"McKinsey Global Institute study estimated that cities would generate 70% of the new jobs created by 2030, produce more than 70% of the Indian gross domestic product and drive a fourfold increase in per capita incomes across the country." Smart city is a city that makes sure that all our citizens have a good quality of life. Also its cities where people are able to meet their aspirations.

Smart cities highlight the stronger relevance of cities for society and populations in a country marked by strong technological development. The Smart City Mission is being worked upon in close coordination with the projects like Make In India and Digital India. As per the Make in India programme, a few smart cities are already coming up across the country such as Kochi Smart City, Gujarat International Finance Tec-City (GIFT) in Ahmedabad, Naya Raipur in Chhattisgarh, Lavasa in Maharashtra and Wave Infratech's 4,500-acre smart city near New Delhi. Cities are going through a deep transformation – the main driver is digitization.'

SMART CITIES CHALLENGES

Today's cities face significant challenges – increasing populations, environmental and regulatory requirements, declining tax bases and budgets and increased costs. Moreover, the cost of Information and Communication Technologies has plunged making it economical for the government to implement them. Citizens are increasingly getting instant, anywhere, anytime, personalized access to information and services via mobile devices and computers. And they increasingly expect that same kind of access to city services. There is an urgent need to think very differently about how to solve the problem. The India Smart Cities Challenge is a competition designed to inspire and support municipal officials as they develop smart proposals to improve residents' lives. In the Indian context, the approach is necessarily different. Since many Indian cities lack basic infrastructure, institutional frameworks, and proper governance, smart city initiatives will first and foremost involve providing basic civic requirements and making the infrastructure robust and scalable. Given below are some of the key challenges that governments/businesses in India will face while implementing their smart city strategies:

- 1 **Acquisition of Land:** The biggest challenge is the acquisition of land for creating smart cities. The land acquisition law might prove to be a deterrent and make the acquisition costlier, thereby making the residential and commercial units costlier. While the government is considering amendments in the Land Acquisition Bill, these changes may take time.
- 2 **Replacing Existing City Infrastructure to Make It "Smart City-Ready"**
There is a number of latent issues to consider when reviewing a Smart City strategy. The most important is to ascertain the business case that will justify the replacement of existing infrastructure. The integration of formerly isolated systems in order to achieve city-wide efficiencies can be a significant challenge.
- 3 **Economic Growth:** Economic growth is the key for the setting up of a smart city. The growth of the city depends on the mix of industries and sectors. A clear plan of vibrant economic growth of the city provides the right mix of livelihood to those migrating to it.
- 4 **Dealing with different stakeholders:** One of the other main challenges in the Indian smart city space is that (usually) software infrastructure in cities contains components supplied by different vendors. Hence, the ability to handle complex combinations of smart city solutions developed by multiple technology vendors becomes very significant.
- 5 **Employment Opportunities:** The other area of concern is the kind of employment these smart cities will generate. While the smart city will act as a centre of economic growth, it should also provide the right mix of livelihood to those migrating to it. Else, the migration of people will continue to pose a threat to the overall socio-economic scenario of the city.
- 6 **Investment in Infrastructure: India requires around 120 dollars per capita per year in average spending so on overall basis its one trillion dollars of capital investment and one trillion dollars of operating in operational expenses investment over the next 15 years so from that perspective there is a huge gap because normally we spend something like 1/8 or 1/10 of this that's why we can see that urban infrastructure is lagging enormously in India so from that perspective even a small drop is always welcome and the smart cities mission which focuses as a facilitator mechanism on getting our cities to a world- class level . A new city would take a long time to develop both the requisite economic drivers and the infrastructure - only after that will it see people stepping in. By the time the city is habitable and has a basic population, the project would at least be 7 to 10 years in the making. Unfortunately, the current funds available for this sector are only for the short-term of 10-15 years. Unless the development of the city is done out of funds that have a 20 to 30 year horizon, these projects are unlikely to survive. India needs a sea change in the way it looks at funding these cities, or their infrastructure.**

Commenting on the development, Arindam Guha, Senior Director, Deloitte in India, said: "The Smart City Challenge continues to generate significant enthusiasm throughout the country. With the addition of these 27 cities, a total of 60 cities are now eligible for funding under the programme." The high interest and participation levels in the Smart City plan development phase now needs to be sustained through quick implementation on the ground, he added.

ROADMAP FRAMEWORK

The aim of the presented below smart city roadmap framework is to put forward a new vision and strategies of creating and developing better digital lives. When we are designing a city what we really doing is to design a way of life, what kind of life will make us happier so the first thing before we do anything is to take some time to dream without restrictions what the ideal way of life in a city would be, what would be the ideal city would be it's about having smartness in every aspect of the city. The answer to these questions are it means a smart way of governing , it means smartness in the way

institutions are managed, it means smartness in the way big pieces of infrastructure are set up and designed and maintained and down to the smallest pieces of what seemed to be low tech innovations but are smart nonetheless. The focus should be more on aligning the strategic goals of government with that of the cities so as to make the city more economically competitive, developing the strategy in co-operation with the ICT companies and foreign collaboration. The implication of the study is to meet the challenges of tomorrow by focussing on the needs of people and building new services through human-centred design. In response to this trend, cities need to put greater focus on IT dexterity. Cities need ecosystems of applications that can, while still remaining simple and agile, be bolted together to tackle the most challenging problems, and can be easily scaled up where greater capacity is needed.

The crossroads of future Internet technologies and smart cities persistently appearing the shift to the cloud, smart city pilots, and city-wide open platforms of embedded systems. These areas are of primary importance for city policy makers all over the world that are deploying strategies for smart cities, e-infrastructure and e-services to address the contemporary challenges of competitiveness and sustainable development. Thus, the roadmap allows formulating some policy recommendations to city authorities for mastering the new interdisciplinary planning for intelligent / smart cities and the interlinked layers of digital technology, people-driven innovation ecosystems, urban activities and infrastructure.

DISCUSSION

From the present review, one can easily understand that smart city mission is been a very competitive process as some of the other states saying that their city also should have been there in the first 20 but it's absolutely clear right from the beginning that it has been a competitive process and the city challenge was very well evolved at the very outset. Besides it is the role of the city leader to push the city on the road to become smart. They must have bold vision and mission specifically around technology. What does technology mean for the city and what ways can it contribute towards quality of life and at that time you know did some research and it came up with this vision statement which was to build and enable a leading digital city.

One of the things with city governments that people have a perception of is that they don't take risk to go ahead invest in the infrastructure to make it smarter more connected city and then we're willing to make that investment and to allow people to experiment to run pilot programs and to really be innovative. There is really a need to do work like a start-up. The smart city solution remains an integrated database and decision making system that incorporates innovative ICT technologies to simultaneously generate, process and analyse spatial, transport, energy, municipal services and socio-economic data, the capability and resource base to enable holistic decision making and finally a governance system that encourages informed and prompt decisions.

Cities, of course, can get around the problem of creating smart city proposals by employing consultants-if they are willing to pay. Nevertheless, there will be many challenges beyond; even after cities get picked. It is the city leaders ability to interpret such data in all its complexity and holistic scope, special- purpose vehicles function will have to be formed to implement the smart city mission- the state and the urban local body , freedom of action must be given to them, to run situation for energy efficiency, cost efficiency and financial feasibility and use them all for efficient economy, safer and well performing spaces, effective governance and responsive mobility that would truly drive us to smarter cities.

1346 PLANNING PARADIGM SHIFT FOR URBAN SYSTEMS IN OUR NEAR FUTURE

Hidehiko KANEGAE

Ritsumeikan University

ABSTRACT

Our society is forwarding to new drastic different technology driven society that shows us modern time was calm plateau. Passions and desires of human beings drove to be realized both in reality in physical/ spatial reality into their cities and in virtual reality (VR) & augmented reality (AR), VR&AR hereafter *multilarity*, into their cultures and sciences which ancestors imagined and thought of their passions and desires in their time as same as present human beings do.

This paper aims to discuss and to draw following ideological 2 issues of planning paradigm Shift for urban systems in our near future which covers both reality in space and *multilarity* in our urban phenomenon including new urban dynamics under rapid industrial transformation pressure.

Smart City, autonomous urban systems, will be lead our cities fully equipped by intelligence explosions and emergence of super-intelligence revolutions based on big-data analysis, specified A.I. systems with deep learning, quantum computing, IoT/ IoE, Industry4.0 which is so called “Technological Singularity” in 2045, that revolution changes our cities, urban, suburban and rural drastically like disappearing car parking lots, industrial transformations, full autonomous factories without labours, urban vegetable factory & smart agriculture in rural area, autonomous fleet logistics and warehouses and drone delivery systems. At the same time, new urban planning systems raises new type of “New Technology for planning” and “New Technology of Planning”. Former one is fully 3D digitalized city database and simulators in a cyber space like “Virtual Singapore” developed by Dassault Systems, if real estate developer submits Singapore government 3D CAD development plan data for entire buildings complex, those data will be put into “Virtual Singapore” and simulated analyzing many situations like Thurman-wind phenomenon changes will be tested in the systems. Latter one is ontology planning systems with multiple city sensors’ aggregation sets which will be fundamental of Smart Society.

Secondly issue is explosion of economic growth both without employment and without labors under Industry4.0 and smart agriculture makes drastic changes our life styles in our future society. Explosion of economic growth will be achieved by A.I. production/ service tax will be replaced instead of labor’s income tax. But at the same time, many of labors will be fired that shifts our life styles from labor to gaming. Engaged economy is constructed with shared economy and basic incomes from explosion of economic growth. Instead of annual average of hired working hours will be reduced, playing time in the game becomes longer rather than another pastime like watching TV. Playing electric games and watching games together became formal games as same as Olympic games right now in 2017. The eSports becomes large new industry around the world and attracts new generations’ important life events. Our sound future will be achieved gaming society for keeping sustainable governance both in private sectors and public sectors.

Key words: virtual reality, augmented reality, multilarity, smartcity

1 INTRODUCTION

It is common terminology for “*Technological Singularity*³¹³ (2045)” by Raymond Kurzweil but expanded terminology “*multilarity*³¹⁴” by Prof. Tom M. Mitchell are shown ICT magazines and news sites recently.

This paper aims to explore discussing about and also drawing following ideological two issues of planning paradigm shift for urban systems in our near future which covers both reality in space and *multilarity* in our urban phenomenon including new urban dynamics under rapid industrial transformation pressure in near future time-span.

2 HISTORICAL BACKGROUND FOR URBAN DYNAMICS

This chapter reviews history of Paradigm shift with Industrial Revolutions which made drastic impacts toward urban systems changes which is so called urban dynamics.

It is very common city structure in Figure1 that there are three conceptual spaces where are located core (urban), ring (suburban) and rural in the city or urban region likewise a greater-city-region after Industrial Revolution since 1830s, nowadays so called 1st Industrial Revolution in Table1. According to rapid expansion of economic growth by factories

313 Raymond Kurzweil, Google’s Director of Engineering, is a well-known futurist who predicts that during the 2030s some tech will be invented that can go inside your brain and help your memory. He says it will be a future of unparalleled human-machine synthesis and claims (technological) singularity will happen by 2045 which is when humans will multiply our effective intelligence a billion-fold, by merging with the intelligence we have created.”

<http://www.kurzweilai.net/>

314 Prof. Tom M. Mitchell founded and chairs the Machine Learning Department at Carnegie Mellon University. Stephen. Ibaraki Microsoft MVP uploaded his interview to Microsoft-TechNet where showed that Prof. Mitchell said “...I take this singularity hypothesis as something like there will come a time when computers are more intelligent than people and what’s going to happen then?...The whole idea that there is a single question to ask (are they smarter than us or dumber than us?) is I think misguided and we should replace the singularity notion by multilarity and just say it’s not an all or nothing or one or zero kind of question. There’s a whole vector of different competences...I don’t think computers will get stupider over time and I don’t think people will either, but I do think that computers will get better than us at more of those things and I think that’s the more interesting way to think of it. I think it’s a disservice to the discussion to pretend that there is a single notion of computers being more intelligent than we are...”

Since the city as a shelter had surrounded walls long time ago, the same urban planning was existed. It is not so old established current urban planning in these 2 -3 centuries which are driven by new technology and engineering introduced that is so called “Modern urban planning” was established according to the progress of the industrial revolutions. Basically, urban planning since modern days started after the (first) industrial revolution which is space control systems only intended for (urban) economic development. At the beginning of urban planning did not have functions to protect urban residents from poisons and environmental pollution, or to protect urban dwellers from natural disasters.

The worst situation of the urban planning in London during the (first) Industrial Revolution. Urban planning is deviated towards the development of a social infrastructure, such as development of ports and transportation networks to decline economic growth from shortage of infrastructures, and the system of the waste is also left to natural self-cleaning systems of the environmental carrying capacity of entire city and surrounding areas. Human has been implementing urban planning as a tool of economic development for a long time. Particularly, bringing the energy of fossil fuels to cities made a place of mass production of artificial factories which have production function of the artifacts as industrial in the space of the city agglomerated many populations of labors, workers from rural areas or foreign countries as geek immigrants. Those process of the agglomeration of dwellers/ inhabitants into the city core, many households have no window, the inner door had many room's doors to avoid taxes, and three to seven households live together in such worst environment in one house that caused health problems several times like bronchial disease and infectious disease.

