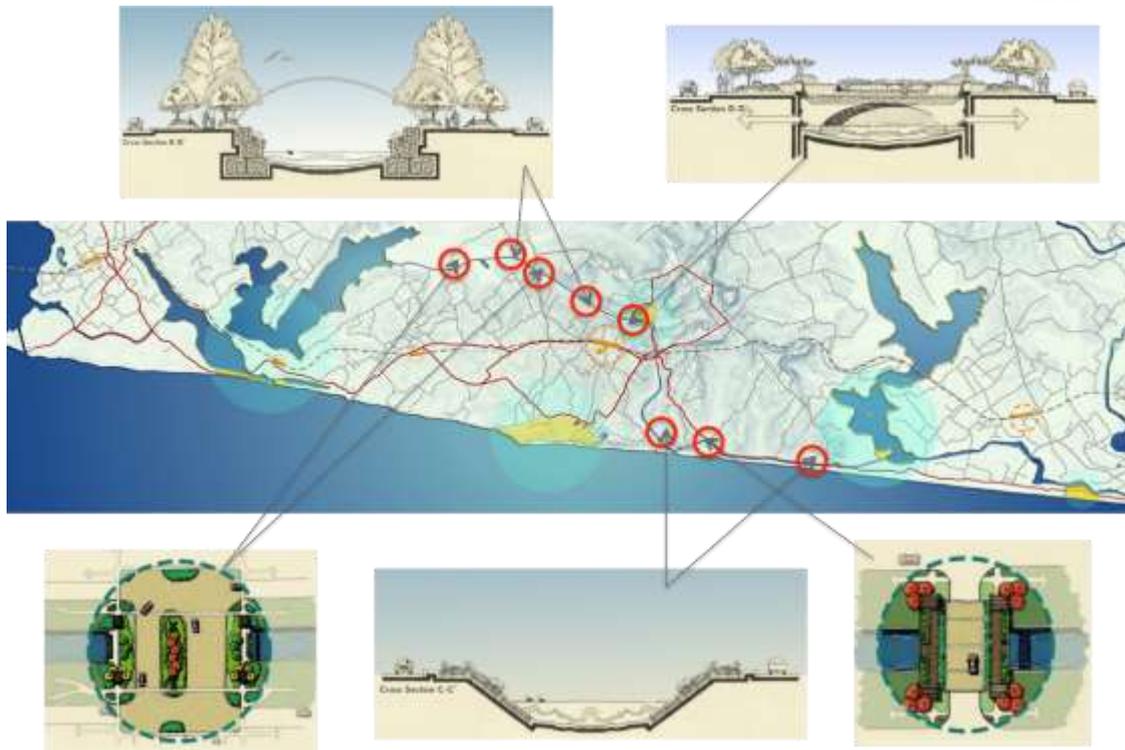

Figure 74: Development at Proposed Nodes along T.S. Canal

The Varkala Tunnel connecting Chilakkur backwater area is expected to be navigable with the assistance of Government of India and Government of Kerala at a cost of Rs. 100 crore including drudging in the area. The project is to be taken up under GOK/GOI/LSGD assistance.

4.7 Golden Island

a. About the Site

Ponnumthuruthu, also known as Golden Island is 20 km from Varkala and is known for its Shiva Parvathi temple. It is home to many birds like cormorants, egrets and herons, eagles and gulls. Various water birds too can be seen here. The mainland on the other side of Ponnumthuruthu is a coir village. There is a small coir-making unit near the ferry.

This island is known for the Shiva Parvathi temple, which is also called ‘Thuruthukshethram’ by the natives. The temple is situated amidst thick coconut groves, which has grown over the entire stretch. Valiyapurackal family owns the island and the temple. The temple is more than 100 years old and the entire island is temple property. Royal Family used to hide their cache of gold and ornaments on the island in order to keep it safe and hence it obtained the name, Ponnumthuruthu and is known for its Shiva Parvathi temple which is 100 year old and the entire island is temple property. The temple was in ruins for a long time but about a decade ago, it was rebuilt. Valiyapurackal family owns the island and the temple. The importance of the temple is during two main festivals.

1. Sivarathri is a major festival celebrated at the Siva Parvathi temple at Ponnumthuruthu. It is the festival that makes alive the otherwise less frequented island. Many devotees spend the night on the island during Sivarathri and the place lit with lights is an enchanting sight.
2. Nagapanchmi is the other important festival celebrated by the local people.

b. Major Issues

The major issues of the area:

- The backwater is not much known to tourists
- There is no proper information available about the island
- There is no proper signage’s from Varkala leading to this island
- The island is owned privately and no basic facilities are available viz. toilets, drinking water facilities

c. Potential for Development

Tourism at Golden Island can flourish more because of its historical importance with presence of flora and fauna. The access to the place could be strengthened further by promoting back waters boating. The surrounding area has immense potential to develop. Various high end resorts can come up and the place can be open up for tourist. The backwater is surrounded by has residential area. Home stays can be promoted in these areas, so they can experience tradition and culture.

d. Proposal

The orange color in the map shows the potential area for development of tourism related activity. Various viewing points are created, they acts as an independent nodes for development of various activities. The activities which are proposed in these nodes are fishing areas, boating facilities, high end resorts, home stays etc. there is proposed pedestrian bridge connecting view point-6 and view point-7. Each of these nodes has viewing towers. Various other proposed activities are further listed below. This island is also a major connectivity to the waterways proposed.

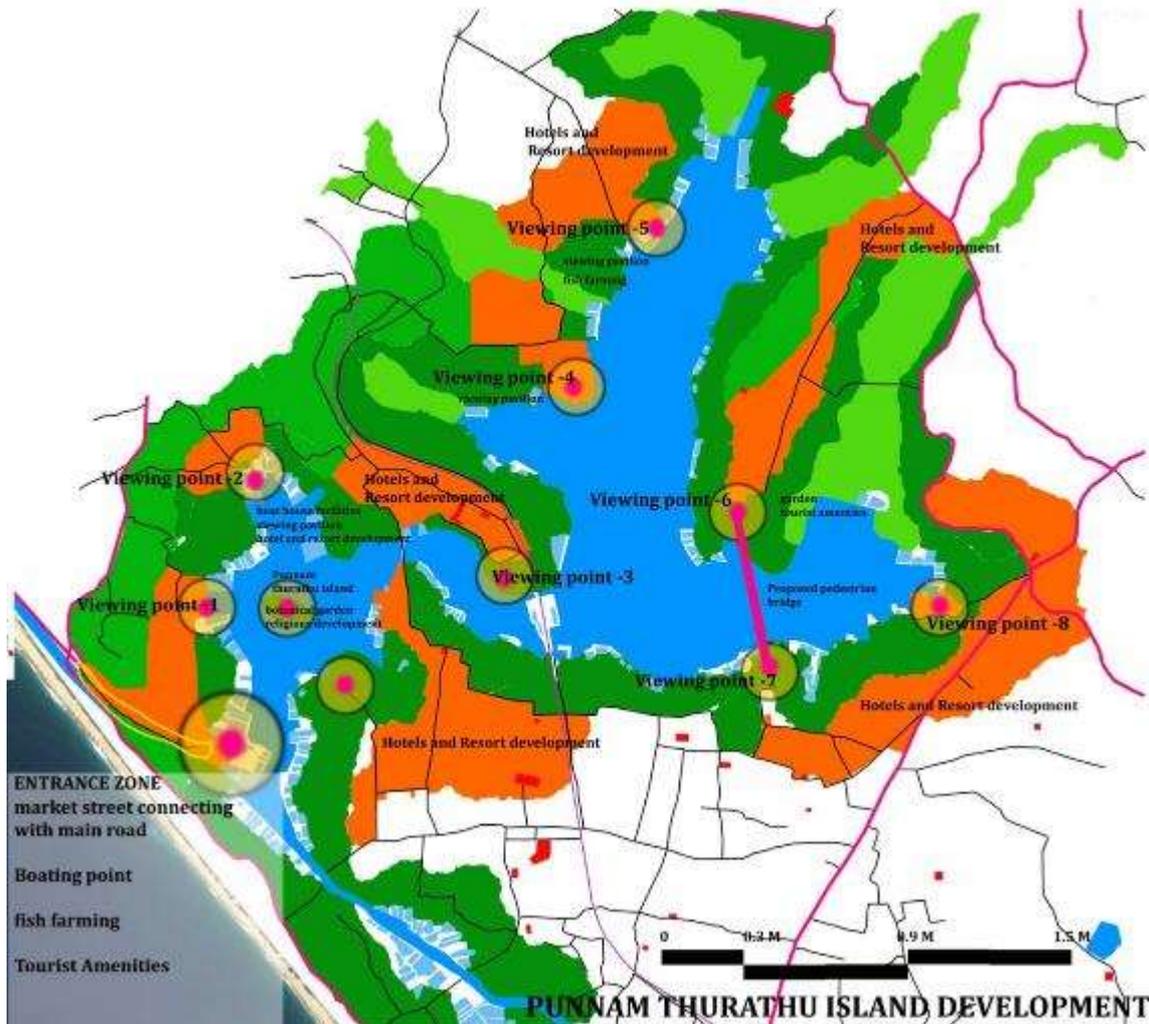

Figure 75: Proposed Tourism Activities along the Golden Island

Activities to be taken up include:

- Improvement of connectivity mainly from Trivandrum and Varkala town, as it is the major entry point to this back water
- Providing the signage's on the way
- Alternate entry point to the island and improvement of the existing entry point by providing proper path ways
- The designated platform structure for boat which is safe for every age group
- Provision of basic facilities inside the temple
- Awareness among the people by small campaign
- Templates of flora about its type and importance

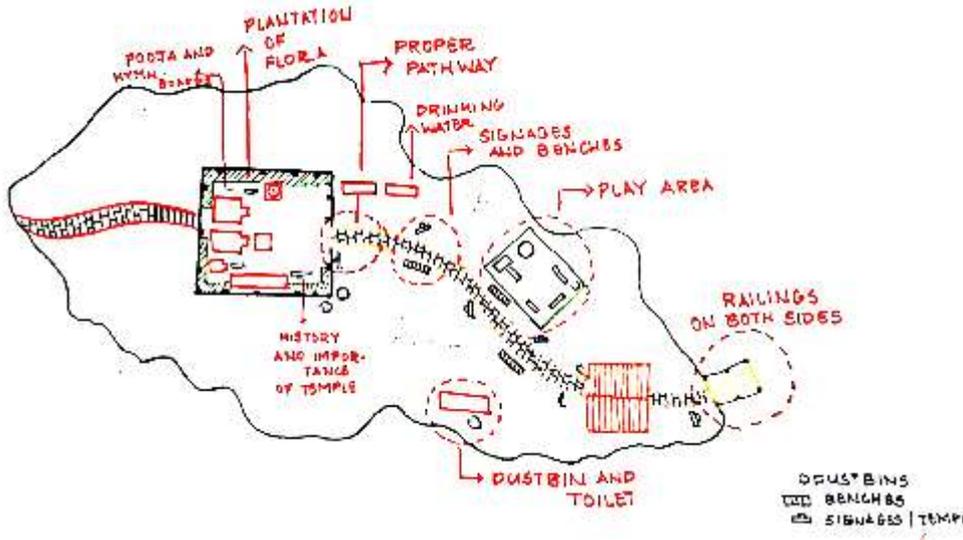

Figure 20: Location of Infrastructure Facilities in the Island

4.8 Identification of Future Area for Development with Urban Design Guidelines

The area earmarked along the sea in the figure mentioned below has high potential area for development. They are in immediate vicinity to the north cliff and helipad. These areas are less densely development as compared to the area in the north cliff and helipad is highly dense. The sprawl of development - hotels and resorts are spreading on either side of the north cliff. The northern side area is - Odayam, Manthara, Vettakada beach and southern side area is - Enikkal and Chilakkur beach.

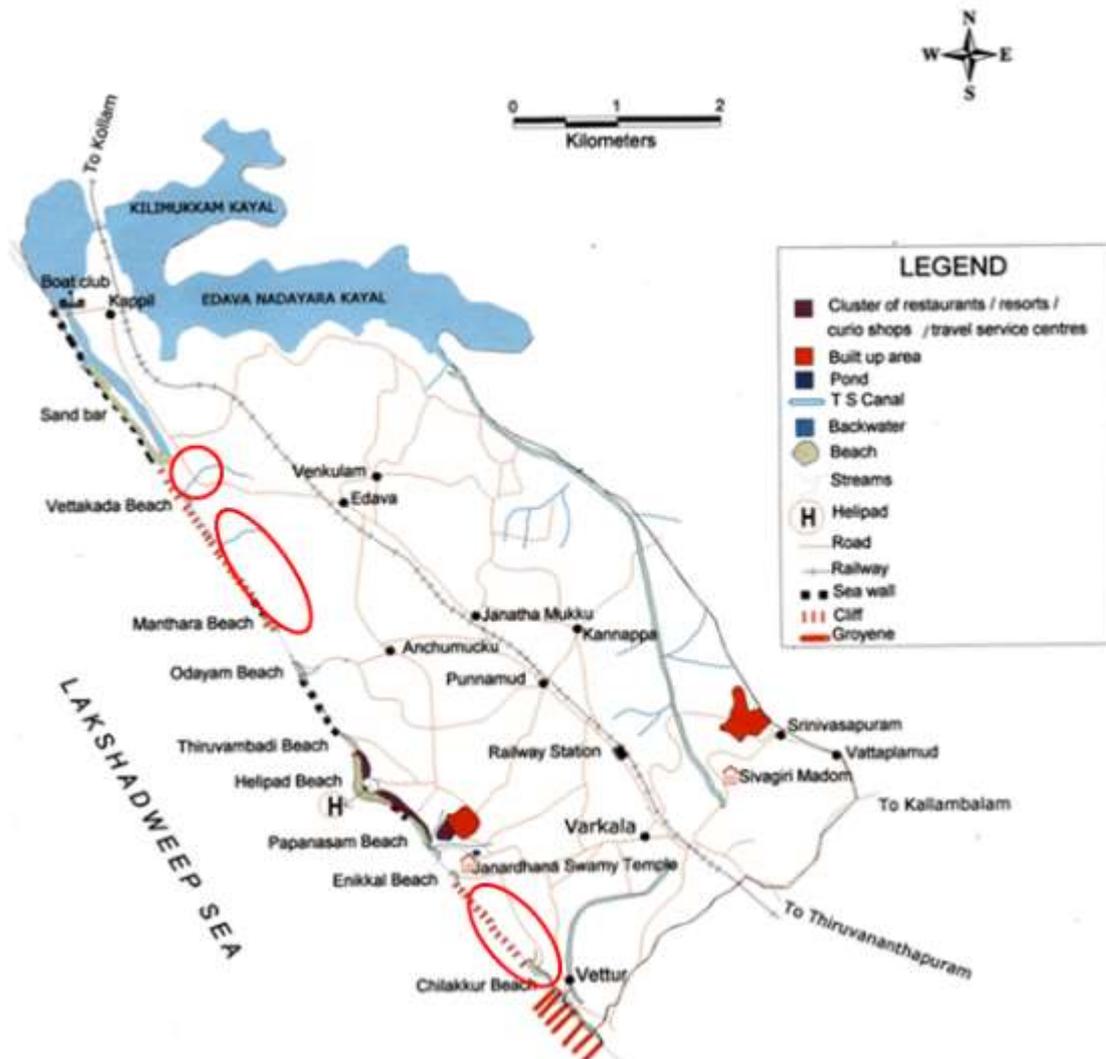

Figure 21: High Potential Areas for Development along Kappil Lake
A. Beach tourism in Chilakkur

The average beach area in Chilakkur in the peak tourism season is 8750 sq. m. and 1500 sq. m. in the off-season. The Chilakkur area has some fishermen's colony and groins to prevent the attack of the sea. Compared to other areas the sea in Chilakkur beach is rough, especially in an off-season period. But in a peak season, the beach is beautiful with a panoramic view of the sand and the view of fishermen's boats including country boats.

B. Beach tourism in Vettakada

The beach in Edava panchayat has an available beach area of 450 sq. m. in the peak season and only 250 sq. m. in the off-season.

These two cliffs have high potential area to develop in near future. To control the since coastal areas are sensitive zones, tourism activities dictate proper planning and protection measures. Concentration of developments in the narrow stretch of landmass has already caused problems like overcrowding, insufficient infrastructure, environmental issues, unhealthy competitions etc. The landuse / land cover analysis demonstrated potential tourism sites towards the northern region, and sufficient hinterlands towards the east, which has to be developed through proper planning and encouragement.

Following urban design guidelines to be followed:

- Strict implementation of CRZ norms
- Bio fencing (5- 10 m) from cliff edge
- Footpath width from limit of bio fence
- Immediate prevention of all development activities from 100 m of cliff edge
- Strengthening water drainage system on larger scale

E. CONCLUSION

The Main output of this paper to provide guidance to planners. Non-government organisation and policy makers in deciding whether tourism could work for particular ecofriendly tourist destination and integrating it with needs of local community and it can be sustained over the long term.

The paper briefly demonstrates the suggested development of the town of Varkala, a famous religious tourist destination in the state of Kerala, and 7 panchayats surrounding the town. The area considered for development, herein, showcases the dominant existence of Vegetation, Urban plantation and Agricultural activities. However, the increasing number of tourists and unregulated development along the cliffs of the town has resulted in the destruction and pollution of natural environment.

The physical infrastructure in the region needs to be upgraded to satisfy the existing and the anticipated demand of tourist & local population. This paper, thus, provides a list of planning principles that can help overcome the existing shortcomings in the region and ensure balanced development. Based on the projected resident and tourist population, the paper proposes a land use plan which shall guide the development activities till the year 2041.

In addition to this, it proposes Local Level area based planning with the aim of utilizing the potential of various tourist spots and places that can enhance the overall quality of life of neighbourhoods and the region as a whole.

The town is home to an array of religious monuments and natural and geological spots such as beaches and cliffs which have the potential to attract tourists, if developed in a certain manner. Thus, it has been proposed to develop places like the North Cliff, the Papanasam beach and the Varkala Tunnel in order to tap their tourism potential and regulate the kind of development taking place therein. Secondly, various potential tourist spots have been identified which can be developed in order to attract more tourists and generate tourism-related activities. Thus, 'Local Area Planning' has been adopted as a tool to refurbish the existing spatial fabric of the region and to establish Varkala as an exotic tourist destination on the national & international charts.

1004 MONITORING IMPACT OF LAND USE & LAND COVER CHANGE IN LIVELIHOOD ZONES ALONG THE NARMADA RIVER RIPARIAN BUFFER ZONE, MADHYA PRADESH, INDIA

Sonal Tiwari¹, N.R. Mandal², Kakoli Saha³

¹ Department of Architecture, ^{2,3} Department of Planning, School of Planning and Architecture Bhopal, Neelbad Road, Bhauri, Bhopal-462030, India, Email: sonal@spabhopal.ac.in

ABSTRACT

Riparian zones are dynamic components of the landscape that support many ecosystem functions vital to the health and productivity of watersheds. Stretched over 7126.1 sq km of area, Narmada riparian buffer zone supports livelihoods in three states in India, namely Madhya Pradesh, Maharashtra and Gujarat. Construction of dams and expansion of urban areas has modified the Narmada riparian zone while deteriorating the riparian health and livelihoods. For the purpose of the study, extraction and delineation of Narmada riparian zones were done from 30 m Digital Elevation Model or DEM. Shape files of Livelihood zones and land use & land cover of this area from 2004 to 2015 was acquired from Food and Agriculture Organization and Central water commission of India respectively. Using this data, spatial change on eleven major land cover & use classes was measured. A sample area was identified for detail study. The livelihood zones were then assessed individually to see the relationship between the change of land use and land cover and livelihood changes in that zone. From the measurement it was found that Forest and Scrubland area has greatly reduced and have been transformed into agricultural land and gullied areas. Scrublands and forests provide biomass over which various livelihoods are dependent. Percent change of areas was analysed with respect to existing livelihoods in the region. The loss of scrublands has also led to caused severe erosion and sedimentation on river beds. The sedimentation has caused changes in geomorphology of banks, riparian flora and fauna and subsequently affecting related livelihoods. This paper presents a case study of this livelihood change in the riparian zone triggered by land use & land cover alteration in the area studied as above.

Keywords: Land Use and Land cover change, Riparian buffer zone, Narmada River, livelihood zones,

1. INTRODUCTION

For centuries the river’s diverse and productive ecosystems have provided a wealth of natural resources supporting the livelihoods of millions of people living along the banks of the river and its tributaries (Ketelsen, 2017). Land Use and Land Cover change in riparian zones is expected to present serious challenges to availability of water and nutrients. As a result of land use and land cover change and possible changes in plant community composition, structure, and forage quality the net primary production and therefore feed availability will change as well.

1.1 Interrelationship between riparian zones and livelihoods

Water supports livelihoods of all people through water-consuming agricultural and industrial activities, through consumption and sanitation and through environmental services (Simon E. Cook, 2009). As per United Nations report on Water and Jobs almost half of the global workforce is employed in eight water and natural resource-dependent industries: agriculture, forestry, fisheries, energy, resource intensive manufacturing, recycling, building and transport. As the global water resources deplete due to pollution and area loss, so do the associated livelihoods. The riparian edges has different type of landforms which are point bars, flood plains, riparian forest, scrubland etc. These numerous resources in turn support a variety of livelihoods (fig.1).

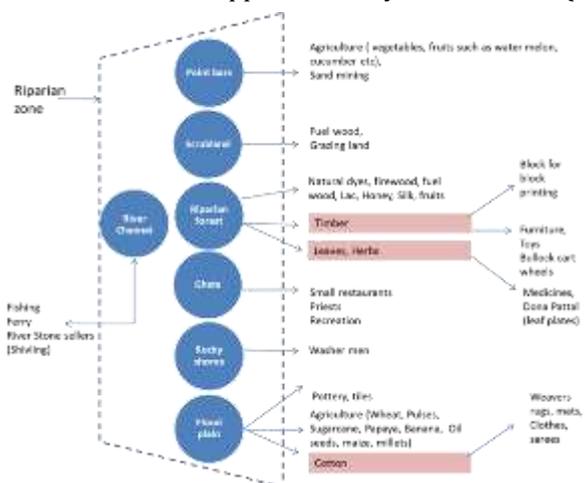

Figure 1. Interrelationship between riparian landforms and livelihoods source author

The forest support a diverse array of livelihoods and also provide a rich life to the people living around. The ‘Baigas’ of Amarkantak from Achanakmar Biodiversity Reserve in Madhya Pradesh rely heavily upon forest for medicinal herb extraction as these are the traditional medicine men of the tribal community. ‘Ojha’ community of the Hoshangabad district of Madhya Pradesh depends entirely upon extraction of leaves and bamboos for their livelihood (Dona Pattal or

organic plate making and Bamboo mats weaving), and Vishwakarma community of same district make Lacquer toys from ivory pale wood of Doodhi tree (*Wrightia tinctoria*) harvested from nearby riparian forests (table 1) These raw materials are extracted from various zones of riparian ecotone. The scrubland and forest communities provide a resource base for many traditional livelihoods.

1.2. The livelihoods in the Narmada valley riparian zone

River Narmada is said to be the lifeline of Central India. Stretched over 92,672.42 Sq.km sq km of area, Narmada riparian zone supports livelihoods in three states in India, namely Madhya Pradesh, Maharashtra and Gujarat. It is a major perennial source which provides drinking water, fishes, water for irrigation of farms, dense forests, rich plains and plenty other sources which are means of survival and sustenance for the people living in the region. For example, the forests which are close to river have a great diversity and provide numerous resources which in turn support lot of indigenous household industries and livelihoods.

Riparian zone has dynamic environments characterised by strong energy regimes, substantial habitat heterogeneity, a diversity of ecological processes and multidimensional gradients (Vyas et al., 2012). Agriculture, fishing, biomass extraction are the most common occupation in the riparian zone. Communities such as fishermen families living on the river banks, boatmen, priests are the major inhabitant of the riparian zone. As the river is considered holy and sacred along the entire length religious ceremonies are performed on the river banks. The river supplies water to the diverse agricultural zones along the course of the river.

A number of dams have been built along the entire course to harness hydro power from the river. The issues of livelihood are subject to great regional variations, and range from subsistence based economies, small scale household industries and peoples to formal and registered employment and activities. Many aboriginal communities continue to live near the banks in the primitive manner depending entirely upon natural resources. However this number is constantly reducing as the ecosystems are under constant pressure by urbanisation. The present study analyses the impact of land use land cover changes on livelihoods along Narmada riparian zone.

2. BACKGROUND STUDY ON NARMADA RIPARIAN BUFFER ZONE (RBZ)

Riparian buffer zone (RBZ) is an area on flood plains of river and shows characteristics trees, usually accompanied by shrubs and other vegetations along a river, stream or shoreline that is managed to maintain the integrity of the waterway to reduce pollution and to provide food, habitat and thermal protection for fish and wild life. The unique ecological functions of riparian zones are linked to dynamic biophysical processes and interactions across multiple spatial and temporal scales. Riparian buffer zones help in controlling soil or sediment erosion, maintaining water quality, provide habitats for different aquatic organisms, flooding & temperature control and construct a stable river bank (Vyas et al., 2012).

Considering the importance of the of Narmada RBZ, it has been subject of study for a long time. Status of Riparian Buffer Zone and floodplain areas of was assessed by Vyas et al. (2012). Micro level assessment study was also performed on tributaries of Narmada river such as Chandi Nalla (Chaurasia et al., 2015; War et al., 2014) and Bhagner stream (Bashir et. al., 2015). So far no study has been done on Monitoring impact of Land Use & Land Cover change in livelihood zones along the Narmada RBZ with relation to livelihoods. This paper proposes a method to analyze changing patterns of Land Use and Land Cover and their impact on livelihoods on Narmada RBZ. The riparian buffer zone of river are getting highly degraded.

3. STUDY AREA & DATA USED:

Narmada basin lies between east longitudes 72° 38' to 81°43' and north latitudes 21° 27' to 23° 37'. The basin is bounded by the Vindhyan ranges at north, Maikala range at east, Satpura ranges at South and Arabian Sea at west. Since, Narmada basin covers a huge area (92,672.42 sq km), a smaller zone namely Central Narmada Sub Zone covering 7126.1sq km area is selected for the study (Fig.2).

30 m Digital Elevation Model or DEM were used to extract of Narmada riparian buffer zone. Shape files of Land Use and Land Cover map of Narmada basin and broad Livelihood zones for the year 2004 , 2008 and 2014 and were acquired from Central Water Commission and Food and Agriculture Organization of India respectively. The images were then used for subsequent analysis.

4. METHODOLOGY

The methodology for monitoring Land Use and Land Cover change is comprised of 3 steps which are 1) Delineation of Riparian Buffer Zone within Central Narmada Sub Zone , 2) Analyzing Land Use and Land Cover change within Central Narmada Sub Zone, 3) Identification of livelihoods through secondary data and correlating livelihood changes to field studies

4.1. Delineation of Riparian Buffer Zone within Central Narmada Sub Zone

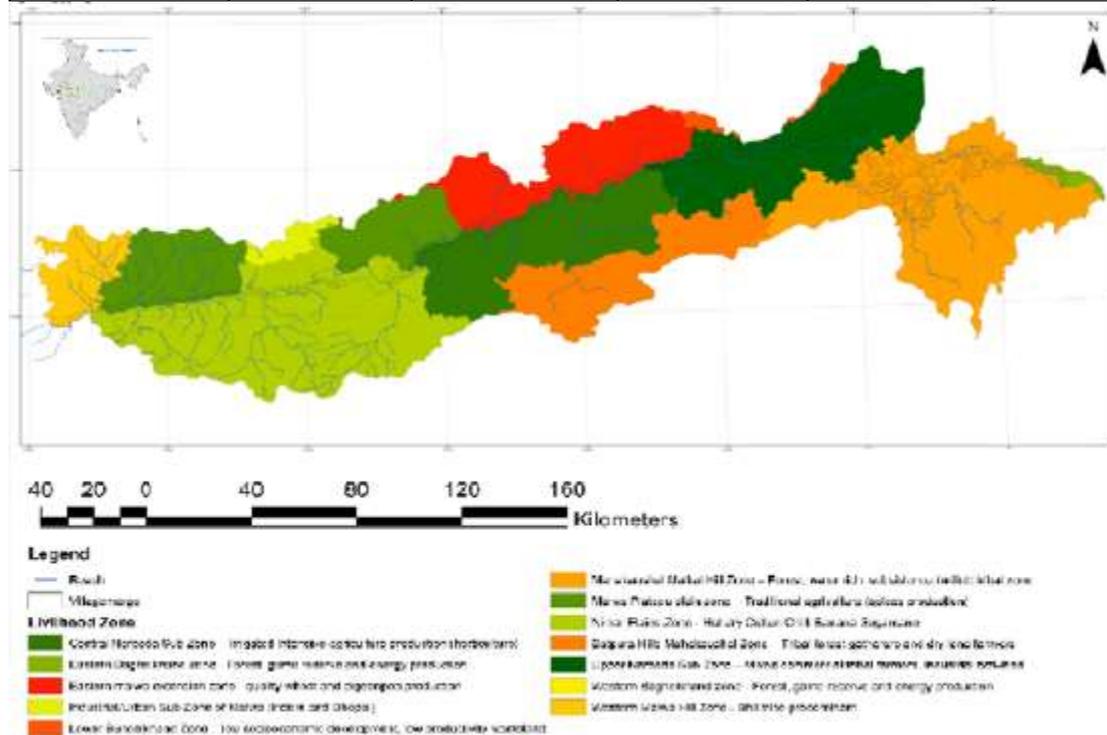

There are three major livelihood zones in buffer zone namely Upper Narmada valley, Middle Narmada valley, Lower Narmada valley. Central Narmada Sub Zone falls within Middle Narmada Valley zone.

After selection of the study area the next step is to draw a buffer zone around the river. The exact width of a buffer zone required for riparian corridor protection is widely disputed. Buffer width recommendations found in the literature vary

from as little as 25ft to as great as 300ft (Palfrey and Bradley, 1982). River Narmada is a eighth order stream midway and becomes 12th order stream at the confluence with the sea. It is also one of largest river basins of the world. Buffer recommendations given by Yale university (Riparian Buffer Zones: Functions and Recommended Widths, prepared by Ellen Hawes and Markelle Smith, April, 2015) suggests that a fifth order river should have a buffer of 300m; Hence buffer of river Narmada should be greater than 300m. The flood plains exceed 700m in certaiin areas while in certain other areas they are within 300m. As the major objective of the study is to identify livelihoods along the course of the river and their relationship to the river hence the entire village boundary on both sides of the river was considered to delineate the RBZ (fig#). The width of the villages varied from 500m to 1000m with an average width of 600m. The Riparian buffer zone area was used as a mask to clip Land Use and Land Cover layers and used in subsequent analysis.

4.2. Analyzing Land Use and Land Cover change within Central Narmada Sub Zone

Land use/land cover	Total (2004) sqm	Total (2008) Sqm	Change (2004-2008) sqkm	Total (2015)	Change (2008-2015) sqkm	Total change (2004-2015) Sqkm

Map 1 Livelihoodzones of River Narmada

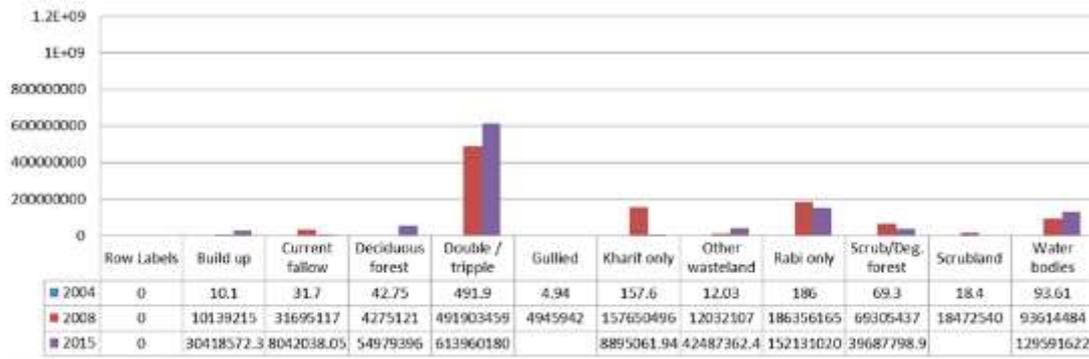

Figure 2 Table Land use land cover change summary of riparian buffer zone of Central Narmada sub zone

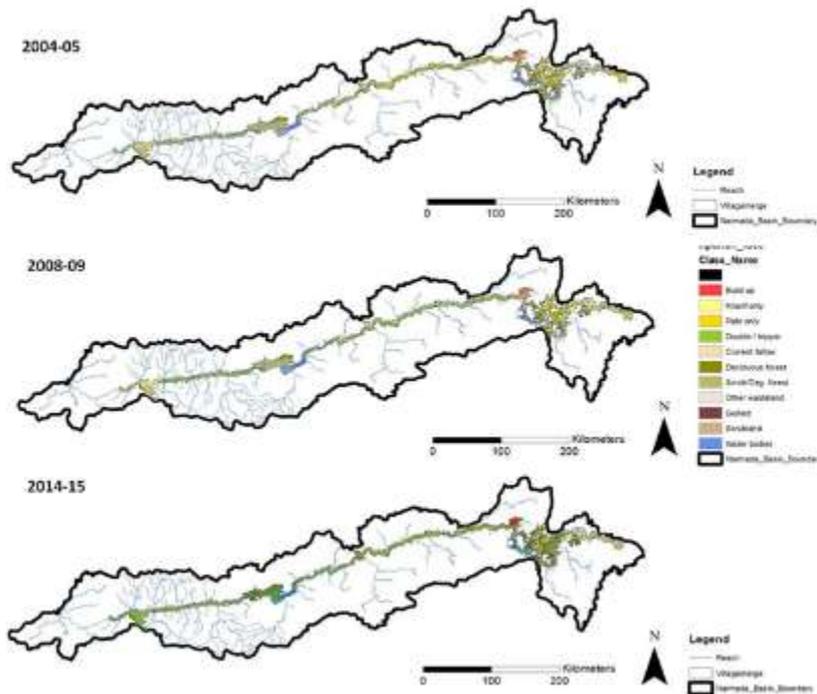

Figure 3 Riparian buffer zone of River Narmada

The land use land cover change study has indicated that the double triple cropping area has increased manifolds in the region 122%. The site visit confirm the same observation. Borewells and pumped supply from Narmada river allow multiple crops. The area of scrubland which is observed in Narmada river edges and flood plains has decreased 55%. Site visits have suggested that anthropogenic activities such as sand mining etc. can be a cause for this. The scrublands edge are essential for ecosystem productivity of a riverine landscape. They help purify water, control floods etc. Numerous resources such as grasses, lac (*Laccifer lacca*), fruits etc are harveset from these zones. Agriculture has replaced other livelihoods such as of the region which are forest and scrubland dependent.

4.3 Identification of traditional livelihoods

Literature review of District Gazettier of Hoshanagbad and Seoni districts and site visits led to identification of 32 different type of livelihoods in the study area. These are listed in table 2 with description. While some number of households practicing a livelihood has increased there has been a decline in certain other livelihood households. Table2 List of traditional livelihoods of Central Narmada Region

Sno	Type livelihood	Description	Photograph	Image source
1	Ayurvedic drug manufacture	Sellers of medicinal herbs such as Bramhi, Harad etc. These herbs are extracted from forests and river valleys. A nursery is maintained by herb collectors in the front and backyard of their houses. Some of the plants grow in the houses while some are collected from forest areas.		Author

2	Dona Pattal (leaf plates)	The leaf plates and cups are made from leaves of Bauhinia are used as disposables. the usage of these plates are less frequently seen nowadays due to replacement with foam or plastic disposable plates			(2018)
3	Tusser and Kosa silk production	Manufacture of varieties Tusser silk, Eri silk (such as Tusser feeding on Sal trees and Terminalia species, Eri on Castor-oil plant leaves etc.).			
Figure 76 Silk saree					
4	Lacquer wood work	A typical wood work from Wrightia tinctoria tree which is coated and polished with wax.			
5	Natural color preparation	Natural color are prepared by drying of herbs, leaves flowers etc.			
6	Lac bangles production	Lac is the scarlet resinous secretion of a number of species of lac insects. The harvested sticklac is crushed and sieved to remove impurities. The sieved material is then repeatedly washed to remove insect parts and other soluble material. The resulting product is known as seedlac . <i>Kerria lacca</i> can be cultivated on either cultivated or wild host trees Dhak (<i>Butea monosperma</i>), Ber (<i>Ziziphus mauritiana</i>), Kusum (<i>Schleichera oleosa</i>) Lac coated wooden sticks and bangles			
7	Rope , broom manufacturing, Bamboo and cane works	Making of brooms from palm leaves,			
8	Chatai (floor mat), baskets	Making of bamboo mats which were used as partitions inside houses and used along walls			

9	Wheels of Bal gadi (Wheels of Bullock cart)	Wheel manufacture			
10	Cotton ginning and weaving	Removal of seeds from cotton			
11	Dal (pulses manufacturing)	Dal (pulses manufacturing)			
12	Tel ghani (Mastaerd, sesame etc) and ghee ()etc	Grinding of oil seeds to produce oil			
13	Dehusking and crop processing	Dehusking and crop processing of wheats, pulses etc			
14	Agricultural implements	Manufacture of ironore farming implements			
15	Phool kheti (Marigold farming)	Farming of marigolds on the river flood plain			
16	Vegetable farming	Vegetable farming			
17	Wheat cultivation				
18	Earthen making pot	Making of earthen pots			

19	Leather shoes	Removal of leather from animal and making of bags and shoes			
20	Lime production	Lime manufacture			
21	Ironsmithy	Making of iron implements and utensils			
22	Cement factory	Lime Stone quarrying for cement production			
23	Silver and goldsmithy	Making of gold and silver ornaments			
24	Structural clay products (bricks, tiles)	Structural clay products (bricks, tiles) Making of roof tiles and blocks			
25	Bidi rolling	Manufacture of Tobacco filled leaves of Tendu			
26	Brass work, Kaskut (Brass and Zinc) Bronze Kaansa utensils	Brass work, Kaskut (Brass and Zinc) Bronze utensils			
27	Mining	Mine of Argentiferous galena, silver, coal, sand for cconstruction			
28	Sandstone Quarrying	Sandstone Quarrying			
29	Kachar kheti	Kachar kheti (farming on point bars or sandy banks of river Narmada) of watermeons, cucumber etc.			
30	Dyeing	Dyeing of textiles and threads			

31	Fishermen	Fishermen			
32	Plantation	Plantation of banana, sugarcane, mango, kathal, amrud, nimbu etc.			

Change of livelihoods in Central Narmada Sub Zone

Identification and correlation of traditional livelihoods

Conclusion- changes of LULC effecting the livelihoods

Sno	Type livelihood	Change in household numbers practicing a livelihoods (increase/ decrease)	Associated land cover	Reasons
1	Ayurvedic drug manufacture	Decrease	Forest	Decrease in forest area
2	Dona Pattal (leaf plates)	Decrease	Forest	Decrease in forest area and access to forests
3	Tusser and Kosa silk production	Decrease	Forest	Decrease in forest area and access to forests
4	Lacquer wood work	Decrease	Forest	Decrease in forest area and access to forests
5	Natural color preparation	Decrease	Forest	Decrease in forest area and access to forests and market pressure have replaced natural dyes with chemical dyes.
6	Lac bangles production	Decrease	Forest	Decrease in forest area and access to forests
7	Rope , broom manufacturing, Bamboo and cane works	Decrease	Forest	Decrease in forest area and access to forests
8	Chatai , baskets	_ Decrease	Forest, shrubland	Decrease in forest area and access to forests
9	Wheels of Bal gadi (Bullock cart)	Decrease	Forest	No more requirement as change in ploughing technology has happened.
10	Cotton ginning and weaving small scale	Decrease	Farmland	Change in technology and modern machinery has replaced small scale workers
11	Dal (pulses manufacturing)	Increase	Farmland	
12	Tel ghani (sarson, til etc) and ghee etc	Increase	Farm based	
13	Dehusking and crop processing	-	Farmland	
14	Agricultural implements	Decrease	Farmland	Change in technology and modern equipments have replaced traditional equipments
15	Phool kheti (Marigold farming)	Increase	Farm based	
16	Vegetable farming	Increase	Land	
17	Wheat cultivation	Increase	Floodplain	
18	Earthen pot making	Increase	Floodplain	
19	Leather shoes			

20	Lime production	Decrease		Change in technology
21	Ironsmithy	Decrease		Change in technology and new machinery
22	Cement factory	Increase	Land mining	
23	Silver and goldsmithy	Increase	Land mining	
24	Structural clay products (bricks, tiles)	Decrease	Land	Modern construction techniques and technology
25	Bidi rolling			
26	Brass work, Kaskut (Brass and Zinc) Bronze Kaansa utensils	Decrease	Land based	
27	Mining	Increase	Land	Increase demand of construction materials such as sand, aggregate etc.
28	Sandstone Quarrying	Decrease	Land	
29	Kachar kheti	Increase	Land based	
30	Dyeing	Increase	Pointbar, water	
31	Fishermen	Decrease	River	Decreases fishes number
32	Plantation	Increase	River based	
33	Broom making		Scrubland	

The study shows that ten out of thirty livelihoods identified are forest or scrubland dependent. forest and river based livelihoods have decreased significantly.

The results of land use and land cover (LULC) clearly show that changes were significant during the period from 2004 to 2015.

Reduction in scrublands and forest areas: The scrublands have decreased significantly to create more land for farming. The highly productive flood plains covered with forests or scrublands are degraded and are either infested with invasive species or have undergone severe erosion. The scrublands are seen predominantly on edges of rivers, tributaries, slopes in Narmada river riparian zone. These are also present on fragile or sensitive areas and hence they play a role in safeguarding the ecological values of landscape. Loss of scrublands in certain areas has led to increase of gullied and ravine lands.

The forest area has not much changed however there is a significant reduction in diversity of the forests. Also much of the forest area fall under protection category which inhibit extraction of forest resources. Fragmentation and discontinuity of forest patches has also led to degradation of forest and reduction in number of specific species types of species. Interviews and discussion with local people revealed that there has been a significant fall of certain species form the forest.

Change in double triple cropping area: A significant increase is seen in double triple cropping areas. Loss of landscape diversity of this area such has resulted in loss of livelihood diversity of this area. Intensive agriculture practice involves pesticides and herbicides eventually causing ground and surface water pollution. Motor pumps and canals provide year round supply for water for irrigation.

Increase in gullied area: The gullied land has increase substantially due to development occurring in the innermost zone of the river. The fallow lands have degraded and converted to gullied and eroded lands. The steep slopes which were stabilised with vegetation have been deeply affected on removal of it for various purposes. Urban development is happening right till the edge of the river which is affecting the the vulnerable slopes of the river. The gullied land is highly degraded and unfit for any use.

The increase in gullied areas indicate towards loss of vegetation cover in steep slopes and valley region. The area of water bodies have increased due to construction of numerous dams in the catchment.

Increase in urban area: Increase and almost doubling of built up area has reduced the grassland and scrubland region which were supporting many livelihoods such as of pastoralists etc. the severe reduction in numbers of livestock and pastoralists is indicated by these.

The riparian zone ecosystem of River Narmada is degrading fast due to extensive anthropogenic acivities in the buffer area. Livelihoods depending on healthy ecosystem are at risk of loss and extinction.

CONCLUSION

The forests and scrublands are located on steep slopes, ridges, fluvial plains and edges and hence are significant in safeguarding the landscape as well as resource base to rural communities.

The increase in wasteland, scrubland and gullied land is alarming and indicates towards degrading landscape of the River. The gullied land is unfit for any purpose and requires conservation as it does not support any livelihood and hence the increase of gullied area should be checked. Indegenious livelihoods have a very small foot print and remain confined to a region. A changing ecosystem can severly affect their resource base and survival. Livelihoods supported by fresh water (fisheries etc), forest and scrublands (toy makers, bamboo mat makers etc) are under stress due to changing land use in

the riparian zone of Central Narmada river. Lack of new technology, innovation, reducing resource base and confinement to the region are posing threat to many of these livelihoods. Changing market trends where they have been replaced already by intensive technology are some of the challenges that have to be tackled.

1040 ACCESSIBILITY CONFLICTS AND DISPARITIES IN THE URBAN WATER SECURITY OF THE DARJEELING TOWN IN EASTERN HIMALAYAS, INDIA

Ashish Chhetri, Lakpa Tamang

Department of Geography, University of Calcutta

ABSTRACT

Several studies have highlighted the problems of water crisis in the hill towns of the eastern Himalayas but no significant work has been done with the quantitative assessment among the different parameters that contributes to water accessibility and security of this region. The popular findings emphasizes the local water sources or natural springs referred locally as Dhara as the major sources of water and plays a pivotal role in meeting the daily water demand in most of the hill towns. However, in case of Darjeeling town with the failure of the Public Water Distribution system to cater the growing population along with the topographic nature of the region, the local water sources are located in varied patterns carrying uneven discharge capacity and accessibility. Thus the situation has given rise to a decentralisation of the local water source via private and community level initiatives. There has been a rising tussle between these two mechanisms of decentralisation, claiming the ownership of different local water sources and exerting their influences on the water security among the masses.

The present study attempts to fill the research gap assessing the Water Accessibility Index (WAI) through different parameters like Terrain Difficulty (X), Distance (Y), Dependency (Z) and total Availability of Spring Water (Q), the study finds a significant determinant WAI attributing the numerical values from 0.1 to 1.0 to different variables. The findings suggest that the areas of high water accessibility index (above 0.5) covering the Eastern Slope of the town have favourable terrain, limited population and abundant water supply, where as the areas of poor WAI (below 0.5) on the western slope is featured with difficult terrain, restrained water supply and sprinkled settlements. Thus, there exist a huge spatial disparities and accessibility conflicts which have predominantly influenced water resource management and water security in the town.

Key words: Local water sources, Water Accessibility Index, Accessibility Conflict, Urban Water security.

INTRODUCTION:

Darjeeling, a small Himalayan town, located on the average elevation of about 6710 feet is more famous for its world class tea production, scenic beauty of Himalayan landscape and highly pleasant socio-climatic environments. The town is currently inhabited by 1,32,000 population (Indian census, 2011) and like many other Himalayan tourist destinations, Darjeeling also attains the popularity to attract more than 3,00,000 domestic and foreign tourists every year. Such a huge influx of tourist particularly during the rainless months of the year often endures an acute water crisis situation in the town. Some aspects of water security in the town is also dependent essentially on the nature and flow of tourists which demands additional water for its services. During the tourist seasons the town is almost incapable to manage balance between water demand and supply and hence induces a water deficit of about 13,32,5000 gallon per day (Annual Report, 2014, Darjeeling Municipality). "Despite its prominent natural endowments, including the location's high average rainfall and abundant springs, many might be surprised to find that fresh water in the town is in short supply. In fact, regular access to water can be one of the most pressing resource challenges for Darjeeling residents and visitors" (Drew and Rai 2016). Darjeeling town resembles one of the oldest municipalities in India established in 1850 by the British empire. The municipality set up was designed to cater the requirements of the then population of about twenty to thirty thousand, but with the ever-increasing population in the town, the municipality is not in a position to cop up with the requirements of the present day population. consequently the town is facing several problems such as shrinkage of internal spacing in the town, rapid and unplanned urbanization, high population influx, poor water supply and sanitation, unscientific waste management system, air and noise pollution, and uncollected refuse, which is turning it into a miserable slum like location in the hill. All this unwanted circumstances have severely affected the pressing problem of water scarcity and water resource management has become a conflicting issue in the town. In fact, water problems in the Darjeeling region is embedded in the predominately complex hydro-geological settings lumped with the 'historically entrenched configurations of unequal spatial developments and legacies of socio-political contestations' (McFarlane, 2011).

There exists hundreds of natural springs locally called as Dhara which sustains major share of the domestic water requirements in the region (Boer 2011). The ridge top location of the town despoils it to fetch water from the low lying sources and hence is dependant solely on the locally available water sources be it the natural springs, muhan (spring source), jhora (drainage) and seasonal streams. "The Himalayan region is a source of countless perennial rivers, paradoxically the mountain people depend largely on spring [ground] water for their sustenance" (Tambe et al. 2012). Spring water is used for almost all the domestisc, agricultural and commercial purposes and hence bears immense socio-cultural importance for the origin and evolution of mountain settlements. Springs are also considered as the purest source of water and also hold a typical religious value among different religions particularly in Hinduism. Springs are often equated with place where the deities reside and is locally referred as Devithan. "Sacredness of spring water is expressed through the concept of chokho pani, meaning pure, sacred, or clean water" (Lama and Rai, 2016). Hence the availability and accessibility to natural springs have always affected the socio-economic augmentation of Darjeeling town. However the spatial distribution of these natural springs is very uneven and haphazard thereby exhibiting a complex accessibility tendencies towards the use of spring water for domestic as well as commercial purposes. On top of this, the steep slopes, mountain aquifers in the aberrantly stratified hard rocks, and unplanned growth of settlements have made

it very difficult to bring in equitable accessibility to spring water in the region. As a result different springs at different places have varied accessibility tendencies and are being used accordingly undertaken by different management institutions such as Samaj (a community based organization), private water vendors, P.H.Es and the municipality.

"In the Darjeeling region, community and market-based approaches to manage and access water operate as hybrid systems (Josi, 2015). The town receives its major share of public water supply from the Sinchel catchment area, where the two lakes such as the North Sinchel Lake and the South Sinchel Lake having the capacity of about 20 million gallons and 13.5 million gallons respectively. Since both the lakes were built during British age in Darjeeling, the lakes are not in a position to cater water demand of the present day population in the town.

Hence, Public Water Distribution system is failure to cater the water demand of the growing population in Darjeeling town. The rapid growth of urbanization, increasing population stress with the rising demand of water has led to striking challenge in the supply and management of water in Darjeeling town. In the recent years due to wanton expansion of concrete settlements over the catchment areas of the natural springs the town is experiencing drastic fall in the supply of water which has worsened the situation of water crisis enduring an estimated water deficit of about 1.33 million gallons/day. However to get access to drinking water people have adapted themselves on the alternative sources of drinking water be it the natural springs, drainages and rainwater harvesting. Such situation has given rise to a decentralisation of the local water supply system via private and community level initiatives in the region. These two mechanisms of decentralization of the existing water supply systems are highly antagonistic in nature and there has been a rising tussle between these two mechanisms of decentralisation, claiming the ownership of different local water sources and exerting their influences on the water security among the masses.

THE STUDY AREA:

Darjeeling municipal Town is situated on the lower part of *Darjeeling – Jalapahar Ridge* in the Siwalik Himalayas, between 26°31' to 27°31' N and 87°59' to 88°53' E. This range extends northward from Ghoom, at first rising abruptly to a height of 2366m, then gradually decreasing to 2100m at Chowrasta and again rising to 2149m at Observatory Hill. The town had a populaiton of about 1,32000 according to Census, 2011which is increasing rapidly due to several socio-political significance. The town represents a cosmopolitan society where majority of the people are Gorkhas.

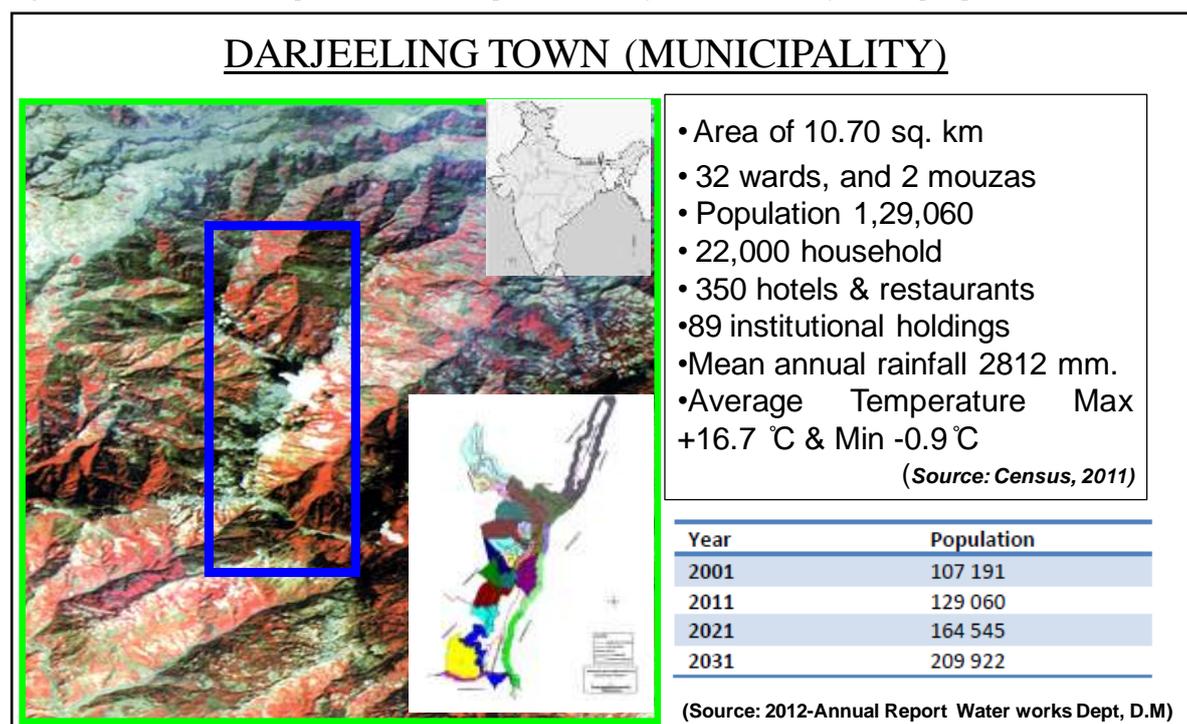

Figure 1: Location and demographic statistics of Darjeeling town

MATERIAL AND METHODS:

The present paper emphasises on the overall study of the water management system through the development of conditional framework that measures the nature of accessibility to drinking water at different places and their impact on the various mechanisms of management system in the town. The authors undertook extensive field survey in and around Darjeeling town covering the parts of Darjeeling municipality During the year 2016-17 to study the aspects of drinking water security and management in the town. The field survey was conducted with the help of a questionnaire, semi-structured interviews, and focus group discussions for the collection of qualitative data; the authors also undertook the process of measurement of water volume of the ten major springs (in litres/minute) for twelve months to generate quantitative primary data.

The study covers two major aspects, firstly the assessment of different parameters of accessibility to spring water such as Terrain Difficulty (X), Distance (Y), Dependency (Z) and total Availability of Spring Water (Q), which were used to

develop Water Accessibility Index, all the parameters that combines information for WAI are marked by numerical values ranging from 0.1 to 1.0 in which the characteristics and intensity of the parameters were also processed with the help of 5 point Likert scale; secondly the impact of such accessibility index to spring water was studied to understand the feasibility stand of private and community based water management in the town. The identification of ten major springs of both eastern and western slopes of the town were done on the basis of population dependency over the individual springs to study the variability of water discharging capacity of the springs. The volume of spring water discharge was measured following simple measure in which whole water of the spring was diverted and released from a single point and was collected in a bottle of one litre capacity and was recorded with real time value to have an estimate of the water flow per minute. Later such data of different springs were processed with the population dependency over the springs and were considered as the major element to study water accessibility and security of the region. The examination and analysis of data of the select springs based on water volume and accessibility has enabled the authors to understand the controlling factors for the feasibility and prevalence of either private or community based initiatives for the management and supply of water which may be sustainable and highly cost effective in the town. The interactions with various members of the local *samaj* (a community based organization) and dependants on the individual springs were very useful in understanding the nature and functioning of the existing water supply system across the town.

As to brought about further interpretive focus to the study most of the sources of secondary data collection have been used such as review of published literatures, journals, articles, books, magazines etc. Maps and other significant information have been gathered from the institutions such as municipal offices, forest departments, settlement office, NGOs, libraries, colleges and online sources.

ACCESSIBILITY ASSESSMENT OF THE SELECT SPRINGS IN THE DARJEELING TOWN:

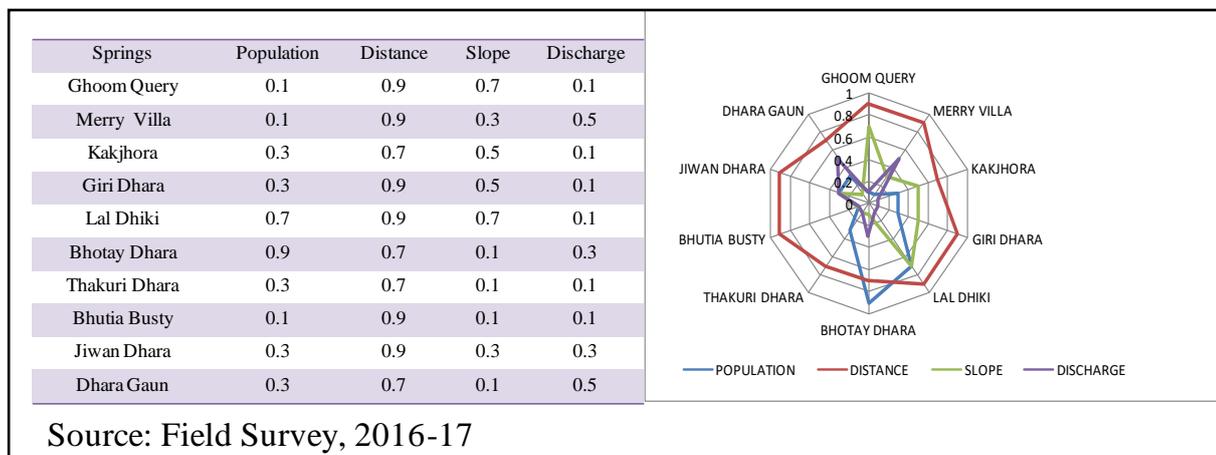

Water availability and accessibility are the two key elements to water security in any region. In the hill-urban centres like Darjeeling these elements are highly accountable for sustainable water management and its equitable distribution (Jeanne L. Nel et al. 2017). Majority of the inhabitants in Darjeeling town is dependent on the natural springs and *Jhora* (local drains) as the main source of drinking water. There are about hundreds of such springs across the length and breadth of the town (Boer 2011; Tambe et al. 2012). However these natural springs which supply water to almost whole town do not exist everywhere and exhibits several dots like (point of outlets) heterogeneous locational distribution along with varied discharging capacity. "Water source areas often only occupy a small fraction of the land surface area but supply a relatively high amount of water to the surrounding region" (Meybeck et al., 2001). Hence every part of the town has diverse tendencies with regard to access to the local water sources bounded by several factors like terrain difficulty, distance, water volume, population dependency, ownership, governance etc. (Josi et al. 2011). Such varied factors of accessibility to local water sources have given rise to different forms of water management and supply system in the town. This paper focuses to study and analyse the impact of uneven water accessibility on the existing water management system by computing Water Accessibility Index (WAI) for different Springs and their zone of influence. In order to construct the base-framework of WAI in Darjeeling town four major parameters, viz. the terrain difficulty (slope), distance, population dependency and total quantity of available water, which are likely to influence the accessibility to spring water have been included as the key elements for calculation and proceedings. All these parameters of WAI have been marked with 5 point Likert scale codes and resultant WAI are represented by the numerical values ranging between 0.1 to 1.0 which were further analysed and processed to compare and contrast among the different select springs. While giving weightage to the difficulty of terrain as one of the key parameters of WAI, it was computed by preparing a questionnaire using 5 point Likert scale, in which the terrain difficulty was categorised in 5 numerical values or codes such as steep uphill-1, gentle uphill-2, straight-3, gentle downhill-4 and steep downhill-5. Similarly the another parameter population dependency was computed as the total number of dependants per spring by referring 5 point Likert scale codes such as less than 400 population-1, 400 to 800 population-2, 800 to 1200 population-3, 1200 to 1600 population-4 and more than 1600 population-5. The average distance, one of the key element of WAI, was computed with the 5 point value of Likert scale such as below 1km-5, 1km to 2km-4, 2km to 3km-3, 3km to 4km-2 and above 4km-1, by measuring the real ground distance between the spring and the core settlement area having relatively highest number of dependants. The unit quantity of total water availability of the spring was measured by taping the water source into a single outlet and by collecting the water in a bottle of one litre capacity and was recorded with real time value to have an estimate of the water flow per minute. The obtained data of water discharge per minute of all the select springs was statistically processed and on the basis of their individual monthly variation of discharge the data was marked by separate codes following 5 point Likert scale analysis.

Sl. no.	Name of the springs	Municipality Ward no.	Average water discharge (lit/min)		Average distance	Nature of slope	Population dependency (approx)	WAI	
			Lean season (Dec-May)	Normal season (June-Nov)				Dry season	Normal season
1	Ghoom Query	2	3.67	13.75	5	4 (Gentle downhill- western)	1	0.45	0.5
2	Merry Villa	6	2.17	3.495	5	2 (Gentle uphill- western)	1	0.45	0.5

Table 1: The Water Accessibility Index (WAI) of the 10 select springs of Darjeeling town

In table1 computed using 5-point Likert scale marked to four major select parameters, calculated from the data collected during the field survey by the authors in the 2016-17. It is evident from the table that different springs represent different WAI which not only varies from spring to spring but also differs seasonally. While considering the WAI parameters mostly nature of the slope or terrain resembles more diversities in terms of carrying Likert scale codes with spatial consideration and the water discharge of the spring is the another highly fluctuating parameter which has significantly influenced the WAI of the respective springs. Apart from this, the other two parameters viz. distance and population dependency show more or less common values in Likert scale which have still in combination with the other factors have categorized the whole sets of WAI into two genre as the areas of relatively low or poor water accessibility index and relatively high water accessibility index. it can be seen that the two different slopes i.e. western slopes and eastern slopes represent contrasted WAI having relatively high water accessibility and low water accessibility respectively. The figure1. shows the influence of different parameters and their interdependency on the computation of WAI of different springs.

Source: Field Survey, 2016-17

Figure 2: Comparative representation of different parameters used for WAI computation

The table1 further shows that there exist a high variation in seasonal range of water discharging capacity of the natural springs which in turn influences the tendencies of water accessibility of the respective springs. The people are more accessible to spring water during normal seasons as all the springs have high range of average water availability of about 20 to 60 litres per minute but the same springs are less accessible during dry months (from December to May) when their water discharging capacity decrease significantly. Some of the springs even become dry during the months of April and May while the others become very insignificant to cater almost constant water demand in the area.

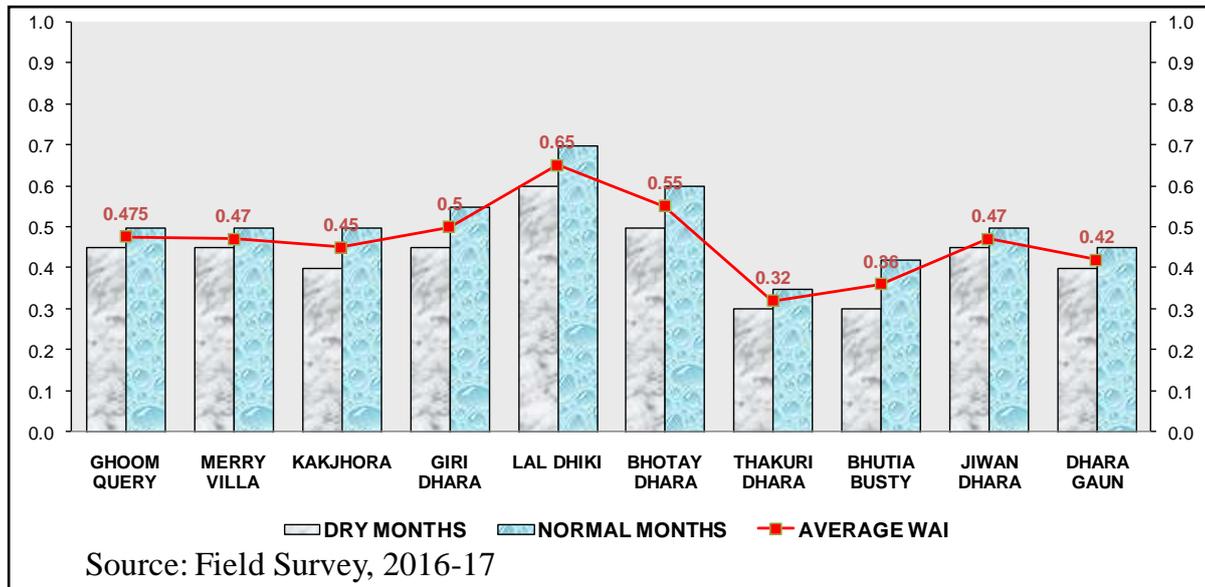

Figure 3: Seasonal trend of WAI of the selected springs

The fig. 3 shows the trend of seasonal variation of the WAI indexes of all the select springs in which it is vivid that there is a significant gap between the WAI of the dry months and the normal months of the year. The highest average WAI of about 0.65 is found in Laldhiki spring which holds the central market location, very adjacent to the passing road with comparatively high water discharge throughout the year. Whereas the lowest WAI of 0.32 is associated with Thakuri Dhara which is located at the steep corner eastern-slope of the village where the discharging capacity of the spring is also not enough to cater its nearby population.

DECENTRALISATION OF WATER MANAGEMENT IN DARJEELING TOWN:

Improvement of water management and distribution system to secure water availability and accessibility is an inevitable phenomena in any growing urban centres. Similarly in Darjeeling the ways of water management system has undergone several stages of evolution and modification. Initially the town has centralised water supply system for all the citizens but however today such centralised system have been modified and there exist a hybrid system of a combination of public, private and community based initiatives (Josi, 2015). Failure to provide requisite supply of drinking water in the town, centralised public water distribution system seems futile to the urban poor who are compelled to survive on the alternative sources of water. A public report of the Darjeeling Waterworks Department (2012) notes that 95 per cent of the existing pipeline and valves were laid by 1930. This system is in great need of repair, revitalisation and improvement (Drew and Rai, 2016). Consequently, the 'Decentralization of water resource management' has become one of the most susceptible and intervening act to take on the situation of water crisis in Darjeeling municipal area. such decentralisation of water management system is taken up by the two robust initiatives be it the private water vendors, which is highly profit oriented management system and the community based initiative which is for non-profit services. Both the institution of decentralised water management system have a strong tussle of holding their control over the locally available water sources such as the natural springs to supply water in the town. There exists more than 32 natural springs in Darjeeling town (Boer 2011). The community and private initiatives have always been the most dominant institutions who are managing the storage and distribution of water from these springs and thus some of them are openly accessible to all and some have restricted access. Various samaj (a community based organizations) have come forward with a common will and service to manage the natural springs and are acting as a medium for decentralization of water management system in the region. As samaj looks after the demand and supply of water of its own members and hardly the outsiders are provided water from the managed springs there still exist accessibility conflict to local water sources to general public. On the other hand, most of the springs are located on private land (82%) (Tambe, 2012), and are being managed by the individual water vendors who supplies water only to its customers who have to pay significant amount of money to the spring owner quarterly or annually. The residents are compelled to pay for water as the public water supply is highly irregular and not enough to cater the water demand of every household and this has given rise to a robust water market in the town. There are numerous systems in place to accommodate this market. Some of the distribution is very small scale with enterprising individuals selling water that they have sourced from nearby springs, some supplies water from their private springs and some sells water in litres through private water tankers for earning handsome profit (Drew and Rai). On the contrary to private water supply, the different *samaj* are focusing on supplying water to their people for welfare purpose. *Samaj* are self funding and basically made for the social welfare and upliftment of the community itself. "*Samaj* is a self organized grass root level social institution. In Darjeeling there are around 130 different Community based organizations" (Joshi et al., 2011). Since *the Samaj* of each village or an area is meant for social assistance and welfare of their community, the efforts to acquire and ensure equitable water resources are a natural extension of the purpose of *samaj*. " A large number of springs dot the landscape around the town, these water sources provide a non-centralised distribution system that many *samaj* are able to utilise" (Drew and Rai 2016). Hence different samaj have come forward to strengthen the water accessibility and security in the town. In a nutshell it could be

summarised that the water management system in Darjeeling town have undergone transformed from a simple centralised to a hybrid decentralised system to sustain the management of water supply system at a local level.

FINDINGS AND CONCLUSION:

Sustainability refers to the most desirable situation where there is an equilibrium of resource availability and consumption. But the growing hill town like Darjeeling is far behind to attain such kind of sustainability particularly in terms of water management and supply. It is evident from the above study that the town suffers from the restricted supply of water enduring a huge accessibility conflicts between private and community based mechanisms to manage and supply water from the local sources. While considering the analysis of the WAI of the select springs it was found that the entire town is divided into two zones having diverse water availability, accessibility and security phenomena. The western slopes of the town is more accessible with relatively favourable supply of spring water to the local residents. WAI is also highly variable from springs to springs, seasons to seasons and from region to region with unequal supply and distribution. There is a rising tussle regarding the water accessibility between the private and community based institutions and it is often seen that the local water sources or springs having high accessibility are more actively controlled by the community based organisations or samaj and the low accessibility springs are being captured by the private water vendors. The conflict is always there in terms of water accessibility be it managed by the community or by private institution for in case of community management water is equitably distributed among the members of the samaj but are sometimes restricted to the outsiders or non-members, where as the private water supply system is limited to the rich people and deprives the urban poor. Hence the urban poor who own no springs are forced to live in a situation of water poverty in Darjeeling with no concerns from the government, community or any other agencies. As a consequence there exist a huge spatial disparities and accessibility conflicts which have predominantly influenced water resource management and water security in the town.

1085 THE ROLE OF SOCIAL MOVEMENT FOR EQUITABLE WATER ACCESS IN URBAN, CASE FROM DHARAN AND DHULIKHEL OF NEPAL

Kaustuv Raj Neupane, Suchita Shrestha

Southasia Institute of Advanced Studies, kaustuv@sias-southasia.org; neupanekaustuv@gmail.com

1 INTRODUCTION

According to [UN](#) report (2014) the world's rural population has already stopped growing, but it can be expected nearly 1.5 billion urbanites to be added in the next 15 years, and 3 billion by 2050. Similarly, World Bank (2016) reported South Asia's urban population is poised to grow by almost 250 million people by 2030. Between 2000 and 2011 the region's urban population expanded by 130 million. Urbanization has a long term impact by the convergence of living standards between urban and rural areas as economic and social benefits spill beyond urban boundaries. But these positive trends can be undermined by the pressures of urban population growth on infrastructure, basic services, land, housing, and the environment. Estimates suggest that at least 130 million of South Asia's urban residents live in slums and are disproportionately deprived of basic infrastructure and access to basic services. Urban land is expanding much faster than urban population, a phenomenon known as urban sprawl. It is driven in part by increasing urban land consumption by the wealthy and the increasing separation of rich and poor communities within cities. Sprawl undermines the efficiencies of urban living, and it marginalizes poor people in remote or peripheral parts of cities, often in dense informal settlements or slums. Among the basic services, relationship between water and cities is crucial. Cities require a very large input of freshwater and in turn have a huge impact on freshwater systems.

Nepal comes under the five most populous countries in the South Asia region along with India, Pakistan, Bangladesh and Afghanistan. According to World Bank current access to water of urban residents in Nepal is 90.9 % (2015) which has declined than previous decades of 1990 which constitute 96.5 %. This declining trend in water access in urban residents and elevated growth of population size of town is because of many rural villages have been merged into the adjoining municipalities. This process of urban expansion without the development of proper basic facilities has led to create a phenomenon of core and periphery within the cities of Nepal. The core area includes the economically and politically dominating community. Peripheral region usually lies around to the core cities while slums which are found scattered within the core with low economic status and politically powerless are also considered as peripheral community.

Based on this contextual setting, we try to argue that this misbalanced economy creates tension and triggers 'social movement' eventually enhancing 'spread effect' of urbanization from core regions to peripheral areas to minimise imbalance. This paper examines the challenge of equitable water distribution in peripheral regions and the perspectives and contribution of social movements to address the unfulfilled water need. We will draw empirical cases from two towns of Nepal namely Dharan and Dhulikhel cities which has witnessed urban movement for access to water in peripheral regions. This paper will draw out perspectives and experiences on how organized citizens conduct social movements and what are the outcomes of these urban movements. The findings helped us to reveal what has been achieved by the social movements in terms of water access and redistribution. Section 2 elaborates on theoretical approach used in the study. Section 3 describes the methodology, section four deals with context of urbanization and water supply status in towns of Nepal, section 5 analyses of urban social movement in case study cities and last section draws conclusion from the analysis.

2 ANALYTICAL FRAMEWORK

Initially, this paper will look through theory of core and periphery which divides the study cities under two groups- 'core and periphery' (Friedman, 1966). Core area is considered as economically, socially and politically active whereas peripheral region is weak in all the aspects. It is considered that there is continuous struggle between core and periphery for the resources which sometimes take a form of Urban Movement. An urban social movement is "a conscious collective practice originating in urban issues, able to produce qualitative changes in the urban system, local culture, and political institutions in contradiction to the dominant social interests institutionalized as such at the societal level" (Castells' (1984, p. 278). There may be reason to define urban social movements by their opposition to the state if it can be shown that the state is the major opponent of the urban working class on issues regarding the modification of the urban environment, and that such opposition to the state defines a historically specific form of urban conflict (Fincer, 2013). Further, urban social movement believed in the potential for radical change of noninstitutionalized urban political action. The urban social movement refer to a level of an effect, not to type of organizations. The effect could be urban (improvements in public services) or political (changes in power relations). This 'material' emphasis meant that the focus was always on what was said (Pickvance, 2003) . The urban water movement sector as social movement is based on the sector's orientation on and preferences for social change (McCarthy and Zald, 1977). We will try to analyse the output of these social movements from the cases referred

3 METHODOLOGY

This research has used review of existing literatures, news in daily newspaper and in-depth interviews for collection of secondary data. Key informant interview (KII), in-depth interview with locals, focus group discussion (FGD), local stakeholders workshop are some of the sources for primary data. The analysis is qualitative comparative analysis of case study sites of two cities of Nepal.

4 BACKGROUND : CONTEXT OF URBANIZATION AND WATER SUPPLY STATUS IN NEPAL

Nepal is one of the ten least urbanised countries in the world. However, it is also one of the top ten fastest urbanising countries. In 2014, the level of urbanisation was 18.2 per cent, with an urban population of 5,130,000, and a rate of urbanisation is of 3 per cent (UN DESA, 2014).

There is a trend towards the development and creation of new municipalities and a concurrent decrease in the number of Village Development Committees (VDCs). Muzzini and Apericio (2013: p.28) argue that the reclassification of rural into urban areas is an important driver of urban growth. The development of new municipalities is largely due to the merger of VDCs in Nepal (Devkota, 2014). The number of municipalities has increased drastically in recent years. At the time of the 2011 census, there were 58 municipalities (CBS, 2012). 62 new municipalities were declared in 2011/12, a further 72 in 2014, and 25 in 2015, which brings the total to 217 after implementation of new local levels of governance as according to the new constitution. (P.K. Pradhan, personal communication, 29th October, 2015 as cited in Bakaria, 2014 and The Himalayan Times, 2017). The level of urbanization in Nepal remains low but the pace of urbanization has remained faster and is likely to remain so in the future. Only 17.1% of Nepal's population resided in 58 designated urban areas according to the 2011 census. However, with the addition of 159 municipalities in 2014/15, 40% of Nepal's population reside in 217 designated urban areas (NUDS, 2017).

In spite of high number of residents, only 32.9% of households have access to piped water supply in urban Tarai as compared to 81.2% of households in urban hill. However, quality and quantity of drinking water is insufficient in all urban regions. Slum dwellers and squatters are largely excluded from the formal water supply network (UN-HABITAT, 2010: p. 64). The time, resources and effort needed to fetch water has become a challenge to the urban poor, who are often compelled to buy water from private tanker services (UN-HABITAT, 2010: pp. 63-65). This is especially the case as urbanisation in the developing world and is much related to the failure of responsible agencies, which have left multitudes with insufficient and unsafe services while few upper tiers of society gets good by centralised systems (Malama and Kazimbaya- Senkwe, 2004).

Safe drinking water is considered as human right as considered by Nepal's constitution. According to Constitution of Nepal 2015, under Fundamental Right and Duties Section three article 35 and sub article, the Right relating to health and sub article 4 says, "Every citizen shall have the right of access to clean drinking water and sanitation." This statement clearly provides legal strength for demand for clean water. However, in order to have individual pipe connection in dwelling or yard of a house legal documents like land ownership certificate, approval of building construction certificate including citizenship certificate. Due to this legal provision many of the squatters are deprived of the clean drinking water and sanitation as they cannot have individual pipe connection in their houses.

5 CASE STUDIES

5.1 Dhulikhel

Dhulikhel lies in the mid-hill region of east-central Nepal. Dhulikhel is part of the Kavre Valley in Kavrepalanchowk district, which comprises Dhulikhel, Banepa and Panauti as major urban centers with a population of 66,405. Dhulikhel Municipality is a rapidly emerging satellite city of Kathmandu—the capital city of Nepal and it bears prime importance from commercial point of view and trade link to Tibet—the autonomous region of China. Kathmandu University, Dhulikhel community hospital, hotel/restaurant/lodge, business, agriculture and a community managed drinking water system are an integral part of the local economy. Dhulikhel municipality was previously divided into nine wards. As per the decision made by the Cabinet on 2015, it is now divided into 13 wards annexing Kavre Nitya Chandeswori Village Development Committee. The central Dhulikhel gets drinking water from a community managed drinking water supply project. The system has been operational since 1991.

Context of Core and Peri Urban

Dhulikhel Village Panchayat used to depend upon local sources of water along with a water distribuion system built in support of Indian Embassy until the period of early 80's. As the water supply was not sufficient, local leaders started exploring additional water supply system to the village. They approached German support agency (then GTZ) that was working in Bhaktapur, a nearby city of Dhulikhel. After the series of consultation and field visit, GTZ agreed to support Dhulikhel with a water supply project. As the budget for water supply plan was too high for a village and it was deemed ineligible to have project of that size. Hence the decision to upgrade Dhulikhel village Panchayat into Dhulikhel Municipality was made. The population of town was only 6000 while it needs 10000 of individuals to be the municipality. So Dhulikhel incorporated some adjoining rural villages (Bajrayogini, Srikhandaapur Village Panchayat and some parts of Kavre Village Panchayat) in 1986. However, the proposed water supply project was designed for area that covers previous Dhulikhel village panchayat only that includes ward no 2,3,4 and 5 of newly formed municipality leaving behind the annexed surrounding villages. For our study, previous Dhulikhel Village Panchayat that comprised of ward no 2,3,4 and 5 are called the core region as they have individual pipe water connection and other surrounding village that were merged to Dhulikhel i.e. ward no 1,6,7,8 and 9 of new municipality but were deprived of the water supply are termed as the peripheral region.

Water Supply Situation in Peripheral Wards

After the completion of GTZ supported drinking water supply project in 1990, core Dhulikhel had drinking water supply for 24 hours a day whereas the periphery used to rely on their usual sources such as spring with limited water supply.

This inequitable practice of water supply in terms of both quality and quantity has gradually created a contestation between core and periphery community. Core people claimed that the water supply project was designed for them only and therefore were not ready to share the water to the peripheral settlement. In the contrary, people from periphery argued that- since they were also part of the same municipality, water has to be equally distributed to them as well. This was the main reason behind the contestation between these communities. Beside this—the periphery community felt the dominance of core people who are united for their geneological integrity in several decision making events.

Formation of Struggle Committe and Urban Movement

The locals of peripheral region united to form a struggle committee in the year 2006 to demand the acces to drinking water from the existing supply system. They argued that they belong to the same Municipality and has been paying equal tax to the authority as the core cities people do. They initaly started dialouge with Municipality and Dhulikhel Drinking Water and Sanitation Users' Committee. They had series of appeal for pipe connection.

For example, in 1994, Dhulikhel invited the then Prime Minister, Mr. Girija Prasad Koirala to formally inagurate the GTZ supported water supply project. However, the people from periphery stood against the inaguration ceremony until the water was supplied to their settlements as well. Discussions were held between them and ultimately the inaguration ceremony was halted. Again in 1998 after the local government election, the then His Majesty King Birendra was invited to inagurate the system. Same group of people from periphery went to royal palace with a request letter (*Binti Patra*) of 1130 signatures so as to halt the inaguration program until the water was distributed to periphery. As the king was interested to visit Dhulikhel and inagurate the system- both core and periphery peole had a negotiation under which core had to support periphery on further improvement of ongoing water supply system to their settlement. Finally they agreed on distribution of water from the central system using optimum use of local sources as the short term solution and explore other alternative sources and projects for the longer term solution to address drinking water problems in periphery region. After the agreement- this water supply system was formally inagurated by then king Birendra.

However, DDWUC stalled on its decision and water was not supplied in pheripheral community as promised earlier. The peripheral region people was outraged and retaliated against this disparity. As a result, in the year 2008, mass demonstration and highway blocking was the major social movements displayed by the peripheral community. They also broke the intake pipe of water supply connected to Dhulikhel core city. Creating a swarm, equipped with sledgehammers and excavation tools, the angry locals destroyed the pipe line due to which the water supply had completely halted in the whole core region. Dhulikhel was without water for two weeks. Residents of core had to go through hard times in collecting water from nearby streams and standpipes. They had to rely on alternative sources like local springs, tankers by limiting the use of water with the basic/ unavoidable activities only. Passengers suffered a lot while the road was blocked during the protest. Thus, the inequality between core and periphery specifically on water resource sharing further worsened. The leaders of protest committee said, as state had already become republic state, and being the resident of such state the core community should not think the water supply system as their own individual property.

Outcome

After the mass protest of 2008 by periphery region, DDWUC finally decided to share water. Now, nearly more than 1000 HH in peripheral region has water connection from the existing Dhulikhel Water Supply Scheme, however, it is inadequate. This extension of service to the peripheral region automatically validate the residents to have voter right and right to declare candidacy for the comittee's 4 yearly election. As a result, representatives from each peripheral ward has been included in the decision making board i.e. DDWUC. As a part of initiation to address the aformentioned agreement between core and periphery community, municipality explored an alternative source in Kushadevi VDC which is about 15 km far from Dhulikhel. Now, it has been agreed as one of the major source for Asian Development Bank (ADB) funded Kavre Valley Integrated Water Project.

5.2 Dharan Sub-metropolitan city

Dharan is one of three sub-metropolitan cities in eastern Nepal, in the Sunsari District, and is situated on the foothills of the Mahabharata Range in the north with its southern tip touching the edge of the Tarai region at an altitude of 1148 ft. (349m). It serves as a gateway trading post between the hilly region and the plains of Tarai region. Major educational hubs from traditional Sanskrit education (Pindeswor Campus, Nepal Sanskrit University), Medical Sciences (BPKIHS), Purvanchal Engineering Campus (Tribhuvan University), Central Department of Food Technology Hattisar Campus among other educational institutions as well as hotels, production industries, retail businesses, agriculture, religious places, and local users managed drinking water system are an integral part of the local economy in Dharan. As it is proposed to be the headquarters of the one of the new federal states of Nepal and the weather is fairly moderate, the inflow rate of migrants from other districts is high and noted up to 41.5% in 2011 by Central Bureau of Statistics, Nepal which clearly indicates that existing limited water plans will not be able to address the concerns of water security of the rapidly burgeoning population.

Dharan municipality was previously divided into nineteen wards. As per the decision made by the Cabinet on May 8, 2014, it is now divided into 27 wards annexing Panchakanya and Bishnupaduka VDCs to upgrade the municipality to sub-metropolity in December 2014. Dharan has population of over 200,000 and all these local residents and increasing number of migrants to this hilltop city are reeling under an acute shortage of drinking water. Many of them have been forced to walk long distances, queuing for hours to fetch water or use untreated water from local rivulets. Dharan Drinking Water Corporation has only been able to supply 15 million liters of water whereas the demand is 30 million

liters per day. Dharan receives 1800 mm rainfall annually, mostly falling between late June and early September. According to government of Nepal, about 98% of Dharan households have access to piped water but this water supply is largely confined to rainy season, with the supply being intermittent, untreated and unsafe. There are several water issues and challenges to be addressed in terms of climate adaptive equitable water management strategies and practices in the context of Dharan's rapid urbanization, increased inflow of migrants, expansion of infrastructure development, tourism services, changing climate and modern farming practices.

Context of core and periphery

Dharan is the fast growing city that lies in the eastern part of Nepal with population growth rate of 2.29 % and 41.5 % people migrated from other districts (CBS, 2011). Dharan being a foothill town, it has been major market hub since early days. Within the city, the squatters have been occupying the land from a long time and with the pace of urbanization and establishment of B.P. Koirala Institute of Health Sciences in 1997 brought a considerable increase in squatter settlement. The growth rate of the squatter families before 1989 was 50 to 100 families every year which rose to the rate of 300 to 400 families per year after 1997 (Agrawal, 2002). In Nepal, squatters comprise an estimated 10% of the urban population, but some urban areas like Dharan have three times higher (MOUD, 2015).

In Dharan there are about 84 squatter settlements with 6621 HH and population size of nearly 35000. Most of these settlements reside in the flood plain areas of Seuti and Shardu River and some in sloppy hills and nearby forest areas. The people in squatter have migrated from the hills for employment and for getting rid of the hardships in hilly areas. These squatter inhabitants crush stones and/ or work in informal sectors for living whereas those inhabiting near forest area cut trees and sell woods in the market for their livelihood (Agrawal 2002).

In Dharan, government owned corporation named Nepal Water Supply Corporation (NWSC) supplies drinking water at household level. For the new private connection of water pipe, NWSC needs land ownership certificate and a recommendation from the Municipality. This provision curtailed the connection of water at the individual household at squatter settlements.

For our study, in case of Dharan, we consider houses that have individual land ownership and thus have privilege for individual water connection as a group of core community who are economically sound. All of the squatter settlements are considered as periphery community which consist nearly 6000 households. These areas are economically weak and high prevalence of parasitic infection due to poor water supply (Chongbang et al., 2016). They have provision of communal tap in the squatter settlement however water is insufficient for them.

Social Movement for Private Connection

A national level NGO called *Nepal Basobas Basti Samrakchan Samaj* (NBBSS - Nepal Settlement Protection Society) works on inclusive society and upliftment of slums led this movement. At earlier stage, NBBSS had submitted their concern letter time and again to District Administrative Office, Municipality and Water Supply Corporation. However, they did not respond to any of those concerns and kept on ignoring the delegations.

The suppressed and infuriated group of people then united and a manageable dissatisfaction changed into uncontrollable riot. On February 1, 2010, squatters padlocked the room of Chief Executive Officer of Dharan Municipality demanding for private pipeline connections in the squatter settlement. They also picketed at Nepal Water Supply Corporation (NWSC) for the whole day chanting slogans. They protested rallying from the squatter settlements with placards and slogans then changed into a mass gathering after reaching the office of Dharan Municipality. Similarly, they warned to padlock NWSC office from February 9 if their demands went unheard. They had demanded municipality to provide approval for pipeline connections and later the issues was settled down after dialogue and negotiation with NWSC and municipality. Municipality agreed to provide recommendation to NWSC on the basis of the NBBSS recommendation. Thus, the squatter people started getting individual drinking water connections.

Outcome

Municipality and leaders of squatter settlements reached to an agreement that Municipality will provide recommendation letter for installation of individual connection with support letter of Nepal Basobas Kendra. Finally, Dharan Water Supply Corporation started installing private connection of pipe to individual households. After this movement, 700 household slums have private water pipe connections.

"Individual water pipe connection not only gives us potable and easy access of water but after payment of monthly bills, it becomes a legal evidence/ document to prove that we live in cities. This creates us for many opportunities".

Slum leader of Dharan

Recently, a water supply project funded by Asian Development Bank has recognised squatter settlement as beneficiaries of the project for connecting private water supply. This has assured them with regular supply of drinking water for the near future.

6 DISCUSSION

Based on the empirical case studies, there are similarities as well as differences in terms of social movement.

In both the cases, urban social movement were triggered after major national movement i.e. "Peoples' Movement in Nepal" called as *Janandolan* 2006. In both the sites, it is observed that the dispute started from peaceful protest for drinking water which gradually developed and took a bigger form that rightly triggered after the national level political

reform movement. The stakeholders claimed that they had contestation and demand for drinking water even before but the protest was triggered after the National Republican movement. The national movement made squatter people think that they should not be treated as second level citizen when country is itself moulding in a new structure and that ultimately motivated people to protest. This reflects that these movements are guided by the concept of human right to water as a public good.

In both the cases, there is still inadequate water access but it is due to the participation of their representative in the decision making process. The peripheral region have felt that they belong to the same community or to the city dwellers. "Water policy development and reform is primarily a politically- not technically-driven process" (Seppala, 2002, p. 379). Similarly in one of our case study town Dharan, the legal requirements were changed for water access through the social movement.

In both sites it was observed that either with their influence or power or some legal provision core always wants to hold its power, treat peripheral people as an intruder and resists from allowing others to share the resources.

7 CONCLUSION

With the urban social movement, the peripheral region has achieved the water access and felt no more hegemonic by the core region. This type of local level urban movement has brought some policy changes which need to be learnt in future by other cities as well in order to manage future conflicts related water service. Water policy and development practice need to be sensitive and inclusive and decision need to be made on the basis of reform generated by movements on water politics.

ACKNOWLEDGEMENTS

This paper is outcome while working of Climate adaptive water management practices in cities in south asia research project. We would like to acknowledge Roshan Man Bajracharya, Ngamindra Dahal, Chandra Pandey and kamal Devkota from SIAS. Similarly, we would like to acknowledge International Development and Research Centre, Canada for providing financial support for the research project.

SS01.2. Water management in South Asia: From conflict to cooperation

1101 WATER SHARING BETWEEN INDIA AND PAKISTAN: AN OPPORTUNITY FOR COOPERATION AND PEACE-BUILDING

ABSTRACT

Bitter political rivalry between India and Pakistan has led to the two countries fighting four wars since both countries achieved Independence from the British Empire in 1947. Political tensions over the Kashmir dispute and cross-border terrorism continue to simmer. This has complicated Indo-Pakistan water sharing relations in the past and will persist in the future. In the aftermath of the 2016 Uri attack on the Indian Army brigade, the Indian Prime Minister stated that blood and water could not flow together. There have been many disputes over India and Pakistan's shared waters, especially over construction of dams on the Indian side of the border (such as Baglihar Dam on River Chenab and Kishenganga project on the tributary of River Jhelum by India) and demand for greater share of the water in India (since currently it is less than 20 percent under the Indus Waters Treaty). Climate change is also exacerbating the situation and it could only worsen in the future as the Indus is one of those rivers that have maximum dependence (151 percent) on glacial meltwater. Furthermore, politico-security issues such as the role of the distribution of waters of the Indus in the Kashmir dispute and the threat of using nuclear weapons by Pakistan against India if the latter chokes water supply have escalated the resource conflict to the level of being labelled a potential water war. However, one must remember that despite political and military antagonism, the principles of the IWT have been adhered to by both countries, even during the wars. The Indus (and its tributaries) is the lifeline of Pakistan and the effects of environmental change are being felt on both sides of the border. Instead of revising the treaty and wrestling over riparian politics, India and Pakistan could work towards integrated basin management as water security is emerging as a critical issue in both countries. Groundwater management in the border regions are left out of the negotiations even though the aquifers are shared and are fast depleting, especially in the Punjab provinces on both sides of the border. Water management negotiations are the biggest confidence-building and peace-building measure, which could potentially transform relations between the two countries in other sectors too. In this context, the paper would trace the history of water sharing relations between India and Pakistan amidst political and military hostility. It would throw light on the conflicts between the two nations over the distribution and management of the waters of the Indus Basin from a geopolitical perspective. The debate between 'environmental conflict' and 'environmental cooperation' (at the regional level) will be used to provide a theoretical background to the paper. Finally, it would analyse how joint river and groundwater management could help build trust and confidence between them and explore mechanisms that could bolster such initiatives. The prescriptive approaches of "regional peace-building" and "conflict transformation" will be analysed to understand the future of hydro-diplomacy between the two countries.

1221 REVISITING TRANSBOUNDARY WATER MANAGEMENT IN SOUTH ASIA: THE BRAHMAPUTRA CASE**Nora Babalová**

South Asia Democratic Forum (SADF)

ABSTRACT

The impacts of climate change, water scarcity, and water diversion activities have the potential to trigger regional instability in various areas around the globe. The natural place to look at is the Brahmaputra River, an international watercourse that crosses national boundaries between China (Tibet), India, and Bangladesh. In an attempt to study the current state of cross-border water resource management in the Brahmaputra basin, the present paper analyses the relations of major riparian states over the Brahmaputra River; explores the main hindrances to effective cross-border cooperation; examines social and environmental impacts of large-scale hydropower projects; and identifies relevant types of approaches to water management. This paper investigates the Brahmaputra basin not as mere physical space divided by national borders, but as a 'shared space', where domestic politics intersects with international relations. It argues that the management of the Brahmaputra's water resources is influenced by the lacking sense of shared space which translates into weak regional cooperation. This paper argues that the management of the Brahmaputra's water resources is influenced by the lacking sense of shared space which translates into weak regional cooperation.

Key words: Water Management, Dams, Brahmaputra, China, India, Bangladesh, South Asia

1. INTRODUCTION

'Transboundary water management is policy arena where domestic politics and international relations intersect' (Xie & Jia, 2016, p. 681).

The Brahmaputra River originates in the Tibet Autonomous Region of China and passes through Southwest China, two Indian states, and Bangladesh. The Brahmaputra is known as Yarlung Tsangpo in Tibet, the Jamuna in Bangladesh, and as the Brahmaputra in India. For consistency, the present paper uses the term 'Brahmaputra' to identify the river throughout the whole basin. The Brahmaputra is part of a larger complex known as the Ganges, Brahmaputra, and Meghna river system. Most of these riparian countries are 'currently undergoing rapid industrialization while also facing the pressing needs of improving their water management capacities and fighting climate change'; and it is thus cause for concern how these countries will cope with the 'challenge of realizing sustainable water resource management' (Xie & Jia, 2016, p. 678). As rivers originating in Tibet provide water and livelihoods for millions of people living in downstream areas (Buckley, 2014), it is imperative that actions towards meeting the national objectives of upstream countries are not taken unilaterally. In this paper, actions that fall in this category are constructions of large dams or water diversion projects.

In recent years, the number of large-scale dams along the Brahmaputra River increased in response to China's and India's rising energy needs, growing populations, rapid urbanization, and high poverty levels. Given the rugged and high-altitude terrain of the Brahmaputra basin, it was long thought impossible to access the river's enormous energy resources (Watts, 2010). Therefore, the Brahmaputra River has fewer dams than the other two major South Asian river basins, the Indus and Ganges (Samaranayake et al., 2016). The Brahmaputra was in fact one of the world's last undammed rivers until China began constructing a series of dams on sections upstream from the Brahmaputra Canyon, as the waterways of mainland China were already packed with dams (Chellaney, 2013; Buckley, 2015).

The rivers of Tibet²⁸⁴ are seen by China as a new resource of hydropower since they hold the highest hydropower potential in the world (Buckley, 2015). In India, the Brahmaputra flows through two Indian states of Arunachal Pradesh and Assam, and accounts for about thirty per cent of the country's water runoff, hence constituting a major source of potential hydropower as well (Chaturvedi, 2013). Bangladesh, on the other hand, faces the biggest threat from the upper riparian countries' activities (China and India) since up to seventy per cent of Bangladesh's population resides in the river's basin (Samaranayake et al., 2016). The creation of comprehensive basin-wide water management plan is hindered by unresolved disputes, including border claims and clashes over water diversion: the territorial dispute over Indian-administered Arunachal Pradesh and the general lack of trust with regard to the ongoing dam constructions in Tibet and Northeast India are major hindrances to larger cooperation between China and India.

The present paper examines the Brahmaputra basin not as mere physical space divided by national borders, but as a 'shared space', where domestic politics intersects with international relations. This is because challenges related to climate change, increasing water scarcity, and large-scale water diversion projects are international by nature and thus require collaborative approach. This paper argues that the management of the Brahmaputra's water resources is influenced by the lacking sense of shared space which translates into weak regional cooperation, as evidenced by the fact that the basin remains one of the least coordinated river systems in the world (Xie & Jia, 2016, p. 678). This paper analyses the geopolitical (interstate) and regional (intrastate) aspects of the Brahmaputra case; the social and environmental impacts of large-scale hydropower projects on downstream ecosystems and river-dependent populations; identifies relevant types of approaches to water management; and explores major hindrances to effective cross-border cooperation

²⁸⁴ The hydropower development in Tibet is an essential part of China's campaign to 'Open Up the West' launched in 2000 in order to encourage economic development in Western China (Samaranayake et al., 2016).

between the basin countries. By applying two research methods, case study and content analysis, the Brahmaputra case is investigated within the limits of quantitative evidence. The following research queries are central to the studied subject: How does the current transboundary river management work in the Brahmaputra basin? What are the social and environmental impacts of large dams on downstream ecosystems and river-dependent populations? What are the limits of 'climate-friendly' hydroelectric industry? What are the main hindrances to effective cross-border cooperation in the Brahmaputra River Basin?

2. CONCEPTUALIZING TRANSBOUNDARY WATER COOPERATION

Approaches to transboundary water management often tend to overlap. We focus on those that integrate environmental, social, and political variables.

First, the ecosystem approach combines 'technological solutions with sensitivity to history, culture and the politics of resource management', while emphasizing the importance of shared understanding of common challenges (Price & Mittra, 2016, p. 21); it incorporates various disciplines, such as hydrology, ecology, geology, and even anthropology and sociology, since it considers that both peoples and cultural diversity are integral elements of the ecosystems (Price & Mittra, 2016). The ecosystem approach seeks to balance the principles of the Convention on Biological Diversity²⁸⁵, notably biodiversity conservation, sustainable use, and equitable benefit-sharing from the use of natural resources (Price & Mittra, 2016, p. 22). Among the major proponents of the ecosystem approach are global initiatives like the International Union for Conservation of Nature (IUCN) or the World Wildlife Fund (WWF).

Second, the Integrated Water Resources Management (IWRM) attempts to address water-related issues around the globe by exploring interconnected aspects of water quality, water use, and water governance (Gamble et al., 2017). It can be defined as a practical framework (Lenton & Muller, 2009) for the coordinated development and management of water, which aims to maximise the 'resultant economic and social welfare in an equitable manner without compromising the sustainability of vital ecosystems' (Gamble et al., 2017).

Third approach highlights the importance of adaptive resource management and institutionalized forms of cooperation (Pahl-Wostl, 2008). The term 'adaptation' or 'adaptive capacity' refers here to the 'ability of a system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences' (Pahl-Wostl et al., 2008, p. 8). In this context, adaptation can occur as a result of expected or unexpected climate change. This approach is especially important when coping with increased uncertainties of climate change as the 'conditions under which such regulations were passed may no longer be fulfilled', meaning that new 'risks need to be negotiated in participatory processes rather than being prescribed by law' (Pahl-Wostl et al., 2008, p. 11). An institutionalised form of water governance like this one would include a firm relationship between structure (water management regime), process (adaptive water management), and outcomes (sustainability of water system), making all elements that guarantee the functioning of a regime interdependent (Pahl-Wostl, 2008). This approach is based on a 'regime theory' which identifies an institutionalized form of cooperation as 'sets of governing arrangements, that include networks of rules, norms, and procedures that regularise behaviour and control its effects' (Keohane & Nye, 1977, p. 19).

3. RIPARIANS' QUEST FOR WATER

3.1 China

Since 2000 China has been unilaterally developing upstream projects (Xie & Jia, 2016, p. 682). China's broadly discussed water transfer plan, the South-to-North Water Diversion Project (SNWDP), which transfers water from the Yangtze River to the water-stressed cities of Beijing and Tianjin, dramatically changed the face of China's countryside, leading to massive displacement of people (Kaiman, 2014; Ghassemi & White, 2011). Holding a record number of the world's worst dam-related disasters²⁸⁶, the human costs of China's massive water projects have always been high (Lovell, 2016). For example, the world's biggest existing hydropower project, the Three Gorges Dam on the Yangtze River in the Central China region, caused the displacement of at least 1,7 million Chinese and is still causing persistent environmental problems (Chellaney, 2013); this project alone has submerged 13 cities, 140 towns, and 1,350 villages; the same dam caused the deaths of some 968 people downstream during the record-breaking flood in the summer of 2010 (Lewis, 2013).

²⁸⁵ The ecosystem approach is based on the following twelve principles of CBD: (1) Objectives for management of land, water and living resources are a matter of societal choice; (2) Management should be decentralised to the lowest appropriate level; (3) Ecosystem managers should consider the effects of their activities on adjacent and other ecosystems; (4) Recognising potential gains from management, there is a need to understand the ecosystem in an economic context — programmes should reduce market distortions, align incentives to promote sustainable use, and internalize costs and benefits; (5) A key feature of the ecosystem approach includes conservation of ecosystem structure and functioning; (6) Ecosystems must be managed within the limits of their functioning; (7) The ecosystem approach should be undertaken at the appropriate scale; (8) Recognising the varying temporal scales and lag effects which characterise ecosystem processes, objectives for ecosystem management should be set for the long term; (9) Management must recognise that change is inevitable; (10) The ecosystem approach should seek the appropriate balance between conservation and use of biodiversity; (11) The ecosystem approach should consider all forms of relevant information, including scientific, indigenous and local knowledge, innovations and practices; (12) The ecosystem approach should involve all relevant sectors of society and scientific disciplines ('Principles of the ecosystem approach', 2017).