After 1st industrial revolution, modern city planning starts for connecting both inner city, intra city and inter city transportation network peripheral cities, towns and villages.

At the beginning and early factory workers had no choice but to live inside of a city (core) like the current big cities such as cities in China and cities in India, with worst air & water polluted toxic urban environment and worse public health conditions. H. Azuma (1991) wrote that “the first authors admire, ironically, the industrial revolution made newly middle class who desired well and safe residential houses and settlements from current inner-city (core area/ urban) poor environment rather in a well condition Ebenezer Howard’s “Garden Cities of To-Morrow (1898)” developed bed towns linked by mechanical lines using fossil fuels. Although Howard wishes to build neighborhood lifestyle with one’s workplace is near one’s home, reality was different from the idea of a rural city due to the proximity of the original job place to the suburbs of the environment. It could be stated that this newly middle class was greatly welcomed as a Great Social Movement (Garden City Movement). Both Letchworth and Welwyn Garden City, prototypes of this bed town, are not only UK phenomenon but also occurred combination of satellite town development around the world. A newly-emergent class of citizens which is so called the bourgeoisie in the society at that time pushed new social movements Ebenezer Howard’s “Garden Cities of To-Morrow (1898)” as intensity of new-town/ satellite-town/ bed-town development outside of the city core with mass-transit. Those new middle class becomes white-color has been driven suburbanization habitants of the 2nd IR in Table 1.

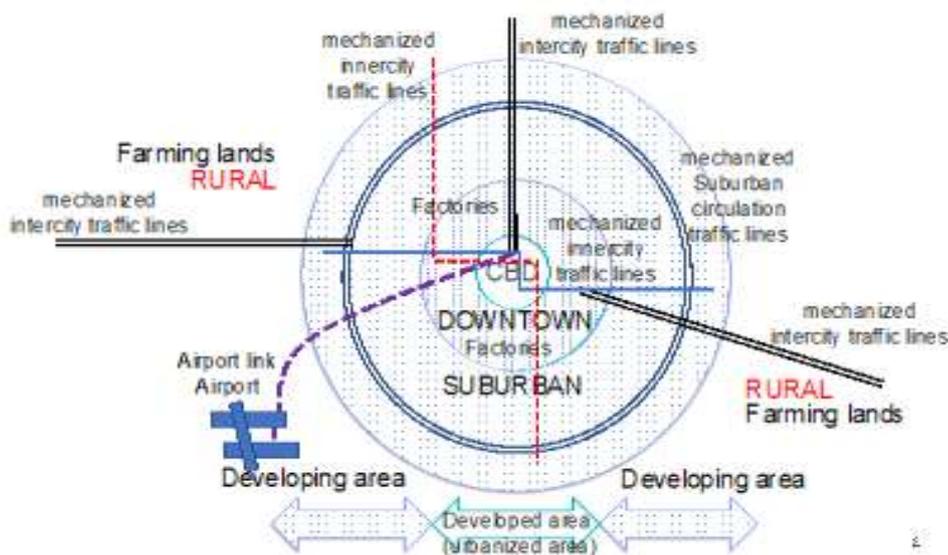

Figure 2: Typical city structure after 2nd stage of Spatial Cycles

In the 2nd “decentralization and growth” stage in Figure 3. It has already shifted major economic growth driving force in megacities around the world from secondary sector to tertiary sector of industry. Such kinds of megacities have almost same structure of Figure 2 where have ring and star connected/network transportations in both core (urban area) and ring (suburban area).

3 URBAN TRANSFORMATION MODEL BASED ON SPATIAL CYCLES MODEL

This chapter reviews theory of “Spatial Cycles (SC)” or “Spatial Cycles Model/ SCM)” by Leonardus Hendrik Klaassen, Nederlands Economisch Instituut, et al. in Figure 3. It is very common structure that there are three conceptual spaces where are located core (urban), ring (suburban) and rural in the city or urban region likewise a greater-city-region after Industrial Revolution since 18 century, nowadays so called 1st Industrial Revolution.

M. G. Docampo (2014) wrote that “The standard model of urban cycles implies an indefinite sequence of growth and decrease between the core and the ring. The basic, more general, and widely disseminated presentation is based on four phases or moments of growth: 1/urbanization, the process of population concentration in cities, also generating suburban rings to the detriment of rural territories; 2/deconcentration (exurbanization) when the urban ring grows at the expense of the urban core; 3/deurbanization or counterurbanization, when both the urban core and its ring lose population; 4/reurbanization, when the core changes again to a positive balance, while the ring loses population.”.

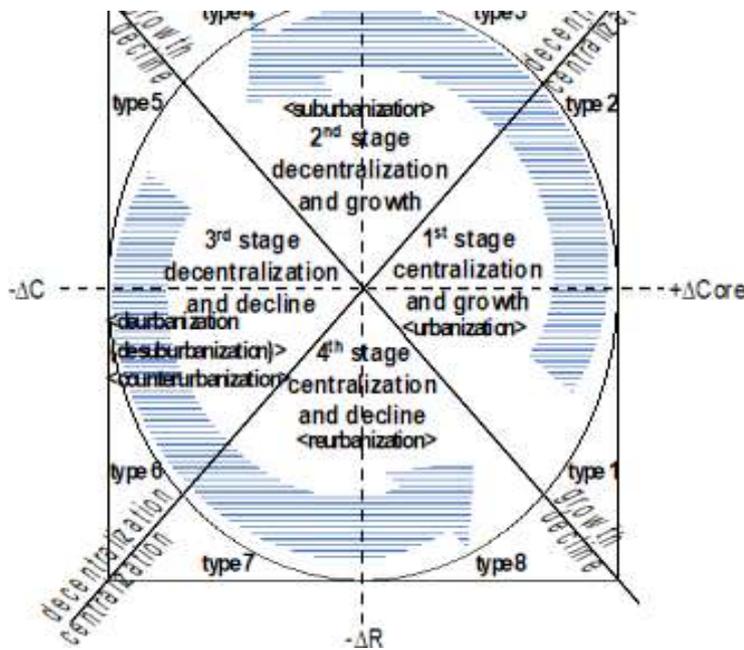

Figure 3: 4 stages & 8 types in Spatial Cycles Model

By the way, Smart City, autonomous urban systems, will be lead our cities fully equipped by intelligence explosions and emergence of super-intelligence revolutions based on big-data analysis, specified A.I. systems with deep learning, quantum computing, IoT/ IoE, Industry4.0 which is so called “Technological Singularity” in 2045.

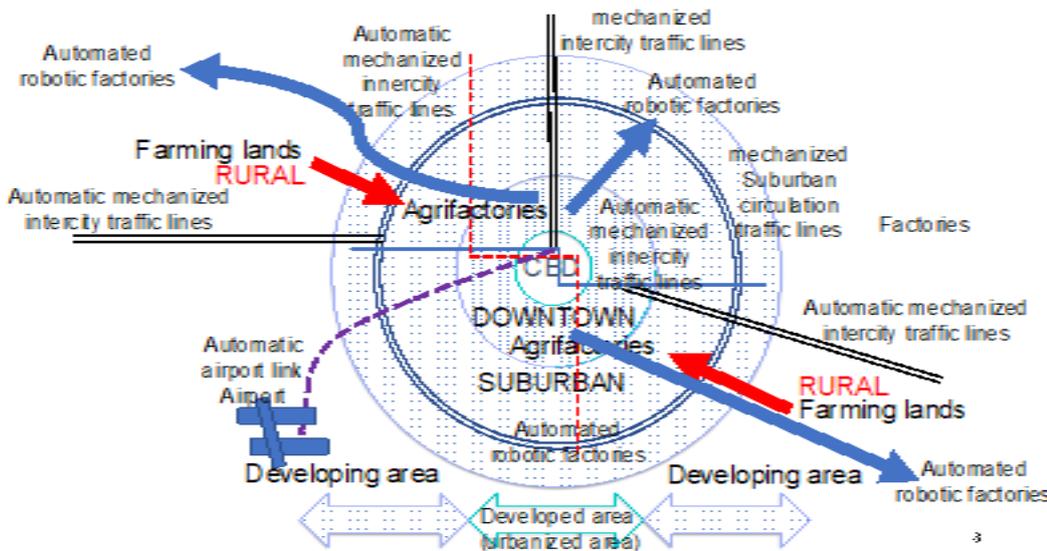

Figure 4: New Urban Transformation near future

Such a new 4th revolution changes our cities, urban, suburban and rural drastically in Figure 4 like disappearing car parking lots, industrial transformations, full autonomous factories without labours, urban vegetable factory & smart agriculture in rural area, autonomous fleet logistics and warehouses and drone delivery systems that are shown Figure 5.

Is Reforming Urban region renewal near future in Figure 5 next 1st stage in SCM? As long as deeply consideration, it seems that compact city, urban renewal, gentrification or gated city are almost the “counterurbanization” in the current stage, but at the same time location free industrial transformation led by new-techs with A.I. and automatic revolution makes our human being free from labor with some redistribution of wealth ways like “basic income” with “shared economy”.

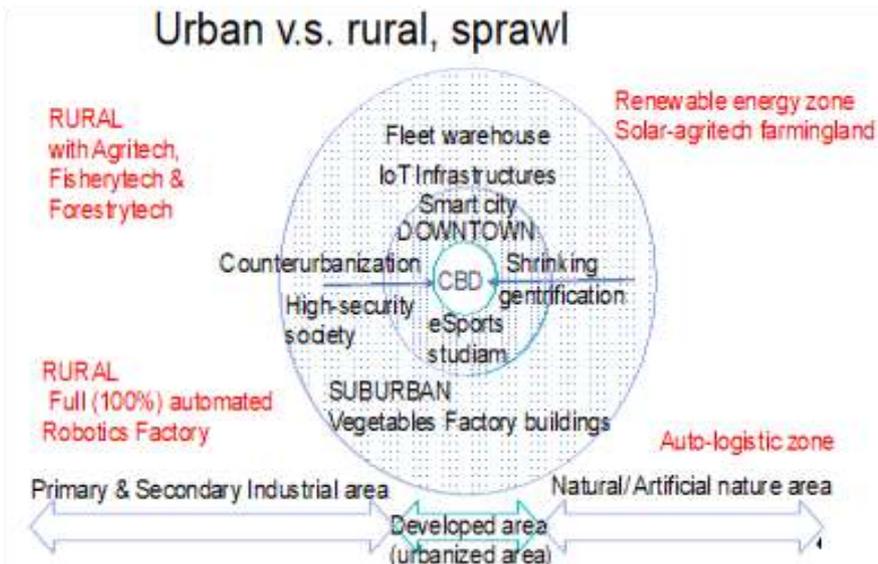

Figure 5: Reforming Urban region renewal near future

Inoue (2016) defined such an advanced automated robotic and A.I. economy as “*Pure Mechanized Economy*”.

At the same time, new urban planning systems raises new type of “New Technology for planning” and “New Technology of Planning”. Former one is fully 3D digitalized city database and simulators in a cyber space like “Virtual Singapore” developed by Dassault Systems, if real estate developer submits Singapore government 3D CAD development plan data for entire buildings complex, those data will be put into “Virtual Singapore” and simulated analyzing many situations like Thurman-wind phenomenon changes will be tested in the systems. Latter one is ontology planning systems with multiple city sensors’ aggregation sets which will be fundamental of Smart Society.

Figure 6: The proposal process and requirement priorities of THSR

4 URBAN TRANSFORMATION MODEL BASED ON SPATIAL CYCLES MODEL

This chapter treated second issue that is explosion of economic growth both without employment and without labors under Industry4.0 and smart agriculture makes drastic changes our life styles in our future society. Explosion of economic growth will be achieved by A.I. production/ service tax will be replaced instead of labor’s income tax. But at the same time, many of labors will be fired that shifts our life styles from labor to gaming. Shared/ engaged economy is constructed with shared economy and basic incomes from explosion of economic growth. Instead of annual average of hired working hours will be reduced, playing time in the game becomes longer rather than another pastime like watching TV. Playing electric games and watching games together became formal games as same as Olympic games right now in 2017. The eSports becomes large new industry around the world and attracts new generations’ important life events. Our sound future will be achieved gaming society for keeping sustainable governance both in private sectors and public sectors.

It is just a sample, Table 3 shows resent prediction of SONY corporation which tells us prior business of SONY was *Financial Services* in FY2017 but in 2018 forecasting would be expected shifting main business pillar of SONY from *Financial Services* to *Game & Networks Services*.