²⁸⁶ For instance, in a serial dam collapses in 1975, after a typhoon hit Henan province in Central China, at least 83,000 Chinese were killed and millions left homeless (Chellaney, 2013).

Recently, China has shifted its dam-building focus from internal rivers in the Han heartland to international rivers that originate in remote and ecologically sensitive parts of the Tibetan Plateau (Chellaney, 2013, p. 234). Now, with its plans to construct large dams on the upper reaches of the Brahmaputra, China plans to divert water from some major rivers in Tibet to feed its 'desperate thirst for clean water' (Buckley, 2014, p. 13); but the diversion of the Brahmaputra's water is a matter China does not discuss in public to avoid bitter reactions from international community and downstream riparians, notably India and Bangladesh (Chellaney, 2009). To do research on Tibet can therefore be extremely difficult; this is also because reporting on a protest in Tibet amounts to leaking state secrets, in response to which Tibetans may face harsh responses by the Chinese government (Buckley, 2014, p. 18)

Following the Zangmu Dam, China's first hydroelectric dam on the Brahmaputra in Tibet, which became fully operational in October 2015, China has announced its plans to construct several more dams along the upper reaches of the Brahmaputra (Samaranayake et al., 2016). One of the announced plans is a mega dam at Metog²⁸⁷ (Lewis, 2013). If created, this dam would be the world's biggest hydroelectric project. However, both Tibetans, for whom Metog is a sacred region, and environmentalists, who warn about seismically active and fragile character of the area, are worried about this project (Watts, 2010). While the dam would probably save a sizable amounts of carbon dioxide, it could also lead to conflict over downstream water supply: blocking of the upper reaches of the Brahmaputra could devastate the fragile ecosystem of the Tibetan plateau and withhold the river's sediments from the fertile floodplains of Assam in Northeast India and Bangladesh (Watts, 2010; Lewis, 2013). Besides the environmental aspects, there are also political and security implications as the dam is supposed to be located close to the McMahon Line,²⁸⁸ a disputed and militarised boundary between China and India. One way or another, the construction of dam at Metog per se would dramatically change the living conditions in this region.

Despite the obvious risks, China continues²⁸⁹ to construct mega-dams in remote areas even at the risk of damaging biological and ethnic diversity and diminishing cross-border flows (Chellaney, 2015, p. 238). Furthermore, it is likely that dams planned in Tibet will not benefit local population since the generated energy will be transferred to power-hungry and water-stressed cities of Beijing and Tianjin farther east while many Tibetans will be deprived of their land; however when protests against hydropower projects occur, they are either prohibited or violently suppressed (Buckley, 2015).

3.2 India's water resource quest

India's 'dam mania' started in the 1960s with the construction of the Bhakra Dam in northern India, which became the symbol of India's green revolution²⁹⁰, and was hailed by the then Prime Minister Jawaharlal Nehru as a 'Temple of Modern India' (Bosshard, 2015). Despite initial successes and high expectations, badly managed irrigation schemes have resulted in waterlogged, saline soils and diminishing harvests, in response to which Nehru described the situation as the 'disease of gigantism' in dam building (Bosshard, 2015). India's most controversial dam project, however, is the Sardar Sarovar Dam²⁹¹ on the Narmada River initiated in 1979 (Mitra, Wolf, & Schöttli, 2006). The project resulted in the displacement of more than 250,000—primarily indigenous—peoples (Bosshard, 2015).

In India, Arunachal Pradesh is considered a new hotspot of global dam building and the future powerhouse of the country. India, along with China, is now building more dams than any other country on the globe (WCD, 2000). Not surprisingly, China is concerned about New Delhi's efforts to construct dams in Arunachal Pradesh as it could further strengthen India's 'actual control' over the disputed region (Samaranayake et al., 2016). Arunachal Pradesh is the most geographically isolated state in India and is home to more than twenty indigenous tribal groups; however the state's sparse inhabitation makes it an attractive prospect for dam builders (Overdorf, 2012).

A total of 168 massive dams were proposed in Northeast India, the majority of which are to be located in Arunachal Pradesh, including the largest of them all, the Lower Subansiri Hydroelectric project, which is located on the Subansiri River, a Brahmaputra tributary (Yong, 2014; Overdorf, 2012). Besides the latter, other major hydroelectric power plants of more than 1,000 MW capacity are planned for the Brahmaputra's tributaries, such as Dibang, Siang, Siyom, and Lohit (Overdorf, 2012).

Protests against mega-dams occur either against domestic or upper riparians' projects, but are barely reported in the media (Sharma, 2012); several anti-dam organisations took place in 2014 in Assam which raised voices against the

287 Motuo in Chinese

288 The McMahon Line constitutes a border between India and China, extending from east Bhutan to Myanmar. Historically, the Line is based on a British colonial claim, drawn as the frontier between British India and Tibet at the Shimla Conference in 1914. In 1949, however, the newly formed People's Republic of China refused to accept the McMahon Line. India, on the other hand, regarded the McMahon Line as a permanent international border. This discord became a major cause of tension between China and India in the 1950s and one of the main reasons for the Sino-Indian war of 1962. Today, the border is known as the Line of Actual Control that separates Indian-ruled land from Chinese-controlled territory. (Mitra, Wolf, & Schöttli, 2006; Florcruz, 2013).

289 China and its state-run companies represent the largest global producer of hydropower and their objective is to further increasing this capacity to at least 450 gigawatts by 2030. China is the biggest financier and builder of dams (both at home and abroad) and boasts a greater number of large dams on its territory than the rest of the world combined. If dams of all sizes are counted, the total number of dams in China is close to 90,000, the majority of which was built during the post-Mao period (Chellaney, 2013).

290 In the Indian context, the Green Revolution refers to the period from 1967 to 1978, during which an economic and agricultural development strategy introduced by Western aid organisations was applied to make India self-sufficient in food grains (Mitra, Wolf, & Schöttli, 2006).

291 The Sardar Sarovar Dam was first envisaged in the 1940s by Jawaharlal Nehru to control the immense Narmada River system. The World Bank financed the dam construction even though the project did not comply with the government's conditional environmental clearance. In the mid-1980s, the Narmada Bachao Andolan (Save the Narmada Movement), a coalition of social movements and NGOs, created strong international public pressure to stop the dam. As a result, the World Bank had to withdraw from the project in 1994 after an independent review found systematic violations of its social and environmental policies. (See Mitra, Wolf, & Schöttli, 2006; Bosshard, 2008; 2015)

completion of China's hydropower project on the upper reaches of the Brahmaputra in Tibet; some activists even threatened to lay siege to the Chinese embassy in New Delhi (Lewis, 2013; Karmakar, 2014). On the other hand, demonstrations against large domestic dam projects recently occurred in Tawang²⁹², in a small town in Arunachal Pradesh, during which at least two participants were killed by the police (The Third Pole, 2016); in November 2016, during a meeting on 'Policy Dialogue for Governance of the Brahmaputra River' in Arunachal Pradesh, a group of anti-dam leaders confronted government officials, clarifying that they are neither against small dams nor against dams as such, but they cannot support the construction of large dams that can spoil their livelihoods, fearing that large dams will flood fertile agricultural land, destroy the fauna and flora, cause the displacement of people, and eventually the loss of cultural identity (Duarah, 2017). The lack of trust is partly caused by the fact that many tribal people who lost their land due to development projects have been denied compensation years after displacement (Chakma & Shimray, 2016).

3.3 Bangladesh

As the lowest riparian, Bangladesh has been the strongest promoter of multilateral cooperation on the Brahmaputra River. Besides the fact that the Brahmaputra is Bangladesh's largest water system, providing approximately sixty-five per cent of the country's river water per year, part of the reason is also the reality that up to seventy per cent of Bangladesh's population resides in the basin, compared to only one per cent of China's and three per cent of India's (Samaranayake et al., 2016). Bangladesh is faced with various natural challenges like floods, riverbank erosion, or diminished water flow, but climate change projections forecast even more floods and stronger cyclones in the near future (McVeigh, 2017).

4. SOCIAL AND ENVIRONMENTAL IMPLICATIONS OF LARGE DAMS: THE 'DISEASE OF GIGANTICISM'

'Human welfare cannot be measured only through economic growth and development, but also should consider the current ecological limits of the planet, allow for fair distribution, and promote an efficient allocation of resources' (Salgado, 2015).

Large dams significantly affect downstream ecosystems and river-dependent populations, and can have disastrous ecological consequences by influencing or reducing the flow of water downstream (Yong, 2014). Some of the identified effects of megadams on natural resources include extensive conversion of land, alteration of the hydrological systems, and disruption of freshwater ecosystems (Salgado, 2015). Major reasons responsible for the increase in producing more large-scale dams in the Brahmaputra region are urbanization, poverty reduction benefits (Welford, 2010), and preference for technocratic solutions with regard to energy production, which is often disrespectful of traditional knowledge and traditional ways of living.

The damage that dams cause to river ecosystems can be immense, 'turning free-flowing waterways into lifeless lakes, killing plants and trees, blocking fish migration and breeding, driving species to extinction, and devastating established patterns of human life' (Lewis, 2013). In Arunachal Pradesh, for instance, it is expected that more than 50,000 acres of forest will be submerged by the proposed hydroelectric projects (Overdorf, 2012). It is not surprising that the impacts of large dams often become the subject of a dispute between the government and civil society (Salgado, 2015). On the one hand, dams can play an important role in enhancing economic growth and social development, but on the other, the consequences of dam building may inevitably impoverish the affected masses (Welford, 2010). In order to avoid such a negative scenario, the respective decision-makers need to explore and assess all alternatives and their impacts before they take a final decision, to find out whether a large dam would fulfill a) the needs of the region and b) the environmental requirements of the disaster prone Brahmaputra basin. Such alternatives might include renewable energy collected from sunlight, wind, and tides (Bosshard, 2015) or a small-scale hydroelectric schemes (Salgado, 2015).

5. EVALUATION OF ATTEMPTS TO ADDRESS WATER ISSUES

Global initiatives advocating for solutions in transboundary water management, in this case principles put forward by the United Nations Watercourses Convention (UNWC), World Commission on Dams (WCD), the South Asia Water Initiative (SAWI), and CNA research study.

The United Nations Watercourses Convention (UNWC), a global framework convention adopted by the UN General Assembly in 1997, emphasizes that in order to achieve equitable and reasonable utilization of water, any decision-making body needs to consider a) geographic, hydrological, climatic, and ecological factors; b) social and economic needs of riparian states; c) dependency of the people on a given watercourse; d) the effects of the use of the watercourses in one watercourse state on other watercourse states; e) conservation, protection, development and economy of use of the water resources; f) the availability of alternatives to a particular planned or existing use. Most importantly, all riparian states shall always enter into consultations in a spirit of cooperation, allowing the exchange of data on a regular basis.

The often cited World Commission on Dams (WCD), which was established in response to growing opposition to large dam projects in 1998, reviews the development effectiveness of dams and develops standards and guidelines for future dams and dam building activities ('The WCD Framework,' 2008). In its seven 'strategic priorities', the WCD highlights the importance of a) public acceptance of key decisions (i.e., recognising rights, addressing risks, and safeguarding the entitlements of all groups of affected people, particularly indigenous and tribal peoples, women and other vulnerable groups); b) exploration of possible alternatives, including the participatory impact assessment;²⁹³ c) post-project

²⁹² Tawang is one of the unresolved border issues between India and China. To the north it borders Tibet and to the south west it lies next to Bhutan (Mitra, Wolf, & Schöttli, 2006). This region was occupied by Chinese troops in 1962 and, together with the rest of Arunachal Pradesh, China continues to claim this entire area and considers it part of South Tibet. (See also footnote 5.)

²⁹³ Impact Assessment includes all people in the reservoir, upstream, downstream and in catchment areas whose properties, livelihoods and non-material resources are/were affected. It also includes those affected by dam related infrastructure.

monitoring and evaluation process of existing dams; d) sustaining rivers and livelihoods by preserving ecosystems; d) recognising entitlements and sharing benefits, for instance through joint negotiations with adversely affected people; e) ensuring public trust and confidence, incorporating incentives and sanctions; and f) sharing rivers for peace, development and security, creating mutual interest in a peaceful and lasting collaboration.

The South Asia Water Initiative's (SAWI), a joint World Bank-UK-Australia-Norway partnership, is dedicated to increasing regional cooperation among riparian states of the Indus, Ganges, and Brahmaputra basins, in an attempt to deliver sustainable water management and in the age of climate change. In doing so, SAWI advocates for the following principles: a) Integrated Water Resources Management (IWRM) approach which includes the adaptation to climate change; b) enhanced transboundary cooperation; c) the principle of inclusivity and multidisciplinary; d) participation and deliberation while ensuring transparency, legitimacy and accountability. With regard to the Brahmaputra such cooperation shall be achieved through strengthening of shared understanding, knowledge and capacity building, investment planning, and reducing vulnerability to flood and erosion.

Authors of the CNA research study (Samaranayake et al, 2016) suggest how the management of Brahmaputra's resources could be improved on a domestic, bilateral, and basin-wide levels. Apart from the aforementioned frameworks, this study provides recommendations for the international community regarding the long-term security implications of discord among Brahmaputra riparians. First, on a domestic level, while China should expand access to more detailed information regarding its dam construction plans on the Brahmaputra to improve trust; India should enhance hydrological data sharing between the center and its northeast governments and inform the local governments about all dam construction projects plans in the region; Bangladesh as the third main riparian needs to seek assistance from the international community to conduct evidence-based assessments of human security impacts in the Brahmaputra basin (Samaranayake et al, 2016, p. 90). Second, bilateral recommendations advise China to consider hydropower as a potential area of cooperation with India, including sharing of hydrological data, humanitarian and ecological cooperation; likewise, if India seeks clarification on China's plans for dam construction and their potential impacts, India should provide the same information about its own plans; Bangladesh, on the other hand, should seek water flow and rainfall data from India and China year-round and request site visits to dams and barrages in both upper riparians (Samaranayake et al, 2016, p. 92-95). On a basin-wide level, China should convene a further dialogue with India and Bangladesh to discuss shared water challenges; India should apply the elements of ecosystem management and ecological protection into discussions of cooperation with both China and Bangladesh; and Bangladesh needs to encourage dialogue with India and China and utilize the capabilities of its active think tank community to analyse specific aspects of basin-wide management of the Brahmaputra with upper riparian counterparts (Samaranayake et al, 2016, p. 95-97).

5.1 Evaluation

Recommendations included in the UNWC, the WCD seven strategic priorities, the SAWI four key principles, and the CNA report, were selected based on their relevance to the subject matter of this chapter. These sets of recommendations present a balanced combination of both universal and region-focused principles (especially those outlined by SAWI and CNA), where the rules should be based primarily on the work of experts in the field, including teams of anthropologists, natural scientists, NGOs, and those who hold local knowledge. What needs to be achieved in the context of the Brahmaputra is a shared vision for future water sharing projects and an improved mutual understanding of the individual needs of all the actors involved. States shall be obliged to meaningfully interact with tribal communities on projects that affect their lands; real-time information exchange between upstream and downstream countries is necessary in order to prevent natural disasters and catastrophic consequences and; in coping with extreme events from climate change, adaptive management practices are of equal importance as well. In addition, decision-making processes and planning shall always focus on long-term impacts and its interlinked aspects, especially in regard to indigenous or tribal peoples, who could face displacement and should thus always participate in decision-making processes. And, when some of these negative impacts (e.g., displacement of people) cannot be avoided, relevant compensation measures must be put in place to lessen the suffering.

CONCLUSION

International concerns about the environmental and social impacts of large-scale dams has been increasing since the beginning of the twenty-first century. Both urbanization and states' preference for technocratic solutions for energy production are responsible for the rapid growth of large-scale hydropower projects in South Asia. Some of these solutions, however, are disrespectful of traditional knowledge and local ways of living. Large-scale hydropower projects in areas prone to natural disasters may result in negative social and environmental impacts that can spur new migration or refugee flows.

The current water management of the Brahmaputra's water resources is negatively influenced by the lack of cooperation within the region on managing shared water resources. The lack of cooperation hinders the creation of comprehensive basin-wide water management plan due to which there is no institution capable of promoting effective collaboration. This is because several disputes like border claims or clashes over water diversion remain unresolved. In particular, the territorial dispute over Indian-administered Arunachal Pradesh and the general lack of trust with regard to the ongoing dam constructions in Tibet and Northeast India are major hindrances to larger cooperation between China and India. Although the two countries have agreed to share hydrological data, there is still no institutionalized form of cooperation. Therefore, enhancing responsibility towards downstream countries and regions, especially towards the lowest riparian, Bangladesh, remains on the agenda.

1289 REDEFINING ACCESS TO WATER: CASE OF SLUM DWELLERS OF HYDERABAD**S.V Sreepada¹, S Goswami²**¹Asst. Professor, GITAM University, Visakhapatnam, India²Asst. Professor & Area Chair, Environmental Planning, CEPT University, Ahmedabad, India**ABSTRACT**

While availability of water has been widely discussed, access to water has always been one of the least discussed issues in India. The importance of access and availability of water has been raised by the UN in SDG's at international level, however India's definition and interpretation of access to water has been meekly restricted to availability of source (improved/ unimproved drinking water facility). The data collected by various national organizations like Census of India or National Sample Survey Organization, are often compiled to understand indicators of water availability, yet a collective and an informed approach is lacking in the current scenario. When it comes to urban poor and slums, access to water is probably even crucial, especially when availability does not assure accessibility. Therefore the primary objective of this paper is to understand the importance of redefining access to water and to identify the parameters which determines access to water.

In order to examine why access to water is important and how access to water is defined and interpreted by different agencies, wide range of literature was reviewed. In order to examine the parameters affecting accessibility, primary survey was conducted in ten selected slums from across the whole Greater Hyderabad Municipal Corporation (GHMC). The slums were selected based on its location within the city, and legal status. From the selected slums a total of 110 households were selected using stratified random sampling method. The questionnaire was designed to capture physical, economic and social parameters which determines access to water. Interviews were conducted with the key persons representing different layers of service provider. Focus group discussions were conducted with women, and kids from selected slums.

It was evident from the study that, access to water is just not having a facility at a prescribed distance, but a reliable, efficient and affordable service with safe quality and adequate quantity of drinking water should determine the accessibility. One of the major observations of the study include that the tagged households as having access to water according to current definition really do not have enough water to at least meet their needs. It is evident from the study that, understanding of access to water as of today is dominated by the mechanical approach of service provider only. It should be relooked from the view point of consumers.

Key words: Access to water, Availability of Water, Water Supply in Slums, Slums in India

1 BACKGROUND

According to Census 2011, India's urban population share has increased from 27.81% in 2001 to 31.16% in 2011 which is 377 million approximately. With the current rate of urbanization it is projected that by 2031, about 600 million people will reside in urban areas i.e., an increase of over 200 million in just 20 years (GOI, 2013). The urban sector in India is currently facing the biggest challenge in providing basic services like water supply to the increasing population. Around 65% of the slum population is covered in individual tap connections and are supposed to be having access to water, but report of HPEC, 2011 suggests that at the present state of service delivery, the average Indian receives 37 LPCD to 298 LPCD for a limited duration. Insufficiency of water often pushes people to pay tenfold higher than an average price and walk longer distances to obtain water. Women bear the maximum brunt. They are forced to spend time and energy collecting water for the household use, resulting into loss of earnings as well as leisure time.

Global monitoring of water access has been at place since 1930's initiated by League of Nations Health Organization which was later taken forward by WHO and UNICEF. Since then there has been many policies and programs and directed to improve the water availability to the urban poor and the slum dwellers. The MDG's recognizing the need addressed and included the target of halving the people without sustainable access to safe drinking water by 2015 which was recently carried forward in SDG as Goal 6 (UN, United Nations General Assembly Draft outcome document of the United Nations summit for the adoption of the post-2015 development agenda, 2015). This was adopted by the Indian government through 11th five year plan where the development is focused on the service provision in slums through programs like Basic Services for Urban Poor (BSUP) and housing programs like (IHSDP) programs (MoHUPA, 2011). These programs addressed the access to water by making an attempt to provide sufficient coverage of water infrastructure.

Internationally there are many definition of access to water. The JMP which is formed to monitor the progress of drinking water and sanitation by WHO & UNICEF defined sustainable **access to safe drinking water** as people **using an improved water source for drinking purposes**. India following the footsteps of these international policies derived its definition for access to drinking water source from these programs. A report published in 2011 by Census of India on "Houses, Household Amenities and Assets –Drinking water data" defines access for the first time. The definition has two major components, the first one being distance to the location of source and the second one being the source of drinking water. According to the definition, any urban household having source of water in 100 meters of distance is considered as having access to water source.

This definition of having source of drinking water within 100 meters of distance is often interpreted as having access to water. The flagship document of Ministry of Finance, Government of India, Economic Survey 2011-12, which is an important document in highlighting and directing various policies in the country, also interpreted the availability of drinking water source as having access to drinking water source.

It can be inferred that “access to water” is confined to the definition of “access to drinking water source” which is addressed by our national programs by improving the infrastructure coverage for water supply. As a contradiction, many studies suggested that despite the availability of facility within 100 meters, quantity, quality, sufficiency, timings of supply, duration of supply, frequency of supply, storage capacities, and economic conditions of the household plays vital role in access to water.

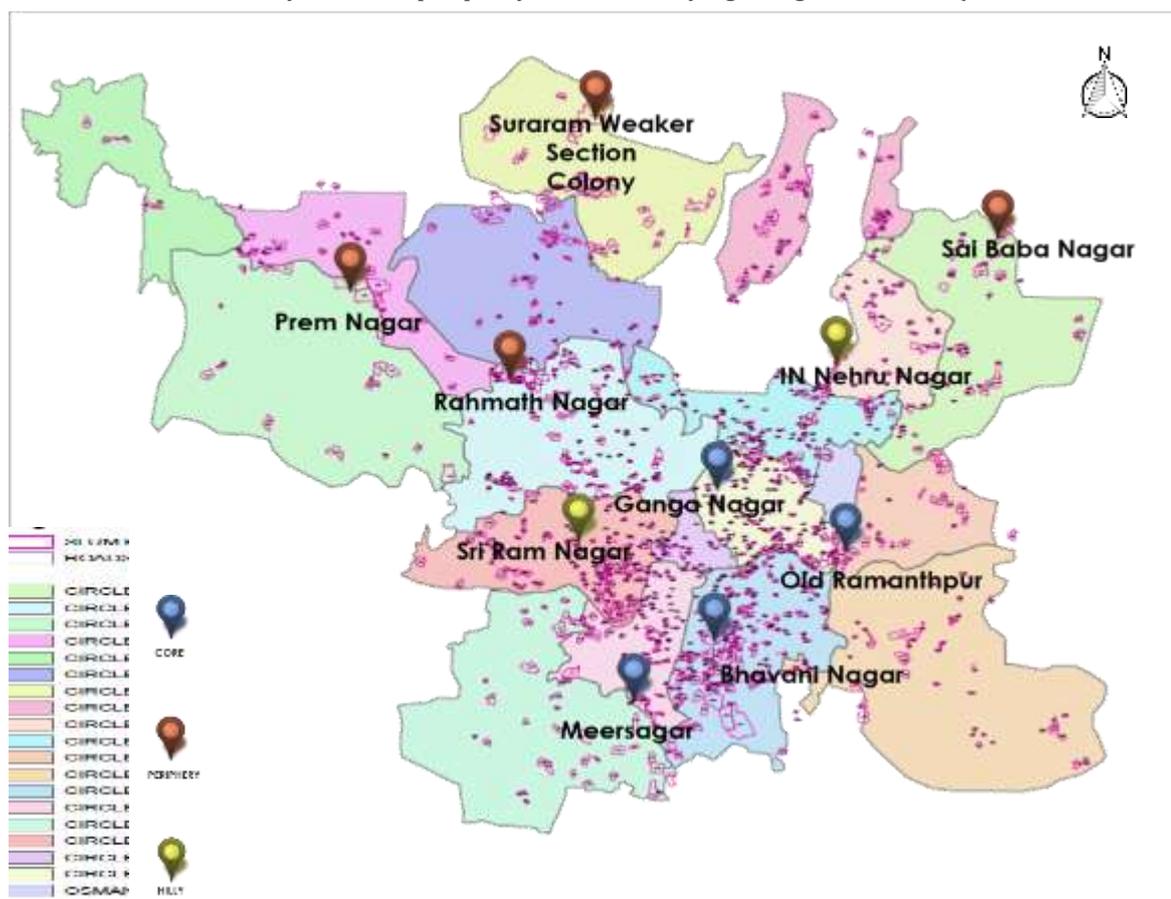

2 APPROACH AND METHODOLOGY

The primary objective of the study is to understand how access to water is interpreted at national and global level. It was studied through understanding of the various national and international literature. Secondary data for study were collected from official reports, documents, research publications and media coverage.

The secondary goal to understand the definition and the parameters that affect accessibility was studied through literature study and mostly from the data collected through primary surveys from the selected slums within the Greater Hyderabad Municipal Corporation (GHMC) boundary. The primary survey specially focused on understanding the selected physical, social, economic parameters from research papers, journal articles, news and print media. The hypotheses is hence tested in the selected ten slums of Hyderabad.

2.1 Selection of the Slums

Slums are the visual evidence of the prevailing disparities in our societies that are most susceptible pockets in receiving adequate infrastructure, especially drinking water. Even amongst these settlements, the location, size and the status (notified/non-notified) plays an important role in deciding the access to water. Therefore, the selection of the slums were done on the basis of the settlement typology and the geographical location in the GHMC area. These ten slums are spread across the whole GHMC area, covering all the five zones. For a better understanding, the slums are studied in context of the locations such as hilly, core and periphery area with varying recognition status (notified& non-notified).

Source of Map: GHMC

Figure 77 Map showing selected slums from various circles in GHMC area.

Table 27: Table showing the details of selected slums in GHMC area.

Area	Zone	Name of the Slum	Status of the Slum	Total Population	Total Households
Core Area	South Zone	Meersagar	Notified	3466	552
	East Zone	Old Ramanthpur	Notified	1720	415
	South Zone	Bhavani Nagar	Non-notified	3574	789

Periphery Area	Central Zone	Ganga Nagar	Non-notified	2242	545
	North Zone	Suraram Weaker Section Colony	Notified	5821	1414
	West Zone	Prem Nagar	Notified	9699	2399
	East Zone	Sai Baba Nagar	Non-notified	5039	1189
	Central Zone	Rahmath Nagar	Non-notified	5909	1470
Hilly Area	North Zone	IN Nagar	Notified	5366	1396
	Central Zone	Sri Ram Nagar	Non-notified	1924	484

Source of data: (GHMC, 2013)

The main occupants of these slums are daily waged laborers with less than one lakh rupees income per annum. The average household size of these selected slums ranges within 4-5 persons per household. The total number households and the population of the selected slums can be inferred from Table no: 1.

2.2 Identification of Key Stakeholders

To understand the interwoven issues related consumer- infrastructure- service; various stakeholders were identified. They are consumers (residents of the slum, in charge/ head of the slum), Service providers (Greater Hyderabad Municipal Corporation, Hyderabad Metropolitan Water Supply & Sewerage Board). The service delivery people includes – tanker drivers, linemen who are key role players in delivering service.

2.3 Selection of Sample Households & Key Informants

From the selected slums a total of 110 households (Core-40 HH, Periphery- 40 HH and Hilly area-30 HH) were surveyed. The households selection is based on stratified random sampling where the households with necessary water infrastructure according to the existing definition were selected. A survey was conducted in the months of January and February of 2017. The questionnaire for primary household survey captured the physical (Type of source, distance, quality, quantity available, round trip time to collect water, timings of supply, Part of the day, frequency and duration of supply), economic (Income of the family, establishment costs, monthly expenditure, and other expenses spent towards accessing water) & social parameters (Caste, Religion, Location of the house within the slum) of access. To understand the system of supply interviews were conducted with the commissioner and staff of GHMC, MD of HMWSSB and technical director. The consumer side issues and challenges are understood through the primary surveys, focus group discussions with the varying age and working groups, and personal interviews with the presidents of the selected slums.

To understand the challenges from the service delivery perspective interviews with linemen, water tanker drivers were conducted. Water is delivered through free tankers, which are ideally sent after a complaint is registered with HMWSSB, however in some areas water is sent periodically.

3 DEFINITION OF ACCESS TO WATER

There has been multiple definitions used internationally by various organizations to study the access to water. The National Statistics Office (NSO) of the respective countries may use definitions in the context of their country. These adopted definitions are generally modified from UN and World Bank, might vary from the definitions used in calculating in MDG's & SDG's estimates. These definitions are generally based on factors like – distance of the source, time and the quantity of water. As there is no internationally one clear standardized definition of access to drinking water, the differences are understood through adopting a process of framing core questions and data summary sheets circulated to the signatory countries.

3.1 International definition and national adoption

After the global monitoring has started, it targeted the improvement of various policies and kept updating the information on the status of facilities which consisted the initial tracking of access to drinking water. This monitoring programme was further carried forward by WHO, which was recently joined by UNICEF to monitor the progress on access to drinking water (Bartram, Fisher, Brocklehurst, & Hossain, 2014). Further to monitor the progress collectively, WHO and UNICEF formed a JMP (Joint Monitoring Programme) during the initial stages of MDG's. JMP interpreted *access* from the recent SDG target 6.1 – “By 2030, achieve universal and equitable access to safe” as sufficient water to meet domestic needs is reliably available close to home

Target language	Normative interpretation
By 2030, achieve	
<i>universal</i>	Implies all exposures and settings, including households, schools, health facilities, workplaces and public spaces
<i>and equitable</i>	Implies progressive reduction and elimination of inequalities between population subgroups
<i>access</i>	Implies sufficient water to meet domestic needs is reliably available close to home
<i>to safe</i>	Safe drinking water is free from pathogens and elevated levels of toxic substances at all times
<i>and affordable</i>	Payment for services does not present a barrier to access or prevent people from meeting other basic human needs
<i>drinking water</i>	Water used for drinking, cooking, food preparation and personal hygiene
<i>for all</i>	Suitable for use by men, women, girls and boys of all ages, including people with disabilities

India adopted the definition of access to drinking water source from Joint monitoring programme (JMP) for water and sanitation. The data for the indicator analysis are however supplied by various organizations at national level for SDG. The organizations who majorly conduct survey are Census of India, National Sample Survey Organisation (NSSO), National Family Health Survey under International Institute for population Sciences (IIPS), Mumbai. There is not any institute which defines accessibility to water but the data collected under census for availability of water source is interpreted as access to water.

The recent report published from the data collected by the Census -2011, “Houses, Household Amenities and Assets – Drinking water data” suggests that the definition of access to drinking water source has two components:

1. Distance to the location of drinking water source
2. Source of drinking water

It is often interpreted that households having access to drinking water source with the mentioned distance is considered as having access to drinking water.

1. Distance to the location of drinking water source

Within the premises: if the source was located within the premises where the household lived

Near the premises: if the source was located within a range of 100 meters from the premises in urban areas and within a distance of 500 meters in the case of rural areas.

Away from the premises: if the drinking water source was located beyond 100 meters from the premises in the urban areas and beyond 500 meters in the rural areas (Census, 2011).

It should be noted that “Premises” has been defined as a building along with the land and/or common places attached to it. A premises may not always have a compound wall or fencing. In such cases, that land or the common place as the case may be, available to the household is treated as ‘premises’

2. Source of drinking water:

The census metadata 2011, categorized sources of drinking water into –

- (1) Tap water, (2) Hand pump, (3) Tube well/Borehole, (4) Well, (5) Tank, Pond, Lake, (6)River, canal, (7) Spring and (8) Any other (Census, 2011).

The source which is majorly used throughout the year is considered and recorded as the main source of drinking water (Census, 2011).

This definition of access to drinking water sources is also interpreted as access to water. The economic survey 2011-12 interpreted this access to water sources as access to water (GOI, 2011).

Another interpretation of the access to sources of water supply can be inferred from the press information released by the Press Information Bureau, GOI stated by Ministry of Drinking water & Sanitation where data derived from census being considered as access to water instead of availability/access to water sources (Ministry of Drinking Water & Sanitation, 2013).

Along with Census, NSSO and NFHS also collects data about the aspects of drinking water. Along with the data required for the MDG, additional aspects like distances traveled to fetch water, time taken to reach, waiting time, quality, sufficiency and details of the supplementary sources, storage mechanisms and method used in taking water. The water used for household activities, it’s sufficiency and rates are also surveyed with a sample based survey (NSSO, 2014). National Family Health Survey (NFHS), collects data on the source of drinking water (categorized as per JMP), location, time taken to reach the sources, responsibility of water in the house and if any efforts to make the water safer to drink

(NFHS, 2014). However these organizations do not have a standardized definition or approach in understanding the access to water as a single entity, but act as enumerating bodies.

From the above list of definitions it can be understood that there is no one common definition explaining the access to water. However in India it can be understood that the definition and data about 'accessibility to drinking water sources' are interpreted as 'ACCESS TO DRINKING WATER'.

3.2 Dilemma of the definition/ Understanding from the local cases:

Water is considered as a public good and has been a part of constitutive right to life and it is the state's duty to provide clean drinking water to its citizens under Article 21 (Anand , Wankhade, Raman, Deb, & MJ, 2016). In addition to the states initiatives, service level benchmarks (SLBs), which are developed by MoUD, have set certain benchmarks like coverage, sufficiency, continuity, quality etc. which should be followed by the state. Even though the SLB's indicators cover certain important elements contributing to access to water, they are not integrated with the location and type of source criteria of the definition. SLB's are clearly service provider's perspective where as there is need to understand the consumer side's availability and accessibility to the resource. Even though many of the slums that are upgraded and provided infrastructure under many national and local programs, there are still accessibility gaps.

Another recent report India Exclusion report-2015, a section on tracing exclusions in water supply and sanitation also suggests the effects of time and quantity issues faced by the households residing in slum areas in accessing water. The social outcomes of having low availability and uneven timings of supply are strongly argued. The data for this section of the report is taken from Census, NSSO (Anand , Wankhade, Raman, Deb, & MJ, 2016).

In addition to the above report, an article by Biraja Kabi Stapathy, analyses that it is important to consider timings of supply, quality of supplied water for a good health quality of a household. He argues that the water coverage is merely a factor and it should be added along with the continuity, quality and safe handling storage factors when considering access to safe drinking water (Satapathy, 2014). The paper on informal markets and willingness to pay for water by L.Venkatachalam, touches upon the issue of being supplied insufficient amounts of water in slums in urban areas, hence forcing them to buy water from informal markets or approach unreliable sources (L.Venkatachalam, 2014).

The literature study projects the importance of the parameters that has to be considered before tagging a household as having access to water. But, a complete absence of specific definition and an interpretation of accessibility to water source as accessibility to water has to be re thought. To understand the accessibility to drinking water, firstly the parameters that affect and promotes accessibility has to be studied. Therefore an effort has been made in this study to examine the physical, social and economic parameters that may influence the access to water in slums.

4. ANALYSIS:

The following chapter explains the major findings of the household surveys and personal interviews with various stakeholders. The analysis is categorized into three major headings – 1) Physical 2) Social and 3) Economic parameters which are further explained through detailed indicators.

4.1 Physical Parameters:

There are many sources through which water is collected by the households. In the case of these selected slums there are private agencies and the local water board supplies water through various modes. The local water board HMWSSB, draws water from the major 6 water sources and treated at various collection and reservoir levels and supplied to the consumers. The water is supplied through individual taps inside the house, tap inside the premises of the plot, community tap outside the premises and tankers.

The water collected is categorized on the basis of usages. The two usages are for

1. Drinking and cooking purposes
2. Other purposes which include bathing, washing of clothes, utensils, cleaning of house and flushing of water closes/ sanitation purposes.

Depending on the quality of water, and the quantity available, the water is collected from the same source for both the purposes or from multiple sources for the different uses.

According to the definition all the households have access to water technically however, in the current survey conducted in these 10 slums, around 56% of the sample households use water from the single source for both the purposes and 44% of the sample households use water from multiple sources depending upon the usage.

Individual tap inside house

Tap inside premises

Tankers

Community tap outside

Table 2 Percentage of households collecting water from various source across location

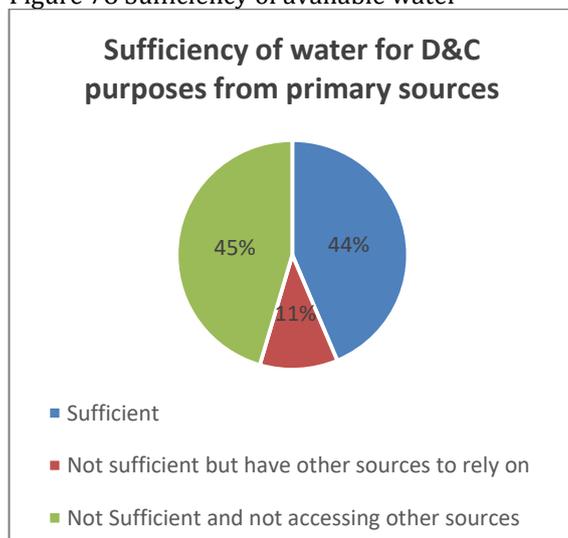

Location of Slums	Households Collecting water from following mode of supply for drinking and cooking purpose				
	Individual tap inside the house	Tap inside premises	Community tap outside the premises	Tankers	Responded Households
Core	0 (0)	25 (63)	15 (38)	0 (0)	40 (100)
Periphery	4 (10)	14 (35)	12 (30)	10 (25)	40 (100)
Hilly area	0 (0)	7 (23)	8 (27)	15 (50)	30 (100)
Total	4 (4)	46 (42)	35 (32)	25 (23)	110 (100)

*Numbers in brackets are in percentages
Source: Primary Survey 2017.

4.2 Sufficiency of water:

Eventhough according to the current definition, the respondent households have access to water, huge insufficiencies of water collected by the surveyed respondents has been recorded.

Figure 78 Sufficiency of available water

The core idea behind this study being the sufficiency of water available to the households, it is noted from the survey that 45% of the households responded insufficiency and as not relying on other sources of water, and 11% of the households have insufficient water and they don't have any other sources to collect water from.

This problem is more in hilly areas where 83% of the households have single source & insufficiency. This problem of insufficiency is recorded to get higher during summer seasons. 99% of the respondent households reported insufficiency of water during summer seasons. The respondents gave the main reasons for insufficiency of water as duration of supply, uneven timings, frequency of supply, pressure of water supplied. The 11% of respondent households mentioned the absence of information about timing of supply, absence of facility & service, loss of income if travelled larger distances. During the study visits, it was quite evident of the closed and dysfunctional taps and long waiting ques. The inference

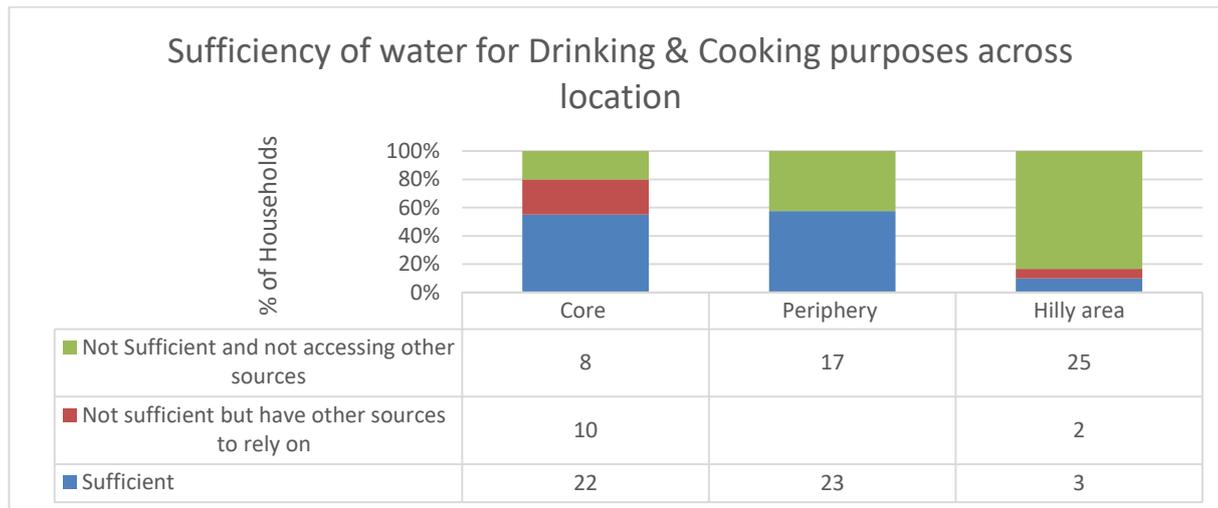

also strongly indicates that having infrastructure is not just enough but equally functioning and sufficient water availability at the consumer end is important.

Figure 79 Nonfunctional tap in a Slum

Figure 80 Taps used to tie cattle and pets in a slum

Source: Primary Survey 2017

Figure 81 Graph showing the varying sufficiency of water available to the households across the location

4.3 Quantity of water collected:

Understanding the insufficiency expressed by the surveyed households, further the data was analyzed to understand the quantities of water collected by the members of the household. When studied, an average of 24.3 liters is collected in core area, 33 liters in periphery and 18 liters in hilly area. This data when looked with correlation with the CPHEEO guidelines water required for drinking and cooking purposes per person per day is 10 litres and for other domestic purposes is 125liters, however the total per capita water collected per day for drinking and cooking purposes, the hilly areas have an average of 3 liters approximately of water availability per capita. Across the location the range of water quantity available ranged from 1.3 liters to 6.3 liters. For half of the sample households surveyed, at least 5 liters of water is also not available for drinking and cooking purpose. On the other side, the water available for other domestic purposes ranges from 1.7 liters to 80 liters. The core area has the least average quantities available and the periphery has the highest average. This was explained by the existing institution of supply. i.e., the private agencies who supply better quantities with efficiency. One important issue that has to be noticed is that this amounts of water collected for all purposes, there is an irregularity in the frequencies of supply. The average quantities might look satisfying with guidelines, but the water quantities ranges from 0.5 liters to 53 liters (these are extracted with relation to the frequency of water supplied and quantities collected).

Table 28 Average quantities of water available LPCD to the households across the location

Location of Slums	Average LPCD available		
	Average of quantity per person per day for drinking and cooking in liters	Average of quantity per person per day for other purposes in liters	Average quantity of water available for all purposes in liters
Core	10.2	14.1	24.3
Periphery	11.9	20.6	33.1
Hilly area	2.8	11.5	17.8
Average	8.8	15.8	25.8

Source: Primary Survey 2017.

4.4 Distance travelled to collect water:

To collect the required quantities of water, ideally some members or some cases all the family members travel to fetch water. The survey recorded the average distances travelled to primary, secondary and seasonal sources of water. People

travel an average of 32 meters for obtaining water for drinking and cooking purposes from the primary source. In case of insufficiency of the available water from this source, people travel an average of extra 600 meters to obtain water from secondary source. This average distance of 32 meters travelled by the household, gets 10 times higher in case of accessing a secondary source and 40 times during summer season. 12% of the sample households rely on secondary sources for water for drinking and cooking purposes and 14% approach secondary sources for domestic purposes. Out of that 12% people had to walk for an average of 600 meters, ranging from 100 to 1500 meters, for a secondary source which seasonally goes up to 3 kilometers. Along with this, the distance to access water for other purposes varies from 5 to 400 meters, which seasonally goes up to 3kms. With insufficiencies and people’s need to access more other sources to meet the requirements, increases the distance of travel.

Table 29 Average distance travelled by the household to collect water from various sources.

Average distance travelled by the households to access water in meters						
Location of slums	Primary Source		Secondary Source		Seasonal Source	
	D&C	OTHER	D&C	OTHER	D&C	OTHER
Core	7.3	10.85	845	675	619.2	668.3
Periphery	7.2	17.69	100	155	965.1	1620
Hilly	74	64	410	315	986.6	1501.6
Average	32.67	31.7	602.38	319.6	846.2	1263.3

Source: Primary Survey 2017.

4.5 Carrying Mechanism, Responsibility, Trips:

The water is carried along the distance from sources through two mechanisms, one is binde which has a carrying capacity of 10-12liters, where people have to make multiple number of trips to collect the required amount, the second one is barrel which can hold 120-180 liters, so ideally water is filled and later transferred upon the requirement from the barrels. The survey showcased that households with barrels as storage elements had better sufficiency. But not every household have space to keep a sump or a barrel to collect and store whenever water is released.

Binde
10-12 liters

make multiple number of trips.

Barrel
120-180 liters

Fill the barrels first and transfer the water upon requirement

Source: Primary Survey 2017.

Figure 82 Images showing carrying mechanisms, women & children involved in collecting water.

It is evident from the study that water when supplied to public posts or nearby taps, not everyone in the household carry water for themselves. So, the responsibility of collecting water is taken up by one or two member of the family. The study showed that mostly in every household female members collect water. Along with female members 25% of the households have children involved in collecting water. In 5% households, every member is involved. To meet the quantity requirements the person responsible in collecting water from the household make multiple trips. In the present study one single trip is considered as travelling from home to source, waiting and return from source to home. An average of 4 trips are made to collect water for drinking and cooking purposes and an average of 7 trips for other hygiene and domestic purposes. The member of the family usually walk to the source, however during summer, autos are used for carrying water. From a focus group discussion, it was told that women are facing the brunt mostly, even during extreme sickness and extreme climatic conditions they are forced to collect the whole quantity of water required for the entire household.

The average time in making trips to collect water was studied. The average time to collect required amount of water is increasing from core to hilly area. For example, it takes an average of 20 minutes to collect water in core area where as it takes an average of 1 hour 20 minutes in hilly areas. The time taken to collect water for drinking and cooking purposes ranges from 10 minutes to 3 hour 45 minutes. During summers the average of 30 minutes to collect water becomes 6 times higher i.e., 4 hours approximately just to obtain water for Drinking & Cooking purposes. This problem of long durations of collecting water is aggravated as water is collected for other purposes. On an average it takes 1 hour 20

minutes whereas during summer season it can go till an extent of 10 hours just collect water for other purposes. The collecting member of the household waits for 2-45 minutes to collect water for drinking and cooking purposes & 15 to 1 hour 40 minutes to collect water for other purposes.

Location of the slums	Average time taken by the household to collect water			
	Source of water during the Period of Survey (January & February 2017)		Source of water in April & May 2016	
	Drinking & Cooking purposes	Other purposes	Drinking & Cooking purposes	Other purposes
Core	20.7 min	52.7	4 Hrs	7 Hrs 33.5 min
Periphery	38.5 min	1 Hr	4 Hrs 20 min	8 Hrs 40 min
Hilly area	1 Hr 13 min	2 Hrs 22.7 min	4 Hrs 32.5 min	11 Hrs
Average	44.2 min	1 Hr 20 min	4 Hrs 16 min	9 Hrs (Approx.)

Source: Primary Survey 2017.

Figure 83 Time taken by the member of the households to access water across the location.

The major part of the day for the person responsible in collecting water is lost in waiting in long ques for the water. Most of the times, the person collecting water leaves their barrels near the water source or the end of their streets and proceeds with their daily work. So the data reflected as 11 hrs which is the average reflects the output of the similar water collecting patterns.

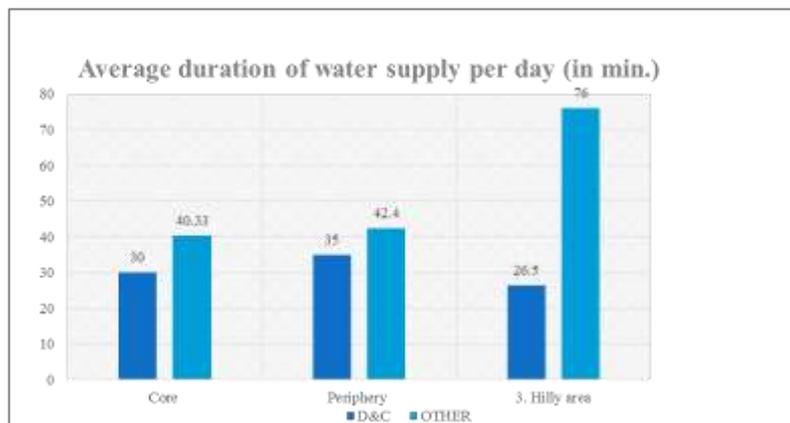

4.6 Timings of Supply, duration and information:

Water for both the purposes are supplied differently at different timings. There is also a category of households having no information about the supply. In this case there us an irregularity and fluctuation of supply timings every day, which makes it difficult for the member of the household to collect water. Here, the information of supply plays a major role. Only 36% of the households have prior information of supply plays a major role. Only 36% of the sample households have prior information and 64% do not have any information regarding the timings of supply. To cope up with this serious issue of unknown timings, most of the households leave the tap open to directly fill the buckets and most of the times which results in overflow and wastage of water. It is a very common sight to see water filled streets whenever water is released by the service provider. 37% of the households rely on neighbors to collect water where as 7% leave the barrels connected to the water taps outside the house. However the timings of supply are mentioned on the HMWSSB website and the actual timings and duration of service delivery are majorly different. It is also common to find women running after tankers to collect water. The water for both the purposes are supplied differently timings.

Figure 84 Images showing broken taps, barrels left outside the houses.

Water is supplied for an average duration of 30 minutes. The supply duration ranges from 5-90 minutes under which 5-6 households relying on these community taps should fill the required quantities. The average duration of water supplied for other purpose is 53 minutes ranges from 30 to 60 minutes. Around 50% of the household population, do not have an access of at least 30 minutes.

Source: Primary Survey 2017.

Figure 8 Duration of Availability of water for the households in minutes.

From the surveyed households none has a daily water supply for cooking and drinking purposes. When looked into detail, the households in core area have more alternate day supplied and as it goes towards hilly area people receive water once in 3 days. With 96% of the population not having service till inside of the house, and absence of information/unaware of the supply timings and frequency, the real stress is borne by the woman or the member responsible in collecting water for the entire household.

Table 30 Households and frequency of water supply for drinking and cooking purposes across the location.

Location of Slums	Frequency of water supplied					
	Alternate Day	Once in 3 to 4 days	Once in 5 to 6 days	Once in Week	Extremely Irregular	Responded Households
Core	16 (40)	9 (22.5)	10 (25)	2 (5)	3 (7.5)	40 (100)
Periphery	13 (33)	25 (17.5)	8 (20)	4 (10)	8 (19.5)	40 (100)
Hilly area	6 (20)	24 (80)	0 (0)	0 (0)	0 (0)	30 (100)
Total	35 (32)	40 (36)	18 (16)	6 (6)	11 (10)	110 (100)

*Numbers in brackets are in percentages

Source: Primary Survey 2017

The households in the slums generally store water in tumblers, bindes, buckets, barrels or sumps with in the house. The storage capacity of binde ranges from 10 to 12liters, Barrel 160 to 200 liters, sump 200 to 350 liters buckets 10 liters. From the conducted study it was also understood that the better the storage, better the sufficiency. For example, the households in the periphery area have a storage capacity of an average of 510 liters per family had better sufficiency.

Figure 85 A street with barrels to store water on either side in a slum

5 ECONOMIC PARAMETERS

A minimum bill for a household connection is 180 rupees for the water supplied from HMWSSB. Unofficially, an amount of 20-30 rupees is paid to the lineman. The amount depends on the duration of water being released. 40-50 rupees is paid to the tanker driver to collect water. The establishment costs being one rupee according to the recent G.O, the slum dwellers end up paying more to the intermediate stakeholders due to their unfamiliarity and fear of not getting a connection. Often in certain slums people pool money and get connection to access to water for other purposes. In one of the slums, people get frequent messages and notices to pay water bills even though HMWSSB did not supply with neither facility nor service. During summer seasons they pay some amount up to 50 rupees for accessing water towards house owners who have water with in their compound.

6 SOCIAL PARAMETERS

There were no caste and religion biases reflected in the surveys of focus group discussions. However, the location of the house inside a slum played a major role. Households located near the roads are treated to be financially stable and have

better access to water as they are close to the road. During another personal interviews with lineman, and the officers at HMWSSB it was highlighted that due to existing narrow lanes it is difficult to provide service till the interiors of the slums.

7 CONCLUSION:

Refreshing the whole idea behind this study of access, in spite of having the source within 100 meters there are inadequacies of water availability, mis-informed timings, forcing the people to rely on secondary sources, leading to spend more money, time and efforts. The definition of access to water has to be critically looked at with the supporting inferences like insufficiencies, longer waiting periods, and larger distances to be travelled which in turn effects the overall well being and health of the family. The study relieves the fact that there is access to facilities, yet there is an inadequacy of service and the service should be looked at an availability perspective on the consumer end rather than service provider's view alone. With the analyzed parameters i.e., the quantity, quality, frequency, duration and timings of supply the existing definition of access to water should be re-thought.

1301 FISHERMEN IN WETLAND REGION OF BANGLADESH: VIEWS FROM THE FIELD EXPERIENCES OF HAKALUKI HAOR

ABSTRACT

Bangladesh is a country of vast wetland. The beauty of Bangladesh lies in her water bodies which are full of natural resources. Wetland resources have been recognized as a major source of income and employment generating fields for marginalized people of Bangladesh. Hakaluki Haor is the biggest eco-based wetland network in Bangladesh. Most of the inhabitants are fully dependent on haor resources. This study attentively observes the socio- economic status of the artisanal fishermen of Hakaluki Haor of Bangladesh. It is explorative in nature. Qualitative and quantitative both approaches have been used to obtain the goals and objectives. Hakaluki Haor of Bangladesh has been selected as study area purposively. Upazillas, unions and villages have been selected through multi-stage area sampling procedure. On the other hand, Households have been selected on the basis of simple random sampling by using random number table. The main objective of this article is to identify the present socio- demographic background of haor fishermen in Bangladesh. In the context of this objective, the researchers have given emphasis on analyzing the actual situation of the household of fishermen in haor perspective. The researchers have tried to find out the social-economic and demographic scenario of haor fishermen of Hakaluki by using observation, interview schedule and key informants interview methods. By using those tools, the researchers have found various forms of findings and observations about the situation of haor fishermen. Study findings have been categorized on the basis of five capitals which are social, human, physical, financial and natural resources followed by the conceptual framework of the study. The study has explored the socio-economic state of the fishermen and most of the fishermen of the haor basin are living in the most awful and vulnerable situation of everyday life in terms of income, food security, housing patterns, health and sanitation condition, child marriage, social relation and state of interaction among the communities dwellers, family planning, decision making issue, power practice, participation in development activities, position in socio-economic institution in respective locality, and education. Child marriage is a common practice in haor area. Most of the decisions are taken by the male persons of the family. It has been observed that fishermen are mainly engaged in fishing for their existence. Therefore, the study has observed that the artisanal fishermen are facing severe crises for their existing profession. Study clearly shows fishermen are gradually shifting their artisanal profession from fishing arena because of various reasons. The researchers have discussed the several issues regarding social, economic, leasing and fishing environment of the fishermen of the Hakaluki Haor. : Artisanal, Wetlands, Haor, Hakaluki Haor, Resources, Bangladesh

SS01.3. Water management in South Asia: From conflict to cooperation

1305 STRATEGIC ALTERNATIVES TO LIFE THREATENING SALTS**PAULO CASACA**SADF, paulo@sadf.eu**ABSTRACT**

The Portuguese head of the 'National Programme for the Promotion of Healthy Food' recently classified salt as the 'public enemy number one' in a press article issued on the occasion of a government project to tax salty food. The article explains how this substance was transformed from one of the most historically prized and essential elements in food and food processing into one of the most toxic health hazards of our time. For a considerably longer period of time, a man-made salinization process has been destroying arable land and aquifers, creating deserts and corroding urban infra-structures. Recent estimations point to 20% of cultivated and 33% of irrigated land in the world as salt-affected and degraded. Drinking water salinity and heavy metal contamination became a major health hazard in the basins and specially deltas of such important water sources as the Indus, the Ganges- Brahmaputra-Meghna or the Mekong. The unsustainable and or inadequate use of freshwater, combined with unsustainable urbanisation practices, resulted in land subsidence and sea water infiltration. They are leading to dramatic outcomes and putting at risk such large metropolis as Jakarta. Meanwhile in cooler climatic areas salt by the million tons is dumped in nature every year for de-icing roads and affecting the environment in insufficiently studied yet certainly negative ways. The reversal of the natural salinization process – through sea desalination – has been ongoing for many decades and decisively affected human life in some desert coastal areas, at considerable energy costs and a mixed environmental impact. In some areas, as in California, desalination plants have also started to operate so as to reverse earlier soil salinization linked to agricultural activity. In the European context, whereas some public authorities – such as the one mentioned at the beginning of this text – are conscious of the importance of the issue, most of them downplay it and do not understand or want to acknowledge its crucial dimension. A project I headed under the present title was summarily rejected by an anonymous jury of an European co-financed call for projects saying '...soil salinization which affects large areas of the developing world - would benefit from having more consortium members from affected, developing countries that have specific issues with salinization and impact upon food production.' That a European-funded body, presumably composed by scientists, considers salinization to be a 'developing world' problem is a clear indicator of the alarming state of denial existing on the issue. In this paper, we defend Strategic Alternatives to Life Threatening Salts to be based on a comprehensive understanding of the challenges accompanied by a global, systemic effort supported by the international community.

1. THE DESTRUCTION OF LIFE THROUGH SALINIZATION

The issue I am highlighting today, salinization, is hardly a novelty; it has been around for thousands of years and has been consensually viewed as the main factor behind the crumbling of early civilisations such as the Sumerian. The scientific knowledge needed so as to understand the crux of this particular matter is also relatively simple.

As a [popular text book to be found in the web](#) explains, salinization (and the related waterlogging process) can be seen as the result of the destruction of the natural water-salt equilibrium.

When irrigation brings more salt to the land than is drained out to rivers (and ultimately the sea), the classic result is salinization. This normally happens in hot climates where flooding irrigation is practiced; when most of the water evaporates, salt is gradually deposited in the land. Otherwise, in the case of waterlogging, a previously existing saline water table gets up to the plant roots through the influx of irrigation water. Saline water tables form under the soil due to the same disequilibria between the salt brought by water mineral erosion and the insufficient drainage (necessary so as to wash this salt to the rivers and the sea).

As the process can develop across a long period of time – encompassing at least several generations – its disastrous long-term results tend to be overshadowed by the short-term benefits of irrigation itself. This happens in spite of the fact that it is fairly easy to predict the future results of these practices.

For the last two centuries, a man-made salinization process has been destroying arable land and aquifers around the world, corroding urban infra-structures and creating artificial deserts. [Recent estimations](#) point to 20% of cultivated and 33% of irrigated land in the world as salt-affected and degraded.

Salinity and heavy metal contamination of drinking water became a major health hazard in the basins and specially deltas of such important water sources as the [Indus, the Ganges-Brahmaputra-Meghna](#) or the Mekong.

The unsustainable and/or inadequate use of freshwater, combined with unsustainable urbanisation practices, resulted in land subsidence and sea water infiltration. These are leading to dramatic outcomes and putting at risk a number of large metropolis; for instance [Jakarta, that is sinking into the Ocean](#).

There is today a novelty regarding the salinization process that makes it even more widespread than in ancient times: its extension to cooler climatic areas. Salt by the millions of tons is now dumped in nature every year for the purpose of de-icing roads; and this, of course, has strong environmental effects. Recent estimates indicate that in the US [up to 20 million of tons of salt](#) have been dumped annually, with [impressive negative environmental and health impacts](#).

The reversal of the natural salinization process – through sea desalination – has been ongoing for many decades now and has decisively affected human life in several desert coastal areas, at considerable energy costs and with a mixed

environmental impact. In some areas, as in California, desalination plants have also started to operate so as to reverse earlier soil salinization linked to irrigation.

2. SALTY OBSERVATIONS

Three years ago, travelling by midday in the Indian Northern Punjab, I was flabbergasted to see huge parcels of land being flooded as the sun stood high and temperatures bordered 40° C. I recalled the first time I arrived in Iraq, in 2004, where I saw a similar scenario in the middle of the desert, in the vicinity of the Euphrates.

Back home, in Southern mainland Portugal, when in 2003 I tried to learn some practical notions of agriculture by buying and exploiting an olive grove, I was confronted by a similar setting: I was only authorized to dig a well (and have water to drink) if I claimed I intended to use said water for irrigating the olive trees. To my surprise, I found that the salts content in water was not taken in consideration in the official analysis. The [Portuguese law](#) only recommended that salt levels remain below 640 ppm. The European legal framework – generally known for its minute detail and comprehensive dimension – is completely silent in this domain.

In 2015, in a conference organised on the fringes of COP 21, I argued for an [inclusive sustainable development strategy](#) meant to overcome the ‘climate change’ monomania. In September last year, in ‘[For a meaningful SDG agenda](#)’, I stressed how this ‘climate change’ unidimensional mind-set undermines the international environmental agenda by preventing comprehensive understandings and plans of action.

Still in 2017, as I integrated a multinational project named ‘[Strategic Alternatives to Life Threatening Salts](#)’, I was stunned yet again as I witnessed an anonymous jury refusing our project by claiming that the issue was ‘not relevant in the developed world’.

Human development in the past three centuries created unprecedented challenges to life in our planet; among them, a possible nuclear holocaust, unparalleled destruction of nature and biodiversity, and changes in the composition and functioning of hydrological, geological and atmospheric systems. These phenomena, of course, present a number of potentially hazardous impacts - among other things, on the earth’s climate.

3. SALTS AS A HEALTH HAZARD

The Portuguese head of the ‘National Programme for the Promotion of Healthy Food’ recently classified salt as ‘[public enemy number one](#)’ in a press article issued on the occasion of the presentation of a government project aimed at taxing salty food.

The article explains how this substance was transformed from one of the most historically prized and essential elements in food processing into one of the most toxic health hazards of our time.

As the author explains, Portugal has a peculiar relation with salt. The existing largest Ancient Roman salt-fish processing ruins are located in Portugal. Salted cod fish is still the quintessential national dish, and salt was indeed and for a long time the country’s number one export.

But what is the assessment we can make of the situation in the above-mentioned deltas of South and South-East Asia, where access to drinkable, unsalted water is denied to hundreds of millions?

Whereas some studies conclude that there is a [strong correlation between high salinity of drinking water and hypertension](#) in areas impacted by salinization, such as Bangladesh coastal areas, we have all the reasons to expect the health problem to be more serious in a region so deeply affected by salinization as South Asia than in a country such as Portugal. Precise studies, however, are lacking.

4. THE GLOBAL WARMING MANTRA

Googling through the drama of salinization, it is hard to escape the sight nearly everywhere: the issue is described as the consequence of ‘global warming’ or ‘climate change’.

It is clear that changes in climate can indeed exacerbate salinization impacts. If we look to [European rainfall statistics](#), we can see that from 1960 to 2015 rainfall decreased annually and most in particular in summer across the South of Europe whereas the opposite has been the case in the North of Europe, that is, rainfall increased there, in particular during the summer.

At the same time, average temperatures have been steadily rising. This situation obviously increases pressures related to salinization. Conversely, the increase in rainfall can mitigate the salinization impact of large-scale use of salt as a defrosting substance in Northern Europe.

It is however not in conformity with reality to transfer to the climate sphere the very well-known impacts of either irrigation by flooding or defrosting by dumping salts. These are completely different phenomena. The salinization is not caused by changes in climate, but it can be aggravated or mitigated by changes in climate. It is thus disappointing to see this reversal of roles being widespread in scientific literature - without any scientific evidence to sustain the claim.

I think the issue does not deserve any in-depth physical scientific discussion since, as we have pointed out, the basics of the phenomenon are pretty simple to understand and its dramatic impacts have been evident for thousands of years.

The problem is rather connected with mass psychological denial of reality when humanity finds said reality to be too hard to be faced. I still remember the explanation I got from the laboratory when I contested the absence of salinity data in the water analysis: 'everyone knows there is salt in our water, why should we go over it?'

So, the immediate conveniences of irrigation or defrosting press us to forget about their nasty long-term effects or to disguise them as unavoidable occurrences which have widespread and diffuse origins (phenomena like climate change). That is, anything rather than facing the need to change our practices.

5. CONCLUSIONS

There is every reason to believe that man-made salinization is a life-threatening phenomenon that is no less important than others, and certainly more important than man-made 'climate change'.

The widespread denial of the importance of the phenomenon is not restricted to those who do not understand it; on the contrary, it is ingrained among political decision-makers and the scientific community. The modern tendency for general attentions to flock around trendy issues while disregarding objective analysis has not been helpful in this respect.

Salinization can only be prevented within a multidisciplinary approach and within an integrated developmental vision, as it centres on the water-food-energy-health-environment nexus and is also impacted by other phenomena (including, of course, changes in climate). More significantly, its dimension and its impact need to be studied in proportion to its importance and with scientific rigour and objectivity.

South Asia is probably the region in the world most affected by the problem; hundreds of millions of lives crucially depend on a successful understanding and feasible solution. This is also a reason why to discuss the issue within the Goa regional science world conference.

1499 GEOPOLITICS OF WATER CONFLICTS IN THE TEESTA RIVER BASIN

Gauri Noolkar-Oak

JWHI Fellow, Both ENDS, The Netherlands

ABSTRACT

The Teesta basin is among the more underdeveloped areas of South Asia and deals with numerous issues spanning across economy, governance and politics, culture, environment, gender, security, and its riverine ecosystems. All these issues varying greatly in intensity and nature are nevertheless linked together by the Teesta which acts as a common thread running through them all.

The basin is known for the lack of an agreement between India and Bangladesh over sharing its waters, however, internal disputes such as the anti-dam movement in Sikkim, the struggle for Gorkhaland, and the 'Save the Buri Teesta' movement in Bangladesh are also significant issues tied to the bilateral relations between the two riparian nations.

The paper focuses on the geopolitics of water conflicts of the Teesta basin. Geopolitics is the study of the relationship between geographical factors and variables, and politics. Water conflicts are disputes over access, ownership, control and use of water resources between any two or more groups. Thus, this paper attempts to look at the current major conflicts within the Teesta basin from a political perspective based on their geographic profile.

Water resources in South Asia have been directly connected to national sovereignty and security for many reasons such as growing demand due to overpopulation and rapid urbanisation, consequent scarcity of the resource, mutual distrust among riparian neighbours, lack of multilateral and holistic initiatives for cooperation, and lack of robust dispute resolution mechanisms. The Teesta basin has a rapidly growing and urbanising population dealing with poverty and a low standard of living. The river, due to heavy damming, chemical contamination, deforestation and climate change, is experiencing erratic flows with a sharp decrease in the total volume of water. There is a dearth of trust and serious efforts to cooperate jointly over conservation of the river and development of the basin. Also, comparing the discourse on the Teesta with the actual conditions of the river and her riparians leads to the conclusion that the interests of the local stakeholders and the health, sustainability, economic value and spiritual importance of the river have not been prioritised in the negotiations over the Teesta. Thus, it can be seen that the Teesta issue is much more than a signature on an agreement.

This paper hypothesises that the phrase 'Indo-Bangladeshi conflict over the Teesta river' is inaccurate, for the Teesta conflict is neither about the river nor a conflict between India and Bangladesh (who share a good rapport), but a product of domestic politics and regional geopolitics, and has little to do with the river and her health. It does not negate the discontent over intense damming upstream and severe reduction in water flow downstream of the Teesta but states that the causes and effects of this discontent are rooted in socio-cultural and economic forces; after an extent, it is no longer about the river and her environment. On closer scrutiny, one can observe that disputes over the Teesta are a façade for various political, social, economic and geopolitical interests playing out at domestic and national levels in both countries. The consequences are borne by the river and her people in the form of environmental damage, low level of development and low resilience towards the effects of climate change. The paper attempts to unearth these interests and provide pragmatic solutions that would not only solve the political disputes, but also promote environmental sustainability, economic efficiency and social justice in the Teesta river basin.

PREFACE

Water conflicts are rarely just about water. On the surface, they are about ownership, distribution, access to, and use of water resources. However, beneath the surface are multiple layers of historical, cultural, religious, political, ethnic and economic conflicts, which manifest themselves time and again through the water conflict. Water conflicts are further complicated by the fact that they occur not only *for* water, but also *through* water and *at the cost of* water i.e. water can be not only a reason for conflict, but also a weapon for and victim (intended, or collateral damage) in conflict. This is exactly what a solo backpacking trip along the entire length of the Teesta river taught me. As I set out from the confluence of Teesta and Brahmaputra at Chilmari, Bangladesh, I met numerous locals, activists, NGOs, bureaucrats, academicians, farmers, businessmen and youngsters who spoke of various issues that beset their region. We discussed history, culture, society, politics and the environment, and the Teesta figured in each of them. For each person I spoke to, the Teesta was a mother, a goddess, a tyrant, a city landmark, a powerful resource, and nature's gift in distress. Her dwindling flows and the tussle to harness as much of her waters as possible for their farms, homes and hydropower stations formed the central theme of any discussion on the Teesta. While everyone had their own narrative depending on their profiles and locations, there was a general consensus that every riparian of the Teesta should be able to access her waters and prosper because "they too are human beings just like us".

In the wider picture, the role of geopolitics was subtle but permeating. Be it the strategically located Chicken's Neck buffered by Sikkim, or the drought-prone northernmost region of Rangpur far away from the markets and growth of Dhaka in Bangladesh, geopolitical conditions played a huge role in shaping the dispute over sharing the Teesta. Moreover, the goodwill and friendly sentiment for India among Bangladeshis, and the insistence of Indians that Bangladesh should get a fair share of the Teesta's waters made me realise that the dispute was not bilateral, but a summation of domestic friction, economic constraints, and political imperatives based in wider geopolitical realities of the South Asian neighbourhood and global phenomena such as climate change.

During my research on the Teesta, I came across a lot of papers that focused on the social, cultural, economic and scientific aspects of the Teesta basin, but very little on the geopolitics of it. I also read many articles that outlined Indo-Bangladeshi relations, the chronology of the Teesta talks and their importance for India and Bangladesh, the local dynamics of Rangpur division, West Bengal's stand on the Teesta issue, the struggle for Gorkhaland, and the anti-dam movement in Sikkim – but each issue was dealt in isolation. Nowhere could I find a comprehensive piece of work that linked together domestic issues of the Teesta **and** bilateral negotiations on sharing the river **and** the geopolitics of the region. This paper is an attempt to establish these connections and provide a clearer picture of water conflicts in the Teesta basin from a geopolitical angle and at the same time, spur more comprehensive and sophisticated work on these lines in the Teesta basin.

This conflict compels one to take a position. Throughout my travel and research, I have noticed the Teesta, at the heart of all disputes and yet silently accepting and nurturing the civilisation squabbling over her - in that lies her divinity. As I prayed at Tso Lamo, origin of the Teesta, I realised I stood for the Teesta, her environment, and their conservation, wellbeing and protection.

Being an outsider, I humbly accept that I have just about scratched the surface of the political, geopolitical, social and cultural dynamics of the Teesta basin. While I am immensely grateful for the valuable insights and help provided to me by the locals of the Teesta as well as all those I met and spoke to during this research, I apologize for any insensitivity or offense that could be perceived through the research and analysis in this paper as it is purely unintentional. Any feedback is welcome.

Gauri Noolkar-Oak

ACKNOWLEDGEMENTS

This paper is the result of a very precious opportunity granted to me by the Joke Waller-Hunter Initiative (JWHI) at Both ENDS, The Netherlands. The JWHI Fellowship has opened doors to so many learnings, opportunities and friendships! My sincere gratitude to JWHI and Both ENDS; without them, none of this would have been possible.

I am extremely grateful to Prof. Vijay Paranjpye of Gomukh Trust, Pune, who has been guiding me for the past two years. His support, teaching and inputs right from the very beginning of this research, have been immense and invaluable. I am also grateful to Mr. Remi Kempers of Both ENDS for his support and feedback throughout the fellowship and helping me sail through it quite smoothly.

This paper is preceded by a solo backpacking trip along the Teesta river, right from the Teesta-Brahmaputra confluence at Chilmari, Bangladesh, all the way up to Teesta's origin at Tso Lamo lake, India. I was able to undertake this adventure all by myself thanks to the wonderful people I met on the way, who generously offered me a place in their homes, lots of help, and friendships to cherish. For their heart-warming hospitality and support, I am indebted to –

Dr. Abdul Matin of Bangladesh Poribesh Andolon (BAPA), Dhaka, who looked after me like his daughter all the while I was in Bangladesh;

Mr. S.M. Harun Or Rashid Lal (Lalbhai), Executive Director of Solidarity, Kurigram, and Adv. S. M. Abraham Lincoln, Public Prosecutor of Kurigram, who provided me with a warm home, guidance and monumental support in the first leg of my Teesta journey.

All the members of Solidarity, Kurigram and their tireless enthusiasm, kindness, friendship and efforts right up to my very last moments with them at the Indo-Bangladeshi border.

Mr. P. Wongden Lepcha of Mangan, Sikkim and his lovely family, who went out of their way and turned the last and most challenging

leg of my Teesta journey into a smooth, untroubled and blissful experience.

Ms. Taposhi Sarkar of Dhaka and her brothers Devashish Sarkar and Suvashish Sarkar, who with their care, friendship and generosity eased my nervousness about being alone in a foreign country for the first time.

Mr. and Mrs. Gartuk of Lachen, Sikkim, who provided me shelter, warm clothes and safe transport for my final trip, to Teesta's origin at Tso Lamo.

Before, during and after my trip along the Teesta, I met many people who helped me generously with information and contacts. Their appreciation and encouragement kept me going. I am very grateful to –

Prof. Pinaki Roy of Raiganj University, West Bengal, for sharing pictures, information and valuable references and contacts with me throughout my research with great enthusiasm.

Mr. L. S. Tamsang, President of Myang Lyang Lepcha Development Board, Kalimpong who sent books and journals all the way from Kalimpong to me in Pune, despite Gorkhaland tensions prevailing in Kalimpong and surrounding areas.

Mr. Bimalendu Majumdar of Jalpaiguri, and Mr. Dinesh Roy of Mainaguri who shared with me valuable contacts and insights on the environmental, cultural and social issues of the Teesta basin.

Mr. Raj Basu, a Siliguri-based film-maker who introduced me to the history and religious makeup of the Teesta basin as well as more people who helped me through the rest of the journey.

And there were more who helped me out of tight spots, confusions and tiring situations, making my journey a smooth, blissful, and an unforgettable experience. In no particular order, I am thankful to – Mr. Sharifbhai Jamil (Blue Planet Initiative), Mr. Rahul Agrawal, Mr. Niraj Pradhan, and Kamran, Mahbub and Javed, and the many, many locals who helped me on the way.

My journey along the Teesta has been inspired by the book 'Empires of the Indus' written by Ms. Alice Albinia. I would like to thank her for writing this wonderful book and for her tips which helped me greatly during the trip.

While writing this paper, I did refer to many books, journalistic articles and government statistics, however many significant points and observations have been gathered from academicians, activists, scientists, journalists and locals I spoke to during this research. In no particular order, I greatly appreciate the help given by – Dr. Kalyan Rudra, Mr. Deoashish Mothey, Mr. Neeraj Vaghlikar, Mr. Shripad Dharmadhikary, Ms. Nikita Das (Prayas), Mr. Arfan Uzzaman, Mr. Samir Mehta, Mr. Siddharth Patil (ACWADAM), Dr. Amit Ranjan, Mr. Md. Tanvir Rahman Nishad, Dr. Mona Chettri, Mr. K. J. Joy and Dr. Shrikant Gabale. I am also thankful to Ms. Prachi Sathe who has designed the maps, Mr. Hrishikesh Gupta who has designed the diagrams for this paper, and Mr. Sumedh More for helping me create the "Tussles over Teesta" website.

This paper has been improved and fine-tuned by Prof. Paranjpye, Mr. Remi Kempers and a number of peers who very kindly invested their time and energy in providing me with thoughtful and encouraging reviews and feedback. In no particular order, I would like to offer my special thanks to - Mr. Samir Mehta, Mr. Arfan Uzzaman, Dr. Abdul Matin, Mr. Himanshu Thakkar, Dr. Partha Sarathi Datta, Ms. Ashwini Dabadge, Mr. Chinmay Bhandari, Dr. David J. Karl, and Mr. Mark Kinra.

As a part of my JWHI fellowship, I also studied a short course in water conflict management at UNESCO-IHE, Delft, The Netherlands, which helped me build the conceptual base and understanding of transboundary water conflicts. I am greatly thankful to JWHI for providing me with the opportunity to study at UNESCO-IHE, as well as to my professors at UNESCO-IHE, particularly Prof. Aaron Wolf and Ms. Zaki Shubber. I am also very grateful to Ms. Mukta Bapat, Mr. Akshay Mahashabde and their two lovely daughters for opening the doors to their wonderful home and making me feel more like a member of the family than a guest throughout my stay at Delft.

My most heartfelt gratitude goes to my family, my parents, grandparents and in-laws, for their continuous encouragement, support and appreciation throughout this fellowship. I feel lucky to not have been held back by domestic constraints and enjoy the freedom to pursue such adventurous journeys and research projects. And last but not the least, my deepest appreciation, gratitude and affection goes to my husband Amogh who stood by me, took great care of me, and helped me in every conceivable way to give my best to this endeavour, and also to my cat, Bokus, who, with his innocence and eccentricity, kept me happy and relaxed through it all.

RESEARCH METHODOLOGY AND LAYOUT OF THE PAPER

This paper presents a geopolitical analysis of water conflicts in the Teesta River Basin. The analysis is qualitative in nature and based on both primary and secondary sources of data. The primary data has been collected through a month-long journey in the Teesta basin, and various interviews, meetings and conversations with experts and stakeholders in India and Bangladesh. The secondary data has almost entirely been collected through online research.

Conflict mapping of the Teesta basin in this paper is based on a matrix of geographical space and political processes over time. Major stakeholders and their positions have been identified and through analysing the power dynamics between them, an attempt has been made to identify their underlying interests. A historical approach has also been taken to understand not only the main transboundary issue over the Teesta, but also domestic problems in Sikkim and northern West Bengal. The role of domestic politics in shaping bilateral relations on the Teesta has been analysed through the lens of Putnam's two-level game theory. The solutions provided are realistic and political in nature, but with the intention to promote environmental sustainability of the Teesta river basin, and efficient use and equitable allocation of its resources.

The paper has evolved through the following stages of geopolitical reasoning –

- a) Identification of the conflict and delineating its geographical space.
- b) Identification of major parties, their positions, intentions and interests.
- c) Analysis of the geopolitical factors related to the problem.
- d) Identifying the opportunities and constraints provided by these geopolitical factors to the major parties involved in the conflict.
- e) Formulating solutions that are pragmatic as well as promoting holistic conservation and development of the Teesta River Basin.

The paper is divided into seven parts. The first part gives a comprehensive view of the Teesta basin and its historic, geographic, demographic and economic features. The second part deals extensively with the conflicts in the Teesta basin. It is further divided into two sub-parts; the first gives a detailed account of the transboundary issue over the Teesta agreement and positions of parties in the conflict, and the second part analyses domestic conflicts on both sides of the border, namely in Sikkim, Gorkhaland and potentially in Rangpur. The third part of the paper presents collectively the case of the local communities across the Teesta basin. The fourth and fifth parts speak of two crucial aspects, namely groundwater and climate change, which have not been addressed in the overall Teesta issue. The sixth part analysis the position and impact of domestic conflicts on the bilateral relations over the Teesta. The seventh part provides a summary with pointed conclusions, and lists out probable solutions and measures from the point of view of each of the major parties involved in the Teesta dispute.

A. INTRODUCTION

The Teesta river originates at Tso Lamo, India and flows through the states of Sikkim and West Bengal in India and the Rangpur division in Bangladesh before pouring into the Brahmaputra river at Chilmari, Bangladesh. Her total length is 414 kilometres with an average annual flow of 60 billion cubic metres (BCM) of water – roughly the amount of water carried by 24 million Olympic level swimming tanks. Over 30 million people live in the Teesta river basin and are dependent on the river for drinking and domestic use, irrigation, industry, domestic needs and cultural and religious activities.

A.1. Nomenclature and History

The Teesta has various versions to her name. In the upper reaches i.e. in Sikkim, the indigenous Lepchas call her ‘Tee-sa-tha’. When she hits the plains, her Sanskrit name is ‘Tri-srota’ which translated literally means ‘three streams’ – Punarbhaba, Atreya and Karatoya – through which the erstwhile Teesta flowed and emptied into the Padma River near Rajbari, Bangladesh (Bhattacharyya A. , 1974) until 1787 when massive floods, most likely caused by an earthquake, led her to shift her course and migrate south-east and empty into the Brahmaputra instead. The Teesta rose to importance as the eastern frontier of the Mughal empire but for most of history, she played second fiddle to the Karatoya River, her easternmost stream, which is mentioned in ancient texts such as the Puranas, Mahabharata, Ramacharitmanas and Chinese traveller Hsuan Tsang’s writings. The Karatoya, once known to be “impassable” in the rainy season (Bhattacharyya A. , 1974) gradually dried up after the Teesta changed course in 1787 and is now reduced to a small stream in Bangladesh.

A.2. The River

Among the 54 rivers shared by India and Bangladesh, Teesta is the fourth largest. The total area of the Teesta river basin is 12,159 km² i.e. roughly thrice the size of the Indian state of Goa, with 2,004 km² or about 17% of it in Bangladesh and the rest in India. Within India, 6930 km² or 86% of the basin lies in Sikkim; in fact, it drains almost the entire state. The flow of the river is highly variable. At the Dalia barrage²⁹⁴ in Bangladesh, the average maximum flow of the Teesta has been recorded to be as high as 7900 m³/s while the average minimum flow has been recorded to be as low as 283 m³/s. Further damming and control of the river has reduced the flow to 28 or even 14 m³/s, especially in times of drought (Mondal & Islam, 2017). The average annual flow of the Teesta is about 60 BCM. The seasonal variation rate of the Teesta is about 1:10, i.e. 90% of her water, roughly 54 BCM, flows in the rainy season from June to September. This means that the flow through the rest of the year is a mere 6 BCM. It is this phenomenon – reduction of Teesta flow during lean season – which is the bone of contention between India and Bangladesh.

The Teesta flows through three states/divisions of two countries, namely the states of Sikkim and West Bengal of India and the Rangpur division of Bangladesh. The Tso Lamo lake, located 5280 metres above sea level (masl), is the origin of the Teesta river, which is fed by the Teesta Khangse glacier descending from the Pahaunri peak located on the India-China border in North Sikkim. The river first flows as a small stream named Lachen Chu up to Chungthang where it joins Lachung Chu and takes the name Teesta.

Figure 86: Total Area of the Teesta River Basin

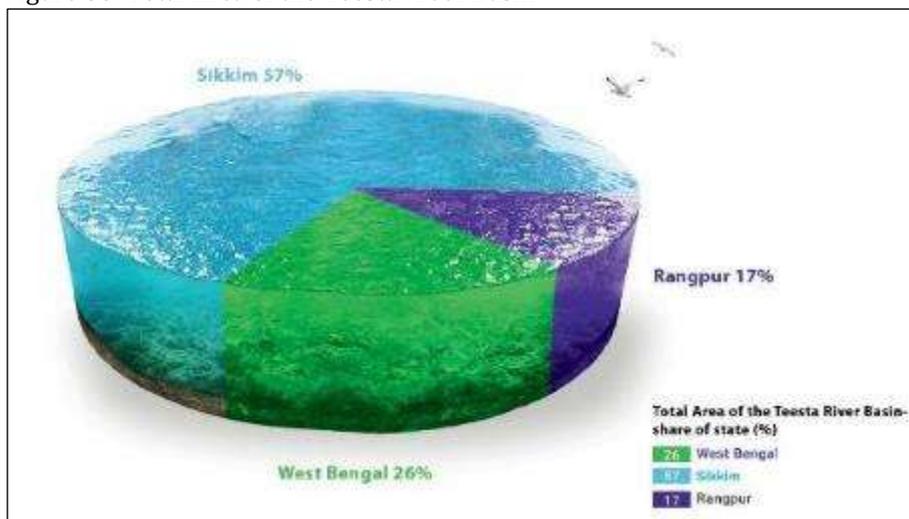

Figure 87: Total Length of the Teesta River

294 A barrage is a type of low-head, diversion dam which consists of a number of large gates that can be opened or closed to control the amount of water passing through. (From Wikipedia)

A.2.1. India

A.2.1.1. Sikkim

The Teesta cuts vertically through Sikkim and drains almost the entire state, flowing fast and furiously for 151 kms through deep gorges and narrow valleys. In just 100 kilometres, she descends from 5280 metres above sea level (masl) to 213 masl, a steep drop considered favourable for hydropower development. As she travels, she is fed by innumerable rivulets and tributaries, and briefly, she forms the border between West Bengal and Sikkim before entering West Bengal near Kalimpong.

A.2.1.2. West Bengal (northern region)

The Teesta flows as the Sikkim-West Bengal border and then through West Bengal, primarily through the northern districts of Darjeeling, Kalimpong, Jalpaiguri and Cooch Behar. She hits the plains at the Coronation Bridge at Sevoke, about 22 kms from the town of Siliguri and transforms from the turbulent, narrow river of the mountains to a slow, wide, braided²⁹⁵ river of the plains. After flowing for 142 kms, it enters Bangladesh near the town of Mekhliganj.

A.2.2. Bangladesh

A.2.2.1. Rangpur

In Bangladesh, the Teesta flows through the districts of Gaibandha, Kurigram, Lalmonirhat, Nilphamari, and Rangpur, all located in the Rangpur division, for 121 kms before joining the Brahmaputra near the town of Chilmari. Here, the river's braided course is further widened and varies from 300 to 550 m in width (Islam M. F., 2016).

A.3. Dams and Barrages on the Teesta River

The Teesta is a heavily dammed river. In its course of 414 kms, about 25 dams have been proposed or built, while 16 have been cancelled for various reasons. Most of these dams, with a total installed capacity of 4336 MW are planned/located in Sikkim.

Table 1: List of Dams in Sikkim and their Status²⁹⁶

Sr. No.	Name of Project	Installed Capacity MW	Latest Status
1	Teesta I (Teesta Stage I HEP)	280	MOU/IA cancelled as these areas fell within the vicinity of Kangchendzonga National Park
2	Teesta II (Teesta Stage II HEP)	330	MOU/IA cancelled due to non-performance of the developer.
3	Teesta III (Teesta Stage III HEP)	1200	Commissioned
4	Teesta IV (Teesta Stage IV HEP)	520	Major works still not started
5	Teesta V (Teesta Stage V HEP)	510	Project Commissioned
6	Teesta VI (Teesta Stage VI HEP)	500	Under construction (facing financial problems)
7	Lachen HEP	210	-
8	Panan HEP	300	Pre-construction works started
9	Rangyong HEP	117	Projects cancelled/not taken up as these areas fell within Dzongu area and in the vicinity of Kangchendzonga National Park.
10	Rongnichu HEP	96	Under construction
11	Sada Mangder HEP	71	MOU/IA terminated as no activities started at site.
12	Chuzachen HEP	99	Project Commissioned
13	Bhasmey HEP	51	Engineering and most items completed
14	Rolep	36	MOU/IA cancelled due to non-performance of the developer.
15	Chakhungchu	50	MOU/IA cancelled due to non-performance of the developer.

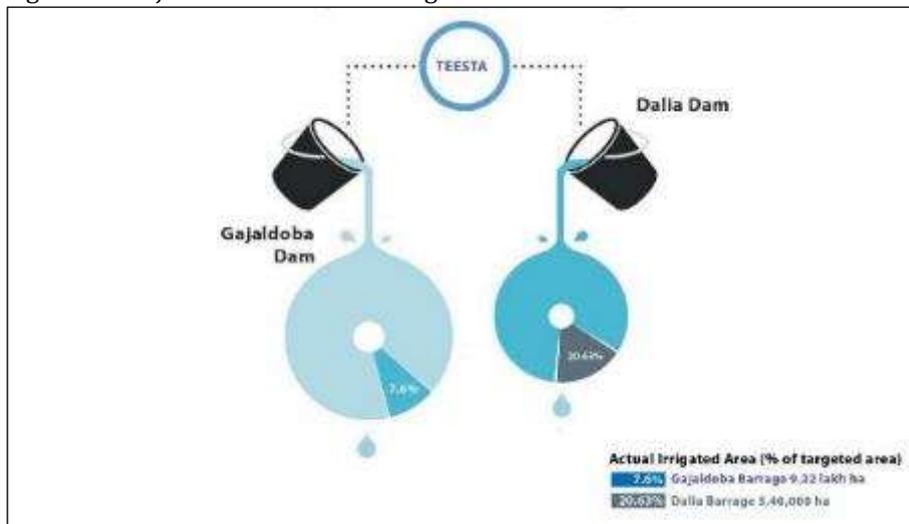

²⁹⁵ Braided Rivers exhibit numerous channels that split off and re-join each other to give a braided appearance. They typically carry fairly coarse-grained sediment down a fairly steep gradient. Additionally, the water discharge tends to be highly variable. Consequently, braided rivers usually exist near mountainous regions, especially those with glaciers (Braided Rivers, n.d.).

²⁹⁶ Obtained from Mr. Samir Mehta, International Rivers, Mumbai on 18-7-2017 and Energy and Power Department, Govt. of Sikkim.

16	Ralong	40	MOU/IA cancelled due to non-performance of the developer.
17	Rangit II HEP	66	Under construction since 2005 (facing financial problems)
18	Rangit IV HEP	120	Under construction since 2005 (facing financial problems)
19	Dikchu HEP	96	Under construction since 2006
20	Jorethang Loop (HEP)	96	Commissioned
21	Lingza	120	Projects cancelled/not taken up as these areas fell within Dzongu area and in the vicinity of Kangchendzonga National Park.
22	Thankgchi	40	-
23	Bimkyong HEP	99	Revised timeline awarded
24	Bop HEP	99	Revised timeline awarded
25	Ting Ting HEP	99	Project cancelled vide Govt. Notification No. 12/Home/2012 as milestones as per MOU not achieved.
26	Rateychu Bakchachu	40	LOI Issued
27	Tashiding HEP	97	98% completed
28	Lachung HEP	99	Revised timeline awarded
29	Lethang HEP	96	Project not granted clearance by National Wild Life Board, Gol. Project cancelled vide Notification No. 12/Home/2012.
30	Suntaleytar HEP	30	MOU/IA cancelled due to non-performance of the developer.
31	Rangit III HEP	60	Project Commissioned
32	Kalez Khola-I HEP	27.5	MOU/IA cancelled due to non-performance of the developer.
33	Kalez Khola-II HEP	60	MOU/IA cancelled due to non-performance of the developer.
34	Rechu HEP	26	-
35	Rahikyong HEP	25	Yet to start
36	Rukel HEP	33	Projects cancelled/not taken up as these areas fell within Dzongu area and in the vicinity of Kangchendzonga National Park.
37	Ringpi HEP	30	Projects cancelled/not taken up as these areas fell within Dzongu area and in the vicinity of Kangchendzonga National Park.
38	Rathangchu HEP	320	Project scraped due to religious sentiments.

After she hits the plains at Sevoke, the two major structures on the Teesta are the Gajaldoba barrage in India and the Dalia barrage in Bangladesh. Each barrage is part of multi-purpose projects (and each of the multi-purpose projects is named the Teesta Barrage Project or TBP) which are supposed to address irrigation and power needs in six districts of North Bengal and seven districts of Rangpur division in India and Bangladesh respectively. Bangladesh had begun the construction of the Dalia barrage before India commenced work on the Gajaldoba barrage. However, both were completed almost at the same time.

Figure 88: Gajaldoba and Dalia Barrages on the Teesta

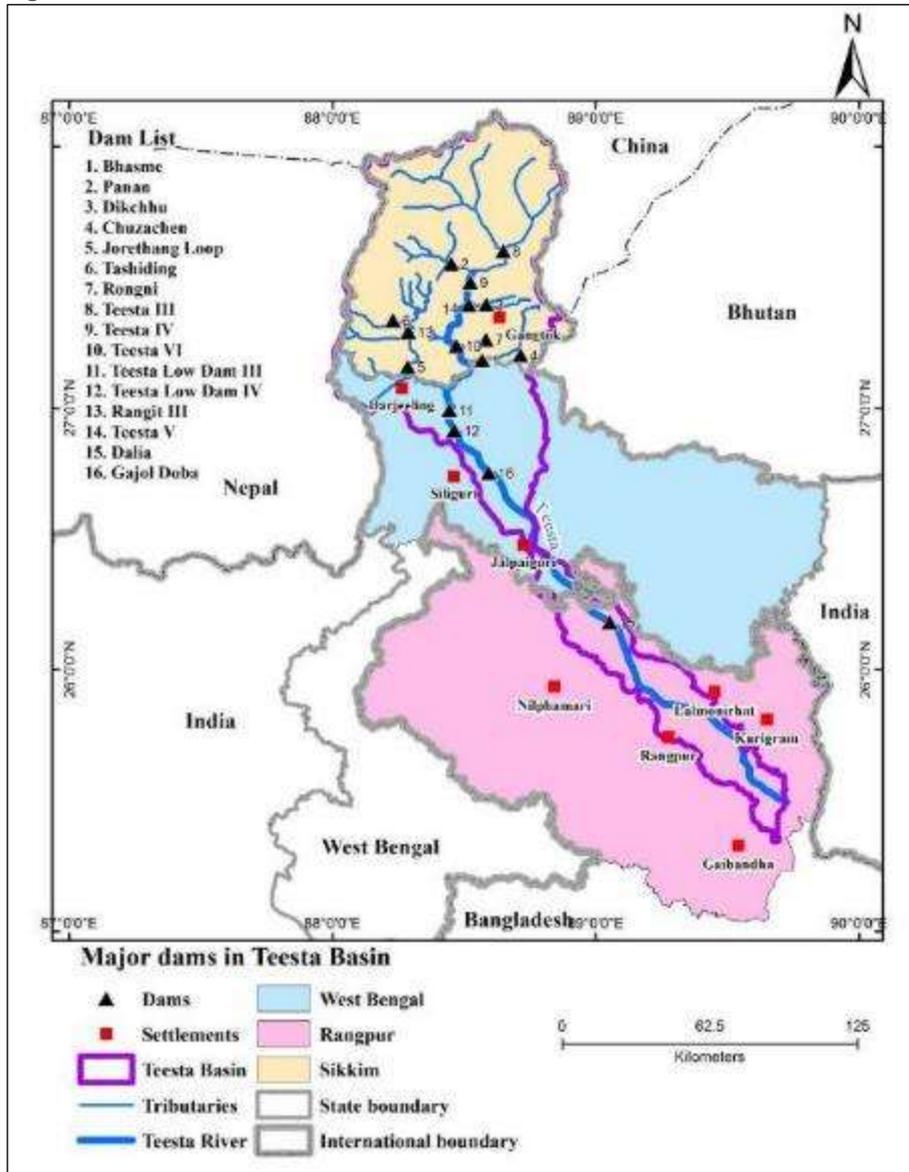

Dalia Barrage - The Dalia barrage is built in Lalmonirhat district about 16 kms south of the Indo-Bangladeshi border and is a gravity irrigation project. It is part of the Teesta Barrage Project of Bangladesh with a total target irrigated area of 5,40,000 hectares (Strategic Foresight Group, 2013), an area almost twice the size of Hong Kong. The total cost of the project is estimated to be Rs. 1,400 crores (roughly USD 220 million). Work on the project started in 1960 and Phase I was completed in 1990, which has been able to provide irrigation to about 1/5th i.e. 111,406 hectares of land.

Gajaldoba Barrage - The Gajaldoba barrage is built in Jalpaiguri district about 66 kms north of the Indo-Bangladeshi border, with a target irrigated area of 92268 hectares. It is part of Teesta Barrage project started in 1976 at a cost of Rs 69.7 crore with a target of irrigating 9.22 lakh hectares and generating 67.5 MW of hydropower in North Bengal. The Gajaldoba Barrage was completed in 1990. By 2011, after spending Rs 1,200 crores (roughly USD 185 million), the project has been able to provide irrigation water to only 66,000 hectares (less than 8%) of land and produce 20 MW of electricity (Kumar, 2013). Two canals drawn out from the Gajaldoba transfer Teesta’s water to two other river basins in the region; one canal flows west to the Mahananda River and the other flows east to Jaldhaka River. After a few years of operation, in 1996, Gajaldoba started drawing and storing excessive water from the Teesta, and the trend of steep reductions in flow every lean season began to be recorded at Dalia. Gajaldoba’s upstream location, its increasing drawing and storage of

Teesta water, and the lack of an agreement on sharing the Teesta waters have rendered the Dalia barrage and Bangladesh's TBP practically useless.

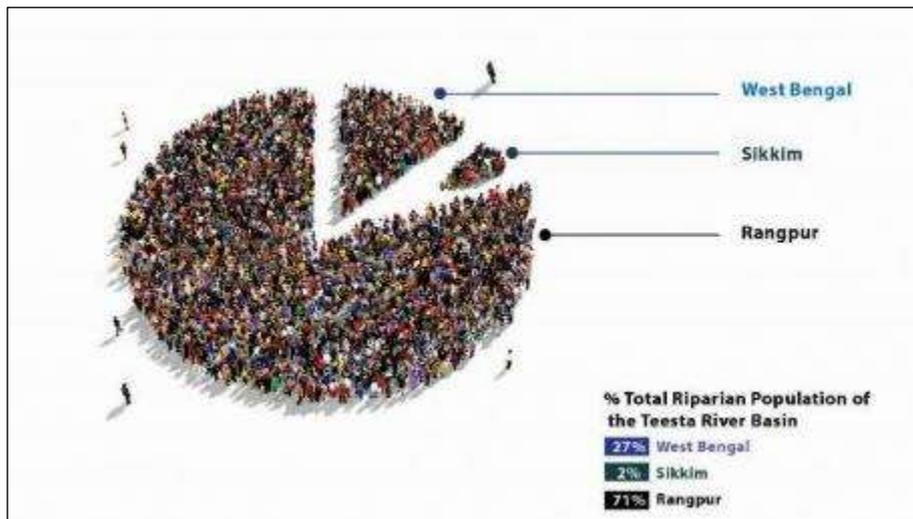

Figure 89: Dams in the Teesta River Basin

A.4. Demography

The Teesta River Basin is densely populated. It is home to around 30 million people – which is half the size of Italy's population – out of which roughly 2% are located in Sikkim, 27% are located in North Bengal and the rest 71% are located in North Bangladesh. It must be noted that the actual number of people living in the Teesta basin in Bangladesh is 9.5 million, but more than 21 million people in the country are dependent directly or indirectly on the river for livelihood.

Figure 90: Population of Teesta River Basin

Out of the 30 million people, 23.4 million or 78% of the population stays in rural areas. West Bengal alone is home to 53% of the rural population of the entire Teesta basin. The rural population is characterised by low level of economic activity, poverty, malnutrition, illiteracy and unemployment and an overall low Human Development Index (HDI) score on both sides of the border. The rural population of the Teesta basin is highly dependent on the river for survival and experiences increasing vulnerability to climate change effects in the region and especially on the Teesta.

Figure 91: Urban-rural profile of Teesta Basin

The cultural profile of the Teesta basin is diverse. Spanning from North Sikkim to North Bangladesh, the basin is home to several tribes, religious groups and communities, both native and migrant. Within a span of 12,000-odd km², the basin hosts almost all major religions, numerous ethnicities, and many communities which have stayed in the region for as long as a few centuries and as short as a few decades. Bengali is the dominant language in the basin due to the sheer size of Bengali-speaking population, but along with it, Nepali, Hindi, English, Tibetan and tribal languages such as Lepcha, Rajbanshi, Bodo, Santali etc. are spoken as well.

A.4.1. India

A.4.1.1. Sikkim

The three major communities of Sikkim are the Lepchas, Bhutias and Nepalis. The Nepalis are further split into ethnic groups such as Limbus/Tsongs, Mangars, Kiratis, Gorkhas etc. Buddhism is the dominant religion in Sikkim while many Nepali communities practice Hinduism. Since the arrival of Western missionaries, some Lepchas have converted to Christianity. Sikhism also has a presence in Sikkim in the form of two gurudwaras, one located at Chungthang and the other on the banks of the Gurudongmar Lake.