Table 3: statement of accounts and forecasts of SONY 2018

FY2018 Results Forecast by Segment (Reclassified)

		FY16	FY17	FY18 Forecast	Change from FY17
Game & Network Revenue (GNR)	Sales	1,848.6	1,992.8	1,988	-04.8
	Operating income	336.5	372.6	390	+17.5
Music	Sales	247.7	238.5	238	-08.5
	Operating income	75.8	127.8	132	+52.8
Publishing	Sales	803.1	1,011.1	983	-28.1
	Operating income	82.8	21.7	42	+20.9
Home Entertainment & Services (HES)	Sales	1,258.7	1,322.7	1,355	+32.7
	Operating income	55.5	68.4	81	+12.8
Imaging Products & Tools (IPT)	Sales	272.5	252.9	263	+10.1
	Operating income	47.3	34.9	25	-9.1
Media Communications (MC)	Sales	338.1	323.7	347	+23.7
	Operating income	15.2	-27.8	18	+45.6
Home Appliances	Sales	375.1	358.5	370	+11.5
	Operating income	-7.5	166.5	160	+93.0
Financial Services	Sales	1,537.5	1,228.4	1,273	+44.9
	Operating income	266.5	118.9	112	-6.9
All Other Corporate and elimination	Sales	-115.7	-87.6	-86	+1.6
	Operating income	-115.7	-87.6	-86	+1.6
Consolidated total	Sales	1,003.3	3,334.5	3,380	+45.5
	Operating income	286.7	734.9	873	+138.1

The fiscal year forecasts for each segment are shown on this slide. I will now turn to the situation in each of our businesses.

Source: SONY corporation; FY2017 Consolidated Financial Results

Recent Japanese younger generation under 18 years plays e-games more than 2 hours per day constantly. Adults also mainly playing smartphone play e-games close to 1 hour/day. It becomes major e-games into eSports universities league, new industry and new pastime arise. Some city has plans to build some eSports stadium in a city.

5 CONCLUDING REMARKS

It was shown that priorities of requirements are potentially changed depending on three types of evaluation axis: time-scale, decision makers, and dynamic factors under long-term paradigm shift makes our 4th industrial revolution. It has a big chance to confirm and test of next Spatial Cycles could be launched or not using ROXI index fitting Klaassen's SCM which the author has not been finished yet. However, new technology makes different types of urban transformation with fully automated robotic factories in the rural area without environmental heavy loading with proper fitting location likewise data center in high latitudes.

1358 RECLAIMING THE LOST IDENTITY: A METHODOLOGY FOR GENERATING SMART URBAN DESIGN SOLUTIONS IN TRADITIONAL CITIES - CASE OF VARANASI**Vidhu Pandey^{1*}, Joy Sen²**

1Research Scholar, Indian Institute of Technology, Kharagpur, India

2 Professor, Indian Institute of Technology, Kharagpur, India

*E-Mail: ar.vidhupandey@gmail.com, TP: +919775837630**ABSTRACT**

Indian traditional cities can be considered as a vibrant microcosm which have evolved gradually over time, amalgamating culture and modernity. However, when we put them in the course of rapid urbanisation then the situation gets drastically modified. These cities are comparatively more sensitive to the issues of urbanization from their modern counterparts because they are simultaneously trying to balance an age old traditional heritage with dynamic needs of a modern civilization. Rapid urbanization takes a toll on the existing urban conditions and start affecting the physical spaces, tending to haphazard urban development. One of the major shortcomings of the phenomenon, as observed is a gradual degradation of urban form, which existed earlier by the virtue of urban patterns of traditional societies. Generally, mitigation of this urban issue is done through charting policies which somehow capitulate in the execution phase. This can be attributed to a lack of integration among indigenous spatial and cultural inputs along with technology in design and renewal procedures. Robust urban design strategies with an innovative approach which bridges the gap between traditional heritage and modern living might be the answer to this issue. This research attempts to find the solution of aforementioned problem through case study based approach. The case study taken here is Varanasi which is revered as one of the holiest among Indian cities and captures the spot of the oldest continuously living city in the world. It has also been nominated among the probable cities which would be converted to a 'Smart City' hence making it the perfect candidate for conducting this urban experiment. This research has been broadly divided into three parts. In the first part, research would examine the shortcomings of current spatial policies regarding urban design in traditional cities by critically reviewing the existing plans, strategies and guidelines. In the second part, the gap between the current scenario and the people's perception of the smart city scenario regarding smart urban design would be highlighted through primary survey and semi structured interview method. In the third part, the research would evolve smart place making based solutions which would provide an alternative to conventional urban regeneration and design policies. These place making based smart urban design policies would not only be able to bridge the gap between the current and perceived perception of city but would also be more sensitive in retaining the character of urban design of a traditional city. The methodology for evolving this research is based on the work of Christopher Alexander viz. 'A Pattern Language'. Network analysis is used as a preliminary analytical method allied with 'A Pattern Language' for validation purpose.

Key Words: Smart urban Design; Pattern Language; Network Analysis; Traditional Cities; Form based codes; Spatial Policies

1 INTRODUCTION

India is a land of diversity and has always held its legacy as a land of myriad cultural dimensions. This includes not only the amalgamated social-cultural scenario but also its tangible expression, the **physical spaces**. The Indian traditional cities have developed in an organic format with their own pace. They can be considered as the vibrant microcosm with each one having its own story of evolution. Physical spaces in India are diverse in their nature and have different interpretations for different facets of life for all concerned stakeholders. When we introduce factors of urbanisation and globalisation in this equation, then not only the urban patterns of these physical spaces start affecting the existing urban conditions but also start governing the course of future development.

A 2013 International Business Times' article writes about India as one of the major stakeholders of this population growth and is predicted to become the most populous country swapping its position with China by 2050 (Bansal, Pandey, & Sen, 2016). As stated in sustainable development goals', more than half of the world's population now live in urban areas. By 2050, that figure will have risen to 6.5 billion people – two-thirds of all humanity. Sustainable development cannot be achieved without significantly transforming the way we build and manage our urban spaces (UNDP, 2016). Not only does it leave the 'new Indian cities' in need to get in tune with latest tools and techniques so as to empower their arsenal with competent urban services but also it requires 'traditional cities' to come at par with their modern counterparts and become proficient in dealing with the urban issues of the new age.

1.1 Traditional cities and issues in Urban Regeneration

The traditional cities have deep-seated cultural values associated with them which render a unique aura to these regional composites. Here, the built environment is the most salient manifestation of heritage. History serves as the base upon which the city thrives, and the Historical Built Environment or HBE is the principal spatial element on which the interplay between time and space is played out. Although historic preservation has played an increasingly important role in shaping urban form yet demolition and removal of historic structures and the haphazard placement of new developments are all too common in the cities worldwide and Indian cities are no different (Chhabra, Healy, & Sills, 2003). Juxtaposition of new development with once historic environments can sometimes empty the latter of their deep and cultural significance (Newman, 2016). Here it is required that those in power of decision making and designing, like urban

planners and designers, must do a better job preserving and modifying existing built forms for new development schemes, rather than the typical Tabula Rasa approach.

One of the major shortcomings of the phenomenon, as observed in traditional cities of India is a gradual degradation of a natural form of a city, which existed earlier by the virtue of urban patterns which helped to distinguish one city from the other. **Generally, mitigation of this urban issue is done through charting urban policies which mostly overlook the indigenous needs and aspirations of the stakeholders on one hand and causes identity crisis by lacking the natural order of spaces on the other hand.** Urban regeneration for such cities generally fails in the execution phases as there is a lack of integrating indigenous spatial and cultural inputs along with technology in renewal procedures. Hence, this study proposes an exploration of urban regeneration strategies through historic pattern based place making approach. This involves, simultaneous consideration of indigenous spatial requirements and cultural responses that befits existing urban fabric. The study attempts to look into the case area through the lens of spaces as a concept and a physical entity since they have gone through a multitude of change in the past few decades and it's important to manage them in the magnitude they are present. This study draws its inspiration from the works of Christopher Alexander viz., A Pattern Language technique and is applied along with allied techniques for observing the various urban spaces against a larger continuum of the sustainable traditional urban environment.

1.2 Rationale of Planning and role of Government

The basic idea behind urban planning is to produce some kind of explicit rationality driven by collective purposes that are capable of regulating the multitude of individual decisions that build the city over time. How this rationality is constructed and what are the underlying criteria and analytical interpretations, remains one of the most critical questions in urban planning. In fact, in order to be effective, a plan should be informed by a stringent diagnosis of the reality it aims to conduct and regulate, and it must also be able to prognosticate, at least to a certain extent and with a reasonable degree of confidence, the expected outcomes of the proposed planning strategies. On both these stages of the planning process – diagnosis and prognosis - objective analytical methods and predictive models are the key. However, in what concerns the physical and morphological dimensions of urban planning, this kind of methods and models remain largely speculative, if not simply absent from the regular practice (Serra, Gil, & Pinho, 2011). Hence a series of not so successful urban endeavours by the development agencies and other concerned organizations leads to turmoil in the minds of citizens and in a way breeds to reluctance of acceptance for designed environments for areas in general and Indian urban scenario in particular.

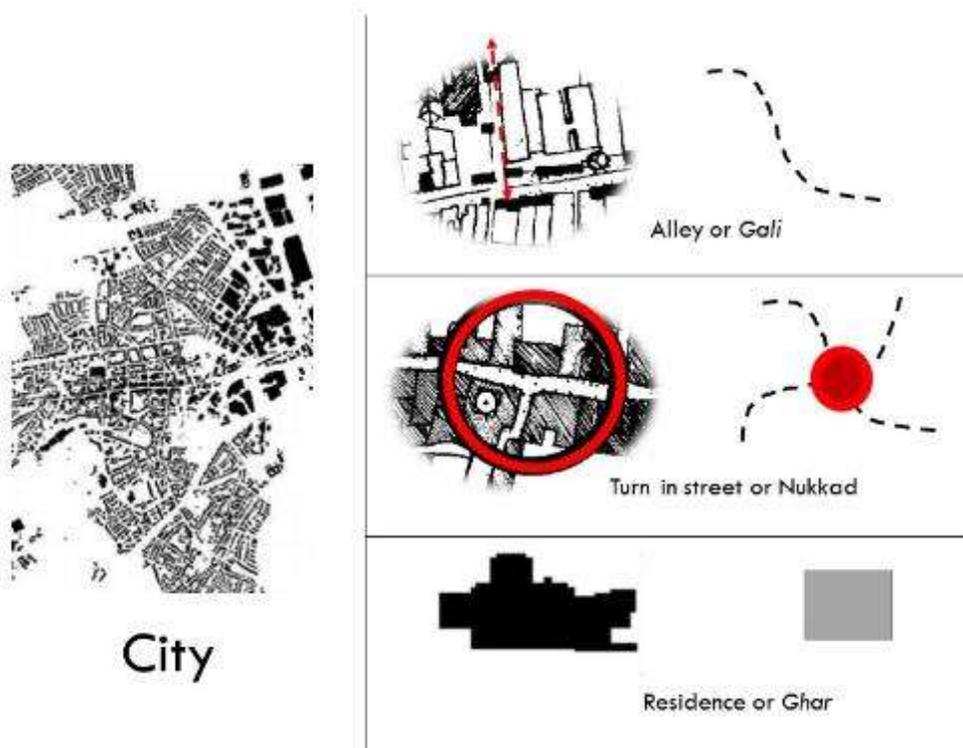

Figure 99: Illustration of city and its components

The consequential effect of the above discussed scenario leads to another observation as of now, that is, the 'design of urban environments' is still an issue of concern for citizens in Indian context especially the traditional cities. The inhabitants of these cities find comfort and a sense of belongingness with the organic layouts of Mohallas (residential colonies), Gali (narrow lanes) and Nukkads (small urban gathering areas formed on the junction/ crossing of streets or lanes) (Figure 1) with which they have started to associate their own identity and any idea to disturb this symbiosis is generally reckoned as an intrusion to the culture of indigenous habitants. Moreover, the general notion propagates 'Designed Environments' as a thing of elites and a domain which doesn't include the everyday man into the loop of the processes. This in turn can be attributed to the fact that the said schemes are never presented in a style or format which

is easily accepted or comprehended by the citizens. The living structure which is needed to sustain us and nurture us and which did exist to some degree in the traditional societies, rural communities and early urban settlements has disappeared. We don't know how to create it or generate it any more. This was not the case long ago, earlier with the help of the shared pattern languages which existed in traditional society, people were able to generate a complete living structure (Saligaros, 2005).

Thus, the need of the hour is to invoke the pre-requisites for a process which can take a holistic view of current urban scenarios and might lead to some plausible conclusion on the steps which could be taken for battling this issue at a grass root level. Hence, the motivation of the research lies in finding solutions to the aforementioned issues in context with the traditional cities in general and Indian traditional cities in particular.

2 GAP AREA IDENTIFICATION

Literature review started with the analysis key topic that is Urban Regeneration so as to examine the various terms involved and their implications on the desired research flow. It was then followed by investigating the urban renewal policies of India and what was plaguing them in the context of traditional cities.

2.1 Urban Regeneration

Regeneration in biological terms is the process of renewal, restoration, and growth that makes genomes, cells, organisms, and ecosystems resilient to natural fluctuations or events that cause disturbance or damage. The analogy can as well be true for a city which is considered as a living organism exhibiting each and every nuances of its life cycle. Oxford dictionary defines urban regeneration as the process of improving derelict or dilapidated districts of a city, typically through redevelopment. It is called as Urban Renewal (in United Kingdoms) Urban Revitalisation (in United States) and is a program of land redevelopment in areas of moderate to high density urban land use. Historically the concept of urban renewal as a method for social reform emerged in England as a reaction to the increasingly cramped and unsanitary conditions of the urban poor in the rapidly industrializing cities of the 19th century (Figure 2) (Worldbank, 2007).