A.4.1.2. West Bengal (northern region)

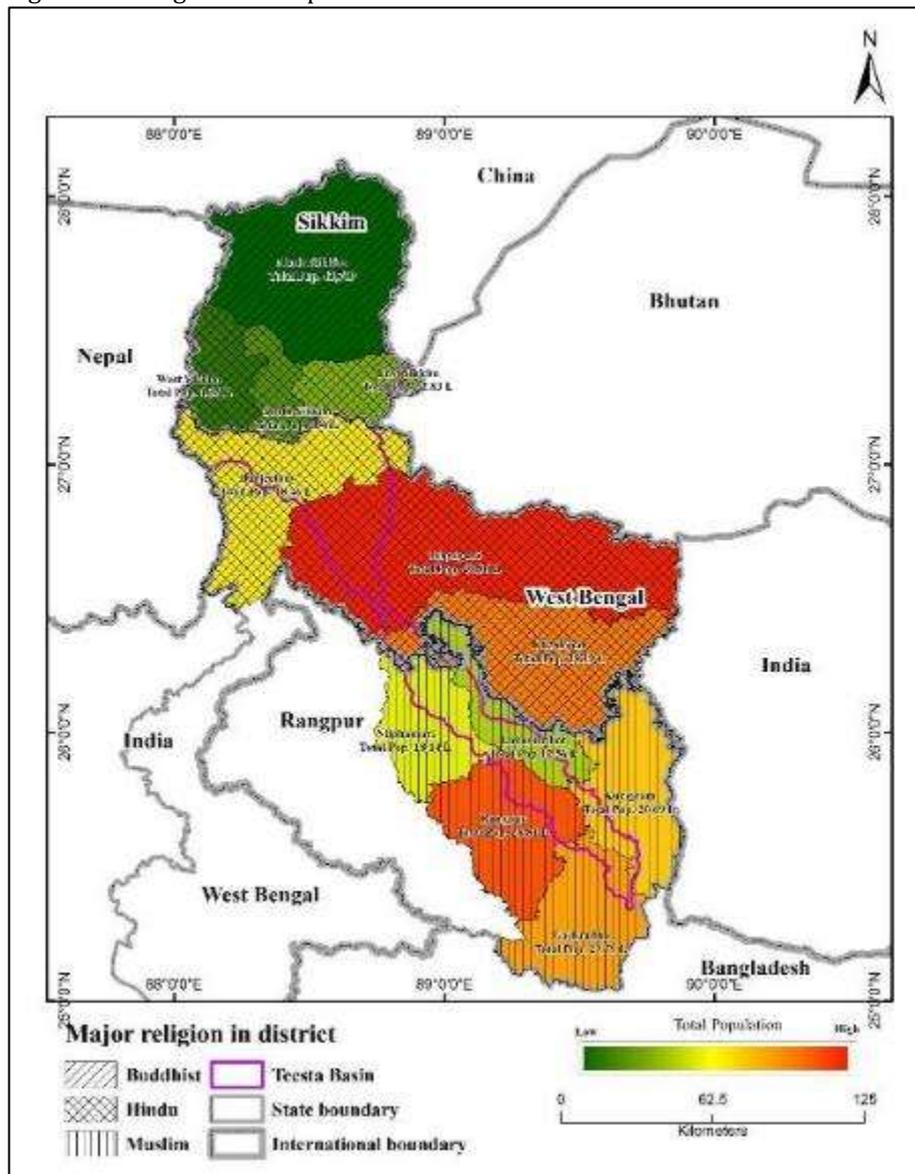

North Bengal is a mixture of ethnic Bengalis, tribal communities such as Rajbanshis, Mech, Rabha etc., Gorkhas and other Nepali communities in the Darjeeling Hills, and business communities such as Marwadis based predominantly in urban areas of Siliguri and Jalpaiguri. After Partition in 1947 and during the Liberation War of 1971, many Bengali Hindus fled East Pakistan and then Bangladesh and settled in North Bengal. Hinduism is predominant in North Bengal with pockets of animism, certain tribal religions and Islam. Buddhist communities are based in the Darjeeling Hills.

A.4.2. Bangladesh

A.4.2.1. Rangpur Division

While most of the population of the Rangpur division is Bengali, it also includes small tribal communities such as the Rajbanshis, Santhals, Oraons, Mal Paharis, Mundas, Malos etc. (Dhamai, 2014). Islam is the dominant religion of the region followed by a minority Hindu population, with pockets of Buddhism, tantric Buddhism, animism and other tribal religions.

Figure 92: Religion and Population Distribution in the Teesta River Basin

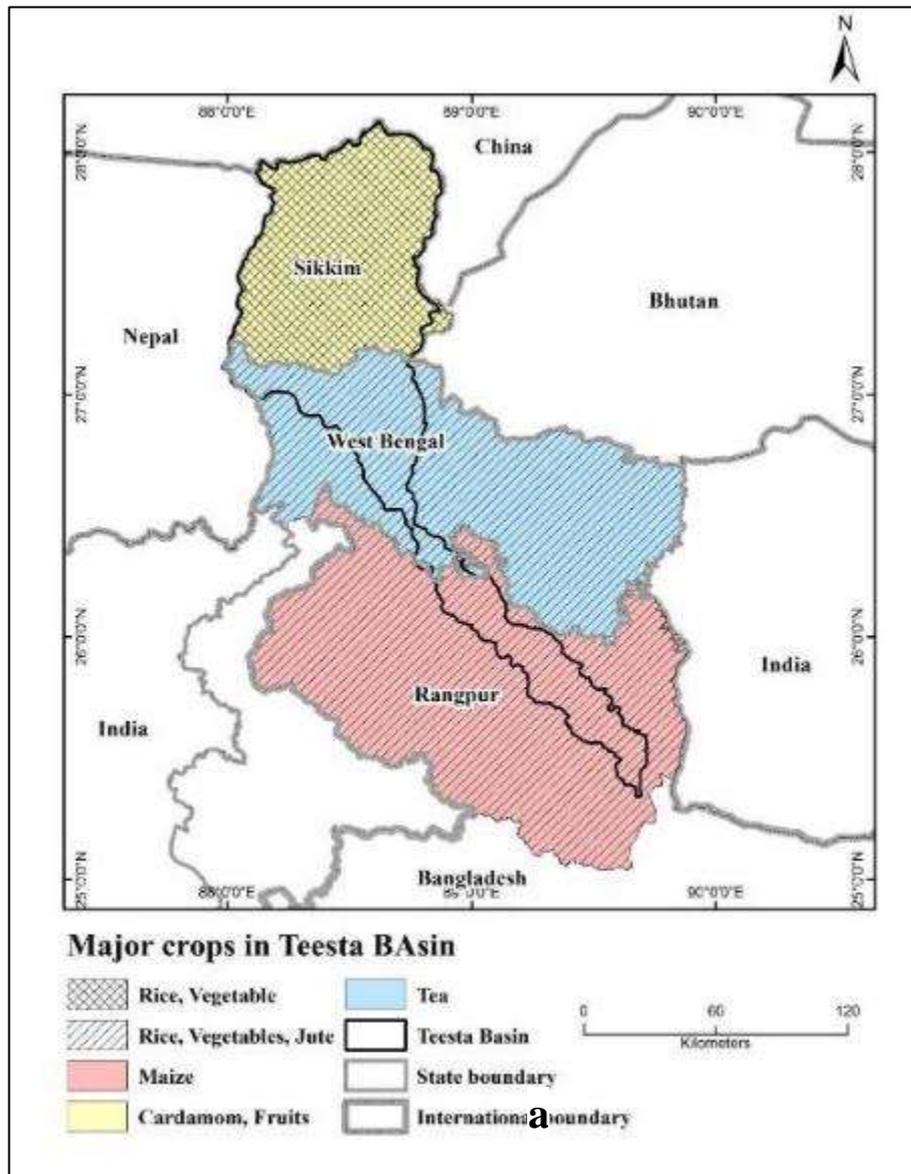

A.5. Economy

Agriculture is the single most major economic sector in the basin which employs more than 90% of its rural population. It is neither heavily mechanised nor commercialised, and subsistence farming is a regular phenomenon, especially in remote and tribal areas. The average cropping intensity²⁹⁷ is high across central and lower Teesta basin, ranging between 1.6 crops per year on the Indian side to almost 2 crops per year on the Bangladeshi side. Irrigation facilities, availability of fertilisers, pesticides and HYV seeds, use of tractors and pumping sets etc. have led to increasing cropping intensity and productivity, but have also induced a steady decline in land fertility over the years.

Figure 93: Major Crops in the Teesta River Basin

²⁹⁷ Average cropping intensity refers to the number of crops raised in the same field during one agricultural year.

In Sikkim, agriculture contributes 8% of the state GDP and employs 69% of the total workforce (Government of Sikkim, 2011). Sikkim is famous as the highest cardamom producer in India. Along with it, the state also produces ginger, oranges, potatoes, flowers, vegetables, cereals and pulses. In North Bengal, agriculture contributes 23.6% of the state GDP and employs about 43% of the total workforce (Planning Commission, GoI, 2010). Rice, jute, potato, maize and tea are the major crops grown in North Bengal. Out of these, tea is both a major cash crop as well as a famous product of the region. Half of the agricultural workforce of North Bengal is employed on various tea estates in the Darjeeling Hills. In North Bangladesh, agriculture contributes 22.25% of the GDP of the region and employs roughly 45% (Asian Development Bank, 2016) of the total workforce²⁹⁸. The major crops on the Bangladeshi side are largely the same as those of North Bengal. Here, tea is replaced by tobacco as the major cash crop. Rangpur district has been traditionally famous for its tobacco production. However, over the years due to health awareness campaigns and changes in crop patterns in the region driven by local, regional and international NGOs, the production of tobacco has dropped steeply and has been replaced with an upsurge in maize production.

There is ample scope for fisheries in the Teesta basin. In rural Sikkim, fisheries are an important source of sustenance, but there is very little commercial value attached to the activity. In North Bengal, fishing is mostly inland but experiences very little development in terms of technology and infrastructure; despite favourable conditions and the presence of a healthy market for fisheries, 40% of the fish consumed in the area is brought from Andhra Pradesh. Fisheries are still an important source of livelihood in the Rangpur division of Bangladesh with more than 90% of the rural folk resorting to fisheries as an alternate source of sustenance as well as livelihood. The village of Tista Bazar in Lalmonirhat district was once famous for its fish market; fishermen from all over the central and lower Teesta basin came there to sell their catch. However, there has been a steep decline in fisheries in Rangpur division due to the reduced and irregular flow of the Teesta and the drying up of her river bed in lean season on an annual basis.

²⁹⁸ These are national figures of Bangladesh. The dependence on agriculture for revenue and employment is higher in North Bangladesh than in other regions of the country, hence these numbers can be taken as a conservative estimate.

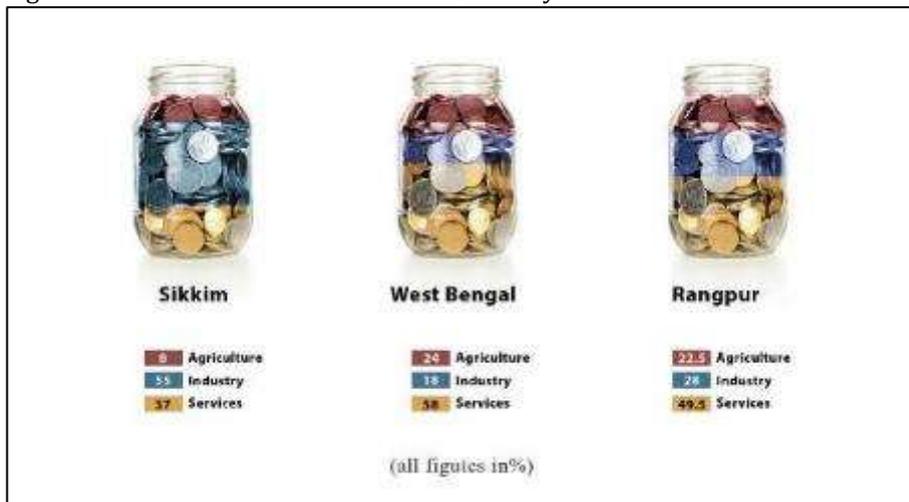

There is no significant industry in the Teesta river basin. In comparison to the state of West Bengal and the Rangpur division, Sikkim is relatively more industrialised; while industry contributes about 18% and 28% to the GDPs of West Bengal and Rangpur division respectively, the proportion of industry’s contribution to Sikkim’s GDP is 55%. However, industry in Sikkim is medium and small scale – largely distilleries, agricultural products processing units and handicrafts – and accounts for barely 0.2% of India’s total GDP (Planning Commission of India, 2014). Most of West Bengal’s industry is located in its southern and western parts; very few industrial units are located in North Bengal. Similar conditions are seen in northern Bangladesh where most of the development in industry, transport and communications is concentrated in the Dhaka division, with the Rangpur division lagging behind in almost all aspects of industrial growth and development (Islam & Noman, 2015).

The service sector is also not very developed, but it contributes the most to the GDP of the region: 37% to Sikkim’s GDP, 58% to West Bengal’s GDP and 49.33% to North Bangladesh’s GDP²⁹⁹. Navigation on the Teesta river was once an important economic activity, but due to dwindling Teesta flows, large parts of the river remain dry for many months each year, whereas excessive swelling of the river in the rainy season makes her a risky mode of travel. Together, both situations have reduced the scope for navigational activities on the Teesta.

Tourism is a prominent sub-sector driving the growth and income of the service sector in the Teesta basin, especially in the upper and middle reaches of the Teesta river. Sikkim is a major tourist hub; an average of 6 lakh domestic and foreign tourists (Department of Tourism and Civil Aviation, Govt. of Sikkim, 2014) visit the tiny state every year. In North Bengal, tourism flourishes in the Darjeeling Hills and Dooars region which also cater to a similar number of tourists on an annual basis (Statistics of Tourist Arrival in Gorkhaland Territorial Administration, n.d.). Melli, a town on the West Bengal-Sikkim border is a famous tourist spot for white water rafting on the Teesta river. Bangladesh as a whole also receives 5 to 6 lakhs of tourists each year, but most of them travel to the Sundarbans and beaches in the south and a negligible proportion trickles to the north. With its archaeological sites, museums, architecture and rural beauty, North Bangladesh has ample scope for increasing its tourism.

On both sides of the border, the natural beauty of the Teesta and her ecosystem are highly underrated. Apart from white water rafting at Melli, the Teesta’s potential for tourism, by and large, remains unutilised. This is also partly because of the river’s deteriorating conditions due to drying up, excessive sand mining and contamination. If sand mining is controlled, quality levels of Teesta’s waters improve, and adequate environmental flows are guaranteed throughout the year, the Teesta river can provide a major boost to tourism revenues on both sides of the border.

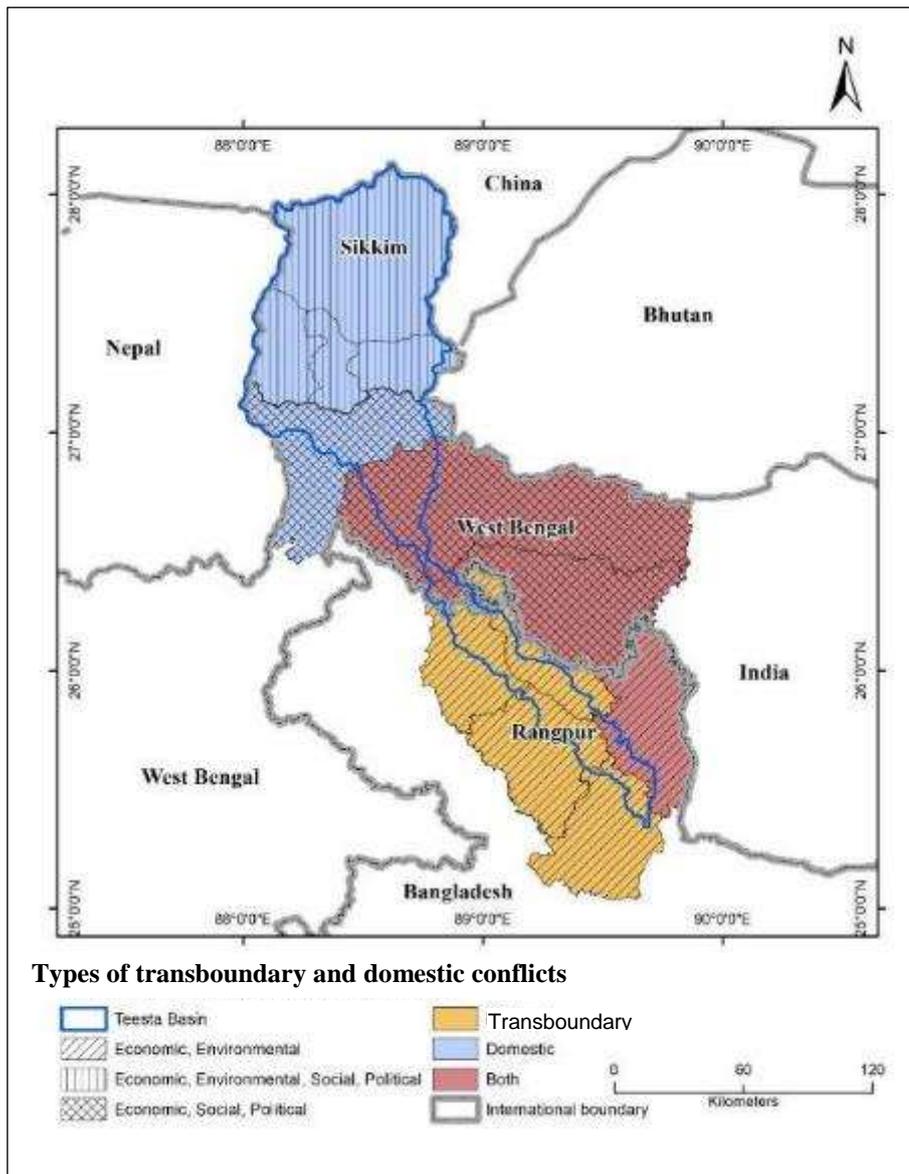

Figure 94: Sectoral Contribution to the Economy of the Teesta River Basin

B. CONFLICTS IN THE TEESTA BASIN

Figure 95: Transboundary and Domestic Conflicts in the Teesta River Basin

299 This is the national figure for Bangladesh. The service sector is largely concentrated in the Dhaka division and other divisions in southern Bangladesh, whereas it is very less developed in North Bangladesh. The contribution of the service sector in Rangpur division’s GDP is lesser than the national average of 49.33%.

B.1. Transboundary Conflict

B.1.1. Signing the Teesta Treaty (India, Bangladesh)

B.1.1.1. The Issue

The Teesta is a perennial, rain-and-snow-fed river characterised by extreme variability in her flows throughout the year. Over 90% of her flow occurs in the rainy season from June to September while the rest 10% occurs in the remaining eight months. As a lower riparian, Bangladesh is completely dependent on India, the upper riparian, for keeping minimum flows in the Teesta river. India has been unilaterally constructing a series of dams up north which have reduced the flows to as little as 14 m³/s during times of drought, greatly hurting the livelihoods of thousands of farmers, fishermen and boatmen downstream in Bangladesh. Conversely, during monsoon season, Indian dams on the Teesta release excess water, causing heavy floods and again disrupting thousands of livelihoods in in Bangladesh. The intensity of damage is particularly more acute in Bangladesh as the size of population and economy dependent on the Teesta in Bangladesh outstrips its counterpart upstream in India. Bangladesh demands a fair share of the Teesta waters in the lean season and minimum guaranteed flows throughout the year formalised in a treaty signed and ratified by the governments of both the countries. Negotiations on the Teesta have been going on for decades and a draft agreement has been prepared, however, the Teesta deal between New Delhi and Dhaka fell through in 2011, and no concrete progress has been made since.

B.1.1.1.1. History of the Teesta Dispute: From Partition to the Creation of Bangladesh

Up until the Partition in 1947, since the Teesta flowed as a single unit through the then princely state of Sikkim and the province of Bengal, both under British India, there was no question of transboundary governance and sharing. During Partition, the All India Muslim League was the first to hint at the looming dispute by asking for Jalpaiguri and Darjeeling districts to be incorporated in East Pakistan on the ground that they were the catchment areas of the Teesta. The rationale was that with the entire middle and lower Teesta basin in one country i.e. East Pakistan, they would be in a better position

to use the erstwhile and future hydropower projects. However, mainly due to their non-Muslim composition, Darjeeling and Jalpaiguri were handed over to India (Ranjan, 2017).

After Partition, Sikkim continued to be a protectorate of India right up to its merger with the latter as a state in 1975. During the 1950s and 1960s, Indian and East Pakistani officials began talks over damming and sharing the Teesta. At the same time, India and Pakistan were negotiating agreements on the Ganga and Indus rivers due to which the Teesta issue took a backseat. After signing the Indus Treaty in 1960, the two countries turned their focus to negotiations on the Ganga, and the Teesta issue jumped up the ladder. East Pakistan outlined a plan to build a barrage on their side of the Teesta which India opposed. Suggesting 'other rivers' for fulfilling India's irrigation and other needs, East Pakistan decided to go ahead with the plan (Islam M. F., 2016); however, it was only in 1990 that a barrage was completed on the Teesta in what was now Bangladesh.

B.1.1.1.2. The Indo-Bangladesh Joint Rivers Commission (JRC)

After the creation of Bangladesh in 1971, the two countries resumed talks over sharing the Ganga, Teesta and other 52 rivers shared by them. In 1972, India and Bangladesh established the Indo-Bangladesh Joint Rivers Commission (JRC) with the intention of "working together in harnessing the rivers common to both the countries for the benefit of the peoples of the two countries", but originally focused on the joint management of the Ganga river basin. As per Article 4 of the Statute of the JRC, the Commission has the following functions –

"(a) to maintain liaison between the participating countries in order to ensure the most effective joint efforts in maximising the benefits from common river systems to both the countries,

(b) to formulate flood control works and to recommend implementation of joint projects,

(c) to formulate detailed proposals on advance flood warnings, flood forecasting and cyclone warnings,

(d) to study flood control and irrigation projects so that the water resources of the region can be utilized on an equitable basis for the mutual benefit of the peoples of the two countries, and

(e) to formulate proposals for carrying out coordinated research on problem of flood control affecting both the countries."

– as well as any other functions their governments mutually agree upon and direct them to do.

However, the JRC could do little in its first 25 years of existence. This was partly because the Ganga Treaty i.e. its most significant task, was given exclusive attention till it was finally signed in 1996. The general meetings of the JRC took place once every two years up until 2010, those of the Standing Committee took place until 2005, and technical level meetings related to water sharing issues began only in 2009. Apart from these meetings, there have been occasional and irregular meetings for flood management, joint scientific studies, dam and site visits, and reaching out to other co-riparians such as Nepal, Bhutan and China (Joint Rivers Commission, Bangladesh). The scenario was not very different for the Teesta. Talks on the Teesta played second fiddle to the negotiations to the Ganga Treaty. After 12 long years in 1983, the governments of India and Bangladesh signed an ad-hoc agreement during the 25th meeting of the JRC to share the waters of the Teesta in the following manner: 39% of the total flow of the river for India, 36% for Bangladesh, and the remaining 25% unallocated, to be decided on the basis of scientific studies carried out in the future. For the next 14 years, no serious development took place regarding formalising the agreement; in the face of the Ganga negotiations, other common rivers were not given priority. It was only after the signing of the Ganga Treaty in 1996 that the Teesta river came into focus.

According to the JRC Bangladesh website, the first meeting of Joint Committee of Experts (JCE) on sharing the Teesta waters was held in August 1997. Since then, seven JCE meetings have been held. Their last meeting was in 2004, while the Joint Technical Group (JTG) on sharing the Teesta met for the first time in the same year. The JTG held four meetings in all; three in 2004 and the fourth and the last one in 2005, after which there was a lull of two years.

During this lull, Bangladesh and China held their first meeting on cooperation over water resources in Beijing in 2006. China is the upstream riparian of the Brahmaputra which is the biggest river of Bangladesh. The two countries signed a Memorandum of Understanding (MoU) to cooperate on various aspects of technology, design and research on the watercourses of the Brahmaputra. It could have been that this alliance alarmed India and spurred it into action; following this development, the Indo-Bangladesh JRC held two technical level meetings regarding the Teesta in 2007 and 2008. During the same time, in 2007, the Govt. of West Bengal (henceforth, GoWB) declared that it could concede at most 25% of the water available at Gajaldoba barrage for both, Bangladesh as well as the river ecosystem itself. Bangladesh vehemently opposed West Bengal's stand and since then, the dispute over equitable sharing of the Teesta intensified.

The Government of India (henceforth, GoI), not wanting to antagonise Dhaka and Kolkata, suggested modifying the ad-hoc agreement of 1983 and dividing the 25% between the two countries so that India and Bangladesh get 52% and 48% of the total flow of the Teesta respectively (Rudra, Sharing Water Across Indo-Bangladesh Border, 2017). In an attempt to pacify both the contenders, the GoI completely ignored the health, or rather, the very existence of the Teesta and the survival of her ecosystems. With 100% of the Teesta's waters being used by the two countries, there was no chance of the river and her ecosystems surviving and sustaining her 30-million-strong riparian population. It would also mean a severe setback to fishing, tourism and navigational activities in the river, creating a deep dent in the rural economy of the Teesta basin. Such a proposal was not only short-sighted and narrow-minded, but also self-destructive. Fortunately, it did not materialise. In 2010, the JRC conducted a field visit to the Teesta river and held its 37th meeting in Dhaka with the specific agenda of determining the sharing of Teesta waters and preparing a draft agreement accordingly. During this meeting, the Government of Bangladesh (henceforth, GoB) reiterated an arrangement it had proposed some years ago

specifically for the lean season. This arrangement which allocated 40% of the Teesta's flow to each country and the rest 20% was to be reserved as minimum flows continues to be featured in the draft agreement to this day.

B.1.1.1.3. Failure of the Teesta Negotiations

The then Prime Minister Manmohan Singh was slated to visit Bangladesh with West Bengal Chief Minister Mamata Banerjee in September 2011 and sign this deal with the Bangladeshi Prime Minister Sheikh Hasina, but at the last minute, Banerjee pulled out of the delegation, protesting against changes made in the agreement which she neither approved nor, allegedly, was she informed of. Apparently, Banerjee had agreed to share Teesta waters at a rate of 708 m³/s (against the prevailing 651 m³/s) with Bangladesh. However, the final agreement which was sent to her just before the Dhaka visit allocated a much higher proportion – at an average rate of 935 m³/s up to 1699 m³/s and apparently with no scientific justification, due to which she cancelled her participation (Sahgal & Dasgupta, 2011). As a result, the talks between New Delhi and Dhaka fell through and the agreement was not signed. As Banerjee's Trinamool Congress (TMC) was the single largest ally of the UPA-led coalition government at the centre at that time, the central government had to accept her decision.

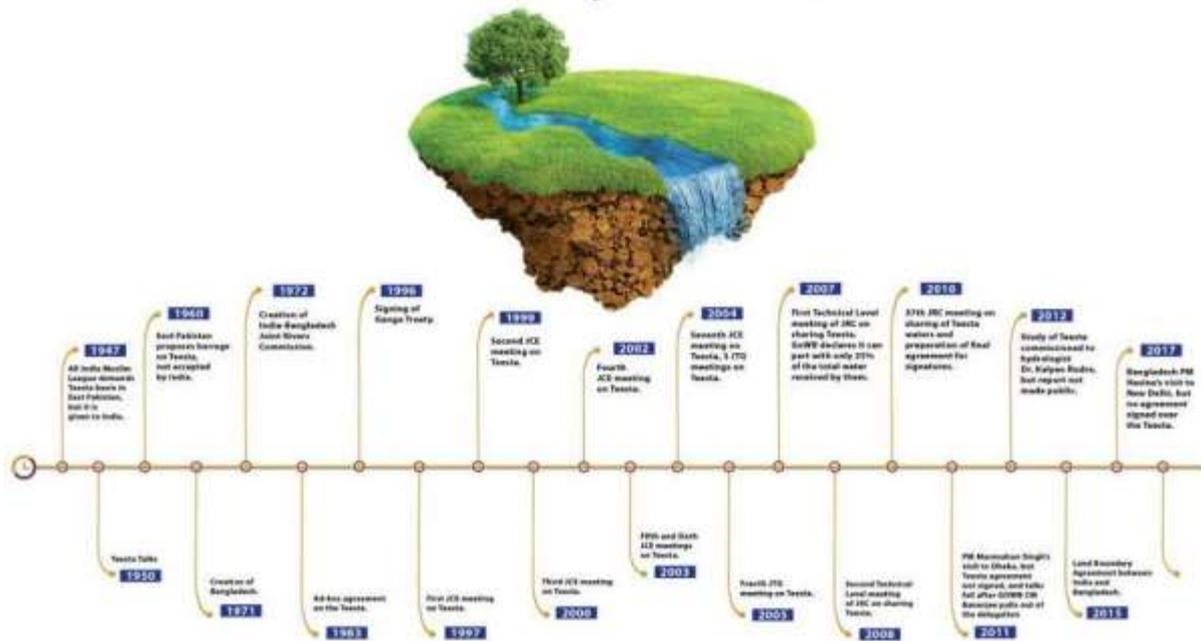

In the same year, the GoWB commissioned a study of the Teesta River under eminent hydrologist Kalyan Rudra who submitted his report in December 2012. This report was never made public and to this day, Rudra is “not authorised by the GoWB to speak on this issue”³⁰⁰. However, Rudra's views on the Teesta issue and his criticism of the entire TBP and the NHPC hydropower projects Teesta Low Dams III and IV, are evident in his paper “Taming the Teesta” (Rudra, 2003). “[S]iltation has been a major problem, with projected capacities decreasing at alarming rates, often before the entire project is completed,” he writes lamenting that “dams that were designed to moderate floods have created floods by releasing excess water at the peak of the monsoon.” Rudra's paper makes pertinent points regarding ecological fragility, economic liabilities, impact on wildlife and tourism, and social consequences of these projects.

In 2014, when the NDA government came into power at the centre, it was no longer dependent on allies to retain power, but getting the Teesta deal signed was still complicated due to political and ideological friction between the centre and the Banerjee-led GoWB. During Prime Minister Modi's historic visit to Dhaka to conclude the land boundary agreement in 2015, Prime Minister Hasina reminded him of “an immediate conclusion” on the Teesta deal. Banerjee had accompanied Modi on this visit, however, she maintained silence on this topic.

There was renewed hope for a Teesta agreement when Hasina visited India in 2017. Hasina and Modi signed 22 MoUs covering defense, education, space technology, nuclear energy, IT, cyber security, trade, R&D, judiciary, shipping, mass media and public health (MEA, GoI, 2017). Modi's support to the agreement and his initiative in breaching the topic increased hopes further, but the agreement continued to remain unsigned as Banerjee steadfastly maintained her opposition to the current nature of the agreement and offered “other river systems” to meet Bangladeshi needs, namely the Torsa, Sankosh and Raidak rivers, all three of which flow down to West Bengal from Bhutan (Ghosal, 2017). Predictably, this suggestion was met with little enthusiasm, and Hasina returned to Bangladesh without a Teesta deal where she was criticised vociferously by her main political rival, the Bangladesh Nationalist Party (BNP) led by Khaleda Zia for giving “unilaterally” while “issues crucial for Bangladesh [...] were not discussed in the visit.” Zia and BNP essentially accused Hasina of failing the people and signing MoUs which would “only increase India's military, political, and geopolitical influence on Bangladesh” and declared that the involvement of Banerjee in the Teesta treaty “undermined the sovereign status of Bangladesh” (Prothom Alo, 2017). Currently, while both GoI and GoB want to sign the agreement, it is the Banerjee-led GoWB which is standing in the way of the finalisation of the Teesta Treaty.

Figure 96: Timeline of the Teesta Dispute

³⁰⁰ As per telephone conversation with Dr. Rudra in April 2017.

B.1.1.2. Positions

B.1.1.2.1. The Government of India (GoI)

The GoI, previously led by the UPA and now the NDA, has shown willingness to sign the Teesta agreement. It is caught between two opposing sides, GoWB and GoB and is trying to balance the situation by offering more engagement, cooperation and aid to Bangladesh in various areas and negotiating with the GoWB simultaneously.

As per the Indian Constitution, water is a state subject, listed as Entry 17 in the State List.³⁰¹ However, entry 56 in the Union List gives the central government exclusive powers to deal with “[r]egulation and development of inter-State rivers and river valleys to the extent to which such regulation and development under the control of the Union is declared by Parliament by law to be expedient in the public interest.” Further, entries 10 and 14 in the Union List place powers regarding foreign affairs and signing of international treaties exclusively with the central government. Hence constitutionally, the central government does not need the consent of a state government while signing an international agreement over a transboundary water body.

Reality though is far different. The UPA was constrained by the fact that Banerjee’s party TMC was their biggest ally in their coalition government at the centre. While there is no such constraint to the NDA government, it is anxious to not aggravate the GoWB with which it already has significant ideological and political differences.

India looks towards Bangladesh as a trusted partner in South Asia, especially in the face of Pakistan and China. Cultural and historical ties with Bangladesh, particularly with Sheikh Hasina, her party Awami League and her government have led to healthy Indo-Bangladeshi relations. New Delhi views Dhaka as a partner in combating terrorism in South Asia, a connector between the North East and the rest of India, and a gateway to East Asia. In order to retain cooperation and friendship with Bangladesh, India cannot afford to ignore their demands, including that of a fair share of Teesta waters.

B.1.1.2.2. The Government of West Bengal (GoWB)

Despite strong cultural and historical ties with Bangladesh and their pro-Muslim appeasement policies, the Banerjee-led GoWB has loudly and clearly voiced opposition to the terms of the Teesta treaty. While Banerjee had consented earlier to a 70:30 arrangement with 70% retained by the Indian side (Das M. , 2015), she has refused to accept the 40:40:20 arrangement as mentioned in the current draft of the treaty. The argument of the GoWB is “to protect the interest of the farmers in the area”. Flows drop drastically in the lean season, partly due to dams upstream in Sikkim holding water in order to generate electricity at peak times (Basu, 2017), and parts of the river are reduced to a trickle. The Teesta is vital for irrigating 1.20 lakh ha of land in five districts of West Bengal – Cooch Behar, Jalpaiguri, South and North Dinajpur, and Darjeeling – which consist of some of the poorest areas of the state and are home to a burgeoning and highly profitable tea industry and the draft treaty in its current form will seriously harm agriculture, particularly the cultivation of Boro rice, in North Bengal (Ranjan, 2017).

However, there is another layer to their reasoning – giving more of the Teesta to Bangladesh can hurt Banerjee and her party TMC electorally. About 30% of the population in these districts (47% in North Dinajpur) is of tribal and minority groups (Das M. , 2015). Also, there is a considerable proportion of Bengali Hindus who have fled East Pakistan during the Partition and then Bangladesh during the Liberation war and settled in North Bengal. The region is also home to sizeable numbers of Marwaris, Nepalis and Gorkhas who have migrated and settled here for trade and employment. Mamata Banerjee and her party TMC are not politically strong in North Bengal which has traditionally been a Leftist stronghold.

301 Article 246 of the Indian Constitution allows the central and state governments of India to make laws on certain subjects which are divided into three lists: List I or the Union List, List II or the State List and List III or the Concurrent List.

In the 2017 municipal elections, the Gorkha Janmukti Morcha (GJM) was a clear winner among Nepalis and Gorkhas, while due to Banerjee's obvious minority appeasement policies, other communities are increasingly distancing themselves from her. Since Banerjee and TMC are looking to consolidate votes in North Bengal, they are in clear opposition of the treaty as it can significantly upset their political prospects in the region.

There are quite a few compelling reasons why the Modi-led GoI, despite constitutional backing and a clear majority for the Bhartiya Janata Party (BJP) at the centre, cannot bulldoze over West Bengal's opposition and sign the Teesta Treaty.

- i. **The Geopolitical Importance of the Chicken's Neck:** West Bengal is a border state and its districts of Jalpaiguri, Darjeeling and Cooch Behar are located in the Siliguri Corridor or more popularly, 'Chicken's Neck', a narrow strip of land connecting the north-eastern states of India with the rest of the country which is important and sensitive on multiple levels. First, it is home to a vital transboundary resource (the Teesta) and shares international borders with three countries, namely Nepal, Bangladesh and Bhutan, with China in proximity. Second, the railway network which passes through this corridor connects to military bases in the northeast and is essential to provide troops with supplies and reinforcements. Third, it is a highly sensitive and socially fragile region: it faces a high incidence of poverty and economic inequality, is home to some of the most backward districts of West Bengal, has seen the birth of the Naxal movement, and now experiences a significant influx of "outsiders" i.e. Nepalis and illegal Bangladeshi migrants. Fourth, the region is impacted by climate change and has been grappling with environmental disasters such as extreme floods and droughts, which directly affect the Teesta River (Oak, 2017).
- ii. **Friction between GoI and GoWB:** The Teesta issue notwithstanding, the current GoI and the GoWB do not see eye-to-eye on many important issues within the country. There is significant political and ideological friction between the two governments which has manifested itself time and again: Banerjee's stinging criticism of demonetisation of Rs. 500 and Rs. 1000 notes in November 2016 ("biggest disaster") and the Goods and Services Tax (GST) implemented in July 2017 ("great stunt") (PTI, 2017), and the row between her and then Defense Minister Manohar Parrikar over army drills at toll plazas in West Bengal in December 2016 are just two and recent incidences in a series of spats between the two governments. At the same time, West Bengal is an important state in terms of security and geopolitics, it shares international borders with Bhutan, Nepal and Bangladesh and is in the vicinity of China. In terms of economy, and it contributes 40% of the GDP of East and North-East India, and 78% and 82% of the national production of jute and tea respectively (PTI, 2016); strategically, it is located on the trans-regional economic and trade route under the 'Act East' policy of the GoI. For all these reasons, the central government is cautious about any increase in differences and wants to minimise the friction in their relationship.
- iii. **Progress of BJP, current ruling party at the centre:** BJP, the biggest political party in the NDA, has historically had a weak presence in West Bengal and has only recently started making inroads into the state. The policy of selective minority appeasement followed consistently by the Banerjee-led GoWB has drawn the ire of the majority sections of Bengali society, especially those who have fled East Pakistan in 1947 and Bangladesh in 1971. The situation is serious enough for the Kolkata High Court to issue three remonstrations over GoWB's actions "to pamper and appease the minority section of the public at the cost of the majority section without there being any plausible justification" (Merchant, 2017). Multiple bans and curtailments on Hindu festivals and rituals, stipends to Imams and Muezzins and repeated incidents of communal violence across the state, eight of which have taken place in just the last year (Talukdar, 2017), have coupled with economic woes and consequently lowered Banerjee's credibility as a balanced leader working in the interests of all sections of the society. Meanwhile, BJP has steadily cemented for itself the position of a viable option to the TMC; the popular vote for BJP in West Bengal has risen from 17.5% in the 2014 Lok Sabha elections to more than 30% in the 2017 West Bengal municipal elections (Mukerjee, 2017). In such a scenario, BJP is wary of taking unpopular decisions (like giving a bigger share of the Teesta to Bangladesh) that could possibly cause a dent in their progress.

B.1.1.2.3. The Government of Bangladesh (GoB)

The GoB has long maintained the stand that they have not been getting a fair share of the Teesta for years, especially during the lean season, and that the dual problem of consecutive droughts and floods in a year has been aggravated due to dams built unilaterally by India on the Teesta upstream. Bangladeshis are also critical of India's river inter-linking project, and even more so of the diversion of Teesta waters to the Mahananda River in the west. Through the 40:40:20 arrangement, GoB is looking to obtain guaranteed minimum flows during the lean season.

The Teesta is a major river flowing through the Rangpur division, formed in 2010 out of the northern eight districts of the Rajshahi division. Rangpur is the poorest division in Bangladesh. Its poverty headcount rate (HCR) is 42.3% and the extreme poverty HCR is 27.7% - both highest in the country (World Bank; World Food Programme: Bangladesh Bureau of Statistics, 2010). This means that 42.3% of the population of Rangpur division lives in poverty while 27.7% lives in extreme poverty. The Greater Rangpur region is historically known to be drought-prone and was among the worst hit regions during the Great Bengal Famine of 1942-1944 as well as Bangladesh's famine of 1974. The region is particularly vulnerable to seasonal hunger³⁰² which, combined with recurring droughts and floods, has induced large-scale climate change-linked migration and is significantly responsible for illegal cross-border migration from Bangladesh to India. In

³⁰² Seasonal hunger is the recurrence of poverty and food deprivation during a certain period such as the sowing season every agricultural year. In northern Bangladesh, this period falls between September and November.

addition, ecological vulnerability (particularly to frequent floods and river erosion), poor connectivity to urban areas, distance from markets and political neglect have contributed to the poverty and backwardness of the region.

However, at the same time, the Rangpur division is also known as the 'granary' of Bangladesh (Kumar, 2013). Maize, followed by rice, is grown extensively in the Greater Rangpur region. Other crops such as jute, chillies, potatoes and various vegetables are cultivated as well. While most of Bangladesh has a predominantly 'rice economy', the Rangpur division enjoys significant crop diversification (World Bank Group, 2016). Moreover, as contamination of groundwater due to arsenic is affecting agriculture in southern Bangladesh, the onus of maintaining food security is increasing on Rangpur. For a poor country like Bangladesh, food security is paramount, and hence, the waters of the Teesta are more crucial than ever.

While natural conditions and geographical distance from economic centres such as Dhaka and Chittagong are responsible for the backwardness of Rangpur division, years of political neglect, lack of public investment in infrastructure and education, and development of local industries, urban centres and markets are responsible too. The vacuum thus created has been exploited by anti-social elements such as smugglers (Strategic Foresight Group, 2013) and Islamist terrorist outfits such as the Harkat-ul-Jihad-al Islami Bangladesh (HuJI-B) and the Jagrata Muslim Janata Bangladesh (JMJB) to set up their bases and hide-out places (Terrorist and Extremist Groups - Bangladesh, n.d.).

In order to combat the lagging economy, seasonal deprivation and vulnerability, and extremism, the GoB believes that Teesta, the principal river of this region, must flow optimally throughout the year for them to harness her waters for economic development and social stability. Further, the unilateral exploitation of Teesta waters in India and the visible drop in Teesta's flow in Bangladesh have upset the local Bangladeshi people; it is now an emotional issue as well. Hasina's failure to clinch the Teesta deal during her visit to India in April 2017 has drawn sharp criticism from all levels of Bangladeshi society. In the upcoming national elections in Bangladesh in 2018, the Teesta issue promises to be significant in determining the extent of power that will be retained by the Awami League under Sheikh Hasina. Given its secular standing and steadfast friendship, it is in India's interest that the Awami League retains its position as the ruling party.

Purely on the basis of geographic location, Bangladesh is at India's mercy for regulating the flow in the Teesta to ensure adequate flows in the lean season and control of floods during monsoons. However, what lies underacknowledged, much to Dhaka's resentment, is the fact that India is also dependent on Bangladesh in multiple areas they have cooperated upon.

- i. **Connectivity to the North East:** India is connected to its seven north-eastern states solely by a narrow strip of land. Geographical isolation has partly been responsible for the detachment of the north-eastern states from the rest of the country in terms of social cohesion, popular culture and political discourse. The consequences of North East's isolation have been detrimental to India's social, political and economic interests and efforts to bring them into mainstream India have markedly increased in the past few years. Bangladesh, due to the virtue of its geographic location, is an important connector between India and its north-eastern states. Its ports are the North-East's best access points to sea routes and marine trade. Be it transporting electricity, goods, services or people from the North East to rest of India or vice versa, the fastest, safest and most efficient transit routes run through Bangladesh, particularly in the times of natural disasters and other emergencies. The GoB under Hasina has tried to address India's connectivity concerns by opening up numerous transit points all over the Indo-Bangladeshi border, issuing clearance for transport of Indian goods to and from the North East across Bangladeshi territory and allowing Indian ships to use the Chittagong port. India and Bangladesh will also be developing and upgrading the ports at Chittagong, Mongla and Payra together.
- ii. **Combating Islamist terrorism, illegal migration and other anti-social elements:** One of the biggest successes of the GoB under Hasina have been to crack down on Islamist terrorist outfits in Bangladesh. It has supported India's stand on terrorism and cooperated regularly in capturing and handing over a number of terrorists who have been destabilising India's North East and contributing to the spread of Islamist terror across both countries. The GoB has also provided regular intel to India over the movement of terrorist groups around and across the border. Similarly, it has actively cooperated with GoI to control rampant smuggling of drugs, timber, ivory and cattle across the border, as well as tried to curb illegal migration from Bangladesh to India through more stringent border controls and regular intel to GoI. Dhaka's efforts have contributed greatly in minimising threats, attacks and illegal activities, and increasing overall stability in the eastern region of India.
- iii. **Trusted partner in South Asia:** In a volatile and deeply distrusting South Asian neighbourhood, the GoB under Hasina is the one partner which has steadfastly supported India in various areas from diplomatic cornering of Pakistan to restoring and firmly protecting the secular fabric of its country time and again. Hasina has gone great lengths to strengthen bilateral relations with India and change the latter's image from an oppressor to a friend at the risk of antagonising BNP and the rising numbers of Islamists in the country (Talukdar, 2017). Bangladesh is also a strategic partner and gateway to India's 'Act East' policy. Through Bangladeshi ports, it can establish a cultural and economic route to East Asia and engage more actively with the region. In the face of the current Rohingya crisis and instability in Myanmar, another strategically placed neighbour, Bangladesh is the only dependable partner to take the 'Act East' policy further for now.
- iv. **Combating China's Influence in South Asia:** India realises that Bangladesh's friendship is vital if it has to check China's influence and strategic incursion in South Asia. While China is already making headway in Pakistan and Sri Lanka through the China-Pakistan Economic Corridor (CPEC) and the recent USD 1.1 billion deal over Sri Lanka's

Hambantota port (PTI, 2017), it has also begun on India's eastern front. In November 2016, China and Bangladesh signed deals worth USD 25 billion, and Bangladesh has been obtaining most of its military hardware from China, its latest purchase being two Chinese submarines (Bhaumik, 2017). Bangladesh and China have also been cooperating on the Brahmaputra since 2006 for augmenting cooperation on managing water resources. India has reasons to be alarmed as China and Bangladesh move closer to each other; the more China intrudes in South Asia, the more is regional stability at stake.

B.1.1.3. The Current Draft of the Teesta Agreement

While this whole dispute is centred around signing the Teesta agreement, the actual agreement and its contents have garnered little attention. A major reason for this can be that the draft of this agreement is hard to access; it is not available on the official websites of the water-related ministries of both the countries for public viewing and scrutiny. In a country like India where water data has been a sensitive issue and guarded closely by a rather paranoid government and bureaucracy, this does not come as a surprise. Earlier, a draft version of the agreement (Annexure IV) could be found on the website of 'Water Beyond Borders' for the year 2010, but recent verification (October 2017) shows that the draft is not available on that website anymore.

Annexure IV of the draft agreement (the only part of the agreement which was available) makes rather detailed provisions for allocating the water flow in the lean season between India and Bangladesh based on a formula mentioned in Annexure I and also keeps aside 20% flow as "share of river" i.e. for maintaining environmental flows during the lean season. Multiple sources have confirmed that the formula entails a share of 40% each to India and Bangladesh. Further, point ii) of Article II has a special provision for ensuring a minimum quantity of the Teesta to Bangladesh if the Teesta's flow falls below a certain level. The agreement also elaborates on the schedule of the sharing mechanism (Annexure II), a dispute resolution mechanism, pushes for structured data collection and sharing between the two riparians, and takes water quality requirements into account (Annexure III).

Assuming that the actual agreement would be the same or similar, it can be seen that the content of this deal is woefully inadequate in addressing the concerns and development of the entire basin. There are no provisions for disaster prevention, management and mitigation, tackling climate change, harnessing, sharing and conserving groundwater, maximising environmental flows and making them economically viable, river conservation and efficient water management measures, preservation and enhance of the cultural heritage (and consequently tourism) of the Teesta, protection of the basin's ecosystems, and overall human and environmental wellbeing of the basin. The Teesta is not a bucket of water from which mugs of water can be drawn and handed around in the hope of solving everyone's 'water problems'. She is a complex entity, connected to the environment, communities and economies through an intricate web of give and take. She percolates into the lives of her riparians through various layers, and not all of them are tangible and measurable. Simply dividing up her waters is therefore never a holistic solution to the issues in the basin.

The agreement, then, clearly needs to be about more than just minimum flows and 'fair' shares. While 20% minimum flows are a good start, ways have to be found to take this share to 30%. These environmental flows will serve fisheries in both countries, facilitate navigation, and boost tourism, thus creating sustainable employment and maintaining social and economic security in the basin. Both countries need to consider this advantage of adequate environmental flows and think beyond conventional large structural interventions.

It must be remembered that the GoI and GoB indeed managed to get the Ganga treaty signed, but after almost three decades of negotiations. Even then, the Treaty has not been deemed satisfactory on several grounds. For one, it does not provide for any joint development activities of the Ganga basin, beyond flood control, and even then, Bangladesh as well as the Indian state of Bihar face floods due to the Farakka barrage (which is the main point of contention between the two countries) as well as climate change. There are no provisions to tackle climate change and its impacts in the Ganga basin. Without joint development efforts, the river and her communities remain degraded and impoverished respectively. The Ganga Treaty also does not provide a 'minimum guarantee clause' to safeguard minimum flows in lean season, unlike its predecessor in 1977. The dispute resolution mechanism of the Ganga Treaty too is inadequate as it does not provide for an arbitration mechanism for the settlement of the dispute, unlike the Indo-Nepali Mahakali Treaty and the Indo-Pak Indus Waters Treaty. Moreover, since the JRC has focused completely and only on the Ganga, the rest of the rivers have been neglected and no more agreements have been signed yet.

The Indus Waters Treaty signed by India and Pakistan is frequently cited as among the most successful water treaties globally, and in South Asia. Having withstood three wars and nearly constant hostile relations between India and Pakistan, the IWT stands a strong chance of being considered as a 'model' treaty for further water cooperation in South Asia. However, despite its resilience, the IWT has its own limitations. The treaty excludes two riparians of the Indus basin, China and Afghanistan. It allocates three of the six rivers in the basin to Pakistan and the remaining three to India, and is not based on joint efforts towards cooperation and development of the Indus basin. It has a robust dispute resolution mechanism, but there are no provisions to tackle climate change, improve the basin's ecology and biodiversity, manage groundwater aquifers and boost local economy in a joint manner. In this sense, the IWT is limited to preventing conflicts and is not fully equipped to tackle issues of climate change and groundwater and establish holistic cooperation between the two riparian countries.

Thus, the experience with the Ganga Treaty of 1996 shows that simply having an agreement does not guarantee proper conservation and utilisation of the river, while the success of the Indus Waters Treaty has failed to bring about joint

conservation and holistic development of the Indus basin. In both cases, the details of the agreement make a huge difference.

B.2. Domestic Conflicts

B.2.1. India

B.2.1.1. Hydroelectric dams on the Teesta in Sikkim

B.2.1.1.1. The Issue

Sikkim was an independent Himalayan kingdom until 1975 when it merged with India as its 22nd state. The Himalayas run right through the state which is also home to the third-highest peak in the world, the Khangchendzonga. Sikkim is situated in the north-eastern part of India and shares international borders with Nepal, China and Bhutan. Due its geographical location and terrain, Sikkim has been relatively cut off from contact with the rest of India and seen little industrialisation. Since joining India, the predominantly rural economy of Sikkim has been reliant on funds and assistance from the central government in almost all developmental areas. The Teesta river, with its steep drop of more than 5000 m within a distance of 100 kms, is hence considered as a valuable resource from which hydroelectricity can be produced to power the economies of Sikkim and other power-deficit states for considerable revenue. As per the website of the Department of Energy and Power, Government of Sikkim (henceforth, GoS), Sikkim's free share of hydroelectricity is of 12% in the initial 15 years and 15% for two decades after them, while the rest of the power would be sold to states as far as Punjab, Haryana, Uttar Pradesh and Rajasthan. Sikkim's tourism industry, organic farming, horticulture as well as overall economy could benefit greatly from an increased and consistent supply of electricity. As a result, the GoS set on a dam-building spree and by 2011, had awarded 38 projects to roughly 20 private and public firms in India (Huber & Joshi, 2015). As of the year 2017, 16 of them have been cancelled while the rest are either commissioned or in various stages of construction (Table 1).

These hydropower dams have been designated as 'run-of-the-river' projects considered to be environment-friendly, and are supposed to make non-consumptive use of water. However, quite a few papers such as but not limited to Vaghlikar & Das (2010), Kohli (2011), Bhutia (2012) and Shah (2013) have shown that the real consequences of these dams are very different. Most of these 'run-of-the-river' projects are actually large dams with significant storage capacities so that water can be held back for daily peaking power generation, and with underground tunnels, some as long as 18 kms for diverting water. Even though this water is eventually returned to the original course of the river, it does not alter the fact that the river bed lies dry in patches where water has been diverted and stored, sometimes for 24 hours or longer. Travelling up and down the Teesta, it can be seen that she no longer flows consistently; at some places, she trickles while at some, she swells due to the irregular and unsynchronised holding and releasing of her waters by the dams. Further, blasting of tunnels has caused immediate and visible impacts in the surroundings. Landslides have become frequent causing degradation of land, property and domestic water supply; heaps of rocks and heavily eroded mountain sides are a common sight while travelling across the state. Environmental Impact Assessments (EIAs) have not taken cognizance of the severity of this fact, just as they have downplayed the risks and hazards of building so many hydropower dams in an area like the Eastern Himalayas which experience significant seismic activity.

Reasons behind cancelling the 16 dams mostly pertain to vicinity to the Khangchendzonga National Park and 'non-performance' of the companies who were assigned the project. The HEP at Rathangchu was cancelled for religious reasons. This was the result of the first anti-dam movement in Sikkim, led by environmentalists, Buddhist monks and other devout Buddhists under the banner of Concerned Citizens of Sikkim (CCS) who protested vehemently against the dam which threatened to destroy Rathangchu, a sacred river for the Buddhists, and the Khangchendzonga Biosphere Reserve nearby. There were numerous public protests which included monks from monasteries all over Sikkim, and the matter went to the Supreme Court. In 1997, the then newly elected Chief Minister of Sikkim, Pawan Chamling pulled back the project in the honour of "the sentiments, religion and culture of the people of Sikkim" (Huber & Joshi, 2015).

The movement picked up again with the Affected Citizens of Teesta (ACT) in 2004, a group of young Lepcha activists who took it to an unprecedented scale. The ACT began with protesting against the dams Teesta III (at Chungthang in North Sikkim) and Teesta IV (just south of Mangan, district headquarters of North Sikkim) and eventually included five other dams planned near Dzongu, a traditional 'reserve' of the Lepchas, namely Panan Hydro Electric Project (HEP), Ringpi HEP, Rukel HEP, Rangyong HEP, and Lingza HEP. A fiery protest by the ACT in the form of numerous street protests, petitions, cases in the National Green Tribunal (NGT) and a record of several hunger strikes stretching for 915 days led to the cancellation of projects at Ringpi, Rukel, Rangyong and Lingza, while as of 2017, Panan, Teesta III and Teesta IV are at various stages of construction against which the ACT and its associates, namely Sangha of Dzongu (SOD), Concerned Lepchas of Sikkim (CLOS), Citizens Forum of Sikkim (CFS) and the Sikkim Association for Environment continue to agitate.

Elsewhere in Sikkim, another 12 dams have been cancelled, but others continue to be constructed and operated. In 2011, the controversial "Prevention and Control of Disturbance of Public Order Bill" which banned processions, hunger strikes, and any other form of public agitation was tabled by the GoS and raised an uproar of such proportions that the bill had to be recalled (Huber & Joshi, 2013). However, resistance persists, and the tension between the government and civil society continues to simmer in Sikkim.

B.2.1.1.2. Positions

B.2.1.1.2.1. The Anti-Dam Activists

The activists and their supporters are rightly concerned about the deceptive labelling of the dams as ‘run-of-the-river’ projects and that a) 70% of the river was to flow from the tunnels constructed for diverting the water for electricity generation and b) about 150 tonnes of dynamite was used to construct 1 km of a tunnel; the sum total of dynamite blasted for the construction of tunnels of 30+ hydro-projects impacted the brittle Himalayan mountains to their core and increased landslides to the detriment of human lives, land and property (ACT, n.d.).

However, the fears and issues are much deeper. Due to Sikkim’s difficult terrain and isolated geography, Sikkimese society has evolved to be small and close-knitted, and is characterised by emphasis on ethnic and tribal identities. Dzongu, the hotbed of this conflict, has traditionally been a Lepcha bastion which was formalised in 1958 as a part of the erstwhile Sikkimese queen’s estate. When Sikkim became an Indian state in 1975, their identity, along with that of other Sikkimese communities was safeguarded through Article 371F of the Indian constitution. However, the hydropower projects brought with them an influx of migrant labour. Not only were the locals not given employment, but the outsiders came in such large numbers that they threatened to make the indigenous tribes, especially the Lepchas, a minority in their own state.

The ACT, its supporters feared erosion of local cultures and religion; they pointed at the friction between Buddhists and Sikhs over sites such as Gurudongmar Lake sacred to Buddhism as well as Sikhism and the Sikh attempts to rename the lake. Further, isolation had also kept them away from specific health conditions and diseases which were common in the rest of the country; the migrants mingled with the locals and brought with them these diseases, thus impacting public health in Sikkim. Also, after the stipulated time of their work at the hydropower project, they continued to stay in Sikkim and eventually earned voting rights. The local communities, especially the Lepchas who are already a small community were alarmed at this. Electoral politics being all about numbers and demography, they saw this as dilution of their political rights, and a threat to the protection which Article 371 accorded to their ethnic group and identity.

Accompanying these fears was the nature of implementation of project-related activities. The EIAs were fraught with significant errors, and many of them had completely ignored important components, such as seismic activity, which contributed to the ecological fragility of the region. Public hearings were manipulated; protestors were pressurized and threatened (Huber & Joshi, 2015), facts were suppressed, and approvals were forged (Mazoomdaar, 2017). There had also been numerous delays, errors, neglect in the case of resettlement and rehabilitation, and even a blatant portrayal of basic and mandatory facilities such as electricity, primary healthcare centres, roads, schools etc. as “advantageous individual gains” (Huber & Joshi, 2015).

At the initial stages, the activists, particularly ACT, were rather stubborn and aggressive in their approach, which put them at odds with both, the affected local communities as well as the state GoS. Two instances prove this point.

In the first, in 2007, the GoS set up a review committee to look into ACT’s demands. The committee’s recommendations would be submitted within a month of its formation and would be binding on the government in exchange for ACT calling off the hunger strike to sit down with the government and decide the composition of the committee. The ACT responded with a fresh set of numerous conditions. Negotiations collapsed, with the Chief Secretary of Sikkim accusing them of not being interested in solutions and that they were infiltrated with anti-Sikkim forces (Wangchuk, 2007). The ACT could have taken up the offer and played an important role in forming a balanced committee that would have put their grievances ‘on record’ and influenced its recommendations. It took a while for the negotiations to revive, but precious time had passed by then.

In the second instance just previous to the collapse of negotiations over the review committee, a delegation of dam-supporters from Dzongu issued a statement saying that they were not aligned with the hunger strikes led by ACT and CLOS, and their No-Objection Certificates still held good if they were granted better compensation rates for lost land and other safeguards in a timely and orderly manner. They refrained from commenting on the anti-dam activists and their hunger strikes and stuck to their stand, but the ACT responded rather harshly, which eventually led to two bitter, untrusting camps among the people of Dzongu. Around the same time, Lepchas from Darjeeling staged a protest against the projects in Dzongu by blocking National Highway 31A, the sole road connecting Sikkim to the rest of the country, thereby cutting Sikkim off India. The protest lasted for two hours and affected traffic mostly on the Sikkim side, irking many common Sikkimese people. The GoS also was displeased and considered it as an outside interference in state matters (Wangchuk, 2007).

More than a decade has passed since the protests were launched in Sikkim, and the anti-dam activists have seen victories as well as failures. Over the years, the protest has moved from opposing hydroelectric dams in principle to keeping Teesta’s tributaries free of hydropower projects, with each of the party making a few compromises in the process. However, the concerns of ACT and its supporting organisations persist.

B.2.1.1.2.2. Dam Supporters among Local Communities

The Sikkimese people have been sharply divided over the hydropower projects. Even the community in Dzongu has split into two groups, one of those who support ACT and its sister organisations in their anti-dam stance and a second of those who see the projects as an opportunity for development, livelihood and prosperity. While both groups share fears over outsider influence and domination on local culture, religion and politics, they differ significantly on ways to address the situation. Unlike the blanket opposition imposed by the anti-dam activists and their supporters, the pro-dam segment believes that a robust system of adequate checks and balances would resolve the issue. While ACT and other activists

carried out protests, the pro-dam group has repeatedly issued letters and declarations that they were not a part of the protest and were willing to cooperate with the administration and the power companies if their conditions were met. Instances of friction with ACT and its supporters put them further apart from each other and at one point, there was a total absence of trust and dialogue between both the camps (Wangchuk, 2007).

The pro-dam segment, especially of Dzongu, had compelling reasons for supporting the hydropower projects. Unlike the rest of the state which benefited from the tourism boom, Dzongu stayed untouched, with poor infrastructure and low economic activity. Its cardamom plantations were hit by a decline in productivity and market value. In such a situation, the land owners of Dzongu saw the hydropower projects as a chance to sell their lands at a rate many times higher than their market value – in August 2007, the GoS finalised the rate for land acquisition for the Panan project at Rs. 18 per sq. ft. for agricultural land and Rs. 16 per sq. ft. for barren land, when the market rate hovered around as low as Rs. 2 per sq. ft. The 9-fold jump was the highest rate that the state government had for any project anywhere in the state, and it was accompanied with another 30% of the amount as a compensation. This was too much for the Lepchas in Dzongu to ignore.

Further, opposition to these projects meant opposition to the state government, which had unique repercussions in Sikkim. Sikkim's 'success story' of a flourishing tourism sector, organic farming, and fairly developed infrastructure even in some of its remotest areas masks the fact that almost 20% of the Sikkimese population lives below poverty line, and even though it has one of the highest per capita incomes in the North East, much of this income is generated from public employment (18.5% in Sikkim compared to the national average of 6.3%). This is just one of the many indicators emphasising the dependency of the local population on the government instead of other private economic activities for generating income (Chettri, 2013).

Further, it also overshadows the overwhelming dependency of the local communities on the state administration for the provision of many goods and services, employment opportunities, and subsidies, the distribution of which varies along ethnic lines. The GoS has complete control over this distribution which is often influenced by short-term political interests. Due to such high level of dependency on the government, the locals automatically face restrictions on expressing dissent; control on distribution of basic facilities and resources enables the state to silence any opposing voices and coerce the locals into conforming with its agenda (Chettri, 2013). Naturally, many locals were unable to voice any opposition towards the projects even if they wanted to for the fear of being stripped off government benefits and left alone to fend for themselves. The monetary and employment benefits (at least as projected initially) of the projects were thus an obvious choice for many.

B.2.1.1.2.3. Government of Sikkim (GoS)

Since its amalgamation with India 42 years ago, Sikkim has seen only two full-term Chief Ministers, Nar Bahadur Bhandari (1979-1994) and Pawan K. Chamling (1994-present), with no robust opposition to either. Coupled with the government's stronghold on basic necessities and resources, and the fact that open dissent is not a traditional aspect of the Sikkimese society, the resultant nature of democracy in Sikkim is quasi-feudal, with little space for sustained and systematic disagreement and criticism of the state within civil society.

This is the primary reason why the strength and tenacity of the Lepcha movement against dams took everyone, including the state, by surprise. The GoS initially ignored the protests, but as they grew in volume and number, it had no option but to respond. The GoS tried working out all sorts of solutions with the anti-dam activists, from offering to set up a review committee to look into the demands of the ACT, to restricting the flow of outside labour in Dzongu, to cancelling about 16 projects up until now. Talks collapsed from time to time, but each time they resumed, the GoS seemed to work towards a solution that would safeguard everyone's interests. However, hydropower project continued to be built in Sikkim and problems pointed out by activists and local communities continued to hamper the economic, ecological and cultural interests of the region.

The GoS maintained a careful balance of coercion, persuasion and incentivisation in order to advance its agenda. Depoliticizing of dams (shifting the responsibility of the projects to private, non-governmental actors), promoting selected facts and 'there-is-no-alternative' (TINA) narratives (Huber & Joshi, 2015), pressurizing protestors through threats and public criticism, and more subtle means such as financing local festivals and celebrations were some of the tactics used by both GoS and private hydropower companies to round up approval and curb dissent. The systematically built dependence of locals on government machinery for basic necessities, employment and subsidies contributed to the use of *saam-daam-dand-bhed*³⁰³ by the establishment and the private sector.

However, the dam building spree in Sikkim has been slowing down. From 27 hydropower projects allotted to various public and private companies in 2007, the number has come down to 16 in 2015, with many projects being stalled or abandoned due to financial reasons. The hydropower projects on the Teesta in Sikkim are at various stages of construction and experience inordinate delays, governance and clearance issues and huge cost overruns. For instance, the original cost of the Teesta III project has almost doubled from Rs. 5702 crores to Rs. 11382 crores by the year 2015, while the original completion deadline for the Teesta IV project was 2011-2012, which was then shifted to 2016-17 (Datta, 2015); as of November 2017, the project is yet to get environmental clearance and major works have not started (Energy and Power Department, GoS, 2017). Further, the risk of increased landslides due to intensive tunnelling and

303 An ancient Indian saying which outlines four ways of getting a task done. Saam – through requests, pitches, advice; Daam – through monetary incentives; Dand – through punishment; Bhed – through 'divide and rule' policy.

seismic activity (Sikkim falls in seismic zone IV; zone V has the highest risk) have also added considerably to the costs of completing these hydropower projects.

In the face of widespread, aggressive and persistent opposition, high ecological risks, and mounting financial problems, the Chamling-led GoS went to great lengths to consolidate hydropower projects in Sikkim for reasons, many of which received the nod of the GoI as well. Elaborated below, they sum up the geopolitical and economic importance of hydropower projects for Sikkim.

- i. **Economic independence:** The most significant driving force behind the hydropower project building spree in Sikkim is economic independence from central aids, funds and development packages. After annexation into India in 1975, Article 371F of the Constitution was created specially to preserve certain laws and social, political and economic rights of the indigenous communities of Sikkim. Additionally, it also granted Sikkim the status of a 'special' state which enables it to this day to receive a special share of grants and funds (apart from those included in the National Planned Expenditure) from the central government plus a separate contribution by the central government amounting to 90% of the total costs of Centrally Sponsored Schemes in the state. Sikkim's small, largely agrarian and poor economy is heavily dependent on these funds, and is able to secure them only as long as it is a 'special' state. In an attempt to reduce this vulnerability, the GoS views hydropower as a financially lucrative option. As per the contracts signed over the projects, an average of 12% of the power generated is allocated to Sikkim, while the rest of it is sold to other states in North India. Given the direct correlation between availability of electricity and economic growth, the GoS hopes to stir up Sikkimese economy and bring more prosperity to the state through, in the words of Chamling, its own 'white gold' (Huber & Joshi, 2015).
- ii. **Cautious and cordial relations between GoI and GoS:** Since Sikkim is a crucial border state surrounded by three countries – Nepal, Bhutan and China – it is unlikely that it will ever lose the status of 'special' state. Sikkim plays the very important role of providing a buffer between China and the very vulnerable Chicken's Neck. China particularly has an active presence at the border. The latest standoff between Indian and Chinese troops at Doklam in Sikkim in July 2017 led to the Chinese state-controlled media calling on Beijing to "reconsider its stance over the Sikkim issue" and push for a 'pro-independence movement' in Sikkim (Patranobis, 2017). While this rhetoric gained traction in neither of the establishments, such a possibility is very real and cannot be taken lightly. The geopolitical vulnerability and significance of Sikkim has led to successive central governments carefully maintaining cordial relations with the state and not interfering in its peculiar ethnicity-driven politics and quasi-feudal democracy. However, even though GoI has continued to allot funds generously to Sikkim, it sees an opportunity to meet the needs of a power-hungry India in Sikkim's untapped hydropower potential which is more than 5000 MW and up to 8000 MW at peak times (Department of Information and Technology, GoS, 2016), and has thus encouraged the proliferation of hydropower projects in the state.
- iii. **The 'clean' image of hydropower:** Hydropower development is an attractive option to energize Sikkimese economy because of its 'clean' image which fits perfectly with Sikkim's reputation for eco-friendly policies. Sikkim, with its untouched verdant beauty, almost non-existent industry (and pollution), and fully organic farms is famously known as the 'green state' in a country otherwise reeling under the harmful effects of industrial pollution and fertiliser-soaked agricultural lands. A host of policies and eco-friendly initiatives in Sikkim, ranging from afforestation to state-wide bans on plastic bags have drawn appreciation and numerous awards for the state, including the 'Sustainable Development Leadership Award' for CM Chamling at the World Sustainable Development Summit in 2016 (ANI, 2016). Being "the cheapest green power available to mankind today" (Huber & Joshi, 2015), hydropower only enhances the image of the state and its government.

B.2.1.2. The Struggle for Gorkhaland

B.2.1.2.1. The Issue

Gorkhaland is a separate state demanded by the Gorkha community which resides in the extreme north of West Bengal. Its proposed area consists of Darjeeling district, surrounding Darjeeling hills, parts of Siliguri subdivision and parts of the Dooars region, all in north Bengal.

The aspiration and struggle for Gorkhaland is almost a century old, when the region was under British control. Historically, Gorkhaland has not been an independent state; the region was passed around among the regional powers of Sikkim, the Gorkhas, Bhutan and the British. In the early 20th century, when the Darjeeling hills were an administrative part of British Bengal, the Nepali-speaking Gorkhas began to dominate the region, while indigenous tribes from Sikkim settled down as minorities. What further propagated the influx of communities in the region was the tea sector; the British brought with them cheap labour from Nepal, eastern India and even China, while Marwadis and Bengalis flocked to the tea estates to take up salaried and clerical positions. The Gorkhas and other local tribes found themselves increasingly at the bottom of the flourishing tea ladder, which, along with practically no affinity with Marwadi and Bengali cultures, united them in their rejection of their artificial integration with Bengal. This culminated into the demand for a separate administrative unit for Darjeeling district in 1907, and then one for Darjeeling and Jalpaiguri districts in 1929 (Banerjee & Stöber, 2013).

The All India Gorkha League was founded in 1943 with the aim to separate the Darjeeling hills from West Bengal. During the time of India's independence, a public meeting was held in Darjeeling to voice local aspirations for autonomy. The District Committee of the Communist Party of India (CPI) even issued a memorandum pitching for the creation of a 'Gorkhistan' out of Darjeeling Hills, southern Sikkim and Nepal. However, CPI's West Bengal faction opposed the idea vehemently and rooted for the Darjeeling hills to remain a part of the newly created state of West Bengal, a position upheld henceforth by every government of the state, irrespective of the ruling party (Benedikter, 2009). The nationwide exercise of linguistically organising Indian states evaded Darjeeling hills in the 1950s. Nepali, the language spoken by about two-thirds of the population in the Darjeeling hills was simply not considered as an official language until 1961 by the GoWB and in 1992 by GoI (Mitra, 2017). The Gorkha National Liberation Front (GNLF) was formed by Subhash Ghising in 1979 and a long, tumultuous struggle for Gorkhaland was launched. The struggle continued throughout the 1980s, with the GNLF approaching the Prime Minister of India demanding a separate state and the recognition of Nepali language under the 8th schedule of the Constitution. The struggle began to turn violent and at its peak in 1986-88, nearly 1200 people succumbed to the political violence.

The then GoWB finally yielded to a compromise – the 'Darjeeling Gorkha Hill Council' (DGHC) was formed in 1988 under Subhash Ghising's chairmanship. Under the DGHC, territorial autonomy was granted to the sub-divisions of Darjeeling, Kalimpong and Kurseong, and a few villages from the Siliguri sub-division as well. However, without legislative powers, the DGHC quickly descended into inefficiency, financial problems and non-democratic functioning. For years, the DGHC did not meet, no economic planning was undertaken, and accountability was severely compromised. In short, the DGHC had wasted the opportunity.

In 2007, Ghising was toppled from his position as the Chairman of DGHC and was succeeded by Bimal Gurung of Gorkha Janmukti Morcha (GJM) who launched a fresh struggle for Gorkhaland. Under Gurung, a bill for creating the Gorkhaland Territorial Administration (GTA) was passed in 2011. The GTA replaced DGHC and had more administrative, financial and executive powers than the DGHC, however, they were still not vested with legislative powers. GJM proposed to include 398 mouzas³⁰⁴ from Siliguri and Dooars in the GTA and expand its territory but was furiously opposed by the Bengalis who had increasingly come to view the Gorkhas as 'outsiders' and migrants from Nepal rather than the indigenous Nepali-speaking population of the region.

Just before the elections for GTA, the Justice Shyamal Sen Commission recommended the inclusion of only 5 mouzas to the existing GTA territory, which angered the GJM and led them to boycott the elections (Nagchoudhary, 2017). However, they came around and after quite a few political upheavals, captured all the seats of the GTA. The Gorkha community continues to lend support to GJM and Gurung as is evident in the May 2017 municipal elections in which GJM retained three of the four municipalities in the Darjeeling Hills.

In June 2017, a controversial decision by the GoWB to make Bengali compulsory in all schools of West Bengal sparked protests in the Nepali-speaking GTA region which saw the move as an act of aggression against their language and culture. The protests which began peacefully quickly spiralled out of control and widespread occurrences of violence were reported. Police and paramilitary forces had to be deployed, which further led to skirmishes between them and the protestors. The protests began with the agenda of opposing the imposition of Bengali language, but the demand for Gorkhaland soon took over, with the GJM firmly stating that "the only thing [they] want now is Gorkhaland" (Special Correspondent, 2017).

The protests collided with peak tourist season of the region, and the tourism sector took a hit not only in the GTA region but also neighbouring Sikkim, the sole road to which passed through GTA territory (Giri P. , 2017), (Chowdhury, 2017).

³⁰⁴ A small administrative unit, akin to a village.

By the time the GJM called off the agitation in September 2017, 104 days had passed, 11 lives and significant public and personal property had been lost (Express News Service, 2017), and the GJM had split with one faction resuming control of the GTA. While the protests have died down, the region is still simmering with dissent among both the Gorkhas and the Bengali populations. Recognizing this, the Kolkata High Court has issued a stay order on the central government's decision to pull paramilitary forces out of the Darjeeling hills (Chatterjee, 2017).

B.2.1.2.2. Positions

B.2.1.2.2.1. The Gorkhas

Unlike the local communities in Sikkim who were divided over the hydropower projects, there is an overwhelming consensus among the Gorkha community over a separate Gorkhaland. While the demand for Gorkhaland is primarily territorial, over years, it has accumulated layers of economic status, language, culture, ethnicity and political clout. The Gorkhas differ from the Bengalis in ethnicity and physical appearance; their distinctly separate languages and cultures have co-existed for more than a century but not blended in. With the tea plantations, economic differences also took root; Bengalis took up all the clerical and bureaucratic i.e. 'white collar' positions while many Gorkhas, along with other tribal communities from Nepal, Sikkim and East India were brought to the tea estates as labourers. Hence, it was only a matter of time that the Gorkhas and other Nepali-speaking communities frowned upon the merger of the Darjeeling hills with Bengal, which they deemed as artificial.

The dissent among Gorkhas increased with the delay in recognising Nepali as an official language; for years, it was not recognised as a second language even at the district level in Darjeeling. The Bengalis dominated economically and culturally, and after independence, they took over politically and bureaucratically as well. The Gorkhas began to feel increasingly trapped – they had neither financial control, nor political clout, nor cultural influence in a state with which they were merged purely in an administrative sense. The only solution, they surmised, was a separate state of Gorkhaland; in the words of Roshan Giri, secretary-general of the GJM, “[o]nly a State in India can provide us with the necessary legal framework for developing our ethnic and linguistic identity” (Giri R. , 2009).

It must be noted that while the Gorkhas have clamoured persistently for a separate state, the idea of seceding from India and forming a separate country is not on their cards. Firstly, the Gorkhas are a patriotic community; the Gorkha regiment is one of the most valiant regiments of the Indian Army. Secondly, they recognise the comparative benefit of staying with India over forming an independent state in the face of complex geopolitical and economic realities of the proposed Gorkhaland. Within India, the Gorkhas are confident of stabilising and progressing as a successful state for various reasons. Economically, the proposed area under Gorkhaland would be home to several tea estates, forests and national parks, and the upper reaches of the Teesta. With these resources, tea, timber, tourism and hydropower will be able to flourish, bringing significant revenue to the state. Politically, there are considerable chances that Gorkhaland will qualify as a 'special' state. Its location in the Chicken's Neck, shared international borders with Nepal and Bhutan, and proximity to China will bring focus and funds from the central government. As a gateway to the north-east, Gorkhaland also stands to benefit from the 'Act East' policy. Socially and culturally, a separate state would enable the Gorkhas to preserve and enhance their language and culture more proactively. However, there are other factors which are not conducive for the creation of Gorkhaland.

- i. **Too small for statehood or too large for social dominance:** The current area under the GTA is about 3300 km² with a population of about 12 lakhs, and has three seats in West Bengal's legislative assembly. With not even a full Lok Sabha seat in its kitty, the GTA-administered area is too small to merit statehood. However, with Siliguri and Dooars, the area of proposed Gorkhaland almost doubles to 6500 km² and its population expands to 32 lakhs which translates into 20-25 assembly seats, and one, or possibly two Lok Sabha seats. However, the population of Gorkhas in Siliguri, and Dooars is not in majority; these areas are dominated by Bengalis and Adivasi tribes. Essentially, if the total population of the newly proposed area is considered, the Gorkhas will not emerge as the dominant community. In fact, they will end up being a minority in their own state and gain neither political clout nor cultural mainstreaming which they have been seeking through Gorkhaland. In other words, a larger Gorkhaland would defeat the very purpose of Gorkhaland.
- ii. **Risk of a new state in the Chicken's Neck:** A separate Gorkhaland's location in the Chicken's Neck would possibly mean the 'special' status, but it could also mean a challenge to the new, inexperienced administration. The region is sensitive on multiple levels – political, strategic, military, economic, social – and any weakness or folly in this region can have serious ramifications in terms of security. While military and security are the domains of the central government, daily administration, law and order and internal peace are under state administration. Whether a new, inexperienced state government with a record such as that of its predecessor DGHC can successfully carry out these duties in unique and highly sensitive situations is a serious question.

B.2.1.2.2.2. The Bengalis

The Bengalis, both within and outside the Darjeeling hills oppose the creation of Gorkhaland. They argue that the area now proposed to be Gorkhaland has been as much a home to them as to the Gorkhas. While they accept the GTA, they are against the inclusion of areas from Siliguri and Dooars in the proposed state on the grounds of Justice Shyamal Sen Commission's verdict and that these areas are not predominantly Gorkha, but home to a mixture of Bengalis and Adivasi tribes. Rather, the Bengalis have started viewing the Gorkhas increasingly as 'outsiders'; the open border policy with Nepal has led to a huge influx of Nepali migrants to the region. These migrants share common language and culture with

the Gorkhas and hence in the eyes of the Bengalis, the Nepali-speaking communities are ‘taking over’ not only the Darjeeling hills, but also areas of Siliguri and Dooars which have traditionally been a Bengali and Adivasi stronghold.

For many Bengalis, Darjeeling is traditionally a part of their state. It features in their literature as a place of beauty and recreation, and has an exceptional sentimental value attached to it. For Bengalis, the Darjeeling hills contribute to the unique image of West Bengal – the only Indian state with both, the Himalayas in the North and the sea in the south – which is similar to India itself in a miniature form. They are ready to make concessions to the Gorkhas (the GoWB publicly apologized to them for imposing Bengali language in all schools of the state) but they are also resolute in keeping West Bengal unified. It cannot be forgotten that the Bengalis have seen partition twice, first in 1947 and second in 1971. Many Bengalis have fled East Pakistan and Bangladesh before settling down in Darjeeling, the surrounding hills, Dooars and Siliguri. For them and even for West Bengal as a whole, the idea of a third partition is simply unacceptable. Banerjee’s poignant words sum up the collective feelings of the Bengali community: “Bengal cannot suffer the pain of yet another partition”.

B.2.1.2.2.3. The GoWB and GoI

The GoWB has unequivocally opposed the creation of Gorkhaland from the very beginning. Barring the one memorandum issued by CPI in 1947, neither the Left nor Banerjee’s TMC have indicated any support for the creation of Gorkhaland. The fact that even the slightest whiff of support to Gorkhaland would severely impair their popularity within the Bengali community – the largest in West Bengal – is a strong political reason for the parties to oppose the Gorkha movement. However, there are other reasons, especially from the point of view of a ruling party, as well.

- i. **Economic importance of Darjeeling hills to West Bengal:** The Darjeeling hills are economically important for West Bengal as they have flourishing sectors of tourism and tea. In 2014 alone, more than 6 lakh tourists visited the areas under the GTA. In the same year, the areas of Darjeeling and Dooars produced over 187 million kgs of tea, which amounts to about 60% of the tea production of West Bengal (Tea Statistics, n.d.). Darjeeling and Jalpaiguri districts have the highest per capita incomes in West Bengal (Planning Commission, GoI, 2010) and tea, a financially lucrative cash crop, is an important contributor. If Gorkhaland becomes a separate state, West Bengal will lose substantial parts of two of its more prosperous districts and see steep reduction in its revenues.
- ii. **Control over Teesta’s flow to West Bengal:** If Gorkhaland is formed, it will be the upstream neighbour to West Bengal and will control Teesta’s waters before they reach the Bengal plains. The GJM is fully aware of this; amidst the strikes, rallies and violence of 2017, GJM chief Bimal Gurung warned that he would halt ongoing hydel projects, Teesta Lower Dam III and IV on the river as a “non-cooperation movement against the West Bengal government”. That the statement did not materialise into reality is another story, but the fact remains that an independent Gorkhaland, with or without the graces of the central government, can certainly use the dams to halt flow of the Teesta downstream to West Bengal. If Gorkhaland is created, West Bengal will lose two hydropower projects worth 292 MW to the new state. Currently, the Teesta Barrage project in North Bengal produces only 20 MW of electricity, and based on its slow and dismal progress, it looks unlikely that it will meet its original target of generating 67.5 MW of electricity. Hence North Bengal is relying on the Teesta Lower Dams III and IV for fulfilling its power needs. With Gorkhaland in the picture, West Bengal will have no option but to buy power from the new state, thus stretching its finances.
- iii. **Weakening of GoWB’s position in the Teesta issue:** the Gajaldoba Barrage built on the Teesta river is located in the Dooars region, downstream of the Teesta Lower Dams III and IV. Since all three dams are currently located in West Bengal, the GoWB holds a key position in controlling the flow of the Teesta to Bangladesh, and in the whole transboundary dispute. Even if GoWB retains the Gajaldoba barrage, losing Teesta Lower Dams III and IV to Gorkhaland would reduce GoWB’s control over the flow of the Teesta and weaken its position in the Teesta transboundary issue.

Given these reasons, it is clear that no government (and no party aiming to form government) in West Bengal would support the creation of Gorkhaland.

National political parties have historically shown little interest in the matter. The BJP had initially sided with the Gorkhas; in 2009, it contested and won the Loksabha seat from Darjeeling, with its candidate Jaswant Singh voicing active support for Gorkhaland. However, over the years, BJP has carefully retraced its position. It is currently trying to pave its way into West Bengal and fears that vocal support to Gorkhaland would seriously hamper its progress in the rest of the state. The state’s BJP cell too has openly stated that even though they empathise with the agitators and stand for their development, they do not support the creation of Gorkhaland for now. However, one cannot rule out the possibility of a BJP-led GoI pushing for the creation of Gorkhaland sometime in the future. The strategic location of Gorkhaland regarding the Teesta sharing issue as well as the current government’s demonstrated capability to take bold and swift decisions (demonetisation, GST etc.) has raised the possibility (and hopes) of a separate Gorkhaland. If and when such a decision is taken, it would be heavily dependent on the status of the Teesta issue, India-Bangladesh relations, political climate in Bangladesh and the political and economic situation of West Bengal, to name a few.

B.2.2. Bangladesh

B.2.2.1. Domestic Conflicts in the Teesta Basin – A Possibility for the Future?

As far as one can see, there are no major domestic conflicts in the Teesta Basin in Bangladesh. Unlike Sikkim and West Bengal who face turmoil, the overall situation in Rangpur is that of relative stability and peace. In fact, Rangpur division is one of the more peaceful areas of Bangladesh. It is among areas least affected by political violence, militant activities, rebellions and insurgencies, and *hartal* (strike) violence with considerably less casualties than many other areas of Bangladesh (Suykens & Islam, 2015). Rangpur has been a shelter for Islamist militant outfits such as Harkat-ul-Jihad-al-Islami Bangladesh (HuJI-B) and the Jagrata Muslim Janata Bangladesh (JMJB), but the division has by and large stayed out of the ambit of their attacks which have been concentrated in areas in and around power centres like Dhaka and Chittagong. Security-wise, its distance from urban epicentres like Dhaka and Chittagong has benefitted Rangpur.

Multiple sources and field visits convey that Rangpur's principal problem is the reduction in the flow of the Teesta. It is true that there are more than a dozen other rivers flowing through Rangpur including the mighty Brahmaputra, however, except for Teesta and the Brahmaputra, many of these rivers are too small to support a significant size of population and agriculture throughout the year. Also, the Brahmaputra flows in the far eastern part of the division while the Teesta is closer to the central part. To the west of the Teesta, there is no major river running through Rangpur. Teesta river is the only major source of water for most of the division. Hence, even if the Teesta basin in Bangladesh covers only 2004 km² area inhabited by 9.5 million people, more than 21 million people in the country are dependent directly or indirectly on the river for livelihood.

Further, the fact that Rangpur is far away from economic centres and markets such as Dhaka and Chittagong, has led to its decades-long neglect. It was only in 2010 that the region was separated from Rajshahi division and focused upon for development. Effectively, Rangpur has been prioritised for only seven years now and has a long way to go before it sheds off the tag of a backward division. The GoB has been taking efforts along with many NGOs to boost agricultural production, public health, literacy and resilience to natural disasters. In all these areas, water availability and management are key to achieving progress and hence, the administration has set its sights on the Teesta which is the fourth largest river in the country and the largest river in Rangpur division after the Brahmaputra.

For anyone familiar with the Teesta conflict, it is no news that India's actions upstream of the Teesta are hurting Bangladesh, the downstream riparian. However, domestic issues of the Teesta basin in Bangladesh are not covered as extensively by Bangladeshi media, academia and policymakers. A recent public outburst in Ulipur town of Kurigram district, Rangpur division provides a glimpse into some local issues in the Teesta basin of Bangladesh.

B.2.2.1.1. 'Save the Buri Teesta' movement

A local movement to 'Save the Buri Teesta' a 30-km-long distributary³⁰⁵ of the Teesta was launched in Ulipur upazila of Kurigram district of Rangpur Division in February 2017. The Buri Teesta emerged as a distributary of the Teesta river at Arjun village of Ulipur upazila and joined the Brahmaputra river at Kachkol area under Chilmari upazila. Its flow was controlled by two regulators (sluice gates) by the Bangladesh Water Development Board (BWDB) at Arjun and Kachkol. However, due to heavy floods in 1988, the sluice gate at Arjun collapsed. Since then, BWDB blocked the flow of Buri Teesta and it started silting rapidly. In the process, all agricultural land in its vicinity became unusable in the dry season. Along with agriculture, local navigation (including recreational activities such as annual boat races) and fisheries were severely hit. Slowly, the Buri Teesta fell to neglect – even a simple bridge could not be constructed over the small river due to petty local politics, lack of funds, and obstruction from locals, most of whom were poorly compensated for their land at the site of construction (Asaduzzaman, 2012). The Buri Teesta is almost dead now and its dry bed has been grabbed illegally, mostly by rich and powerful locals, and turned into agricultural fields for regular cultivation. Some have also created and sold plots in the river bed for commercial uses.

The 'Save the Buri Teesta' movement has four clear demands – a) digging at source-point of the Buri Teesta in order to rejuvenate the flow, b) reconstruction of the sluice gate at Arjun, c) immediate eviction of illegal land grabbers to restore the course of the river, and d) immediate dredging of the river bed. In March 2017, more than 5000 people of Ulipur came out on the streets to form a 2-km-long human chain urging authorities to rejuvenate the Buri Teesta river (Daily Star Correspondent, 2017). The very next month, a procession of around 4,000 people carrying water bottles and pitchers went to the Khepar Bridge over the Buri Teesta. They poured water in the river, in a symbolic move to recreate the flow of water and urged authorities again to prevent the river from dying. The mayor of Ulipur municipality supported the movement, insisting that normal flow of the Teesta and Buri Teesta were essential for the local environment (Staff Correspondent, 2017). In May 2017, the movement went to Dhaka. The Ulipur Samity at Dhaka formed a human chain yet again in front of the National Press Club in which natives from Ulipur and Kurigram staying in Dhaka and leading environmentalists of the country participated in large numbers. Directly addressing the Prime Minister, the organisers and participants reiterated their four demands in front of a large crowd. (Staff Correspondent, 2017).

The movement has received the attention of the concerned authorities. The Executive Engineer of BWDB Kurigram has agreed to build a new sluice gate at Arjun in the next fiscal year stating, "if the local lawmaker assists me, the project may be approved quickly" (Wahed, 2017). The Upazila Nirbahi Officer (UNO) of Ulipur took up the issue with the Assistant Commissioner of Kurigram district. It was also discussed by Kurigram's District River Protection Committee under the National River Protection Commission. All eyes are now on the coming fiscal year when works on the Buri Teesta will begin.

B.2.2.2. The Teesta Narrative and Conflicts

³⁰⁵ A distributary is a branch of a river that does not return to the main stream after leaving it.

That unilateral actions by India upstream on the Teesta have severely affected her flow downstream and rendered Bangladesh's Teesta Barrage Project partially useless is an undisputed fact. However, the popular narrative in Bangladesh portraying Indian actions as the singular problem and a bilateral treaty on the Teesta as the singular solution does not take cognizance of the shortcomings in water infrastructure, management and conservation practices in the country.

Multiple studies conducted by both Bangladeshi as well as non-Bangladeshi researchers confirm the definite deterioration of the Teesta and the reduction in her flow over the past few decades, especially after the Gajaldoba barrage started operating. However, the availability of Teesta's water, or in general of transboundary rivers flowing into Bangladesh, became a grave issue of national political proportions only in the last 20-25 years. This was due to not only decreasing flows and other climate change impacts, but also political/developmental changes in upstream India. In 2001, the Central Electricity Authority of India identified the Brahmaputra basin as "India's powerhouse" and singled out two states, Arunachal Pradesh and Sikkim, as most ideally suited for hydropower production. Within these new findings, the GoI saw the fulfilment of its twin goals of fulfilling the needs of power-hungry central and western states of India, and bringing the North East into mainstream economic growth.

Accordingly, plans for 168 hydropower projects with a total installed capacity of 63328 MW were drawn up for the north-eastern states, more than half of which were to be in Arunachal Pradesh and Sikkim alone. The Ministry of Power, GoI, also launched the '50,000 MW Hydro Initiative' in 2003 as part of GoI's "Mission 2012: Power for All". Incidentally, Sikkim and Arunachal Pradesh were also the upper riparians for Teesta and Brahmaputra, two major rivers of Bangladesh. Bangladesh was rightly alarmed at the intensive damming activity which India embarked upon without consulting its co-riparians. With high uncertainty of impacts, very little information available due to GoI's opaque dealings, and high stakes for the vulnerable downstream communities, Indian hydropower projects in particular and joint water management in general became key points of Bangladeshi hydropolitics (Kolås, et al., 2013). While civil society groups arranged local protests of aggrieved and vulnerable communities, spearheading the agitation at the national front was the BNP.

To this day, the contestations and protests continue. India's hydropower projects in the North East and the lack of a water sharing agreement, especially on the Teesta, are discussed intensively among the political circles, academia and civil society in Bangladesh. However, apart from highlighting India's actions and the need for an agreement, very little is put forth. Few papers talk about local solutions such as rainwater harvesting in the Teesta basin, or a critical and pragmatic look at the current draft of the Teesta agreement without hurrying to get it signed – such an approach is clearly not mainstreamed in the current political and even academic discourse over the Teesta. The focus instead, of Bangladeshi political class and at least a portion of civil society and intelligentsia is to get an agreement signed and obtain "a fair share of Teesta waters" from India, once and for all. This is particularly crucial for the Hasina government; it will finally silence her critics, especially the BNP, who have been alleging that her government has 'sold over' to India. A deal over the Teesta will also go a considerable length in consolidating the Awami League's position in northern Bangladesh, more so if the agreement is signed before Bangladesh's national elections in late 2018/early 2019.

The media too has clamoured vigorously for the agreement with little incursion into its details. An analysis of media coverage around the Teesta agreement from 2010 to 2012 conducted by the International Union for Conservation of Nature (IUCN) points out that when the Teesta deal fell through in 2011, the media in both countries resorted to "a blame game" and indulged in "a fair amount of partisan and unattributed reportage". The report highlighted the fact that the "least detailed aspects of the proposed Teesta agreement in the media during this period were: the rationale on either side of the border for the water-sharing agreement, the contours of the agreement, and the strategies being explored, if any, for pushing for the agreement to take place in the near future" (Bhushan & Ahmed, 2014); looking at media coverage of the Teesta since then, it can be seen that little has changed.

It would be prudent to remember here the Ganga Treaty which despite being signed and implemented, has failed to address issues of the Ganga River basin on both sides of the border. Pushing for an agreement and a share of the river deemed as 'fair' by narrowly defined parameters would work in nobody's interest; better to have no agreement instead of a detrimental one. However, geopolitical realities and political equations on both sides of the border have now made the Teesta agreement (in whichever form) imperative. Given the importance of the Hasina-led GoB for India, the Teesta agreement is bound to be signed sooner than later. However, if all the efforts are focused solely on getting a signed agreement and a fixed quantity of water from India without proper infrastructure, technology, distribution systems and management practices in place, it is highly likely that domestic conflicts over the Teesta will occur in Bangladesh after the agreement is signed. In order to prevent this from happening, Bangladesh needs to have a framework already in place to store, manage and distribute the waters efficiently, equitably and sustainably. Both countries need to ensure that issues such as climate change, river and groundwater conservation and sustainable development are adequately addressed in the agreement itself. As the downstream riparian state with the development and stability of its poorest region at stake, Bangladesh needs to realise the urgency and act proactively.

A. LOCAL COMMUNITIES OF THE TEESTA

Teesta's riparian communities are largely rural and agricultural, characterised by low level of economic activity (a small service sector and an almost non-existent industrial sector), poverty, low level of human resource development, weak access to markets, and an overall low standard of living. They are highly dependent on the Teesta river for survival and livelihoods, and many of their cultural and religious practices involve her in various capacities. Within an area of little more than 12000 km², the Teesta basin holds extraordinary cultural diversity; almost all major religions are represented, and various languages, ethnicities, tribes, and two nationalities can be found staying together. However, always clubbed

together as one monolithic group, the different interests, aspirations and concerns of the local communities are rarely taken into serious consideration. Through activism and a more vocal civil society on both sides of the border, it is now possible for the local communities to ensure that their fears and needs are heard. As gathered first-hand and through secondary sources, the primary issues of the local stakeholders are as follows.

- i. **High apprehension about dams and other built structures on the Teesta:** Right from North Sikkim to Kurigram, locals are highly sceptical and even fearful of the big dams and barrages built across the Teesta and their effects on the river's health and ecology. The anti-dam movement is the strongest in Sikkim, partly because most of the dams on the Teesta are concentrated there and partly because the impacts on the state's fragile ecology have been immediate and severe, but communities downstream are critical of the Gajaldoba and Dalia barrages as well. Those who supported the construction of the dams in Sikkim as well as those who see economic opportunity in the Gajaldoba and Dalia barrages are nevertheless anxious about impacts of the structures on the surrounding environment, their society, and the health of the river.

In Sikkim, there are concerns regarding safeguarding of indigenous cultures and the religious value of the Teesta, disaster mitigation and management, and obtaining the electricity supply as promised by power companies and the state government. In North Bengal, the locals worry over dams in the Darjeeling hills and Sikkim, the devastating floods caused due to their unsynchronised release of water especially in the monsoons, overall environmental degradation, and the effects of a rapidly deteriorating Teesta on their farming and fishing activities. The Bangladeshis are most upset over the Gajaldoba barrage and the resultant irregular flows of the Teesta, leading to droughts in the lean season and floods in the rainy season, year after year. The Dalia barrage, now almost defunct due to Gajaldoba upstream, is unable to meet irrigation and other water needs of the Bangladeshis, causing severe stress to their livelihoods. Project affected people across the basin are concerned about adequate and timely land compensation and employment opportunities.

- ii. **Climate change and disasters:** Local communities in the Teesta basin are experiencing climate change first-hand. Rising temperatures, greater snow melt, season shifts, erratic monsoon patterns and increase in severity of natural disasters are a current reality in the Teesta basin. Further, the effects of climate change have been aggravated by unchecked dam building in the region. The largely agrarian nature of the local population makes it extremely vulnerable to climate change and combined with a lack of latest knowledge, technology and resources, the socio-economic and environmental risks for Teesta's local communities are high. While many tribal and riverine communities have been picking up the signs from their surroundings – through observing river flow, behaviour of surrounding wildlife and climate patterns – they find it challenging to access regular, reliable and easily understandable data on what is happening to their land, water and climate. This inaccessibility obstructs farmers, fishermen and other people whose livelihoods are vulnerable to the vagaries of nature from taking timely and informed decisions to prevent or minimise their losses and arrange for substitute income.
- iii. **Migration and social upheavals:** the cases of Sikkim and Gorkhaland shed light on the sensitive nature of social and cultural diversity in the region. With two partitions, an annexation, and the birth of an eventually violent socio-economic movement (the Naxalite movement), the Teesta basin carries high social risks. Its geopolitically sensitive location makes it even more vulnerable to external interference or worse, provocation. Its economic backwardness and uneven development lead to considerable rural to urban migration, as well as an influx of migrants from Nepal and Bangladesh into Gangtok and Darjeeling-Jalpaiguri areas (which are the most developed areas of the region). There is vocal discomfort and even outrage about migrants from Nepal and Bangladesh.

Opposition to Nepali migrants is largely socio-economic, as legally, India shares an open border with Nepal. However, there is no such arrangement with Bangladesh, and a large number of migrants are illegal. In 2004, the estimated numbers of Bangladeshi illegal immigrants to West Bengal and all of India were 12 million and 5.7 million respectively (Das P. , 2016). As of 2017, the total number of Bangladeshi illegal immigrants in the country is said to be 20 million (Tripathi, 2017). This number has radically altered population dynamics in West Bengal and the North-East, leading to communal fears in the region and drawing ire at a national level. While local riparians in the Teesta basin recognise that many of these migrants, legal and illegal are fleeing, among other things, environmental and economic crises, they feel that this influx is an infringement on their lands, resources, opportunities and rights. Many North Bengalis have vouched for giving Bangladesh a fair share of the Teesta with the hopes that this might improve the agricultural situation in North Bangladesh and curb illegal immigration.

- iv. **Weak representation of local concerns and interests:** local communities across the basin feel that their actual concerns and interests find little space in bilateral negotiations and mainstream media. Many civil society organisations and activists have raised awareness about various local issues in the Teesta basin especially on the Indian side, but at the negotiation table as well as in the existing draft of the Teesta agreement, these issues are not addressed. A stakeholder survey conducted by The Asia Foundation in 2013 in the Teesta basin indicated that there was "little propensity to conduct public consultations on issues that directly affect the local people", with about 78% of the respondents never being invited to share their views before the start of a development project (Prasai & Surie, 2013). Since the survey sample was not large enough to be statistically significant, the results could be debated. However, first hand field research for this project echoed these results across the entire length of the river. For stakeholders to be heard, there has to be a platform, and only civil society initiatives can create it.

Another survey by Prasai & Surie (2013) indicated that 33% of Indian residents and 43% of Bangladeshi residents resorted to media outlets for making their voices heard, while almost similar proportions also took their concerns to local politicians. In the case of media, Bangladeshi stakeholders have fared better than their Indian counterparts. This is because the Teesta issue resonates with a larger base in Bangladesh than in India due to its geographical compactness and relative homogeneity as compared to India's vast size and variety of issues which compete for national attention. With local politicians and government officials, there hasn't been much success as negotiations have been restricted to the highest levels of the political ladder. Not only the local communities but also other important actors such as hydropower companies, prominent activists and NGOs in the Teesta Basin, and even the Chief Ministers of West Bengal and Sikkim and the Divisional Commissioner of Rangpur have been excluded from these negotiations.

The common man on both sides of the border is undoubtedly influenced by the political and media narrative over the Teesta. Fuelling his discontent is the visibly declining and deteriorating flow of the Teesta, leading her to a slow and painful death, year after year. It is natural that local riparian communities of the Teesta are emotional about her waters and her possible extinction. However, instead of letting their political representatives and the media take disadvantage of it, they need to move beyond emotions and look at the Teesta as a strategic, economic, ecological resource that needs urgent care and fortification. It is unfortunate that the bilateral negotiations do not give as much importance to socio-cultural and economic impacts of the Teesta issue on local communities as they do to geopolitical, technological, financial and security aspects. However, these four factors have a direct impact on Teesta's local communities, and must be kept in view in order to devise solutions and policies which can be pragmatic, feasible and more than an academic exercise.

B. GROUNDWATER

One of the most neglected aspects of the Teesta basin is groundwater. Not only no aquifer mapping has been done at a basin-wide scale but also there is no mention of groundwater and the regulation of its use in the existing draft of the agreement. The upper reaches of the Teesta i.e. Sikkim state is home to what is known as a 'mountain aquifer' while northern part of West Bengal and northwestern Bangladesh have alluvium aquifers which are a part of the extensive alluvium aquifer of the Indo-Gangetic plain. Accessing water from mountain aquifers is relatively more challenging than that from alluvium aquifers. They are variable and complex, and their recharge depends largely upon the relationship between slope and the underlying geology. Alluvium aquifers are vast and shallow reserves of groundwater and more easily accessible, but their recharge rate is slow.

Groundwater is used in many places in the middle and lower reaches of the Teesta basin. In the area from Sevoke to Jalpaiguri, dug wells are the main source of drinking water. Sinking tube wells is difficult in this region due to presence of pebbles and boulders hence they are lesser in number. The water table in this region is shallow with small seasonal fluctuations which makes it an almost perennial source of water. However, arsenic³⁰⁶ has been traced in the groundwater, especially in areas very close to the course of the Teesta (Bhattacharyya & Mukherjee, 2008).