Rapid urbanization scars the city's organic growth with its overwhelming demands of space and infrastructure. A city reeling under its pressure can succumb to its ill effects and lead to congested cores and sprawling suburbs which in turn add to the grievances of the citizens. It is a multifaceted phenomenon and can have various perspectives to look into, spatial and economic being one of them. Interventions on sub-city and neighbourhood level need to be applied so as to restore the city to its native stage. These restorative measures or redevelopment can be accounted to urban regeneration. Just like any process has its own appraisal and critique, similar is the process of Urban Regeneration: On one hand it has been termed as a way of becoming a growth engine, an efficient reform mechanism, and a way of enhancing existing communities whereas on the other hand it is beckoned as a tool of demolishing neighbourhoods and a means of control mechanism. There is always an inherent tension between **top-down technical and managerial** approaches to urban regeneration and **bottom-up or grassroots environment needs, expectations, and initiatives** (Worldbank, 2007).

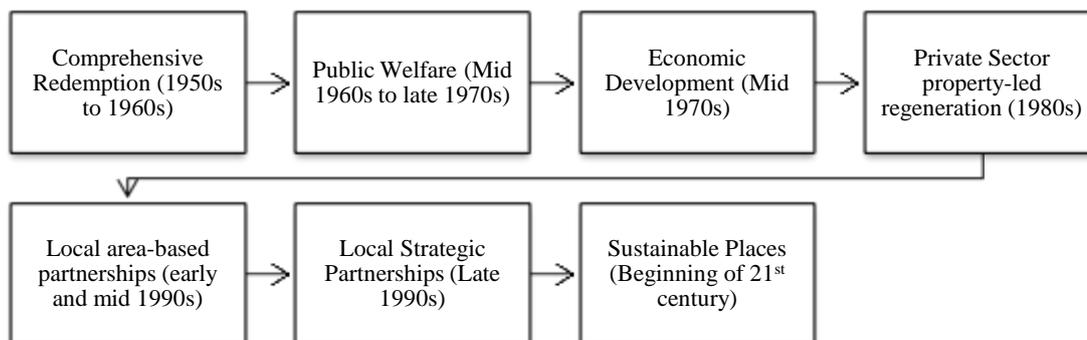

Figure 100: Evolution of Urban Regeneration (Worldbank, 2007)

One can distinguish in each historic city specific urban patterns or features such as the nature and density of land uses, height of buildings, width and pattern of circulation routes (roads, alleys, and footpaths), building typologies, as well as specific infrastructure components. These form the components of the 'Urban Tissue' (Steinberg, 1996). Hence, for area conservation and rehabilitation it is essential that the maximum possible preservation of the original tissue pattern should become the prime objective. Experts remain divided on this approach too. Some think it as being too specific to a place whereas others perceive it has a parts to whole solution.

2.2 India's Urban Renewal Policies

India's urban renewal initiatives are discussed as below:

JnNURM

JnNURM or Jawaharlal Nehru National Urban Renewal Mission, was one of the biggest initiative of the government of India for carrying out urban renewal process in the Indian Cities. The primary objective of this mission was to be: Productive, Efficient, Equitable and Responsive in it deliverance mechanism. The mission's focus areas were:

- Integrated development of infrastructure services

- Securing linkages between asset creation and maintenance for long run project sustainability
- Acceleration flow of investment into urban infrastructure services
- Planned development of cities including peri-urban areas, outgrowths and urban corridors
- Renewal and redevelopment of inner city areas
- Decentralization of urban services

The objectives, apart from the other areas, also included renewal and redevelopment of inner city areas which is of interest to this study. The subtasks of this policy have been illustrated in the next segment to get an overall view of the work intended to be performed under this scheme (Figure 3).

Figure 101: Subtasks of JnNURM (Ministry of Urban Development and Ministry of urban employment and poverty alleviation , GoI, 2011)

While investigating the appraisal reports for various JnNURM projects it was found that there existed many anomalies in the documents at the proposal level itself which led to the discrepancies at the execution level. Hence, leading to a lack of effectiveness of the scheme in many of the projects eventually.

HRIDAY

Heritage city Development and Augmentation Yojana or HRIDAY is an ongoing mission developed by Ministry of Urban Development, GoI. It is stated in the policy statement **that it would bring a paradigm shift in India's approach to city development, bringing together urban planning/ economic growth and heritage conservation in an inclusive and integrated manner** with focus on livelihoods, skills, cleanliness, security, accessibility and service delivery (Ministry of Urban Development , 2015).

The heritage development of city is often misinterpreted as revitalisation of few patches, instead it is a holistic development of the entire city. Past efforts of conserving historic and cultural resources in Indian cities and towns have often been carried out in isolation from the needs and aspirations of the local communities as well as the main urban development issues, such as local economy, urban planning, livelihoods, service delivery, and infrastructure provision in the areas (Ministry of Urban Development , 2015).

The main objective of HRIDAY is to preserve character of the soul of heritage city and facilitate inclusive heritage linked urban development by exploring various avenues including private sector.

The objectives of the scheme are:

1. Planning, development and implementation of heritage sensitive infrastructure.
2. Service delivery and infrastructure provisioning in historic city core areas.
3. Preserve and revitalize heritage wherein tourists can connect directly with city's unique character.
4. Develop and document a heritage asset inventory of cities – natural, cultural, living and built heritage as a basis for urban planning, growth and service provision & delivery.
5. Implementation and enhancement of basic services delivery with focus on sanitation services like public conveniences, toilets, water taps, street lights with use of latest technologies in improving tourist facilities/amenities.
6. Local capacity enhancement for inclusive heritage-based industry.
7. Create effective linkages between tourism and cultural facilities and also the conservation of natural and built heritage.
8. Urban heritage adaptive rehabilitation and maintenance, including appropriate technologies for historic buildings retrofitting.

9. Establish and manage effective public private partnership for adaptive urban rehabilitation.
10. Development and promotion of core tangible economic activities to enhance avenues of livelihoods amongst stakeholders. This would also include necessary skill development amongst them including making public spaces accessible and developing cultural spaces.
11. Making cities informative with use of modern ICT tools and making cities secure with modern surveillance and security apparatus like CCTV etc.
12. Increase accessibility i.e. physical access (roads as well as universal design) and intellectual access (i.e. digital heritage and GIS mapping of historical locations/ tourist maps and routes) (Ministry of Urban Development , 2015).

Projected outcomes of HRIDAY Scheme:

The followings are the specific outcomes envisaged under HRIDAY.

1. Clean and improved sanitized environment
2. Improved basic urban infrastructure at existing and emerging tourist destinations and gateways
3. Improved sanitation standards at natural and cultural tourist attractions with convenience and safety for visitors
4. Properly conserved, revitalized and beautified heritage monuments
5. Greater participation by local communities in tourism-related economic and livelihood activities
6. Heritage resources are mainstreamed with city systems and city economy
7. Improvement in the service level benchmarks indicators for urban service delivery
8. Increase in the inflow of the tourist to cities
9. Increase in the duration of stay of the tourist in the town
10. Improvement in social safety and reduction in crime
11. Substantial improvement in local economy and quality of life of its communities

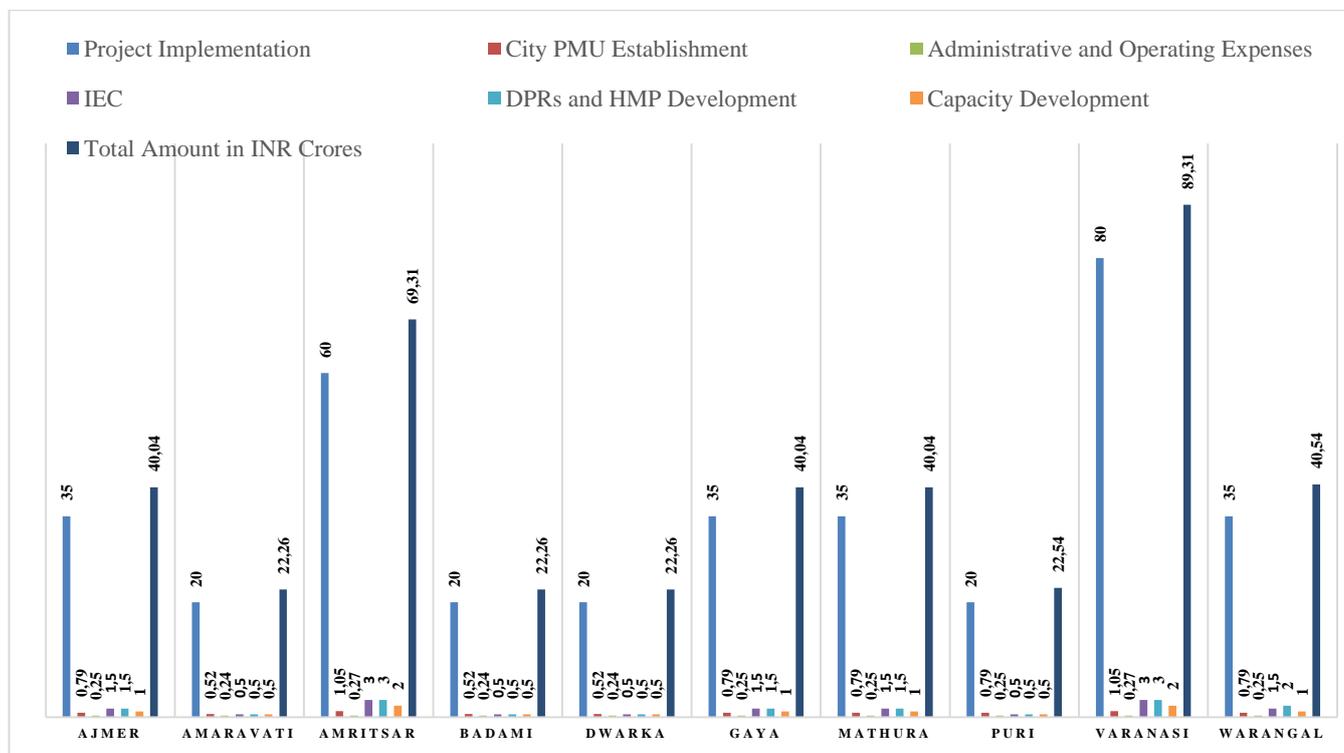

Figure 102: HRIDAY: Budget Outlay (Ministry of Urban Development, 2015)

Figure 4 illustrates the budget outlay of HRIDAY for various cities for the scheme tenure, that is from December 2014 to March 2018. The mission is ongoing hence the total objective achieved by the process yet remains to be evaluated.

AMRUT

Atal Mission for Rejuvenation and Urban Transformation or AMRUT has been launched as a primary mission to provide basic services (e.g. water supply, sewerage, urban transport) to households and build amenities in cities which will improve the quality of life for all, especially the less privileged sections of the society. The objectives of the mission have been grafted on the base of learnings from the previous mission which states that infrastructure creation should have a direct impact on the real needs of people, such as providing taps and toilet connections to all households. This means that the focus should be on infrastructure creation that has a direct link to provision of better services to people (Ministry of Urban Development, 2015).

The mission would be covering 500 cities in this domain for which a total outlay of Rs. 50,000 crores for five years from FY 2015-16 to FY 2019-20, has been allocated.

The Mission will focus on the following Thrust Areas:

- A. Water supply
- B. Sewerage facilities and septage management
- C. Storm water drains to reduce flooding
- D. Pedestrian, non-motorized and public transport facilities, parking spaces
- E. Enhancing amenity value of cities by creating and upgrading green spaces, parks and recreation centres, especially for children (Ministry of Urban Development, 2015)

Major Components of AMRUT:

1. Water Supply
2. Sewerage
3. Septage
4. Storm Water Drainage
5. Urban Transport
6. Development of Green Spaces and Parks
7. Reforms Management and Support
8. Capacity Building
9. Indicative list of inadmissible components

The mission is undergoing hence the total objective achieved by the process yet remains to be evaluated.

Inferences

After reviewing the major schemes which are contributing towards urban regeneration we can give a holistic review of JnNURM only as it has been completed and evaluated. These are as follows:

- 1) Lack of Focus on Cultural input based on historical built environment
- 2) Lack of Public Participation in development works

Though HRIDAY and AMRUT do consider some of the above mentioned ideas in their agenda but it is yet to be witnessed by the country. In aligned to the new policies we also have SMART city initiatives which include traditional cities as the future smart cities too. The purpose of the Smart Cities Mission is to drive economic growth and improve the quality of life of people by enabling local area development and harnessing technology, especially technology that leads to Smart outcomes. Area-based development will transform existing areas (retrofit and redevelop), including slums, into better planned ones, thereby improving liveability of the whole City. This needs to incorporate the above two points which came out as the drawbacks of JnNURM.

Moreover, policy makers in association with urban planners and designers must do a better job of **attaching and recycling existing built forms for new development schemes**, rather than the typical clean-slate approach. The appropriate **reuse of existing vacant heritage structures and the design characteristics of new developments should also play a vital role in future preservation**. The designation of landmarks and iconic heritage structures, salvaging of vernacular elements, inclusion of lost histories, **increased preservation of non-landmark historic structures and strategic applications of renovation and adaptive reuse** can all play a role in increasing the endurance of built environment.

2.3 Pattern Language Technique

Every urban setting is made up of many smaller components. It is this cumulative effect which can be interpreted in the form of language which is expressed as our built environment. The town planner Christopher Alexander invented design patterns in the 1970s. He addressed the challenge that many problems in planning were (and are) too large and complex for one person to consider them in their entirety at one time; and that it is hence necessary to break them down into sub-problems.

Pattern language when first conceived, was based on certain generative schemes that exist in traditional cultures. These generative schemes are sets of instructions which, carried out sequentially, will allow a person or a group of people to create a coherent artefact, beautifully and simply. The number of steps vary: there may be as few as half a dozen steps, or as many as 20 or 50. When the generative scheme is carried out, the results are always different, because the generative scheme always generates structure that starts with the existing context, and creates things which relate directly and specifically to that context (Alexander, *The Origins of Pattern Theory: The Future of the Theory, and the Generation of a Living World*, 1999).

Christopher Alexander in his work 'A Pattern Language' describes design practices which can be used to design spaces at various levels which are aesthetically feasible and functionally viable. This work tries to break down the language of built environment into its components to form a vocabulary of pattern syntax which can be interpreted for various urban levels. This particular research intends to view the direction of research through the lens of Pattern syntax and which can be defined for Indian context (figure 5).

Figure 103: Examples of Pattern syntax from 'A Pattern Language' (Alexander, Silverstein, & Ishikawa, A Pattern Language, 1977)

2.4 Planning support systems (PSS)

In research areas pertaining to urban planning, the decision support systems can be redefined as Planning Support Systems (PSS). It is a new member of a family of computer aid for planners and is closely related to the fields of Large Scale Urban Models and Spatial Decision Support Systems (Brömmelstroet, 2013).

Planning support systems are a subset of computer-based geo-information instruments, each of which incorporates a unique suite of components that planners can utilise to explore and manage their particular activities. The components may include data sets, computer algorithms and display facilities, as well as more abstract theoretical constructs, knowledge and modelling capabilities (Geertman & Stillwell, 2003). A PSS not only act as reservoirs of planning information but can also be used as solution providers for the urban planning problems of modern times

This particular study delves into the domain of area based solutions using smart urban design as an enabler. Although the research is still in the conceptual stage and doing various iterations in finding the right idea, the author would like to put forward the current flow of activities which can be performed to achieve the desired goal. The idea proposes a smart Planning support system which would aid planners and designers to automate their place based urban design solutions and would give them iterations so that the best possible solution can be incorporated for the execution. In the next section author would detail out the methodology to approach such design flow.

3 METHODOLOGY

The urban regeneration scenario in India is based on conventional schemes and strategies which mostly focus on providing or augmenting hard-core infrastructure and generally lack the element of cultural sensitivity while providing the solutions. This research proposes to evolve an integrated system of Place making strategies based on Pattern Language and other allied analysis techniques based integrated system which would provide an alternative to conventional urban regeneration strategies. This study proposes a methodology for identifying appropriate urban patterns from different parts of city areas, best suited for classifying and retaining the character of a city. These patterns should be socially and culturally viable and also economically feasible representatives, eligible to be reiterated during formation of new urban spaces grafted on a historic urban landscape.

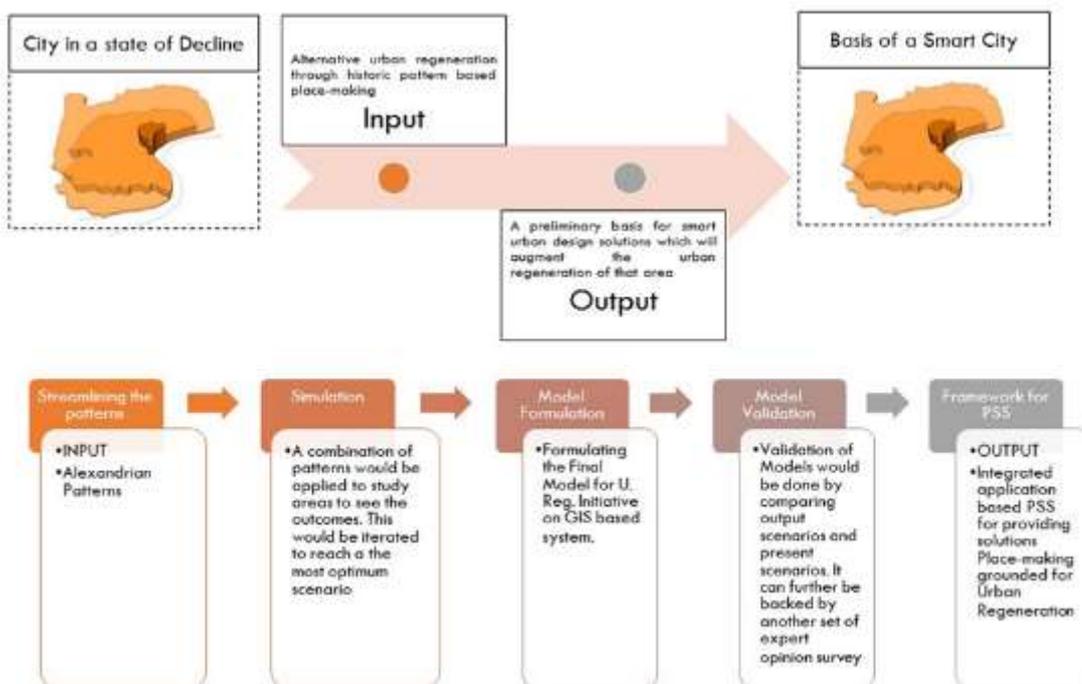

Figure 6: Methodology-Task flow

Organic nature of Indian cities gives them an inherent complexity which needs to be thoroughly analysed before proposing any reform mechanism. The study intends to conclude into a framework of place-making based Planning Support System which could assist the concerned stakeholders (Authorities, Planners, Designers and Users) while making decisions regarding the urban configurations whether it be in core city layers or the outer layers.

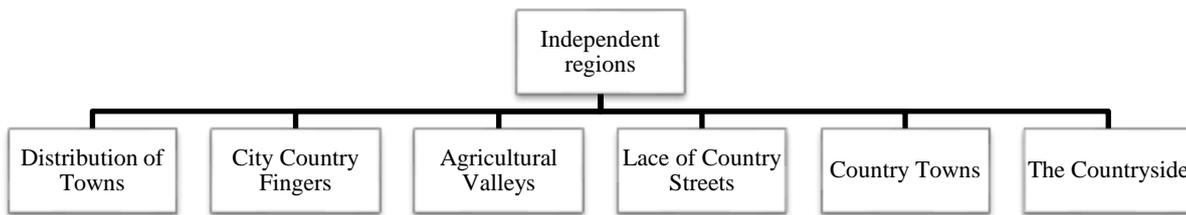

This is an ongoing research and the work which is included in this paper would focus on the very first step that is streamlining and appropriating patterns as per the context of the city.

3.1 Approach for Pattern Mining

The process for pattern mining starts by doing reconnaissance survey of the spots in the city which might have patterns (tangible and intangible) embedded into the urban fabric. The location of the spots is derived by doing extensive literature review of secondary sources and by doing semi structured interviews of the stakeholders which are linked with those spots. In this way author proposes to construct a repository of Patterns.

A Pattern Language has 253 patterns (Alexander, Silverstein, & Ishikawa, A Pattern Language, 1977) illustrated which are broadly divided into three categories, Town Planning, Architectural and Construction Patterns hence forming a hierarchy of patterns. For example, the starting pattern in the book is Independent Regions which is one of the Macro patterns, this is followed by six connected patterns and which again have their own smaller parts. These groups are not mutually exclusive and has many overlapping connections. It is then followed by examples of patterns at various scales which exist in the Alexandrian pattern language.

Case of **Independent Regions**:

Here, if P_N is a macro design pattern then the language which forms this element would be a group of patterns which would be below in the hierarchy to the pattern P_N. Moreover, the patterns are interconnected among themselves (Figure 7).

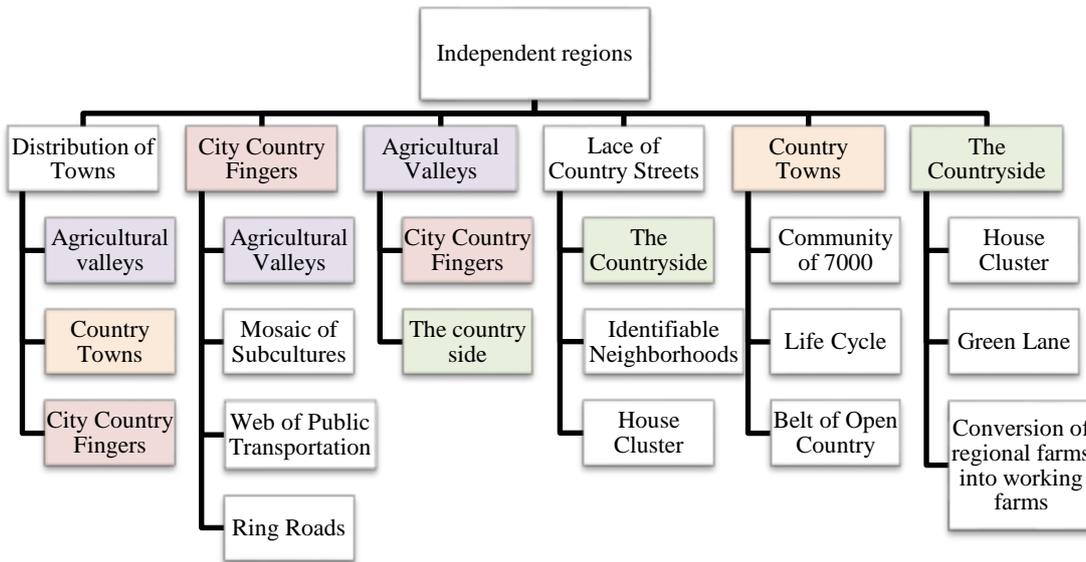

Figure 104: Interconnection among the Sub-Patterns

Eg. P_N = P_{I Reg}

$$L(P_{I Reg}) = f(P_{DT}, P_{CCF}, P_{AV}, P_{LCS}, P_{CT}, P_{CS})$$

Where,

- P_{I Reg} = Independent regions
- P_{DT} = Distribution of Towns
- P_{CCF} = City Country Fingers
- P_{AV} = Agricultural Valleys

- P_{LCS} = Lace of Country Streets
- P_{CT} = Country Towns

For current study author has opted for case study based research and the next section will show excerpt from the semi structures interviews in identifying the possible urban spaces for extracting these patterns.

3.2 Piloting a stretch (field survey)

A pilot survey was conducted in the Panchganga Ghat Zone for the assessing the probability of identifying urban patterns. Reconnaissance survey was conducted along with semi structured interviews for collecting the data of this study. One of the major query was to understand about the public places of that region and how are the people associated with those areas are interacting with them. Details of 21 respondents with one significant question is given below:

Table 31: Excerpts from Interview from Panchganga Ghat Zone

S. No.	Name	Place of Residence	What are the most popular urban places near your residence and workplace?
1.	Renu Aggrawal	Gopal Mandir Compound	Thatheri Bazaar, Vishwanath Gali, Chowk
2.	Rashmi	Govind Ji nayak Lane	Gopal Mandir, Vallabhacharya Temple
3.	Krishna Kumar Rastogi	Barah Dari, Thatheri Bazaar	Panchganga ghat
4.	Mohan Laal Yadav	Panchganga Ghat	Alamgiri Mosque, 5 rivers meeting point (Panchganga), Baba Tailang Swami Math
5.	Raj kumar Sahni	Rajghat	Kaal Bhairav Mandir, Bindu Madhav Mandir, Alamgiri Mosque, Sherwali Kothi, Gopal Mandir
6.	Gaurav Yadav (Information Similar to Rajkumar Sahni)	Bibi Hatia	Kaal Bhairav Mandir, Bindu Madhav Mandir, Alamgiri Mosque, Sherwali Kothi, Gopal Mandir
7.	N. K. Gujrati (Information Similar to Rajkumar Sahni)	Nati Imli	Kaal Bhairav Mandir, Bindu Madhav Mandir, Alamgiri Mosque, Sherwali Kothi, Gopal Mandir
8.	Mohan Laal Yadav	Panchganga Ghat	Panchganga Ghat (Confluence of 5 rivers), Tailang Swami, Alam Giri Mosque, Maths
9.	Raj Kumar Srivastava	Gaumath chowk	Kashi Viswanath, Sankatha Temple, Bindu Vinayaka Mandir, Kashmiri Mahal Haveli (now in Ruins), Kath ki Haveli near Chaukhamba
10.	Naomi Tripathi	Assi Ghat	Gopal Mandir, Tulsidas ji ki Gufa, Bindu Madhav, Panchganga Ghat, Bhonsale Kothi
11.	Nanda LaL Tripathi	Chunar	Gopal Mandir, Kall Bhairav, Kashi Vishwanath, Annapurna Mandir, Sankatha Temple, Panchganga Ghat
12.	Sachiv Kumar Shah	SherWali Kothi (Lion Mansion)	Gopal Mandir, moti jheel Palace, Raman Nivas
13.	Pappu	Nakki Ghat/ Earlier from Teliya Bagh	Kangan Haveli
14.	Arun Pandey	Doodh Vinayak Area/ Originally from Lucknow	Mangla Gauri Mandir, Brahmcharini Mandir, Tailang Swami Mandir, Gokarna Math
15.	Makrand Maheshkar	Brahma Ghat	Bindu Madhav Mandir (Vishnu Kashi). It was established by Aundh state of Maharashtra. Tailang Swami, Sant Eknath Maharaj staying Place (Kutiya), Kangan Haveli, Dakshinmukhi Hanuman
16.	Saloni Tewari	Rajendra Pratap Mitra's (from Bengal) Palace/ Original Family lives in Luxa	Bhairav Nath, Vishwanath, Sankatha mata mandir, Mangla Gauri Mata Mandir, Bindu Madhav Mandir, Panchganga Ghat
17.	Priest of Kangan Haveli (Family of 50 +32)	Kangan Haveli	Mangla Gauri Mandir, Brahmcharini Mandir, Tailang Swami Mandir, Gokarna Math
18.	Mukun Lal and Sushil Kumar	Thatheri Bazaar	Siddhivinayak Temple, Thatheri Baazar, Madhav Rao's Dharara (Now Alamgiri Mosque)
19.	Dayashankar	Panchganga Zone	Sankatha Mandir, Siddheshwari Gali, Lakkhi Chautara
20.	Vishnu Singh	Panchganga Zone	Shops of Thandai (Local Delicacy) Pathak Thandai and Banke Thnadai, Chaukhamba Sweet Shop, Maa Kali's Statue, Tailang Swami's Temple
21.	Dr. Manohar Shyam (9336917365)	Panchganga Zone	Aurangzebi Mosque, Sankatha Mandir, Gauri Mangla Mandir, Panchganga Ghat, Some Foodjoints

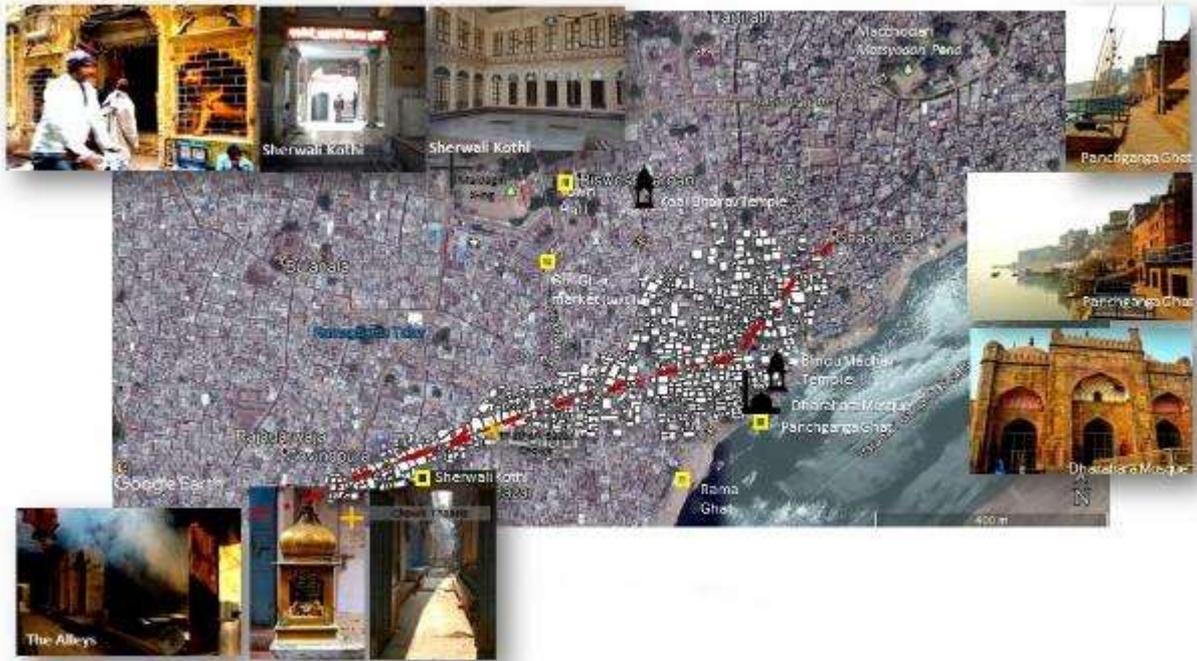

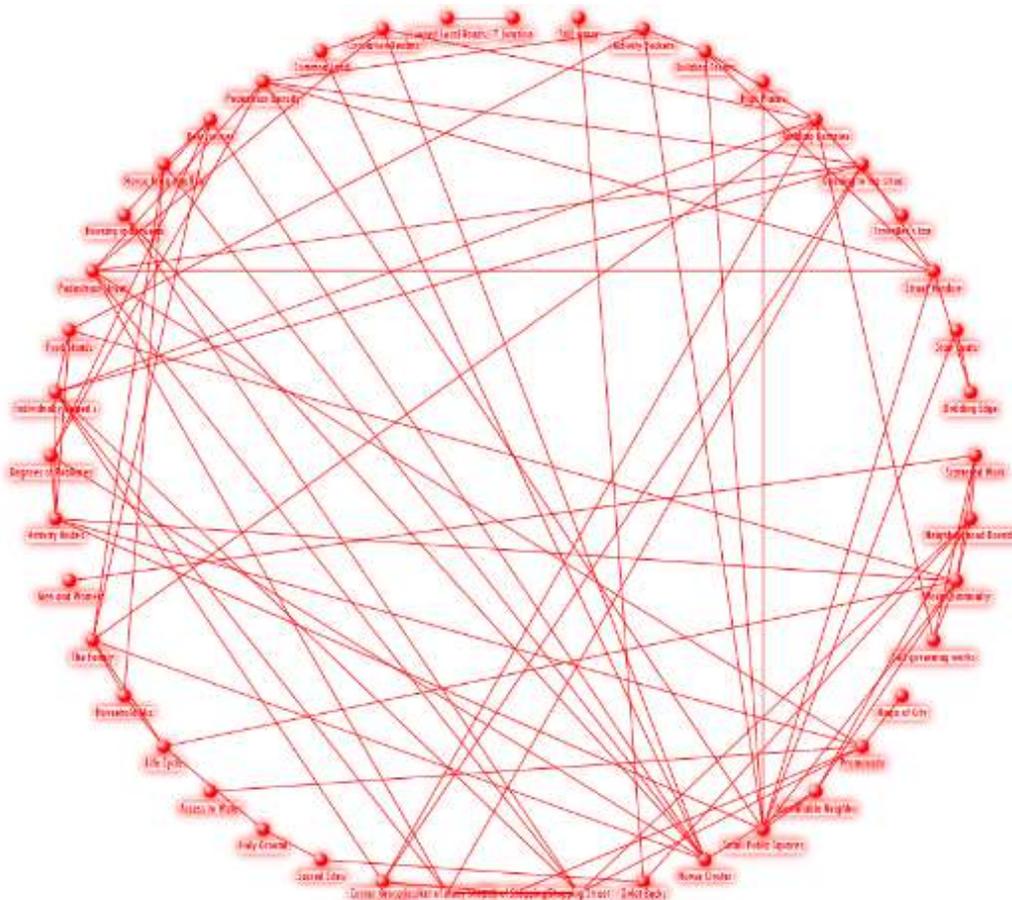

Figure 105: Panchganga Ghat zone

3.3 Conceptual idea for a PSS

The data from the respondents are utilised for extracting the patterns according to Alexandrian pattern language. These can be used as elements of design which can be used iteratively to proceed towards design solution.

Panchganga Ghat- Network Analysis

Process started by creating an edge list in which patterns existing in Alexandrian language were taken as base and through reconnaissance survey of the site, existing patterns were observed. From the holistic edge list, those patterns were dropped which did not exist in the site. All the nodes were recorded. These nodes were then fed into the network analysis software (NodeXL) to understand the kind of relations existing between them and visualising them (Figure 9).

Created with NodeXL (<http://nodexl.codeplex.com/>)

SS02.2. Smart Cities Initiatives for the 21st Century: Myth or Reality

1066 MIND THE GAP: SMART CITIES AS ENTREPRENEURIAL ECOSYSTEMS?

Domingos Santos

Polytechnic Institute of Castelo Branco, CICS.NOVA – Social Sciences Interdisciplinary Centre, Av. Pedro Álvares Cabral, 12, 6000-084 Castelo Branco, Portugal, domingos.santos@ipcb.pt

ABSTRACT

The concept of the smart city gained increasing expression and has become an intensely discussed field in the recent past among, either the research community, either the political stakeholders. In this paper, the importance of deepening the understanding about smart cities entrepreneurial ecosystems is explored. This involves working on existing knowledge about smart cities but extending its application to entrepreneurship and innovation.

This paper aims, first, to contribute to shed light on the meaning of the word *smart* in the context of urban development through an approach based on an in-depth literature review of pertinent studies and then, to establish the links with the determinants of entrepreneurship that can help guide more effective urban development policies. Furthermore, the paper underlines the critical importance of being innovative and entrepreneurial in the approach for smart cities, aiming to deepen and improve policy-making on the subject of promoting entrepreneurial mindsets and contexts, speculating on some principles and guidelines that may help fertilize urban dynamics and build smarter cities. The entrepreneurial ecosystem concept has potentialities that may enable smart cities to adopt more profound and structural broad spectrum strategies to respond to competitiveness urban challenges.

Keywords: Smart city, urban policy, entrepreneurial ecosystem, entrepreneurship, innovation policy

1 INTRODUCTION

Estimates predict that 66% of the world's population will live in cities by 2050. Cities are facing an increasing pressure to deploy themselves as livable and sustainable places that offer many services to improve the quality of life of citizens [47]. Cities have always been economic and cultural poles, but recently they have been augmenting their political importance and their capability to contribute to the wealth of nations. City resource endowment is a competitive factor differentiating the better urban areas and driving localization of RD&I infrastructures, firms, cultural entities, and so on [4, 35]. Calls for promoting and establishing smart cities are all the rage nowadays, and not just in the city management and urban policy context. Academics and urban theorists, engineers and policy makers are involved in a rich variety of contemporary debates on several aspects of what it means for a city to be smart. The smart city approach emerged as an urban strategy that using high technology, and especially ICT, for supporting a participated, attractiveness social and economic development of the cities, upgrading their cohesion levels, their competitiveness profiles and their sustainability. Competitiveness on a global scale is requiring new answers from the territories. The challenges cities and regions are facing require they must be capable of developing further key competences in the exploitation of their assets and strengths. Smart cities are a new approach to the problem of urban competitiveness and differentiation in the global arena assuming that the "one size fits all" archetype cannot be the solution to the problem [25, 33, 45].

The smart city concept is intrinsically associated to the viewpoint that technology is the critical factor for cities to follow the pace of change of society and meet the expectations and requirements of the community. Furthermore, this notion has demonstrated to be crucial in the process of making urban territories more efficient and in offering good quality of life and resource management through increasingly community mobilisation and participatory dynamics. Thinking about smart cities implies to take into account the urban, social, and environmental aspects of urban spaces, otherwise it would signify missing the ultimate strategic aim of the development of cities which means to improve the quality of life of all the community. That is why, arguably, to be considered smart, a city has to comprise dimensions related to governance, planning, infrastructure, and how this is can boost human, social and economic territorial assets [4, 53].

The main objective of this article is precisely, first, to discuss the importance and necessity that the smart city concept incorporates a deeper understanding and implementation of the issues related to entrepreneurship, analyzing, also, the main criticisms those approaches are arising among some researchers. Then, the paper discusses the challenging reconfiguration urban policies have to address in the promotion of smart cities competitiveness, pointing out some axis for the redesign of an entrepreneurial approach to smart cities. Finally, a brief conclusion will summarize the main features of the paper.

2 THE SMART CITY ENTREPRENEURIAL CHALLENGE

Despite there is some kind of compromise that the label smart city symbolizes innovation in city planning and management, its services and infrastructures, a common meaning of the term has not yet been formulated. There is a wide diversity of definitions of what a smart city could be. Nevertheless, two tendencies can be clearly identified in relation with what are the foremost features that smart cities must take into consideration. On the one hand there is a set of definitions that put accent just on one urban dimension (technological, ecological, etc.) leaving apart the rest of the dynamics involved in the urban set. This group of mono-dimensional explanations are misunderstanding that the ultimate objective of a smart city is to provide a new approach to urban development in which all aspects are treated with the interplay that takes place in the factual life of the city [18, 36]. Improving just one aspect of an urban ecosystem does not entail that the difficulties of the whole are being resolved. On the other hand, there are some authors that highlight how the main difference of the smart city concept is the interconnection of all the urban aspects. The intertwined problems between urbanization are infrastructural, social and institutional at the same time and this

interlinking is reflected in the smart city model. From the definitions, it can be noticed that infrastructures are a central piece of the smart city and that technology is the enabler that makes it possible, but it is the combination, connection and integration of all systems what becomes fundamental for a city being truly smart. A smarter city absorbs and disseminates information into its physical infrastructure to improve conveniences, facilitate mobility, add efficiencies, conserve energy, improve the quality of air and water, identify problems and fix them quickly, recover rapidly from disasters, collect data to make better decisions, deploy resources effectively, and share data to enable collaboration across entities and domains [37]. However, infusing intelligence into each subsystem of a city, one by one is not enough to become a smarter city, as this should be treated as an organic whole [10, 43].