Groundwater is extensively used on the Bangladeshi side of the Teesta basin, partly due to decrease in surface water, and partly because groundwater is abundantly available at a shallow level. However, between 1981 and 2011, it has been exploited to unsustainable levels and the decline in groundwater table has been found to be between -2.3 m to -11.5 m. The use of tubewells has proliferated in the region chiefly due to the rapid and widespread expansion of boro rice cultivation which consumes 78.7% of the abstracted water. Together, boro rice cultivation, resultant exploitation of existing groundwater, depletion of surface water, reduction of wetland areas and below average rainfall are major impediments to sustainability of groundwater in the region. Further, a joint study by Ahmed et al., (2004) has found moderate to severe traces of arsenic in about 60-80% of tested wells in the region.

As the volume of surface water in the Teesta and her tributaries decreases due to natural or anthropogenic factors, groundwater will become more and more crucial for fulfilling domestic and agricultural needs. However, there is no shared policy on how the groundwater of the Teesta basin will be used, conserved and improved qualitatively. It is evident that uncontrolled abstraction of groundwater is going to deplete the aquifers. Contamination of groundwater can also make it a scarce resource. If the alluvium aquifers deplete, recharging them, especially the deeper ones, is a slow process, sometimes taking hundreds of years. Surface water depletion is immediately visible and obvious and hence, an easily identified cause for conflict. In the case of groundwater, it is not so; groundwater depletion is relatively slower, inconspicuous, out of human sight, and hence out of human mind. This makes groundwater a potential and serious cause of conflict. While the Teesta basin has a good amount of groundwater, it is only a matter of time that it turns into a scarce or qualitatively unusable resource; the process has already started. Taking cognizance of this silent factor in negotiations, policies and the agreement while there is still time is of paramount importance.

C. CLIMATE CHANGE IN THE TEESTA BASIN

The Teesta basin is an ecologically diverse region, stretching from the Tibetan plateau to the tropical humid plains of Bengal. The basin has an extremely fragile ecology which is sensitive and vulnerable to climate change. It is also prone to earthquakes, droughts and floods, the intensity of which have been aggravated by large dams upstream of the river.

Average temperatures across the Himalayas and on the Tibetan plateau have been rising at rates higher than global average for about half a century now. Temperatures in the Himalayas rose at a rate of 1°C per decade from the 1970s to the 1990s (against mid-latitudinal northern hemisphere average of 0.6°C). As a result of this warming of the Himalayas,

³⁰⁶ A harmful mineral which in its inorganic form can cause cancer of skin, lungs and bladder.

snow-covers and glaciers are melting at an alarming rate, swelling Himalayan rivers and causing huge floods. Many of these receding glaciers end up creating glacial lakes. Water accumulates rapidly as snow and ice melt faster, and sudden discharge of large volumes of water and debris from these lakes causes glacial lake outburst floods (GLOFs), which cause huge destruction in the valleys downstream (Vagholikar & Das, 2010).

All these phenomena are observed in the Teesta basin as the Teesta arises from a glacier and is a perennial snow-fed river. Rising average temperatures are observed throughout the basin, and so are the changes in rainfall. Rainfall pattern in the Teesta basin has become erratic, more intense over a smaller number of 'wet' days with longer dry spells, and will continue to be more so. Such intense rainfall over a short period of time is leading to a high rate of soil erosion and landslides in the upper reaches of the Teesta, and increasing the number and intensity of floods and droughts across the basin. If this scenario continues at the current pace, in the next few decades, it is projected that the melting glaciers will at first swell the rivers with increased meltwater, but then, as the glaciers will continue to shrink, so will the volume of meltwater, and the glaciers will disappear altogether. The environmental ramifications of such an event would definitely be disastrous, but the social, economic and political consequences could be destabilising and catastrophic beyond imagination.

What is worrying is that despite a mammoth amount of research and clear evidence, climate change and its effects find no place in the bilateral negotiations and the existing draft of the Teesta agreement. It is a clearly visible ticking time bomb and yet, large dams continue to be built and the signs continue to be neglected or at best, be 'fixed' by temporary measures. Governments at state and central level might have different agendas, but they are unanimous in their dismissive attitude towards the profound effects of climate change sweeping across the basin.

D. ROLE OF DOMESTIC POLITICS IN TEESTA TRANSBOUNDARY DISPUTE

It is evident that the Teesta dispute is not restricted to the central governments of India and Bangladesh. While GoWB is directly involved in the bilateral issue, India's interests in Sikkim and Bangladesh's interests in Rangpur play an indirect role in the tussle over the Teesta. It is impossible to study this dispute by formally separating domestic politics and bilateral relations between India and Bangladesh; the two are entangled in complex ways with each affecting the other.

Despite failure of the Teesta talks in 2011, it is evident that bilateral relations between India and Bangladesh have been largely smooth. Some friction was definitely created in 2011 but it was temporary, and relations were back on track on many fronts, including the Land Boundary Agreement as well as various agreements in defense, transport, electricity, education, maritime safety etc., being signed over the next few years. Looking back, India's failure to sign the Teesta agreement looks like a speedbump in the otherwise smooth journey of India-Bangladesh ties. Moreover, the central governments of both countries have time and again shown willingness to sign the agreement, as both recognise the importance of the issue for the health of their relationship, which in turn is important for South Asia's stability and security.

Particularly, Bangladesh finds in India a natural ally – culturally, historically, economically and geographically. A secular democracy like itself, India is a trusted partner for Bangladesh in economic development, capacity building, trade, defense, research and development and combating climate change. India too sees a friend in Bangladesh, and especially in the secular Awami League government lead by Sheikh Hasina. Bangladesh is also a strategic partner connecting India to its north-eastern states, fighting terrorism in South Asia, and pursuing its 'Act East' policy. Owing to proximity and geographical similarities, India and Bangladesh experience natural disasters and climate change in similar ways. Both countries are dependent on each other for growth and stability.

It is due to GoWB's opposition that India has not signed the treaty; hence the driver behind the fundamental Teesta dispute is a domestic player. Even though GoI has constitutional powers to override the position of GoWB, geopolitical and domestic realities dictate otherwise. Much to the chagrin of Bangladesh, these factors thwarted the signing of the Teesta agreement. While relations became frosty for a while after the pull out, India more or less got away without signing the treaty, at least in the short term for the following reasons.

- i. India is the upstream riparian, as well as more powerful economically, politically and militarily.
- ii. India's location as well as strength increased its stalling capacity. Bangladesh too tried to stall transit deals which would give connectivity to India's north-eastern states with the rest of the country through Bangladeshi territory. However, Bangladesh could not stall for long.
- iii. Bangladesh has a bigger win-set³⁰⁷. Despite the Teesta negotiations falling apart, GoB braved domestic pressure and cooperated with India over many other issues. Many agreements and deals were signed between 2011 and this day, including almost two dozen deals in April 2017 alone. Due to the size and flexibility of Bangladesh's win-set, India found it relatively easy to 'make it up' to Bangladesh by offering aid and cooperation in other less contested areas and ensure at least satisfactory if not excellent ties.
- iv. In India, there were differences between the positions of centre and state, whereas in Bangladesh, the position over the Teesta deal was largely homogenous. The GoI was able to successfully use the reason of domestic pressure and friction for not signing the agreement: it satisfied GoWB without antagonising Bangladesh into defection from negotiations and deteriorating bilateral relations.

³⁰⁷ A win-set is an array of all possible outcomes that are acceptable to the negotiating party. I have borrowed this concept and related logic from the 'two-level game theory' as elaborated by Robert Putnam in his paper "Diplomacy and Domestic Politics: the logic of two-level games" published in 1988.

However, there is no doubt that an agreement over Teesta's waters is very much in India's interest and India needs the Teesta treaty to secure its friendship and partnership with Bangladesh for a stable and secure South Asia. For this to happen, both India and Bangladesh need to rework their strategies in realising the Teesta agreement. In the case of India, it needs to acknowledge the role of domestic players in the issue not only verbally, but through action. To start with, at least the two state governments need to be roped in. GoI needs to bring West Bengal, the main contender, aboard and include Sikkim as well. The tactic of offering more and more cooperation and aid in various areas to Bangladesh i.e. maximising its win-set will not work after a while; it will certainly be tested in the national elections of Bangladesh in 2018/2019. GoI will have no option but to prioritise signing the Teesta agreement by winning West Bengal's support and aligning the win-sets of Sikkim and West Bengal with its own.

It is an unfortunate fact that as the downstream riparian, the onus of getting the Teesta agreement signed lies on Bangladesh. Lowi (1993) argues that upstream states, due to geographical advantage, do not need to bother with downstream requirements and are in a position to act as they please, especially if they are a powerful regional hydro hegemon (like India and China). However, this is not entirely true in the case of India and Bangladesh as Bangladesh is important for India in many ways which have been mentioned earlier in the paper. As the downstream and non-hegemonic riparian of the Teesta, it is up to Bangladesh to strengthen its bargaining power, and through innovative options and solutions, incentivise India to get the deal through. Increasing bonhomie with China and positioning itself as a crucial partner in combating terrorism in north-eastern India has benefitted Bangladesh, but it needs to consolidate its indispensability further to push India into delivering what it wants.

Beyond the governments who are players at the domestic and international/bilateral level, there is a third level of civil society, environmentalists, academia, technocracy, corporates and activists. Currently, these actors are excluded from the negotiations. However, this does not mean that they do not wield power. Warner & Zawahri (2012) note that these non-state actors "can enter the game and influence the outcome even under conditions of power asymmetry among the riparian states" by using "their specialised knowledge, networks, and 'soft power' to challenge the authority of powerful states and alter the power equation". An example is cancellation of multiple hydropower projects owing to pressure from anti-dam activists and local communities. While non-state actors from both sides have not played a major role in the bilateral Teesta dispute as of now, they hold potential to influence and shape its proceedings. Their presence is of prime importance for the health of the Teesta and her ecosystems, and efficient use and just allocation of her resources on both sides of the border. In the Indian context at least, non-state actors provide heterogeneity in interests and positions at the domestic level. This heterogeneity opens doors for Bangladesh to find supporters on the other side of the negotiating table.

E. CONCLUSIONS AND RECOMMENDATIONS

In the complex web of conflicts in the Teesta basin, the most ignored entity is the river. Heavily dammed, mined for sand, drying in wide patches, deteriorating in quality and reeling under the impacts of climate change, the Teesta nevertheless retains traces of her once pristine beauty. Frequently subject to landslides in its upper reaches and severe droughts and floods in its lower reaches, the Teesta manages to support a population of 30 million people in her basin. She has been directly responsible for their survival and livelihoods features prominently in their cultural, recreational and spiritual lives.

The importance of Teesta to India and Bangladesh is profound. For India, she is the only major river draining two of its geopolitically important state – Sikkim and West Bengal. The Teesta also flows through the Chicken's Neck and separates the North East from the rest of the country. For Bangladesh, Teesta is the principal river in its dry, drought-prone north and north-west region which is also the poorest region in the country. Away from urban centres and markets like Dhaka and Chittagong, Rangpur division's economic growth and development relies heavily on the Teesta river. Both countries naturally want to reap maximum benefits of the Teesta though at current rates of consumption, the total volume of the river, even if used up completely, is insufficient to meet their needs. This scarcity combined with India's upstream location and hegemony is the driving force behind Bangladesh's insistence that a fair sharing arrangement over the Teesta be worked out at the earliest.

On the surface, the failure of Teesta talks in 2011 and the overall lethargy in their progression indicate a gap in Indo-Bangladeshi relations. However, apart from temporary setbacks, the bilateral ties between India and Bangladesh have sailed well and expanded into areas such as education, maritime cooperation, IT, transport and defense. Moreover, the Indian government has repeatedly voiced its consent to signing the Teesta agreement. The bilateral dispute then, is not really just bilateral; the opposition by the Banerjee-led GoWB to the terms of the current draft of the Teesta agreement is the single biggest hurdle to the fruition of Teesta negotiations. While the Indian Constitution grants the central government powers to override GoWB's opinion in this matter, geopolitical realities state that the GoI bringing GoWB onboard before signing the Teesta agreement is in the interest of the country's security, economy and political stability. For Banerjee and her government, retaining maximum of the Teesta's waters for North Bengal is important for gaining political clout in the traditionally Leftist stronghold and assuaging the discontent in the region, especially within the Gorkha community.

The current Bangladeshi government too is anxious to compensate for years of neglect of Rangpur division by securing the Teesta waters for its population, as well as provide an answer to the nationwide criticism of their failure to get the Teesta deal before the country goes to national elections in late 2018/early 2019. In this entire scenario, there is no weightage given to the river's conservation and sustainable use and development, the economic importance of her

resources for sectors like tourism, fisheries and navigation, equitability in access to and allocation of her resources among the local communities in the basin, and her resilience to various impacts of climate change.

Thus, through numerous examples throughout the paper, it has been established time and again **that the Teesta dispute between India and Bangladesh is neither a bilateral dispute between the two countries, nor is it about the Teesta river**. The term 'Indo-Bangladeshi conflict over the Teesta river' has proven to be a misnomer. The political players in the dispute have clear political, economic and security interests; it is the local communities and activists on both sides of the border who have prioritised the Teesta on their agenda. Since the river is directly connected to their social, economic and cultural wellbeing, it is understandable that the local communities strive to restore and maintain her quality and quantity.

However, it must be noted that the river is neither the exclusive nor the topmost priority of the local communities; their struggle for the Teesta is enmeshed with numerous struggles to preserve their cultural, ethnic and religious identities which have regularly overtaken the cause of saving and conserving the river. This has also resulted in difference of opinion and deep divisions within them, unlike political and economic players (such as the hydropower companies) who enjoy a relatively larger support base within their own groups. The vulnerability of local communities to environmental and social phenomena such as climate change, demographic transformations, globalisation and privatisation, and regional political dynamics is responsible for their recurring emphasis on cultural and political identity and economic fortification, sometimes at the cost of the river. The activists and NGOs who support and further their cause understand this and hence their stand too is a hybrid of the issues of the river and other socio-economic concerns of the local communities of the Teesta basin.

A conflict which has intricate layers of economics, domestic politics and regional geopolitics needs solutions that consider these layers as inseparable and legitimate aspects of the problem as well as recognise the personal interests behind each party's position and actions. Such solutions are pragmatic and able to satisfy personal interests, but in the hope that once these personal interests are satisfied to at least a certain extent, the players will acknowledge the bigger picture and collaborate to work towards a greater, nobler goal of saving and flourishing the river, her ecosystems and her people. While we cannot assume that the parties will develop such an integrated, environmental approach after their interests are met, we can certainly incentivise certain actions and policies which would lead to the betterment of the Teesta.

For India, the priority is to sign the Teesta agreement and retain the Hasina-led GoB and its friendship without antagonising the people of West Bengal. The following actions could yield results.

- i. **Involving Sikkim:** Throughout the unravelling of the Teesta issue, the state of Sikkim has been a mute spectator. Despite being the uppermost riparian with thirty-odd dams holding a substantial amount of Teesta's water, Sikkim has never been included in the discourse over sharing the Teesta, neither at domestic level nor at national level. Whether it is the state's location as the uppermost riparian, the fact that it has almost no stakes in the sharing issue, its 'special' status, or the geopolitical importance of its location that has left Sikkim 'untouched' throughout the dispute, Sikkim must no longer be kept away from the negotiating table, especially now that it shares vulnerability to climate change along with the other two regions. The main argument of the GoWB is that the volume of Teesta waters that flows into West Bengal is not enough to fulfil its needs with Bangladesh's demand to spare. Lack of synchronisation of water releases by Sikkim's dams affects the flow of the Teesta to Gajaldoba and eventually to Bangladesh. Hence it is natural, rather imperative, that Sikkim be a part of the discourse on bilateral sharing of the Teesta.
- ii. **A domestic agreement on the Teesta:** The GoI should also work towards a domestic agreement over the release of Teesta waters between Sikkim and West Bengal. In order to get the Teesta agreement signed (and not stall it) soon and especially before Bangladesh goes to national elections, it is important that all the domestic players are aligned with the GoI when it goes to the negotiation table. The domestic agreement can determine the timing, quantity and quality of flow of the Teesta up to Gajaldoba in such a manner that a maximum of North Bengal's water needs is fulfilled and flash floods downstream in southern Sikkim and North Bengal are prevented by synchronising water releases from the dams upstream. The agreement can (and should) also include quality control measures, and joint actions to increase their resilience towards climate change, protecting Teesta's ecosystems, and developing Teesta's economy in an integrated manner. Such an arrangement and its efficient and timely execution would go a long way in blunting GoWB's opposition to the bilateral Teesta agreement between India and Bangladesh.
- iii. **Water use efficiency and conservation plan for the Teesta basin in North Bengal:** It has been established that the volume of the Teesta is no longer sufficient to fulfil the demands of India and Bangladesh. The dwindling supply of her waters, be it due to dams upstream or climate change, calls for extensive demand management through serious upgradation in water use efficiency and water conservation efforts, especially in North Bengal. Since water is a state subject as per the Indian Constitution, planning and implementing efficiency and conservation measures is primarily the responsibility of the GoWB. By expanding its activities into disaster management, groundwater management and sustainable crop patterns, it can develop a blueprint for efficient water management in North Bengal. Through sustained, systematic implementation and proper awareness, the GoWB can fashion this responsibility into an opportunity to a) develop and consolidate a voter base in North Bengal, especially in the rural areas and b) cooperate with GoI on the Teesta agreement without fearing opposition from local communities and its adverse political consequences.

On the other hand, the West Bengal unit of BJP can also spearhead water use efficiency and conservation efforts in the Teesta basin in order to pave its way into North Bengal. In North Bengal which has traditionally been a Leftist stronghold, such a move would make BJP look more centrist than right wing, and not only enable the central BJP-majority government to take the unpopular decision of giving more of the Teesta to Bangladesh, but also improve the chances of BJP performing well in the West Bengal state elections in 2021. Further, such efforts would also gain traction among local communities, environmentalists, environmental NGOs and activists who are more likely to lend actual on-ground support to the GoI in conserving Teesta waters for West Bengal as well as sharing them equitably with Bangladesh. However, while the political opportunities are enormous, the risk of water use efficiency and conservation turning into a mere tool for political gains and thus being treated with a shallow, farcical approach is very real. Care should be taken that this does not happen.

- iv. **Other sources of power in Sikkim:** Sikkim's dams, though environmentally harmful and socio-culturally disruptive, are a crucial source of revenue for the state, and of power for states as far as Punjab, Haryana and Rajasthan. Hence, for economic and energy reasons at least, complete dam removal is not a practical option. However, there are two other options which GoS and GoI can explore in Sikkim. The first is constructing many micro and mini hydel projects in place of some of the dams, especially those which hold large storage capacity. Studies exploring dams that could be replaced with smaller, non-storage dams should be carried out. Also, in order to prevent micro and mini hydel projects from creating the same adverse social, cultural, economic and environmental impacts which large hydropower projects do, care needs to be taken that these projects are backed by inclusive planning, active participation of local stakeholders and strict adherence to environmental regulations.

The second option is using solar energy. The steep drop in solar energy prices and a record low of Rs. 2.44/kWh in 2016-17 (Das, Gambhir, Sarode, & Dikshit, 2017) has made solar energy an attractive, clean and cost-efficient option for fulfilling the power needs of a sunshine-abundant India. It is true that Sikkim does not have the large, flat spaces which are required to install solar panels in order to generate solar energy on a large scale. However, it can definitely explore investing in rooftop photovoltaic (PV) systems for its houses and buildings. Further, large scale solar energy production is very much possible in Punjab, Rajasthan and Haryana and must be encouraged to reduce dependence on hydropower.

With solar energy and micro and mini dams, Sikkim will truly be able to maintain the image of being an 'eco-friendly' state. This will certainly have an impact on Sikkim's revenues in the short run, but by investing in and upgrading its tourism, service and organic farming sectors, Sikkim can generate substantial revenues (even if not as much as the current hydropower projects) and definitely provide wider employment options to its local population than the hydropower projects could. These moves will go a long way in pacifying the discontented Lepchas and other local communities, as well as curb the environmental degradation in the region. It must also be noted that given Sikkim's strategic location and the current geopolitical realities in the Himalayas, it is highly unlikely that Sikkim's 'special' status and consequent benefits will be taken away. Hence Sikkim (and India) should consider the economic, social, environmental, cultural, inter-state and international impacts of its dams and take serious efforts to reduce their numbers and impacts in the Teesta basin.

- v. **Greater (incremental) autonomy for Gorkhaland Territorial Administration (GTA):** The short-term benefits of establishing a separate state of Gorkhaland for both the Gorkhas and the GoI cannot offset long term liabilities and challenges. For the Gorkhas, the current size of the GTA is too small to merit statehood, whereas expanding it to include areas of the Dooars and Siliguri subdivision will reduce them to minority status in their own state, defeating the purpose of Gorkhaland. For the central government, a fledgling state in the vulnerable Chicken's Neck would drain its financial and security resources. Also, there are other ways in which the current GoI can coax or pressurize West Bengal such as increasing its win-set through more funds, resources and other benefits, improving performance in the state during Loksabha elections of 2019, and possibly a regime change in West Bengal in 2021 are some ways in which West Bengal can be brought aboard the Teesta treaty.

In such a scenario, a separate Gorkhaland is neither desirable nor necessary. Instead, more autonomy to the existing GTA in areas of legislation, economy and socio-cultural aspects along with a robust system of checks and balances for greater efficiency and accountability would work in all parties' interests. The Gorkhas would benefit by gaining more control without losing their majority or stability, West Bengal would be able to keep its state intact and access Teesta Lower Dams III and IV, and the GoI would be able to gain more support in Darjeeling for the Teesta treaty as well as the Loksabha elections of 2019. With GoWB onboard, the option of declaring Gorkhaland as a Union Territory can also be explored.

Bangladesh's priority number one is getting the Teesta agreement signed, and particularly for Hasina's government, before the upcoming national elections. While the time frame is too short for all of the following actions are likely to be carried out effectively, the GoB needs to think and proceed along their lines.

- i. **Restricting its win set:** By signing various agreements and cooperating in a host of other fields with India, Bangladesh is effectively allowing India to get away without signing the Teesta agreement. The GoB should recognise areas in which it has the upper hand and try to strike a bargain which would entail India prioritising the Teesta river and the release of its waters to Bangladesh. India recognises the importance of the Awami League-led government for the strength of its bilateral ties with Bangladesh; this factor can be leveraged to start discussions on Teesta afresh and get a better, more comprehensive and fairer deal not only for Bangladesh but also for the local riparian communities across the basin. Bangladesh being the downstream riparian has more

incentive and need (in the short term) than India to ensure a holistic agreement over the Teesta. It must therefore take a pragmatic look at the consequences of foregoing certain cooperative or friendly moves in exchange for the Teesta agreement and choose the terms of its bargain accordingly.

- ii. **Basin-wide approach:** The Teesta is a tributary of the Brahmaputra and the Teesta basin, strategically located the wider Ganga-Brahmaputra-Meghna (GBM) basin. 83% of Bangladeshi territory lies in the GBM basin whereas about a third of Indian territory lies in the GBM basin - its management therefore is key to Bangladesh's overall growth, development and stability in greater proportion than it is in the case of India. Hence, Bangladesh cannot afford to look at it from a myopic point of view.

Even though the Teesta basin is shared only by India and Bangladesh, other countries in the South Asian neighbourhood such as Nepal and Bhutan are upstream riparians to quite a few rivers of the GBM basin. Nepal lies completely in the Ganga basin of which Bangladesh too is a part, while rivers such as Jaldhaka, Torsa and Raidak flow through Bhutan as well as Bangladesh with India being the middle riparian. Bangladesh should look beyond India and work on developing water resources with these countries at a basin level, as it already is with China. The process has already begun; under Bangladesh JRC, there have been five expert level meetings with Nepal since 2000 while a Bangladesh-India-Bhutan group for sub-regional cooperation has met once in 2013. This initiative needs to be sustained and expanded, with or without India, with a basin-wide outlook and corresponding aims to bring about all-round development in the region. Increasing cooperation between Bangladesh, Nepal and Bhutan will motivate India to step up and contribute more substantially to joint efforts on water resources management and development in the GBM basin.

- iii. **Preventing possible future domestic conflicts:** Unlike India, the Teesta basin in Bangladesh is not fraught with conflicts between different domestic constituents. However, the potential for conflicts to erupt after a stipulated share of the Teesta waters starts arriving from India very much exists and can materialise into reality very rapidly if adequate measures for equitable and efficient allocation are not taken swiftly. Besides negotiating for the agreement, Bangladesh should focus on investing in appropriate water infrastructure and cheap and effective technologies. It should also devise and diffuse best practices in water management and governance and put in place a comprehensive framework of robust water laws, rules and regulations to efficient utilisation and equitable allocation of the Teesta waters to the last drop. In the long run, these steps can play an important role in mitigating and preventing water conflicts in Bangladesh's Teesta basin.
- iv. **A far-sighted, more comprehensive Teesta agreement:** The Teesta agreement in its current form is but a narrow, reductionist and state-centric approach towards sharing the Teesta's waters. In the long run, both India and Bangladesh are likely to suffer from such half-baked water cooperation, but in the short run, the stakes for Bangladesh are higher. Before renewing its efforts for signing the Teesta agreement, Bangladeshi water experts and policymakers should take a long, hard look at the content of the current draft of the Teesta agreement and invest time and efforts in making it holistic and truly representative of the interests of the river and her stakeholders. It is true that this will push the signing further into the future, but it is better to have a delayed deal which is beneficial than to have a bad deal finalised hastily. Ideally, the geopolitical consequences of the delay should push both riparians to rework the Teesta agreement speedily and strategically and give it more vision and comprehensiveness. However, given that India is less affected in the short term, it is up to Bangladesh to initiate and propel the process.

Together, India and Bangladesh should also revise the Terms of Reference (ToR) of the Indo-Bangladesh Joint Rivers Commission. Apart from meeting regularly over the joint monitoring of the flows of the Ganga at Farakka, the JRC is carrying out other functions in a rather half-hearted and inconsistent manner. Both countries need to revamp the JRC and convert it into a River Basin Organisation (RBO) operating at the transboundary level, with more powers, more autonomy and a wider scope that includes preserving, protecting and enhancing hydrogeological properties the river, agriculture, fisheries, animal husbandry, water supply and sanitation, groundwater aquifer management, pollution control, sand mining, water for industrial use, water for tourism etc. in the basin. A strong dispute resolution mechanism, and allocation of water and financial resources within the area to obtain optimal results are fundamental. However, other functions such as establishing stakeholder fora and partnerships, and enabling regular interactions between them and relevant government departments are important as well, and need to be incorporated in the main functions of the RBO. Initially, the RBO can begin functioning on a single transboundary river basin such as the Teesta and gradually, it can be expanded to include rest of the 54 transboundary rivers shared by India and Bangladesh as well. While each river basin has its unique characteristics, an overarching, cumulative and integrated agreement and an equally holistic and effective RBO can be aimed for transboundary water security and cooperation between the two countries.

The civil society is most and directly affected by the Teesta dispute and the least heard among all parties. Whatever be its ultimate intention, civil society is the one party closest to placing the actual river and her environment high up on its agenda. In order to safeguard the river and ultimately its own survival, civil society needs to regroup and take the following actions.

- i. **Clamour for a better agreement:** Local communities, activists and NGOs across the basin need to prioritise a better Teesta agreement, drawn on the lines of environmental sustainability, resilience to climate change, economic efficiency and equitable allocation of Teesta's waters. Through community outreach programs, NGOs and activists can spread awareness about the contents of the current draft of the agreement and sensitise local communities towards factors such as climate change, environmental flows, groundwater management, disaster mitigation,

- heritage preservation, and protection of Teesta's flora and fauna which have been omitted from the draft. This sensitisation has to be accompanied by political awareness drives which relay domestic and international political equations, regional geopolitical realities, various narratives of the issue on both sides of the border, and the economics of the Teesta dispute to the local communities in an easy-to-understand manner. The objective is to develop a well-informed consensus in order to negotiate longer and better, and a combination of environmental and political knowledge would empower the communities with a realistic and greater grasp of the situation and further contribute to their struggle. With this multifaceted understanding, the local communities would be in a better position to understand the motives and agendas of their political representatives and bureaucracy and demand a better agreement followed by accountability from them.
- ii. **A more assertive role of the epistemic community**³⁰⁸: The epistemic community too has a huge role to play in this regard. While many studies have been conducted on the environmental, economic, social and scientific aspects of the Teesta basin, its geopolitical dimensions and entanglement of bilateral and domestic politics is rarely focused upon. Deeper and more sophisticated analysis of the geopolitics of the Teesta basin is the need of the hour. The epistemic community needs to probe further into these dimensions of the Teesta dispute and work twofold: on one hand, empower the civil society with their findings and analyses and on the other, advise the negotiating parties at both domestic and bilateral level to implement solutions that would make everyone better off.
 - iii. **Stronger track II diplomacy**: The nature of Teesta negotiations is state-centric and in dire need of more consistent and robust Track II initiatives to solve the Teesta issue, which can be taken up after sufficient progress is achieved in the two areas as mentioned above. Initiatives such as the India Bangladesh Roundtable on Blue Peace in the Eastern Himalayas – convened in Mumbai by Strategic Foresight Group, a Mumbai-based think tank, and attended by 25 senior diplomats, Members of Parliament, former ministers and experts from India and Bangladesh (Strategic Foresight Group, 2013) – should multiply and be publicised extensively in mainstream media. This will play a crucial role in disseminating vital facts and figures about the issues in the basin across both countries and provide narratives which are relatively less politicised and biased to locals in the Teesta basin and the Indian and Bangladeshi population at large.
 - iv. **Push for water conservation measures**: Recognising that decentralised water management and localised solutions are not as lucrative for governments as large-scale irrigation and hydropower projects are, NGOs, activists and the epistemic community should spearhead the spread of water conservation and efficiency practices which can be directly accessible to and implementable by local communities. Rainwater harvesting, farm ponds, rooftop solar PV and water-efficient cropping patterns are some solutions which can be implemented at an individual and community level with NGOs providing technical know-how and access to basic materials. Water security is a crucial aspect of social and economic stability, and access to such easily applicable solutions will go a long way in improving and conserving the river and inculcate both resilience and confidence in the local communities. With their basic risks and vulnerabilities addressed, the communities will then be in a better position to demand overall conservation and development of the Teesta basin.

1641 SPATIAL E-GOVERNANCE FOR CONSERVATION OF WATER BODIES AND THEIR CATCHMENTS IN SETTLEMENTS OF INDIA

Honey Jalali, Sanjukta Bhaduri

Amity University Haryana honeyjalali@gmail.com

School of Planning, sanjukta.bhaduri@gmail.com

ABSTRACT

Water is a prime natural resource, a basic need and a precious asset. Technically it is considered a renewable resource because it can be used over and over again and it has a rain cycle. But the sustainability of this renewable resource is already questionable. The New Urban Agenda, Habitat III, held at Quito Ecuador 2016 recognizes that the inhabitants of developing countries are vulnerable to extreme impacts of climate change and other natural and human-made hazards, extreme weather events, including heat waves, flooding, water scarcity, droughts, and water and air pollution. In the context to these impacts status of water bodies and their catchments which are cushions to the settlements in India needs attention. The country has well developed National Water Policy, State Policies, River Action Plans, Conservation Plans, institutional framework, allocated funds in place since decades but we still don't find methods for successful rejuvenation of water resources. On the other hand development has negatively impacted water bodies.

One such case is the Ganga river flowing through the city of Varanasi (3,676,841 Population) within the Ganga Basin which covers 11 states in India. This city known as the oldest living cities in world with its huge Tourism potential is a land of challenges and opportunities coupled with its complex socioeconomic cultural, environmental and institutional aspects. It is associated with deteriorated Ganga rejuvenation and other pressing urban issues. The stakeholders to the water management challenges include government, private players, civil society and communities. To foster transformation there is a need to build synergy across scales by devolving functions and empowering stakeholders. For immediate contextual solutions or actions, there is immense potential with communities which needs to be tapped. Active community participation can enable revival of water bodies irrespective of their population hierarchies. However the use will be dependent upon the scale of water body and the population it can serve. This capacity building would strengthen communities and make communities resilient to uncertainties. Communities can revitalize traditional methods of water conservation (formalized local solutions) and therefore conserve and monitor local natural resources. Along with the increased autonomy, communities need to be a part of interactive spatial planning. Spatial e- governance can therefore act as platform for people to interact with the government.

This paper will explore mechanism of participation that can be applied for Protection and Conservation of Water Bodies and their catchment for Indian Settlements.

Key words: Spatial E- Governance, Water Bodies, Conservation, Community Participation

1 INTRODUCTION

Water as one of the most essential natural resource, is greatly threatened by human activities. Its consumption and pollution can be associated with specific activities, such as irrigation, bathing, washing, cleaning, cooling and processing. Total water consumption and pollution are generally regarded as the sum of a multitude of independent water demanding and polluting activities.

Some studies reports that there will be a severe lack of drinking water in next 2 decades and this effect can already be seen today but with less severity. Although there is the same amount of water on the earth today as there was when the earth was formed, only 3% of this water is usable and this figure is decreasing with time as more and more water becomes contaminated or polluted.

A 2006 United Nations report stated that "there is enough water for everyone", but that access to it is hampered by mismanagement and corruption, UNESCO (2006) Water, a shared responsibility. Therefore planning and management of water resources needs to be governed. The UN World Water Development Report (WWDR, 2003) from the World Water Assessment Program indicates that, in the next 20 years, the quantity of water available to everyone is predicted to decrease by 30 percent. Also 40 percent of the world's inhabitants currently have insufficient fresh water for minimal hygiene and more than 2.2 million people died in 2000 drought, globally.

The New Urban Agenda, Habitat III, held at Quito Ecuador 2016 recognizes that the inhabitants of developing countries are vulnerable to extreme impacts of climate change and other natural and human-made hazards, extreme weather events, including heat waves, flooding, water scarcity, droughts, and water and air pollution. The forum therefore commits itself to protect, conserve, restore and promote the ecosystems, water, natural habitats, biodiversity, minimize their environmental impact and change to sustainable consumption and production patterns in developing counties.

The developing India in South Asia has about 16 per cent of the world's population as compared to only 4 per cent of its water resources. With the present population of over 1,000 million, the per capita water availability is around 1.170 cu m/person/year. Severe water shortages have led to a growing number of conflicts between users in the agricultural and industrial sectors, as also the domestic sector. Water consumption of 135litres per capita per day (CPHEEO norms) is an unattainable ideal number for many Indian cities. With less than 1,500 cum of per capita renewal water resources per year, India is already classified as a water scarce country.

Also the lack of water availability or accessibility and poor management practices have manifested in poor sanitation facilities, which is among the biggest environmental and social challenges India faces today. In the next fifty years, India is projected to face the challenge of feeding a population of 1.6 billion people with a higher level of welfare than at present. The current view of the Indian government on food security is to hold on to the goal of food self-sufficiency but agriculture is the main consumer of water which will further increase the pressure on the renewable water resources. In order to reduce the pressure on renewable water resources, the Indian government has created National Water Development Agency (NWDA) to study and implement the concept of river interlinking as the solution for water scarcity in the drier regions. This concept means that water abundant regions will provide water to water scarce regions through the connection of rivers. The [Agency](#) had identified 30 links (16 under peninsular component and 14 under Himalayan component). Whether the interlinking of rivers will provide enough water to solve the observed and future water deficiency in the country with contextualized solution is still unclear.

The only long term option for reducing the national water scarcity and remaining food self sufficient is to increase the water productivity in India. The largest opportunity for this increase lies in East India, where there is an abundance of water and a large increase in water productivity seems possible. (The Water Footprint of India, April 2007).

2 PLANNING FOR WATER SECURED COMMUNITIES

The river basins of India are classified into Water Resource Information System of India (WRIS), Central Water Commission (CWC), National Commission for Integrated Water Resources Development Plan (NCIWRDP), Department of Agriculture and Cooperation, (AISLUS) and Central Ground Water Board (CGWB) Basin. This classification suggests different major river basins and delineates many other sub basins boundaries which are for different purpose of surveys and methodological analysis. Therefore even the National Water policy India (2012) recommends that the solutions for water resources must be given at basin or sub basin level. One of salient features of policy is that water sharing / distribution amongst the states should be guided by a national perspective with due regard to water resources availability and needs within the river basin. This means that all developmental projects in a basin should be formulated within the framework of an overall plan for a basin/sub-basin followed by integrated and multidisciplinary approach to river basin planning, catchment management, ecological aspects, rehabilitation of affected communities and establishment of an appropriate organization at the river basin level for ensuring optimum and balanced development of the water resources of a river basin.

Despite of River board Act 1956, no such effective river basin authority has been established in the country though number of basin organizations has been created for limited purposes such as speedy implementation of master plans for specific purposes. Therefore for basin-wide solution, sustainable contextual solutions must be strengthened.

Keeping in mind the sustainability challenges for Indian cities with respect to water sector, a demand focussed alternative approach, preventing urban water pollution, promoting recycling reuse as well as conservation of local resources is significantly required to ensure universal access in case of uncertainty. This can reduce per capita water resources to release the stress on city services and therefore basin. Further how we use, manage, waste or pollute water can determine the sustainability of communities.

Figure 1: Planning for Water Secured Communities

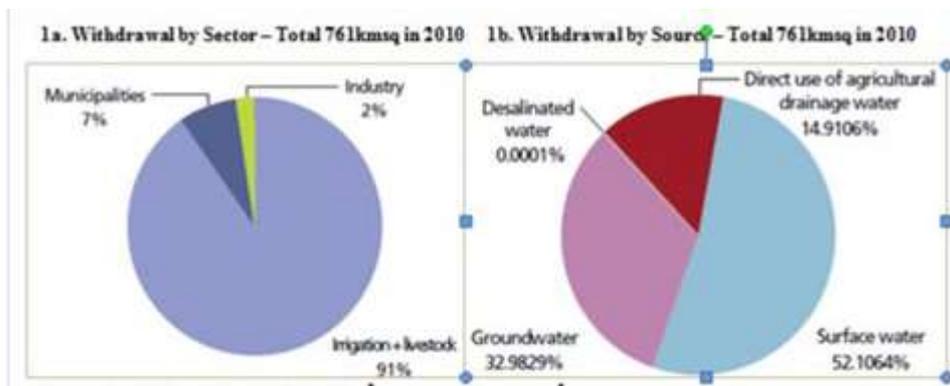

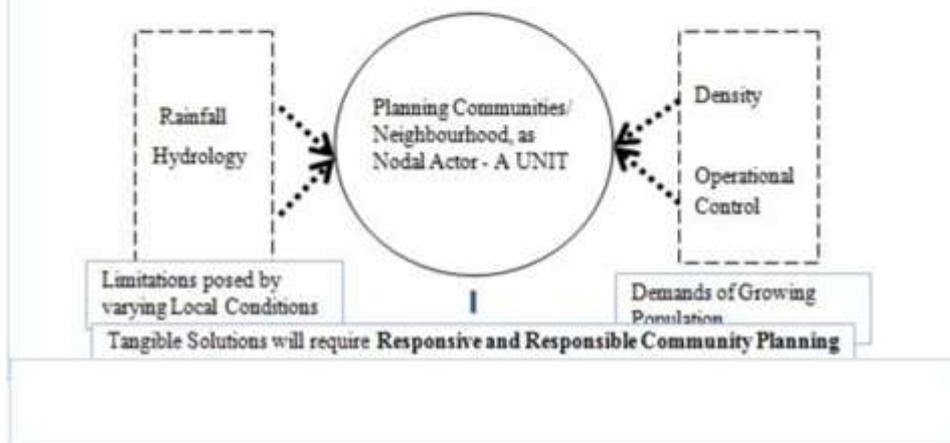

Figure 2: Factors Impacting Communities

Communities with Indigenous knowledge + Conservation of Water Bodies + O & M, Spatial E Governance (supported by SDI) = Continued Water Availability

Source: Author’s Understanding of Literature

For the success of efforts taken to keep up to the sustainability challenges an important opportunity is to build up synergy between all the stakeholders to the adverse effects. These include communities, government, private players and civil societies (representative of communities). Empowering stakeholders and devolving power or functions among stakeholders especially to the communities of a context through mechanism of community participation would enable effectiveness in water body conservation.

3 CHANGING STATUS OF WATER BODIES IN INDIA

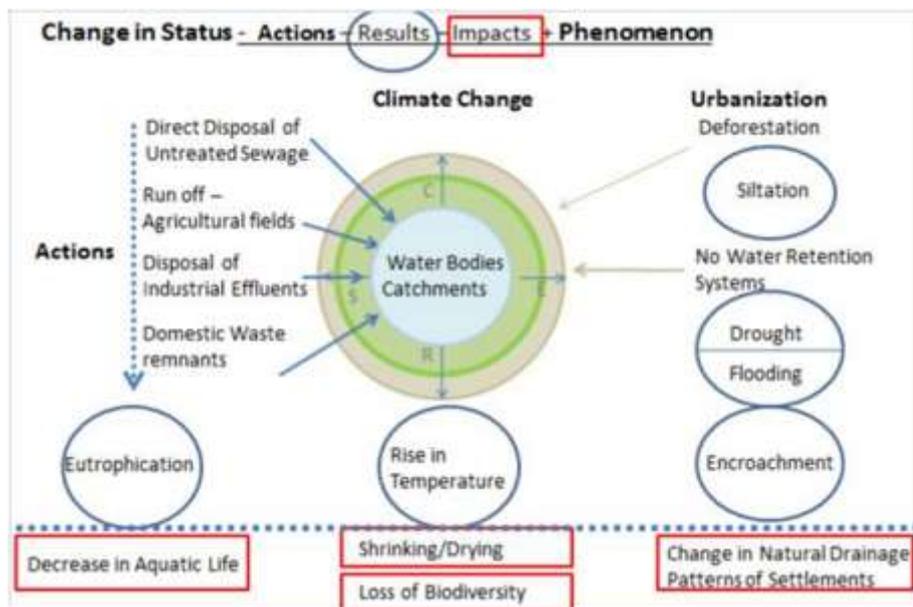

Historically water bodies were the centre of socio-cultural, recreational and economic activities. People used them as important gathering space, for rituals, fishing, boating etc. Over few decades with increased water pollution, people started moving away from river fronts or water bodies. They started residing in areas with high ground water table and have been exploiting ground water reserves. This movement marked the beginning of visible ignorance of man towards water bodies & the rivers, or water bodies gradually became the back of the city.

A very well-known reason for this high level of water pollution is the careless untreated direct disposal or leakage of sewage coming from populated areas into the water body. The tertiary treated water or the grey water achieved cannot be used for drinking purposes.

Therefore the naturally existing water body even when accessible is equivalent to non-existing feature for the people and is slowly becoming a dumping ground or a Nallah carrying waste. The phenomenon of Climate change (high temperatures) and urbanization over decades have added to the stress on water bodies leading to shrinking and drying up. Many Indian cities have faced haphazard unplanned development; consequently many water bodies were lost due to encroachment to accommodate uncontrolled spread of development.

As water is part of larger ecological system, shrinking of a water body also means loss of biodiversity. They remediate pollution, cool their surroundings creating a micro climate and acts as a cushion against adverse effects of climate change and heat waves. Water bodies can serve as emergency sources for water and recreational areas. These are very well connected to other sectors like urban health (reduce vector and water borne diseases), economy & finance (reduce costs of managing floods and scarcity) and ecology & environment of a city.

Figure 2: Changing Status of Water Bodies

Source: Author’s Understanding of Literature

To conserve local water resources there can be 4 revival mechanisms. Firstly there could be **technological interventions** (technologies for water quality management, develop water budgets starting from smallest scale, developing bioremediation & ecological engineering technologies). Secondly, **policy interventions** (developing water conservation policies at city level) or devolving conservation & management of water bodies to local communities. Third mechanism can be as simple as **making information** like water balance, water budget, city water status **available to city dwellers** and allowing them **access to easy statistical and monitoring data to ensure their engagement in the process**. Lastly and importantly is the **economic and financial mechanisms which will assess value of ecological services** (allocating budget for water body restoration and conservation projects & developing livelihood activities to support conservation & management).

For immediate contextual solutions enabling reduction in local water scarcity for all types of uses in India, there is immense potential with communities which needs to be tapped. Active community participation can enable revival of water bodies irrespective of their population hierarchies but all sizes of water bodies cannot be conserved.

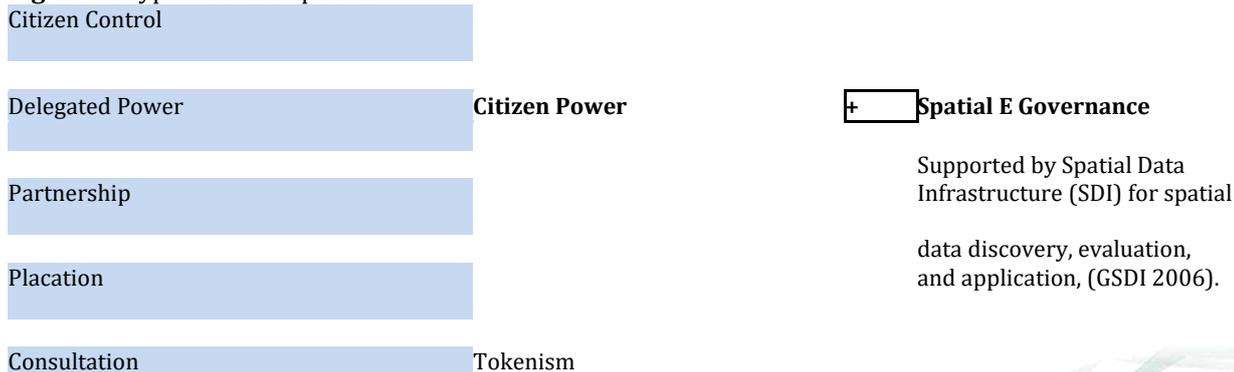

4 COMMUNITY PARTICIPATION AND SPATIAL E- GOVERNANCE

Communities can revitalize traditional methods of water conservation (formalised local solutions) and therefore conserve and monitor local natural resources. However the use will be dependent upon the scale of water body and the population it can serve. This capacity building would strengthen communities and make them resilient to conflicts during scarcity. Water being a common need for all dwellers, will foster community development as all will share common interests and goal. Therefore conservation of water bodies can play vital role in community development as it will involve active inclusion and equity in sharing.

On the other hand Community participation which enables bottom up approach in governance needs to be practiced with spatial e- governance for faster and effective interaction between the two stakeholders, communities and the government. Successful engagement with communities can improve quality of policy being developed, efficient service delivery, opportunity for government to check its reputation among citizens and close collaboration will lead to early notification of issues enabling proactive solutions.

The 6 “C” of successful community engagement includes – capability, commitment, contribution, continuity, collaboration and conscience (Brown and Isaacs, 74). Also the categorisation of various types of people involvement is important in realizing participation in true sense.

Figure 3: Types of Participation

Informing

Therapy

Manipulation

Non-Participation

Source: Eight rungs on the ladder of Citizen Participation, Sherry R Arnstein,

The nature of interaction and level of participation for interactive spatial planning between stakeholders is another set of research. The idea is to improve socio – technical network by educating and make stakeholders aware on the use of spatial data for e-governance apart from collaboration, cooperation and coordination. This is must to address the implementation challenges and realise the development goals.

5 LAYERS IN VARANASI, GANGA BASIN

The city of Varanasi within the Ganga Basin lies in the northern Indian state of Uttar Pradesh. It is a Class II city with a total population of municipal area as 1,201,815 (as of 2011) and total population with Urban Agglomeration is 1,435,113. The total Inflow of Tourists in the year 2013 was 52, 51,413; in which domestic tourists inflow is 95% of the total. Month-wise statistics of tourist shows that the peak season for tourist inflow is between October to March, as all the important fairs and festivals occur within these months. 'Education and research' is the first priority by International Tourists, and 'pilgrimage/spiritual tour' is the main attraction for maximum percentage of domestic tourists.

This heritage city is an example of a traditional human settlement, mix land-use, river edge representative of a culture, of another form of human interaction with the environment associated with its many tangible and intangible aspects. The intangible heritage includes the natural landscapes, and the cultural heritage in form of musicians, dancers and writers. Indian National Trust for Art and Heritage (INTACH) enlists 1700 heritage structures at Varanasi and Master Plan 2011 has identified 5 heritage zones namely

- *The Ganga River and the Riverfront Heritage Zone*
- *Durgakund-Sankatmochan Area*
- *Kamachcha-Bhelupura Area*
- *Kabir Math (Lahartara) Area*
- *Sarnath*

The Ganga and it's Ghats receives maximum attention followed by Vishwanath and Sarnath Temple from both international and foreign tourists. (Rana, Pravin S, 2011). The city has 5 major pilgrimage mandalas; Caurasikroshi Yatra, Antargraha yatra, Avimukta yatra, Nagarpradakshina yatra and Panchkroshi yatra. It takes 5-6 days to complete the yatra passing by 5 halts or villages namely Kardmeshwar, Bhimchandi, Rameshwar, Shivpuri and Kapildhara. This yatra starts and ends at Manikarnika Ghat at river Ganga. This leads to an opportunity to develop these circuits along with tourist infrastructure in order to increase the frequency and duration of stay of tourists at Varanasi which has been stagnant since past few years.

Table 1: Five Zones of Varanasi

City Zones	Density /Landuse	Activities
The Core City (Ghats Area)	High Density in heart of the city	Tourism, other economic and Religious activities.
The Trans Varuna Zone (upper Varuna)	Less Dense outer area of city	Sarnath as tourist attraction.
The South Varuna Zone (central area of the city)	Second highest density of population	Unplanned residential area.
The South Assi Zone	Planned Density	Banaras Hindu University area as attraction.
The Trans Ganga Zone (area outside the municipal boundary but including in the planning boundary.) Ram nagar	Under construction, poor connectivity with core city, lacks all basic services and infrastructure.