Surprisingly, even on the basis of a sustainable approach, meaning that a city has to get a wise equilibrium among economic, social and environmental policies, the smart city concept largely omits, or, at least, undervalues the reference to the need for the cities to be competitive – it is, in fact, as if there is a somehow optimistic vision that, as you digitize the society and the economy, the city competitiveness responds immediately to those investments and increases entrepreneurial and territorial competitiveness. According to this logic, the smart city paradigm seems an illustration of a growing tendency of technologization of the city. Smart city archetypes derive from the key role of digital networks, data, and technical expertise in redesigning the urban environment in the key of enhanced efficiency, information, and knowledge about how, why and when the city functions. In this light, there has been the emergence of a set of critiques focused on critically interrogating the smart city and its myriad iterations [19, 32, 48].

Yet, some authors have been alerting for the need to underline the role the reinforcement of an entrepreneurial strategy can have on the whole functioning of the urban system [5, 9, 24, 25, 26, 28, 37, 45, 53]. From these definitions it can be inferred that the smart city concept implies a comprehensive approach to city management and development (Table 1). These definitions illustrate an equilibrium of the technological, economic and social factors involved in an urban ecosystem. The notions reveal a holistic approach to the urban problems taking advantage of the new technologies so that the urban model and the relationships among the public and business stakeholders can be redefined.

Table 1 - Overview of smart city characteristics

Authors	Smart city dimensions
Kraus et alii, 2015	Underlines the importance of the contextual conditions that need to be fulfilled to promote entrepreneurship and innovation on smart cities
Anttiroiko, 2015	Smart city facing the challenges of being an innovative, entrepreneurial and creative ecosystem, with a strong information technology network
Caragliu, Del Bo, & Nijkamp, 2009	Human and social capital as fundamental basis for urban competitiveness
Kumar et al, 2017	The importance of the smart economy, based on qualified human resources and innovative business strategies for creating smarter cities
Nam & Pardo, 2011	The critical role of information dissemination and knowledge production for strategic purposes
Toppeta, 2010	Creative and innovative vision, entrepreneurial character, use of technology and industries in the IT area
Letaifa, 2015	Holistic vision of the smart city emphasizing the importance of innovation on smart services as a key dimension for urban competitiveness and sustainability
Kourtit & Nijkamp, 2012	Smart cities are based on a mix of human capital (e.g. skilled labor force), infrastructural capital (e.g. high-tech communication facilities), social capital (e.g. intense and open network linkages) and entrepreneurial capital (e.g. creative and risk-taking business activities).
Zygiaris, 2013	Smart cities possess the ability to raise innovation based on knowledgeable and creative human capital intellectual ability that addresses several innovative socio-technical and socio-economic aspects of growth

It is in this context that entrepreneurship has come up a top priority strategy for urban competitiveness promotion. There is a vast array of innovation and entrepreneurship policies but evidence is showing evidence of lack of coordination, *stop-and-go* problems, lack of effectiveness in their design and implementation [20, 51]. There are various interventions that local governments and urban development agencies can make to improve this situation. Knowledge spillovers are crucial to innovation in competitive and sustainable business initiatives, but their exploitation requires an active investment by firms and participation in inter-firm and university-industry relationships [31, 40]. Problems commonly arise when the linkages between the two domains of knowledge exploration (universities, research organisations, etc.) and knowledge exploitation (business, intermediary organisations, etc.) are poor, when there is a lack of non-local sources and outlets of knowledge, or still when related sectors do not work together (3, 7, 38). Over the last few decades, the roles and influence of key stakeholders involved in creating optimal social and economic condition for entrepreneurship has evolved. As the knowledge economy progresses, there is a more rapid pace of scientific and technological development, further advances in ICT and a more effective transition of research to the market place [2, 12, 39]. These and other changes have been conditioning the profile of innovation and entrepreneurship policies that city governments adopt to increase either the birth rate of enterprises, namely new micro, small and medium sized technology-based firms, either economic competitiveness as a whole and, therefore, also territorial competitiveness.

Recent advances on the understanding the innovation process and phenomenon, principally coming from the regional innovation systems approach and from the theorization around the concept of “triple helix”, have given an impulse to entrepreneurship promotion to be understood as an objective resulting from an integrated and systemic policy, involving more and more an ample latitude of spheres of action, namely economic, social and political-institutional [23, 27, 29].

Besides, high levels of entrepreneurship are closely correlated with urban economic growth. Places with abundant new start-ups also usually experience faster income and employment growth. Areas with more small, independent firms far in the past have tended to do better. Unsurprisingly, local policy makers who are looking for ways to revitalize the economic engines of their cities are interested in policies that can generate additional entrepreneurship formats.

The most successful urban territories are those which are characterized by the ability of firms and institutions for adopting voluntary learning dynamics - in products, processes and organizational structures - and to adapt to the pressures induced by market dynamics [11, 22]. Political intervention emphasis should, accordingly, move from the enterprise level (micro) to the level of the *milieu* itself (meso), since it is assumed that it is precisely the innovative territorially embedded dynamics, not necessarily each firm taken individually, which is responsible for the urban innovation upgrading process. There is a need, Dirks et alii argue [14], to promote urban innovators and recognize traditional entrepreneurs as legitimate experts in the area where they work. It is absolutely vital to support them and help upscale innovative and successful local actions. Towards more progressive smart cities, cities should start with people from the human capital side, rather than uncritically believing that IT itself can automatically transform and improve cities [21]. To do all this, it is also urgent to reconsider our strategies towards the urban world. In this respect, it seems important to have a positive approach, that starts from, but is not restricted to local ideas, which focuses on cities communities's strengths and explores the particular opportunities open to them at a international scale - rather than dwelling on their weaknesses and problems, or worse, ignore them.

This means that each city has its own unique characteristics and strengths. Instead of trying to [recreate places like Silicon Valley](#), the concept of smart city is based on building strong entrepreneurial ecosystems by identifying their competitive advantages and leveraging them.

3 SMART CITIES AND ENTREPRENEURIAL ECOSYSTEMS

There is now a tendency to understand the archetyp of a global city-region elsewhere around the world, facing about any expression of territorial specificity as a reply to global restructuring. This created model is then spread and sold back to urban and regional stakeholders as a model to emulate, so producing *new wine in old bottles*, the fundamental question remaining of how much these examples of smart cities are an interpretation of the world and how much they are a mere brand marketing construction.

Definitional critiques are nothing new, of course, but they are fundamental if the smart model is to be taken as anything more than a new glossy way to invest into highly marketable technologies and therefore getting the catching smart tag [22, 49].

Above all, it seems crucial to ensure that discussions over smart urbanism do not become entrenched in an ambiguous idea that smart cities are necessarily qualifying and upgrading developments in the urban dominion [27, 30]. It is important for key concepts such as *smart* not to be simply empty signifiers, and to question and debate what is smart in a way which allows urban politics to thrive, and not to be removed from the need to rethink urban competitiveness.

A recurrent criticism to smart cities resides on the apparent assumption that digital technology is being seen as an end on itself, assuming that the ICT investments will automatically turn the cities into more innovative and competitive world arenas. Some authors already criticize the deficit of social and governance issues on the construction of the smart city approach. It is, nevertheless, rare to question the importance that smart city success also needs to address innovation and entrepreneurial interventions. Till now, on this ambit, the smart city basically configures a classic top-down approach similar to the linear innovation model, which prioritizes scientific and technological research as the source of innovation, and plays down the role of political, academic and economic players in the innovation dynamics [1, 16, 43].

It is important to recognize a smart city as one with a broad commitment to innovation and entrepreneurship in technology, as well as in management and policy making. There is a gap in the orthodox literature of the smart city [41]. The vast majority of authors only cares and addresses technological domains, often disregarding reflections of the policy and managerial side of innovation and entrepreneurship.

While technology in the form of smart city infrastructure is an integral part of a smart city competitiveness, it should only be seen as an enabler to meet the needs of the economic stakeholders [6, 15]. Smart infrastructure development should therefore rely on an entrepreneur-centric approach that responds to the sustainable development needs of firms, thus avoiding the reductionist technology-centric perspective. Smart infrastructure should be chosen and designed with a deep understanding of economic agents' profiles, needs and motivations. Entrepreneurial-focused initiatives in successful smart cities are demand-driven rather than supply-driven, or there is usually a trade-off between the two approaches.

Table 2 - From the "traditional" smart city approach to the entrepreneurial smart city approach

Smart City Approach	Entrepreneurial Smart City Approach
Knowledge as a public good	Institutional and entrepreneurial empowerment as a learning process
Focus on technological innovation infrastructure	Broad spectrum of innovative outputs (hard and soft, including also organizational, market and social innovations)
Focus on high-tech firms	Inclusive logics, encompassing also medium and low-tech firms and traditional sectors
Based on R&D institutions	Strategically focused on firms and, mainly, on the urban socioeconomic <i>milieu</i>

Knowledge diffusion as the main instrument	Stimulation of the absorption capability of firms and on <i>glocal</i> networking promotion
Competitive advantages	Differential advantages; built advantages
Mechanical transfer of successful urban-metropolitan case studies	Pedagogical and experimental approach, contextual policies and instruments
Entrepreneurial demand as a no problem situation	Entrepreneurial demand as a key challenge – search and stimulation of the hidden or latent demand, strategies that go beyond the mere intermediation of RD&I factors with the usual dynamic firms and new technology based start-ups
Based on the RD&I infrastructure	Focus on the firms, on the entrepreneurs and, mainly, on the socioeconomic <i>milieu</i> ; search for an equilibrium between supply and demand driven dimensions
Demand-pull or science-push instruments	Interactive and ecosystemic dynamics

Adapted from: [41]

This renewed entrepreneurial smart city approach must have the fundamental mission of promoting the competitiveness of the productive system in a context of globalization of economic relations and the acquisition of competitive advantages resulting from the ability to innovate. In fact, it should be understood as a means to reinforce urban competitiveness (Table 2).

Thus, business-led urban development has to be emphasised as a smart city key characteristic. A gradual transformation in the urban governance from a managerial to an entrepreneurial focus has to be accomplished. After all, there is a decisive need for businesses in a smart city: public investments are often too marginal to be effective for a cost-intensive smart and competitive urban growth. Companies representing private capital markets are needed to supply the city with a sufficient amount of money. These companies comprise small- and medium-sized enterprises (SMEs) as well as large corporations. To attract them, local governments have to deliver and offer advantageous conditions for businesses [17, 27, 44]. The need for constant private capital should make the smart city attractive for new businesses and what they mean for a smart economy. This is based on the idea of a smart city offering an innovative spirit, which is particularly important for entrepreneurship [30, 46], making a smart city an entrepreneurial city which provides new economic opportunities. Smart cities must increasingly function as seedbeds or incubators for creativeness, innovation and entrepreneurship [5, 32]. Knowledge spillovers are likely to occur as the availability of above the average skilled labour force is high.

We need to underline that that this new set of policy instruments, not being founded on large scales or in infrastructural projects, requires a high degree of decentralization in their design, delivery and management, as well as a consensual and cooperative work among the various actors involved, not forgetting the need for a clear territorial leadership without which it seems difficult to bring together the various rationales into play [19, 39, 42]. This suggests, of course, that an increase in urban capability for innovation inevitably involves new forms of organization and institutional partnership to help improve the structural competitiveness of the companies [34, 35, 50]. If we agree that the intervention by the authorities should give priority to the implementation and strengthening of a relational culture, then policies have to comply with the existing overall network architecture and its specific territorial assets, rather than focus more on punctual and atomized actions. It is, thus, important to reinforce the mechanisms for horizontal coordination and partnership, as well as interface management, avoiding political intervention supported in sectorial logics or fragmented actions. The vast majority of cities will only take advantage from smart cities projects by financing them through robust business cases grounded on a combination of financial efficiency and social, environmental or economic value [17, 26, 35]. The fundamental question seems to be, thus, how territories organise themselves to further enhance policy innovations. This really seems to be the challenge for cities and a critical assessment must be done to the implementation of ready-made recipes [24, 34].