Active Ghats at Varanasi

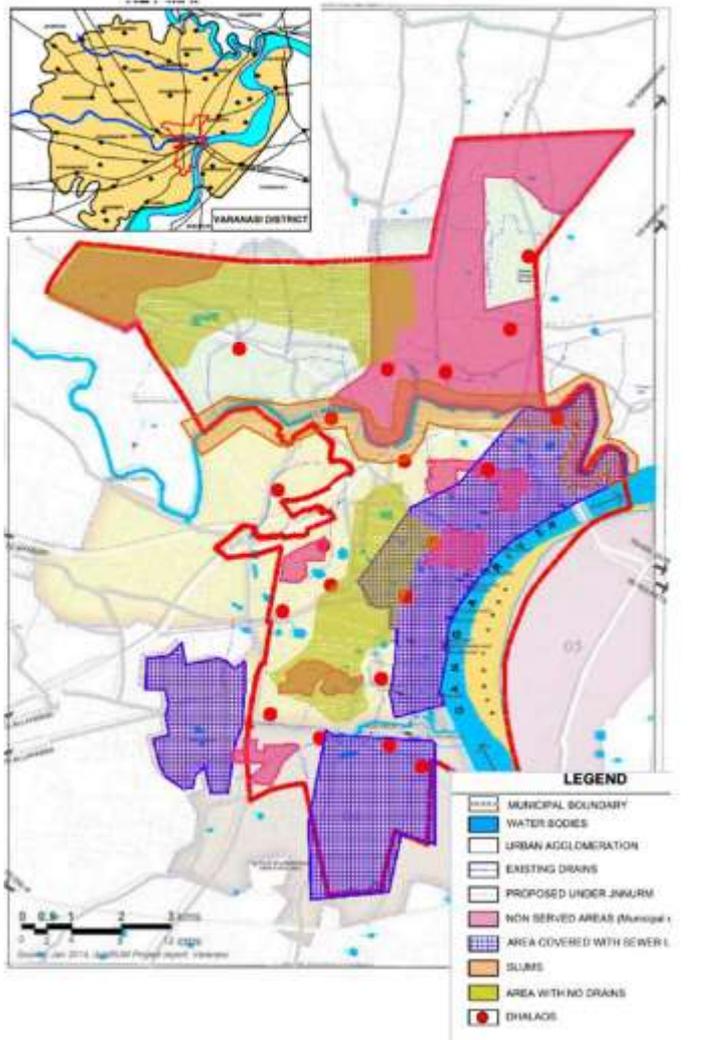

a. Infrastructure Status

Water supply system for Varanasi is as old as 125 years .It was introduced in year 1892 and was designed for the population of 2 lakhs with a treatment plant of 33mld constructed at Bhelupur. At present, the Jal Nigam, which is the supply agency, supplies 170lcpd but the users receive only 70-80lcpd. The 100 years old distribution system accounts for 20% water losses. The lifeline of the town is River Ganga, which takes care of approximately 45% of the water supplied of the town.50% of the water supplied is met out of 112 deep tube wells operated by Jal Sansthan and remaining 5% is supplied by publicly and privately owned 1559 hand pumps.

The raw water extracted from Ganga River at Bhadeni gets treated at two water treatment plants at Bhelupur water works. Capacities of the Water Treatment Plants (WTP) are 60MLD (1954) and 250mld (1994).

Only 30% of the total area is provided with underground *sewer network* with total length of about 400km due to which most of the sewage is disposed in the river Ganga without any treatment. The Trunk sewer 750mm to 2400mm is hundred years old and stretches to 7.4km. There are 2 main and 5 intermittent Pumping Stations (PS) for entire the city. The three Sewerage Treatment Plants (STPs) in Varanasi viz. Dinapur, Bhagwanpur and Diesel Locomotive Works (DLW) STP holds a capacity of 80mld, 9.8mld and 12mld respectively.

Map 1: Issue Mapping, Physical Infrastructure

Source: Studio Work, MUP, SPA Delhi

Solid waste generated in the city is 600 MT at the rate of 0.46 Kg per capita per day. A total of 2100 workers are associated with waste management where 4200 are required and therefore door to door collection is not being practised and waste is thrown on streets (collected by safai karamchari's).

The drains in the city are inefficient and instead of storm water it carries waste from slums and septic tank to Varuna. River. The low lying areas of Ghats experience water logging and associated issues.

The quality of water and the sustainability of the surface water resource is under threat due to pollution, the main reasons for which are discharge of untreated sewage, Solid waste dumping, encroachment of catchment areas and religious activities particularly in case of River Ganga.

Assi Nala contributes 10 MLD of untreated sewage into River Ganga. The Varuna receives sewage from 22 municipal drains located on both side of the river in addition to agricultural run-off at some selected points.

b. Governance

With different agencies like Nagarpalika, State Government agencies at power, influencing parts of city it becomes difficult to comprehend sector wise accountability of agencies in order to understand functioning of the city.

The major issue in institutional setup is that of overlapping roles of different agencies and the gaps and deficiencies in existing system which needs to be build upon via capacity building measures. For sustainable Ganga rejuvenation and Ghat improvement formal and informal sector (26%) needs to participate as one community and work towards sustainable heritage tourism and water body conservation through platform of spatial e governance. This will lead to cleaning of Ghat areas and reduce some percentage of pollutant into the city and consequently into the Ganga.

CONCLUSION

The revival of water bodies is imperative in the dynamic urban scenario of Indian cities and there are many tangible and intangible factors impacting communities and their actions leading to deterioration of water bodies. At urban planning level the five zones of Varanasi have their own set of infrastructure issues ranging from old piped systems, 20% transmission losses, no community taps in public area or slums, ground water exploitation leading to depletion of resources, contaminated water supply and lack of system in new zone. These issues are followed by activities on ghats,

sewage being drained into river as 70% areas are not covered and STP's are either over loaded, directly discharging into river or inefficient.

The strategy is to intercept drains carrying waste of septic tank and toilets, installation of new lines and equipments, reuse of treated water all aiming to achieve service level benchmarks for infrastructure up gradation.

The environmental issues identified are Water Pollution, Poor Air Quality, Risk of Disasters and High Noise levels. Therefore Policies and strategies have been suggested to minimize the issues and to work towards sustaining the environment of Varanasi. Most of the proposals given are sector wise for each zone as each contextual problem is adding to wider catchment and basin issues.

The reasons for the lack of success in Ganga Rejuvenation are the absence of long-term planning, poor co-ordination and failure to sustain existing infrastructure for water and sewage treatment. For wider economic and environmental benefits community participation, access to easy information, education, and spatial e governance clubbed with Public private partnership models for Ghats developments, tourism enhancement, utilization of external aid and global expertise would be an effective tool. This approach may lead to sustainable Ganga Rejuvenation in Varanasi.

1154 EVALUATION OF WATER MANAGEMENT IN COASTAL REGIONS OF BANGLADESH

ABSTRACT

The geographic location, low-lying topography makes water management of southwest Bangladesh as a matter of great importance. Six major land cover/land use types were delineated using satellite data such as forest land, agricultural land, fallow land, water bodies, settlement and gher areas. During 1980-1990 decade, the study area had witnessed substantial increase in forest land, agriculture land and water body, but decreased in settlement and fallow land. LU/LC changes were of highest amount in forest land from 3496.6 km² to 4366.94 km², with a net addition of 870 km² and lowest amount in settlement from 2616.9 km² to 1208.81 km², with a net decrease of 1408.09 km² and fallow lands showed a net decrease of 315.34 km². The share of agricultural land was 14.13% of the total area, which increased up to 19.21%. The water body was increased from a share of 12.21% to 13.86% and gher area faced a slight increment in the total share from 3.48% to 3.6%. At that decade, initial benefits of CEP might be responsible for the escalation of agricultural lands and coastal afforestation started with the objective of protecting the coast from cyclones and foreshore that increased the forest lands. But weak structure and wrong design of the embankment projects caused water logging between this decade that was the reason behind the reduction of fallow lands and also created scarcity of drinking water and extensive salinity and because of these sufferings people had been shifted to another place. During 1990-2000, forest land shrank from 36.26% to 35.06% of the total area while agricultural lands reduced from 19.21% to 18.54%. But fallow lands showed a net decrease of 691.86 km² at that time. On the other hand settlement area was largely broadened from 1208.81 km² to 2027.7 km². Water body and gher area had also increased in area (by 104.12 km² and 5.36 km² respectively). At that time, rivers and canals lost their natural flow because of the poor maintenance of embankments or water management projects that triggered sedimentation which had blocked these rivers and canals and caused upstream drainage congestion of flooding with saline water. This situation was responsible for the reduction of agricultural and fallow lands and also for the escalation of gher areas and water body. With the introduction of commercial shrimp farming in polder areas settlement area had increased and in contrast forest land had decreased. During 2000-2015, major decline with respect to area coverage in the study area was observed in agricultural class (by 573.7 km²) whereas the area of gher was increased (by 801.29 km²). Fallow land shrank from 11.26% to 8.1% of the total area while water body increased from 14.69% to 17.18%. Settlement has decreased in area (by 141.2 km²). In the meantime forestland has increased from 35.06% to 35.35% of the total area.

SS02.1. Smart Cities Initiatives for the 21st Century: Myth or Reality

1240 PEAK-HOUR SPREADING IN PARIS REGION? THE MYTH OF FLEXIBLE WORKING HOURS

Emmanuel Munch

Laboratoire Ville Mobilité Transport UMR T9403 ENPC IFSTTAR UPEM, emmanuel.munch@enpc.fr

ABSTRACT

To reduce congestion during the morning rush hour, the solutions typically advanced are based on technical considerations: it is company schedules which dictate that workers all commute at the same time. One solution proposed by traffic engineers and policymakers is therefore to promote flexible work schedules. Against this background, the article challenges the assumption that introducing flexible work schedules will automatically have the effect of phasing passenger flows around morning peak periods. Drawing on an international literature review and data from the last national household travel survey in the Paris region (ENTD 08), it reveals new findings that are apparently paradoxical. Far from leading to staggered workplace arrival times, flexible working hours would instead seem to be associated with an increase in the concentration of journeys within the morning rush hour.

INTRODUCTION

The standard and symbolic representation of rush hour coincides with what we know about the history of the wage economy and the development of cities during the Industrial Revolution. It was the factory sirens, the time clock at the entrance, surveillance by the bosses and more globally the standardisation of work that determined the simultaneity of working hours (Godard, 2007). Necessary as it was to the proper operation of production systems (Lefebvre, 1968), the collective and uniform imposition of standardised working hours generated rush-hour congestion (Thompson, 1969).

Today, with the rise of the service economy and the “dematerialisation” of production activities in the big urban centres (du Tertre, 2005; Castells 1999), an ever-increasing proportion of the working population is able to access working hours that are no longer subject to the explicit diktat of the employer. The term for this situation is *flexible working hours*. For example in Île-de-France, a region particularly subject to problems of public transport congestion (Koning, 2011), the percentage of working people who set their own working hours is rising steadily, increasing from 24% in 1994 to 30% in 2008 (ENTD 1994 and 2008).³⁰⁹ According to the transport economic literature (Small, 1982; Vickrey, 1969), when individuals experience delays and discomfort associated with rush-hour travel, they try to avoid them by changing their working hours, provided that their contracts allow it. The increase in the proportion of employees able to choose their work schedules should lead to a reduction in rush-hour commuting and contribute to an improvement in travel conditions.

This postulate is reinforced by a theoretical premiss that underpins our shared vision of life in big cities in the late 20th and early 21st century. Whether we describe these urban lifestyles as *postmodern* (Harvey, 1990), *postindustrial* (Godard, 2007) or *hypermodern* (Ascher, 2000; Urry, 2000), the terms overlap to form a relatively unified definition of the ways in which people organise their time, by contrast with the practices observed in the “industrial period” (understood as the period extending to the end of the 1970s). The image of everyday life today as flexible, individualised and desynchronised is contrasted with the collective and temporal rules that previously structured day-to-day living patterns in the city and more broadly in society as a whole (Rosa, 2015; Dubet, 2009; Baumann, 2000). In this view, present-day ways of life in the big cities of the West are a photographic negative of the old ways.

The cause of travel spikes during the industrial period, on the one hand, and the factors driving their mitigation during the post-industrial period, on the other, provide a before and after image of the impact of the organisation of work on the rush-hour phenomenon: in one, the standardised working hours set by employers were the cause of the excessive synchronisation of commuting times; in the other, the end of employer-imposed working times are seen as contributing to the desynchronisation of morning travel.

On the basis of this “belief-image” (Laplantine, 1989), the non-governmental organisations (AFD 2016; OECD, 2010) which set and promote transport policy now emphasise flexibility in working hours as a way to reduce rush-hour congestion. However, these recommendations are only very rarely challenged and their real impact assessed (Shen et al., 2013). Time is still experienced as an abstract and obscure datum that is only very rarely submitted to evaluation in public policies (Coulombel, El-Mahrsi, Munch, 2017).

Indeed, a review of the academic literature reveals a certain vagueness on the issue. There is no discipline that fully takes on board the question of flexible working times and their effects on rush hours (Munch, 2017). Whether in transport research or sociology, there have been no studies that have looked directly at the effects of flexible working hours on the distribution of employees’ workplace arrival times. There is research in the transport field that focuses on rush-hour congestion but only partially tackles the factors that determine working hours. In the sociology of work, there are a few studies in France that draw on Time-Use Surveys to explore the issue of flexibility in working hours, but without ever connecting it with the problem of the rush hour.

³⁰⁹ ENT D for Enquête Nationale Transports et Déplacements (National Transport and Travel Survey).

Given this compartmentalisation and these uncertainties, the goal here is to explore the relation between flexible working hours and the distribution of workplace arrival times: do people who can choose their own working times in reality defer their time of arrival at work more than employees who are still subject to standard working times set by their employers?

In contrast with the common perception, we show that the flexibilisation of working times does not have the effect of distributing passenger flows on either side of rush-hour periods. To the contrary, we reveal findings that suggest that flexible working hours produce effects that run entirely counter to those anticipated.

We thus advance an argument that is apparently paradoxical: far from leading to more staggered workplace arrival times, flexible working hours are in fact associated with greater concentration of these arrival times.

In this way, the article makes a twofold contribution. First, from an operational perspective, it issues a warning against the current direction of certain public transport policies. Second, it contributes to theoretical debates in the social sciences. In fact, by opposition to most social science theories, we show that flexibility in working hours is not associated with the desynchronisation of working times (7/7, 24/24) but rather with their temporal synchronisation and concentration. In the era of pliable schedules, our research therefore qualifies the notion of a growing and general desynchronisation of day-to-day activities (Rosa, 2015; Mallet, 2012).

In methodological terms, we will focus on the morning rush hour because commuter concentration is often more intense in the morning than in the evening (Thorauge, 2015; Fosgerau & Kalrström, 2010) and the inconveniences (discomfort, delay...) associated with it are therefore intrinsically more objectionable. It is primarily for this reason that the potential impact of flexibility in working hours is particularly interesting to study at this time of day.

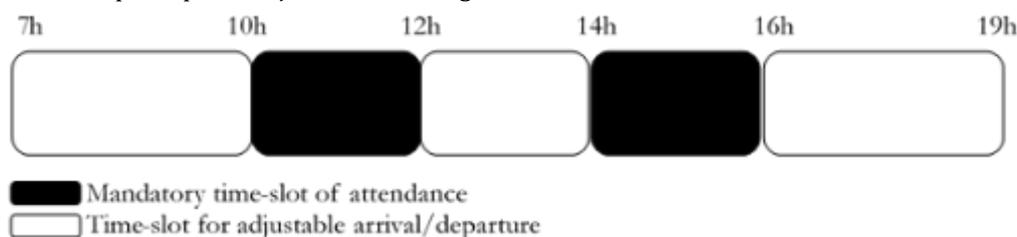

First of all, we will see that in the late 1960s, flexible working hours were precisely conceived as a managerial policy that would enable employees to avoid rush hours. Then, on the basis of an analysis of the scientific literature, we will compare the anticipated effects of flexibility with the effects actually observed on the spread of workplace arrival times. This analysis will reveal conclusions that are markedly less categorical than the predictions of managerial policies. Finally, drawing on the 2008 National Transport and Travel Survey, we will show that the greater the flexibility that employees in the Paris region enjoy in choosing their working hours, the more concentrated are the times at which they actually arrive at work.

1. FLEXIBLE WORKING TIMES CONCEIVED AS A WAY TO SPREAD TRAFFIC FLOWS

1.1 Genesis and conception of flexible working hours

Before looking at the genesis of *flexible working hours*, we first need to define the term itself. There are two levels of definition. First, flexible working hours are defined by opposition to *fixed working hours*: *flexible working hours* are working times that are not officially set by the employer. Second, they can then be broken down into two different degrees of freedom: *free scheduling* and *adjustable scheduling*. In the “freest” scenario, freelancers or autonomous employees are at liberty to arrange their working hours on a daily and/or weekly basis. In the case of employees, we speak of “annualised hours” or “fixed-salary employment contracts”, which nevertheless have to comply with the law on working hours as calculated over the year (35 hours per week, i.e. 1607 hours per year) and on weekly rest times. With a lesser degree of freedom, *adjustable scheduling* refers to the employee’s ability to choose when to arrive at and to leave work, but subject to minimum and maximum thresholds set by the employer. In Figure 1, employees can arrive when they want between 7 a.m. and 10 a.m., take their lunch break at any time between 12 noon and 2 p.m., and leave work between 4 p.m. and 7 p.m.. They must simply comply with the legal limits on daily or weekly working hours, and be present during a fixed range of times during the day (here, 10 a.m.-12 noon and 2 p.m.-4 p.m.).

Figure 1 - The principle of adjustable working times

Source: Authors

When they first appeared, these adjustable working hours were in fact seen as a managerial policy to enable employees to commute to work outside peak travel periods (Pierce and Newstrom, 1980). In the late 1960s, Swiss employers noticed that employees were finding it increasingly difficult to arrive punctually at work (Grossin, 1996). Every morning, significant production time was lost because employees, instead of being at work, were stuck in traffic jams and were often stressed when they arrived. They therefore decided to offer their employees the option of choosing their time of arrival at work within a particular time range, in order to avoid traffic jams.

This approach subsequently spread to Germany (Thoemmes, 2013) and in the 1970s and 1980s was gradually incorporated into public transport policies in the USA and Europe (Hines 1984; Ravel 1983; Lamparski 1978; Baudraz, 1971). Today, flexible working hours are still perceived as an effective tool in the arsenal of policies for managing

transport demand in peak periods (Yoshimura, 2001). A recent example mentioned by the OECD provides an illustration of this confidence regarding flexible working hours:

“More recently, the Spanish Ministry of Work (Ministerio de Trabajo y Asuntos Sociales), appeared to be the key actor in congestion mitigation, because the inflexibility in working hours causes half of the congestion in Spain. This situation prompted the Ministry to soften the working hours of Government employees. This policy also affects very positively to the conciliation of working and family life.” (OECD, 2010, p. 113)

This goal of mitigating congestion during peak periods contributed to the genesis, spread and finally the definition of free or adjustable working hours. The interpretations seem to be taken for granted: as a result of flexibility in working hours, workers adjust their schedules in order to avoid rush hours. As a result, travel spikes are gradually reduced (Orfeuill, 2000). And for the OECD, the reshaping and flexibilisation of working hours mean nothing less than that “Most large urban areas experience some form of peak spreading of the rush hour” (OECD, 2010, p. 40).

1.2 Flexible is the same as variable?

The idea that flexible working hours can support policies to spread commuter flows during peak travel periods is easy to understand in terms of the possibilities that it offers. The problem is that the practitioners involved in these issues, and also certain some of the research, seem to confuse two words: “flexibility” and “variability”. Whereas flexibility refers to the possibility of change, variability refers to actual change (Shen, 2013). Although “there is never an automatic relationship between the existence of a potential and its use by human beings” (Alter, 2002, p. 17), it would seem that in most people’s minds, “flexible workers” must automatically take advantage of the possibility of travelling outside rush hour periods. Flexibility of working hours thus becomes a synonym for journeys actually made outside peak periods.

These general interpretations prompt us to seek to verify what impact, if any, flexible working hours have in actually mitigating flows around peak commuting periods. To perform this verification, we need first to set aside the question of mobilities and concentrate on the question of work. There is no point studying the possible effect of flexible working hours on the staggering of commuting times if this “freedom” does not immediately bring about changes in actual work schedules.

2. FLEXIBILITY IN WORKING HOURS AND OFFICE ARRIVAL TIMES

2.1 Scheduling Preferences models: the “delays” caused by flexibility

Most research that focuses on the question of peak time travel and the avoidance of high congestion periods is based on econometric methods. These studies seek to model the choice of commuting schedules. They generally refer to so-called Scheduling Preferences models (Small, 1982) which are themselves based on the *bottleneck model* (Vickrey, 1969) used to describe road congestion. These models are based on three central hypotheses regarding commuter behaviour:

- Commuters have a preferred time of arrival at work, whether set by the employer or genuinely chosen.
- Commuters are at least minimally aware of congestion periods.
- Commuters are ready to shift from their preferred arrival time in order to travel outside peak periods and therefore to spend less time in traffic jams.

With these postulates, by comparison with workers restricted to set working times, workers with flexible working hours should find it easier to offset time saved on the road against rearrangements of their schedules (in order to avoid peak times). Indeed, studies show that the “penalty” of arriving “early” or “late” relative to their preferred schedule is smaller for someone with flexible working hours than for someone with fixed working hours (Kristofferson, 2013; Börjesson, 2008; de Jong et al., 2003; Polak & Jones, 1994; Hendrickson & Planke, 1984; Small, 1982). By arriving before or after their preferred arrival time and potentially avoiding the rush hour, workers with flexible working hours are not in principle penalised from a professional perspective. Conversely, workers whose working times are set by their employer can be heavily penalised for failures of punctuality.

The same studies also confirm that flexible workers who arrive “late” to work “incur a cost” that is markedly lower (in other words it is easier for them to offset the delay against time saved on the road) than workers with fixed working times. Indeed, commuters with set working times can potentially adjust their work schedules by arriving earlier, but with difficulty if they arrive later. On the basis of these observations, it may be said that workers with flexible working hours are more likely to get to work later than those with fixed working times.

Nonetheless, these models have numerous limitations. The first is that they primarily deal with private car journeys. Despite recent developments (de Palma, Lindsey, Monchambert, 2015), these models are still hard put to model the mechanisms of substitution between higher levels of comfort in public transport outside rush hours and the cost of “staggering” the time of arrival at work (Kraus & Yoshida, 2002). The second is that these models do not specifically concentrate on the question of the effects of flexible working times. The majority of them simply tell us that flexible workers are more likely to arrive at work in the morning after their preferred schedule. Only very rarely do we know the exact time at which the survey subjects travel and arrive at their workplace. For this reason, we do not know whether, with flexible working hours, travel is deferred long enough to take place outside the peak period.

2.2 Research on flexible working times: journeys during or after peak periods

For their part, other researchers have more explicitly studied the time aspects of flexible working hours. The first to have compared flexibility of working times with commuting times were an Irish and a Canadian researcher (McCafferthy & Hall, 1977), and they did it unintentionally. In 1977, they were trying to model the effect of the socio-economic characteristics (income, travel time, transport mode, number of children) of workers with flexible working times in the Toronto region on the probability that they would choose to travel before or after the evening rush hour (4:30-5:30 p.m.).

The conclusions of this study are tinged with a certain disappointment, since the initial question did not seem to have led to convincing results. The econometric model employed was not able to significantly measure the socio-economic criteria governing whether flexible workers adjusted their working times in order to avoid rush hour periods. On the other hand, and more modestly, the analysis enabled the two researchers to make a discovery that clearly prompted them to correct their initial postulate. Whereas they had thought that the observation of workers with flexible working hours would enable them to closely study a particular population subcategory characterised by its avoidance of rush hour, they realised that workers with flexible working hours travelled just as much during peak periods as other workers.

Much later (according to Kahn, 2007), a study conducted in Geneva would also show that flexible working hours do not have an impact on the time of arrival at work in the morning:

“A study conducted by Geneva University’s logistics research unit, looking at the transport habits of the population living and/or working in Geneva, reveals a certain inertia. Individuals who have flexibility in their working hours are nevertheless in the habit of starting work at fixed times. And 74% of them also choose to begin work between 7:30 and 8:30 a.m.” (Kahn, 2007, p. 246)

The results observed in Geneva confirm the observations made by Hall & McCafferthy on evening rush hour in Toronto: the great majority of workers with flexible working hours start their working day during the rush hour. However, these studies do not establish a causal link between flexibility of working hours and the scheduling habits of the employees.

For their part, more recent studies (He, 2013) based on the USA’s National Household Travel Survey (2009 US National Household Travel Survey – NHTS) are able to precisely quantify the impact of flexible working hours on the probability of starting a commute before, during or after the morning rush hour (6-9 a.m.). They focus on the travel schedules of car commuters in San Francisco and Los Angeles. Their conclusions are a hybrid of the findings based on Scheduling Preferences models and those drawn from the observations in Geneva and Toronto. On the one hand, there is indeed a greater likelihood that flexible workers will arrive after the peak travel period than the rest of the population. On the other hand, these differences are minimal: compared with workers on fixed hours and all other things being equal, workers with flexible hours are 3.3% less likely to arrive before rush hour, 4.1% less likely to arrive during rush hour and 7.4% more likely to arrive after rush hour. We would also note that this propensity of “flexible workers” to arrive at the workplace after the rush hour has recently been confirmed by a survey (Yang, Steiner, Srinivasan, 2016) conducted with commuters in the Miami region.

2.3 Lessons from the sociology of work: flexible but within the rush hour

There are few French studies which focus on the links between flexible working hours and actual working hours. To our knowledge, only a few studies drawing on INSEE’s Time-Use Surveys provide information on the link between the possibility of choosing one’s working hours and the actual hours worked in the working day. One such is the study by Laurent Lesnard (2006) based on the 1999 Time-Use Survey. It indicates that compared with employees with fixed working hours, employees who enjoy a degree of freedom markedly prefer *standard working hours*. Through his definition of *standard working hours*, he shows that people who can choose their work schedule maintain typical working hours such as 9 a.m. to 5 p.m. and therefore travel mostly during peak periods. In addition, he observes that where working hours are not imposed by the employer,³¹⁰ work schedules also tend to run slightly later (e.g. 10 a.m. to 7 p.m.) than the working hours set by the employer.

The findings from these different empirical studies make it difficult to argue that more flexible working hours result in working times being staggered and traffic flows being spread around peak periods. From our point of view, we will note that despite the diversity of the field locations, the results tend to converge in showing that there is not a correlation between flexibility and a staggering of journeys over time. True, according to transport research, flexibility in working hours leads to a general deferment of arrival at the workplace. However, this general deferment is not the same thing as a dilution in the concentration of peaktime journeys. Indeed, if all flexible workers delay their schedules to arrive at work at the same moment, congestion is simply deferred, if not exacerbated. In fact, this is more or less what is observed from research in the sociology of work and in the French case. Here there is indeed a correlation between flexibility and a slight delay in working hours, but also and above all a rise in the concentration of arrivals around *standard times* (Lesnard, 2006).

At this stage, this observation of the situation in France needs to be verified and related more directly to the question of peak hours. This requires us to look in greater detail at a specific case to see how flexible working hours reshape the distribution of the morning rush hour.

3. CONCENTRATION OF WORK START TIMES AND FLEXIBILITY OF WORKING HOURS IN ÎLE-DE-FRANCE

³¹⁰ These working hours combine schedules that can be adjusted from one day to the next and schedules directly decided by employees. According to this classification, 25% of French employees (Time-Use Survey 1999) have working hours that are not imposed by their employer.

3.1 Aspects of framing and methodological explanations

In relation to our research problem, Île-de-France constitutes an excellent field of study. It is the French metropolitan region that contains the largest number of working people with flexible working hours (Bouleau & Leroi, 2016) and where the congestion challenges are the greatest (Koning, 2011). According to the last National Transport and Travel Survey (ENTD 2008), and on the basis of a sample of responses from more than 2000 working people living in Île-de-France, 30% of people in work in this region have flexible work schedules. Intuitively, therefore, one would expect Île-de-France to be a region in which the practice of rush hour avoidance would be found extensively (Munch, 2017).

In consequence, in order to verify some of the information arising from the literature review, we look to see whether flexible work schedules in Île-de-France should or should not be associated with more staggered work start times. To achieve this, we use the latest national travel survey which provides very detailed information on the time of arrival at work on a working day and also on the method of determining working hours.

For the Île-de-France region, therefore, we then relate the method of determining work schedules –whether they are fixed or flexible – to the degree of concentration of arrivals in the workplace.

The populations with *flexible working hours* and *fixed working hours* are compared with respect to this degree of concentration for the “half-hour”³¹¹ that contains the largest proportion of workplace arrivals over a day. This is called the *superpeak*. We will compare the intensity of the *superpeak* (in % of arrivals over the half-hour) between the different populations of workers, depending on whether they have flexible or fixed work schedules. In this way, and by contrast with the majority of authors, we will not construct canonical timeslots, such as 7 a.m. – 9 a.m., to observe whether flexibility leads to more or less journeys during, before or after rush hour.

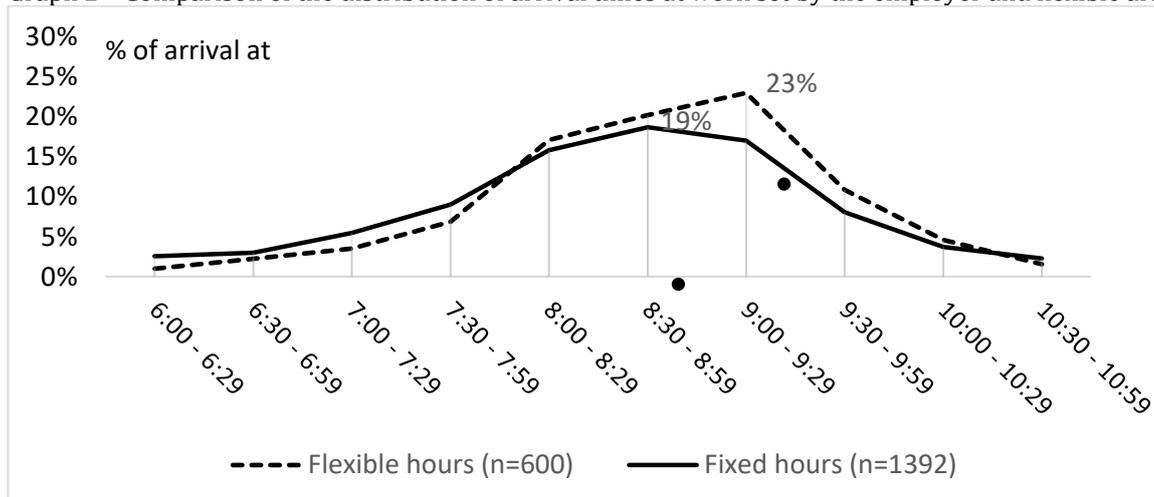

What interests us, at the same time as knowing whether individuals travel during or outside the peak period, is comparison of the intensity of the *superpeak*, i.e. the crucial moment when the density of arrival in the workplace is the most intense.

However, we also assign importance to the temporal position or “the time of the *superpeak*” for each of the populations surveyed. Indeed, a simple accentuation in the concentration of work start times would not necessarily be problematic. The problem arises if the intensity of the *superpeak* for flexible workers is both greater and situated right in the heart of the peak period. It is only under these circumstances that flexible work schedules could be interpreted as particularly negative for congestion on the transport networks. For this reason, it is important to note at this point that, according to the 2008 ENTD, the peak period for workplace arrivals in Île-de-France is between 8:30 and 9:29 a.m. (see Appendix 1).

3.2 Flexibility of working hours is associated with increased synchronisation of work start times in Île-de-France

In the 2008 ENTD, in parallel with a question on the time of arrival at work on the weekday of the survey, respondents who had been at their habitual workplace the day before the survey were asked if it was they or their employer who decided their work schedules. By cross-referencing the answer to these two questions for each individual, we are now in a position to represent the distribution of arrival times at work that are set by an employer and the distribution of flexible arrival times, i.e. the schedules that are set by the workers themselves (Graph 2).

Graph 2 – Comparison of the distribution of arrival times at work set by the employer and flexible arrival times

In Île-de-France, times of arrival at the normal workplace, for a weekday and for the first journey to work. Grouping by 30 minute segment. Produced by the authors. Source: ENTD 2008.

311 The choice of the half-hour time step corresponds to the methods of analysis used by the Île-de-France transport organising authority (Syndicat des Transports d’Île-de-France). In addition, while a one-hour time step does not seem sufficiently close-grained to accurately describe changes in the schedules, a 15 minute time step would not have seemed appropriate, because the hours entered are the declared schedules and most of the respondents enter their work schedules with a degree of precision of half an hour or one hour, and more rarely a quarter of an hour.

Graph 2 highlights two results. First, in Île-de-France flexible working hours are associated with an increase in the concentration of arrivals at work during peak times. For people with flexible work schedules (dotted line), 23% of arrivals are concentrated between 9 and 9:29 a.m.. For people with fixed work schedules (continuous line), only 19% of arrivals are clustered during the period of greatest intensity, i.e. 8:30 to 8:59 a.m..

Secondly, as other authors have observed (cf. point 2.), flexibilisation does indeed seem to correspond to a general delay in the time of starting work, since the spike in arrivals is shifted 30 minutes to the right for people who can decide on their working hours.

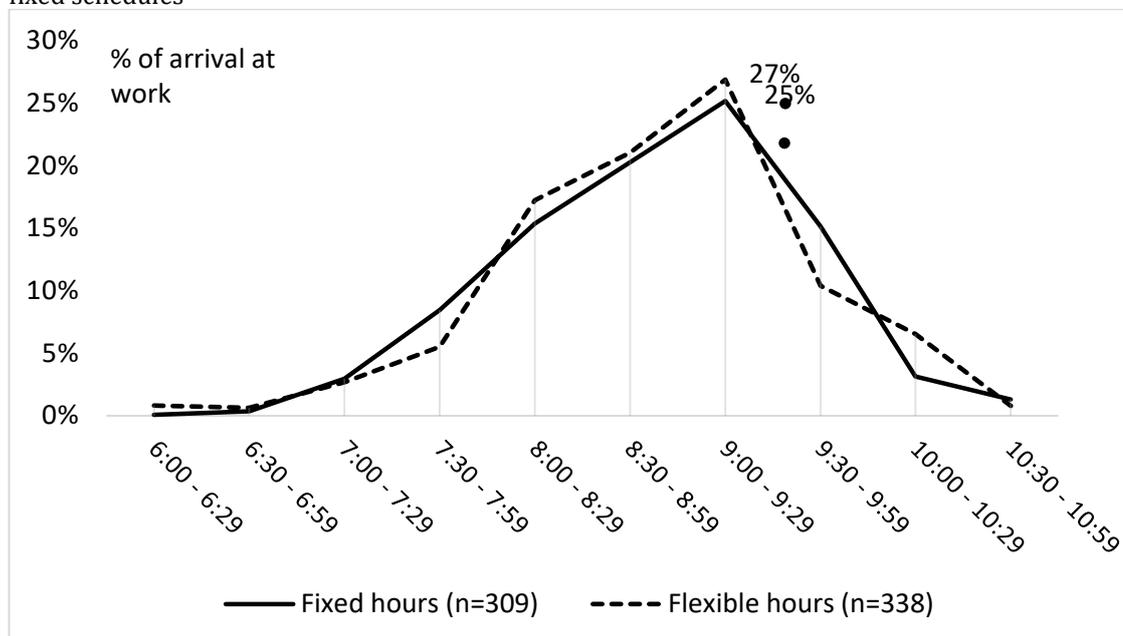

In order to achieve greater certainty on the links between flexibilisation and the concentration of work arrival times in Île-de-France, let us now compare the distribution of flexible and fixed work schedules within a single French socio-professional category: “executives and higher intellectual professions”.

There are several advantages to closely studying the working hours of executives in Île-de-France. First of all, it is a way to smooth out the effect of potential hidden variables that may explain the differences observed between flexible and fixed work schedules. It is known, for example, that regardless of the way work schedules are determined, executives begin their working day later than unskilled workers and office workers (Munch, 2017; Wilson, 1988). Now unskilled and office workers represent 54% of workers with fixed hours in Île-de-France, whereas executives represent 53% of workers with flexible hours in Île-de-France. In consequence, there is a risk that the one-hour delay in starting work for the populations with flexible schedules is not attributable to the method of determining working hours. It could instead be caused by the overrepresentation of executives in the population with flexible hours and the overrepresentation of unskilled and office workers in the population with fixed hours. Working on a single socio-professional category is therefore a way of avoiding this risk of interpretative error.

Next, executives are a particularly interesting subpopulation for the study of the effects of flexible working hours. It turns out that executives are the employees who benefit the most from flexible work schedules in Île-de-France. In 2008, more than half of the executives in this region had flexible working hours. In addition, for these categories of workers, commuting times are perceived as particularly unpleasant “interstitial times”. Indeed, according to the “Stiglitz notes” in the 2010 Time-Use Survey, executives and the higher intellectual professions are the only professionals who classify the morning commute as one of the three most unpleasant activities of the day (Ricroch, 2011). This is also understandable insofar as very few executives have short commuting journeys: only 12% have a commute of 15 minutes or less (OMNIL, 2013).

In looking at the working hours of executives in the Paris region, therefore, we are looking at a population that is inherently extremely sensitive to the problem of the rush hour.

Graph 3 – Comparison of the distribution of arrival time at work of executives with flexible schedules and executives with fixed schedules

In Île-de-France, times of arrival at the normal workplace, for a weekday and for the first journey to work. Grouping by 30 minute segment. Produced by the authors. Source: ENT D 2008.

Yet the observations drawn from Graph 3 and applied only to executives confirm the information drawn from Graph 2 and applied to all working people in Île-de-France. They show that executives with flexible work schedules are clustered more intensely at the time of the *superpeak* than executives with fixed work schedules. Between 9 and 9:29 a.m., the peak in arrivals by executives with flexible working hours accounts for 27% of daily arrivals, while at the same period, the peak in arrivals by executives with fixed working hours only accounts for 25% of the contingent. Although it does not

defer its arrivals,³¹² here again the group with flexible working hours is the group whose arrivals are most concentrated within the *superpeak*.

By cross-referencing the mode of determining working hours with the distribution of arrival times at work in Île-de-France in 2008, we therefore seem to have arrived at an apparently paradoxical conclusion: flexible working times are associated with a clustering in the time of arrival at work.

CONCLUSION

This article discusses the “belief-image” (Laplantine, 1989) that flexible working hours will lead to the phasing of work schedules and a dilution of traffic flows in peak periods. Through a review of the international empirical literature, but above all through the study of the distribution of arrival times at work in Île-de-France, we have identified a set of factors that suggest that this image needs to be turned on its head: the populations who are free to decide on their work schedules globally have a tendency to concentrate their time of arrival at work within the peak period.

This conclusion is not without implications for the congestion observed every day in most big cities. Firstly, in terms of public transport policies, the non-governmental organisations (AFD, 2016; OCDE, 2010) which have promoted flexible working times as a means of spreading traffic flows have, it would seem, gone in the wrong direction. Indeed, if more flexible work schedules lead to greater synchronisation in the times of arrival in the workplace, the effectiveness of such public policies is severely undermined. They might even improve counter-productive, bringing about the reverse of the intended outcome by exacerbating rush-hour congestion. Secondly, with today’s joint dynamic of urbanisation and the tertiarisation of production activities, the percentage of the working population with individualised and flexible work schedules will in all likelihood continue to grow. According to our findings, therefore, the intensity of the spikes in daily commuting and the associated congestion phenomena are likely to continue to increase spontaneously.

This counterintuitive connection between flexibility of working hours and increased concentration of rush-hour arrivals at work recalls other types of surprising findings in situations that lead to variation in travel structure. One is reminded, for example, of the conclusions of Mokhtarian, Collantes and Gerz (2004) regarding teleworking, which demonstrated that teleworkers travel as much if not more than if they were obliged to go out to work, in particular for other reasons (visiting family, shopping...). Or else, in Île-de-France, the general reduction in the distance between the workplace and home would seem unexpectedly to encourage car use to the detriment of public transport (Korsu, Massot, Orfeuill, 2012). Then there is the fact that the increase in the use of new information and communication technologies (ICT), rather than reducing the need for face-to-face meetings, seems to be accompanied by an increase in the number of such meetings (Aguiléra & Lethiais, 2012).

More generally, the revelation of this socio-temporal paradox is an invitation to challenge the way in which sociology traditionally depicts the day-to-day activity patterns of the inheritance of big western cities. At the macrosocial scale, many authors today (Rosa, 2015; Mallet, 2014) speak of a “desynchronisation” in social activities supposedly linked with the flexibilisation of the central link in day-to-day life: work. Except that, while work schedules in Île-de-France seem increasingly individualised and flexible, the times at which people start work also prove to be becoming more closely synchronised at the moment of the arrival spike (around 9 a.m. in Île-de-France).

To move to the microsocial scale, in the light of our findings, it is the foundational assumptions of the econometric models of *Scheduling Preferences* (Vickrey, 1969; Small, 1982) that crumble. The individual freedom offered to employees to choose their working hours seems to be exploited less to escape standard travel times and congestion periods, as assumed by traffic engineering models, than to adhere to the schedules that are already predominantly followed.

Counter to most social science research, this article demonstrates that the individualisation of the relation to working time does not lead to a desynchronisation and diversification of work schedules, but rather to a synchronisation and concentration of working hours. Nonetheless, the theoretical implications of the paradox of working time flexibility and the rush hour remain to be confirmed. For our part, we will refrain from generalising results that are based on a literature review and practices observed at the scale of Île-de-France, in a necessarily specific cultural context. To consolidate our findings further, it will probably be necessary to check empirically whether this socio-temporal paradox also occurs in other agglomerations and regions of the world.

Nonetheless, having described and delineated the phenomenon, it is tempting to look for an explanation for this paradox. It is probably here that our conclusions open up the most stimulating pathways for research. The first research that revealed a paradox between the individualisation and concentration of behaviour patterns (Simmel, 1908) argued that this concentration arose from a process of general rationalisation in the logics of individual action (Weber, 1922). According to this argument, more and more of us are individually free to decide on the form and quality of our actions but, because the logics of our actions are increasingly and uniformly objective and rational and less and less subjective, all of us give them more or less the same form. In this view, we all have a good (and the same) reason to continue to travel during the rush hour.

At this level, however, the explanations are still somewhat too general and too little focused on the question of the temporalities of practices. Once released from regulatory constraints at work, for what reason(s) would we continue to travel during the rush hour, especially in the case of executives in the Paris region, for whom peak time travel is perceived

³¹² This finding confirms the hypothesis that it is above all socio-professional status that is responsible for late or early arrivals, rather than the method of determining the work schedule.

as one of the three most unpleasant daily activities (Ricroch, 2011)? At this point, it is helpful to refer to recent work in the sociology of time. In this domain, the paradoxical way in which we experience day-to-day time is often highlighted to explain this kind of hiatus.

Absorbed by the tempo of life, of the days, weeks, months and years, our experience of time is paradoxical in that we think we possess it, whereas everything suggests that it ultimately possesses us. For Edouard Gardella (2011), for example, “the more time we save, the less we have”. With regard to our subject here, if saving time is choosing one’s time, then the freer we are in our daily work schedules, the less control we have over them. In fact, the wider our universe of choices regarding working hours, the more we find ourselves potentially submerged beneath an ocean of demands. In all likelihood, faced with the pressure of the need for day-to-day synchronisation (work, family, consumption, leisure...), workers who are apparently free to choose their working hours in fact become all the more obliged to fit into the standard and dominant rhythms of life in order to coordinate their multiple activities. Whether we are collectively and explicitly governed by the organisation of work, or individually and implicitly guided by the need to manage our daily schedules, we continue to consume day-to-day temporalities like a mass-produced product.

ABSTRACT

In today's digital age, the initiative of smart city highlights a new wave of developing and reshaping the better digital lives for tomorrow. Digitalization is ensuring a positive force on developing countries to improve their infrastructure and rethinking the role of city leaders in creating better digital lives for smart cities. The core concept behind developing these smart cities is to create highly advanced urban regions and to improve upon quality of life in a larger connected network within society. The role of digital services are critical in this transformation, as it provides the best possible solution to monitor the wide range of aspects of city living and amenities, connecting every citizen to policy-making and administration. The emerging development of smart cities is a visionary step; the use of digital services will enhance its sustainability in through the number of issues in the development of urban lives. As digital India is centred on providing utility to citizens, offering on demand services and digital empowerment, the program will be the nexus of public services, public service providers and the public. On the other hand, some of the digital bangs have affected the smart cities more profoundly in augmenting the existing social dynamism of the community in question. This study is trying to address the emerging issues of comprehensive innovation and digitalization strategies on the people's quality of life in view of discussing the challenges and opportunities for city leaders, citizens and government in creating better digital lives. In thinking about the leverages of digitalization for making smart cities reality, the important questions need to be analyzed that what benefits are associated with a tailored digitalization strategy to the cities for people. Secondly, how well the smart cities are realizing the worth of their information technology, enabling the city to deliver better services more efficiently. The specific objective of the study that we aim is to identify the current approaches of developing digital lives for smart cities and understanding the construct of technology in propelling individual growth. The research design employed for the present study is to showcase the challenges of designing smart cities with people in mind. For the purpose of this a comprehensive and extensive literature review was conducted, analyzing the current approaches of rebuilding the smart cities for the digital age. The implication of the study is to meet the challenges of tomorrow by focussing on the needs of people and building new services through human-centred design. It is also very imperative for the city leaders to improve the services and rebuild the infrastructure for developing better digital lives for the smart cities.

Keywords: Digitalization, Digital Services, Smart Cities

INTRODUCTION

"Smart Cities are those that are able to attract investment"

*Shri Narendra Modi
Prime Minister of India*

India is on the cusp of a digital transformation and it is the collective responsibility of entire stakeholders of India to make sure that the initiatives of smart cities and Digital India mandate transform dream into reality. With the migration from rural areas to urban areas, an international phenomenon, India has also seen similar movements for several years. Now, it is expected that by 2050, 70% population will be living in cities. It is said that this would mean that around 500 new cities would be needed to accommodate this burgeoning population in urban areas. If India properly plans and develops its urban environment, urbanization can provide an efficient way for people to live, enabling economies of scale in the delivery of infrastructure and services. However, without proper planning and services, sprawling cities can become flashpoints of discontent. It is firmly believed that the cities are the engine of growth and intricate bionetwork of many people, public infrastructure and private platforms. Moreover, the proximity and diversity of people can spark innovation, create employment and provide the country's economic engine. Conventionally, city administrations have always been responsible for creating, managing and delivering better ways of living. There has been no dearth of schemes and policies to address the issues that affect the urban sector growth in India.

At the turn of the 21st century, transforming life, transforming India through digital platforms has laid out immense hope of turnaround India's urban centres. India is looking to modernise and in order to keep pace with this development, the Government of India have committed to turning dream into reality by building 100 ultramodern "smart cities" as satellite towns of larger cities by modernizing the existing mid-sized cities across the country. For this, the union cabinet has approved the smart city mission budget and allocated Rs. 48,000 crores for its development. It also renamed the Jawaharlal Nehru National Urban Renewal Mission targeted by the UPA government and renamed it as **Atal Mission for Rejuvenation and Urban Transformation (AMRUT) for which about Rs.50,000 crs. to be allocated for its development.**

The two mission combined is expected to improve the quality of life in urban areas and create better and sustainable cities. Thus as we move to urban economic powerhouses for jobs and opportunities we also have to deal with critical issues like economic hardships such as housing, transport and pollution. And that is really forcing cities to start thinking of how to develop a better digital life for smart cities. The paper addresses the emerging issues of comprehensive concept of smart cities in thinking about the leverages of digitalization for making smart cities reality.

The problem of the research is to analyze how well the smart cities are realizing the worth of their information technology; enabling the city to deliver better services more efficiently and **what are the challenges or stumbling blocks for city leaders, citizens and government that may be encountered in creating the better digital lives for smart cities.**

The aim of this research is to make analysis of understanding the concept of smart cities and outlining a roadmap for the development for citizen, city leaders and government

SMART CITIES CONCEPTS: TECHNOLOGY TREND UNDERPINNING

The age of technology has gifted us with many innovations that affect our lives each day, along with a healthy outlook for how we might use information technology to shape our collective future. Our ability to harness advanced computational power and the internet offers us tremendous opportunities to ignite a revolution of efficiency and improvement to our lives by collecting, processing, sharing, and leveraging data in ways that were previously impossible. “ Smart Cities are new style of city providing the sustainable growth and designed to encourage and designed to encourage healthy economic activities that reduce the burden on the environment while improving Quality of Life(QoL)- such as housing, economy, culture, social and environmental conditions”(Japan Smart City Portal, 2013). Smart city concept is an attempt to answer some of the key questions we dwell into that are: urbanization, contribution to economic growth and challenges to build smart cities.

There are variety of definitions and interpretations of Smart City. It is said that Smart city is an IBM concept in 2008 as part of its Smarter Planet initiative. It is a holistic set of goals where the urban planning can be associated to intensive use of technology so that they have the citizen as protagonist. In the words of Mr. Shirish Sankhe, Director, Mckinsey India, the smartness of city can be defined from all the way to be a technologically smart to all the way to livable and smart and affordable. Smart Cities concept encompasses usually the following areas: smart buildings, smart infrastructures and smart services for citizen of India. According to Mr. Shirish Sankhe, the government is trying to figure out what exactly the missions of smart cities are? The idea of smart cities with IT focus is also there but that has come from the west where the basic needs like clean city, water supply, electricity are fulfilled. They are talking smart city highly IT enabled city. But if smart city is IT enabled then we use IT as the power of technology to be done in better and most efficient way and at a lower cost. The idea of smart cities is to combine the strength of technology to give us the most cost effective solution. That is being the way of modernization and development all over in society. There is a need to create a new city or reshape the old cities.

Prime Minister Narendra Modi said, “Cities in the past were built on riverbanks. They are now built along highways. But in the future, they will be built based on the availability of optical fibre networks and next-generation infrastructure. Smart cities broadly identify themselves with eight key dimensions: Smart Building, Smart term Planning, Smart Waste Management, Smart Safety, Smart Energy, Smart Mobility, Smart Governance, Smart Technology. New Technologies enable the introduction of a new relationship between Local Governments and citizens; in particular regarding the introduction of public on-line services and the use of New Technologies to improve the participation of citizens in public decision-making. In general, e- Government can be considered as a concept that consists in improving public governance and the provision of public services through the use of ICT (e-Government), improving the consultation and decision-making processes using ICT (e-democracy) and improving public policy making, with the use of ICT, incorporating more critical agents throughout the process (e-Government). In all these aspects, the role played by citizens has a special impact. The new relationship emerging from e-Government has led to the emergence of a new kind of citizen, the e-citizen.

On the basis of the above mentioned explanation, the evolving concept of smart cities is increasingly becoming realistic and today the bigger challenges of building smarter cities can be seen across the world. Modern citizens expect to be able to interact with organizations, including digital government through digital technology, not least as private sector firms flood the market with apps tailored to customer needs. And city employees are looking for consumer-grade experiences too. They want user-friendly systems that enable them to be productive anytime and anywhere. In response to this trend, cities need to put greater focus on IT agility. Cities need ecosystems of applications that can, while still remaining simple and agile, be bolted together to tackle the most challenging problems, and can be easily scaled up where greater capacity is needed.

SIGNIFICANCE OF SMART CITIES IN THE INDIAN PERSPECTIVE

India is tackling its growth in the digital age – which gives them far more technology-enabled choices and allows them to build in smartness from the ground up. The urban developments have to be comprehensive including the development of physical, institutional, social and economic infrastructure. Comprehensive development is important in improving the quality of life and attracting people and investments to the city, setting in motion a virtuous cycle of growth and development. Smart cities are urban eco-systems which are represented by these four pillars of comprehensive development. A smart city needs to be a system which grows in an intelligent way is quite compact, it doesn't have sprawl in terms of economic development. One good part of this initiative is that a lot of decentralization is envisaged. The cities are supposed to come up with their own plans and what is it they wanted to do. The real positive in this initiative is the government or political leaders are recognising the importance of smart cities for economic development, growth and from shifting people from rural areas to urban areas.