It should be an important aim to involve SMEs as much as possible on all the ongoing, evolving process, to make sure that their long term needs are duly taken into consideration. It is undeniable that this dimensional group of enterprises may require specific assistance and there is a need for additional empirical evidence of the capacities of the different categories of SMEs so that a more pragmatic appreciation of this sector will be gained in order to formulate targeted policy-measures aimed at stimulating greater SME participation, a *sine qua non* condition for the achievement of a systemic innovation process [46]. It seems important to develop knowledge providers and/or link the firms to external knowledge sources and to promote consistent efforts to reinforce the technology absorption capacity of SMEs - a *glocalisation* dynamics supported by networking inside the cities and beyond. Anyway, public intervention should be closer to SME, they must not be neglected on the construction of the city competitive advantages [13, 26, 30].

The availability and quality of ICT infrastructure and usage, which is considered the most basic characteristic of the smart city [6, 20, 52], has thus to be understood as a starting point for a renewed entrepreneurial strategy that may help increase their innovation and competitiveness profiles.

The problematic of long-term urban competitiveness has become a critical issue, mainly now that the rhythm of structural change imposed by the global economy is dictating new patterns of territorial behavior and competition. That is why, arguably, the promotion of territorially embedded urban innovation ecosystems seems a fundamental and coherent strategy to face contemporary urban development challenges, as long-term urban competitiveness and sustainability has less to do with cost-efficiency and more to do with the ability of firms and institutions to improve their knowledge base and to innovate. Digital skills and entrepreneurs are key dimensions to accelerate the digital

transformation process [4, 14, 39]. The digital transformation of a territory is only possible if local businesses have the accurate talent with the pertinent skill set to acquire and bind the required digital technologies. Entrepreneurial talent is not only important for local companies. Local politicians, universities, and research centres also need to attract key talent, entrepreneurs and *intrapreneurs* with the adequate competences to shape the city's entrepreneurial ecosystem.

Current trends are urban centric, and we are aware the creative class has started to migrate to urban areas in cities around the globe. Lower-cost innovation and less need for physical space have converged and changed the way people work today. As part of the creative class, high-tech entrepreneurs are increasingly preferring to live and work in dense, cosmopolitan urban areas. Even though, there is also a need – not just a technological need, but a political, institutional and governance need – to analyze current smart urban challenges and opportunities, and to study how to integrate smart systems into a framework of urban competitiveness [8, 35, 48].

The smart city isn't a mere technological concept and artifact. The smart city is still an emerging paradigm and therefore not yet adequately integrated into national STI and ICT strategies in most countries. Existing national STI and ICT policies may not adequately integrate the needs of developing smart city initiatives [9, 23, 33]. Doing so involves the strengthening of a supportive innovative and entrepreneurial ecosystem that permits the development of smart infrastructure, including human capabilities, legal frameworks, technology policies, institutional mechanisms and data use policies on a multi-level governance scheme.

A smart city is not only a municipal phenomenon but also a national or global movement. It is important to insert them in the context of global competitiveness. The impact of a smart city naturally surpasses local, regional or national boundaries – smart cities are, by definition, *glocal* territorial protagonists.

On this context, it is worth noting that inter-urban competition can also displace competitive advantages across cities lower down the hierarchy [17, 24]. Some cities may begin irreversible decline as they are outmaneuvered by innovations in other established or emerging cities; this is especially likely where their initial superiority in the hierarchy was based on static comparative advantage [4, 45]. This requires smart cities to actively pursue the formulation and implementation of systematic strategic approaches to innovation and entrepreneurship

4 CONCLUSIONS

Technology is clearly a necessary condition for a smart city, but entrepreneurs' understanding of the concept is about the development of urban fabric for a more qualified and resilient economy. The adoption of up-to-date technologies per se is not a *sine qua non* condition for the success of smart city initiatives. Success, on the economic sphere, is dependent on the way cities involve all stakeholders on an innovation and entrepreneurial dynamics, it is not merely determined by technology or technical capital. Technology itself does not make any contribution to innovation. It seems urgent to overcome the scarcity of strategic analysis on the design of smart cities, evolving from a techno centric intervention to a socio-organizational approach that may encompass, on the economic sphere, a wider mobilization of the entrepreneurial city assets. Smart cities are principally characterized by its innovative, entrepreneurial and creative ecosystem and a strong information technology network. In order to keep up with the increasing global competition in the field of smart cities, they need to develop an entrepreneurial character and an innovative and creative vision.

While it is certainly instructive to examine and learn from successful smart cities, policy makers should be wary about treating them as exemplars that can be easily replicated or emulated in their own territories. Policies rarely travel well: successful strategies in one city do not transfer easily into other urban areas. In fact, given that many of the sources of urban competitive advantage are locally rooted and embedded, policies necessarily have to respond to, and take account of, city idiosyncrasies. It is therefore unlikely that there is one size fits all recipe for promoting urban innovation potential and competitiveness.

Moreover, special attention should be paid to the design of the intervention policy, trying to avoid the classical functional top-down and supply-side approach; innovation-led smart city policies must basically address the questions of enhancing the territorial capabilities to foster interactiveness among the city actors, of engaging the actors in processes of collective learning and of producing strategic knowledge or, more synthetically, to promote social capital. Entrepreneurial smart cities policies should, in essence, concentrate on catching up learning but it is necessary to ensure that the architectures of the policy-design and of the policy-delivery are open and inclusive.

Usually, traditional theoretical frameworks fail to take account of the diversity of actors and activities contributing to urban development and hence failed to reckon the diverse types of knowledge and human skills needed to sustain city competitiveness in the globalizing knowledge economy. The focus should be put, as mentioned before, less on the technological infrastructure initiatives, *per se*, and more on the innovation and entrepreneurial process, as a whole. Policy interventions must recognize the need for international interfaces, while simultaneously making sure that knowledge accumulates domestically and filter out into the economy for re-use, recombination and experimentation.

Smart cities strategies have thus to fully assume a new narrative where cities are seen as growth engines which constitute the key to economic prosperity, suggesting that cities have to apply the mechanisms associated with entrepreneurial promotion in order to survive and prosper as vital entities. The capacity of global cities to remain at the top of both world and national hierarchies seems, more than ever before, linked to their ability to remain at the forefront of economic and institutional innovation.

1155 CRITERIA TO KEEP A CITY WITH A DECREASING POPULATION SUSTAINABLE IN JAPAN - A CASE STUDY OF SUITA CITY IN OSAKA PREFECTURE

Kasumi Susaki

Ryukoku University, susaki@world.ryukoku.ac.jp

ABSTRACT

In Japan, as a result of increase in the number of elderly people and the decreasing number of births, the total population has been declining. Therefore, a neighborhood that meets the needs of elderly people, encourages the birth of children, and maintain diversity of generation and lifestyles is important for the redevelopment of a sustainable city. In this study, questionnaire surveys were conducted, focusing on the lifestyle of dog owners, which is suggested as a healthy lifestyle, based on the World Health Organization's (WHO) criteria of age-friendly city. This study examined Suita City, which comprises both completely planned areas and Sprawling areas in one municipality; questionnaire surveys were conducted and information from Suita City reports, maps, and field work were analyzed to clarify specific issues that should be examined.

Keywords: Sustainable city, Age-friendly city, Friendly city for dog owner, Walkability

1. INTRODUCTION

1.1 Background and Objectives

Recently, both the number and percentage of elderly people in Japan have been increasing, while both the number and percentage of children have been decreasing. As a result of this situation, the overall population has been decreasing.

Regarding the increasing elderly population, it is necessary that neighborhoods meet their corresponding needs as well as the needs of children, since the birth of children must be encouraged. Elderly people should take walks or engage in activities such as volunteerism, hobbies, etcetera, to maintain good health.

In this research, questionnaire surveys focusing on activities that involve leaving one's house were conducted. The surveys were administered in two different types of residential areas; one was developed under the strong plan related to C. A. Perry's theory of neighborhood units and the other was developed in a sprawling manner. Survey results from the two areas were compared and neighborhood factors affecting friendliness were analyzed.

Another perspective studied in this survey was keeping dogs. It is suggested that dog owners should walk their dogs and this activity is associated with healthier lifestyles.

1.2 Research Method

In this research, Suita City in Osaka Prefecture was evaluated. As previously stated, one area of Suita City was planned and developed according to Perry's theory of the neighborhood units (hereafter, New Town area) introduced in the 1920s, and the other area was developed in a sprawling manner (hereafter, Sprawling area). These two areas were easy to compare because they were located in the same municipality.

Several reports from survey questionnaires conducted by municipalities, plans related to urban regeneration.

A survey questionnaire was conducted in the abovementioned two areas. Between 14 and 16, 2017, 500 questionnaires were delivered to mailboxes in each area (total - 1,000).

The number of collected questionnaire was 378, including 203 from the New Town area and 175 from the Sprawling area. The collected questionnaires represented 37.8% of the total distributed questionnaires (40.6% in the New Town area and 35% in the Sprawling area). In addition, geographical information about the area obtained from maps and field work was analyzed.

Finally, results of the analysis were judged using the World Health Organization's (WHO) age-friendly city criteria; the findings highlight several issues that required careful and precise investigation.

1.3 Preceding Studies

In the Japanese context, studies on activities involving leaving one's house have focused on elderly people, particularly on their walks. Research on walking activities of children are generally associated with nursery schools or preschools activities. Such studies have been conducted carefully and precisely in specific areas. However, no study has compared the two areas mentioned herein.

In this research, investigations for both areas were conducted comparatively, although the analysis can be considered rough compared to preceding studies. The results of this research are generalized and helpful in identifying issues careful examination.

2. SUITA CITY

2.1 Suita City

Suita City has population of about 370,000 and an area of 36.0 km² (Suita City, 2018). Suita City is surrounded by Osaka City, Toyonaka City, Minoh City, Ibaraki City, and Settsu City (Suita City, 2015). Most of the area has been urbanized and

used for residential purpose. There are five university campuses and several research centers in the area. According to reports published by the municipality, about 70% of the residents are satisfied with their neighborhood and public transportation, and 61% are satisfied with green areas and open spaces.

Figure 1 Japanese population by age range

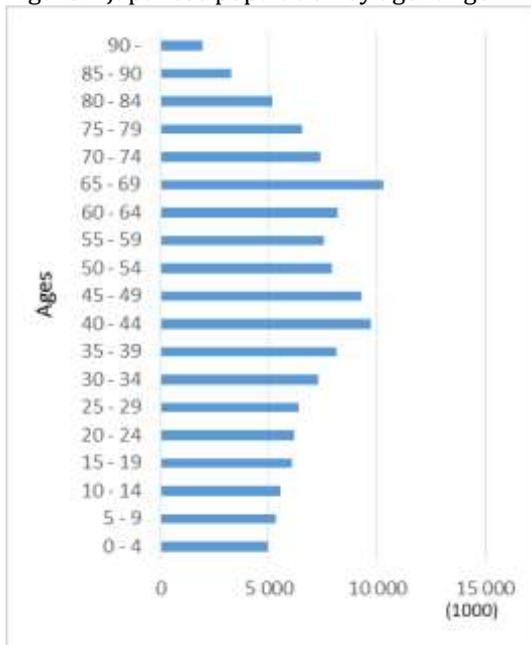

Figure 2 Suita City's population by age range

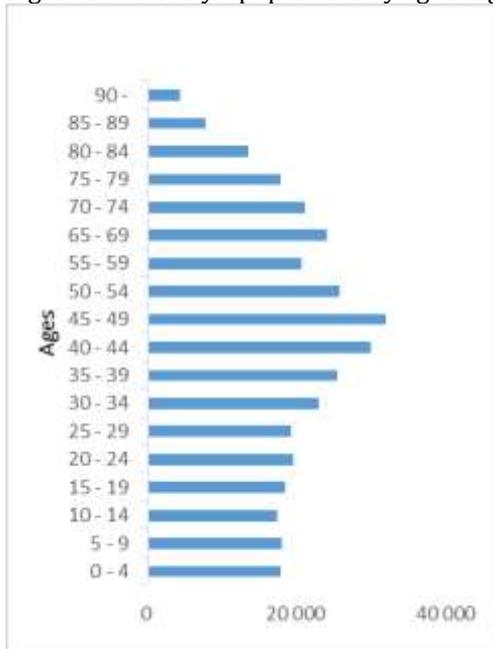

Figure 1 presents the distribution of Japanese populations by age range. Figure 2 presents the same distribution for Suita City and exhibits a similar shape.

2.2 New Town Area

The New Town area was originally constituted hills. The development of towns began in the 1960s; the first residents settled in the area in 1963. In addition to the development of neighborhood units, railways were constructed with several stations that are accessible from each neighborhood units. Because of the original topographic features, the areas have gradients. Furthermore, there are many slopes.

In the New Town area, the theory of neighborhood units was modified and shopping centers in neighborhood units were placed at the center of each neighborhood unit, although most of them have become outdated. These units also include parks and green fields.

In addition to a detached housing area, there are apartment houses organized by the municipality and the Urban Renaissance Agency (UR), condominiums, and employees' housing of several companies. All types of houses are mixed in one area. Recently, several apartment homes organized by municipalities and UR have been replaced, most of them become with high-rise apartment buildings. The landscape has been changing, and open spaces have been decreasing. Moreover, young families have been coming into the area.

Figure 3 shows New Town area's population and the shape is different from that of Suita City's. Many people have lived in the area since its initial development, and more people have moved to the area with the development of apartment homes.

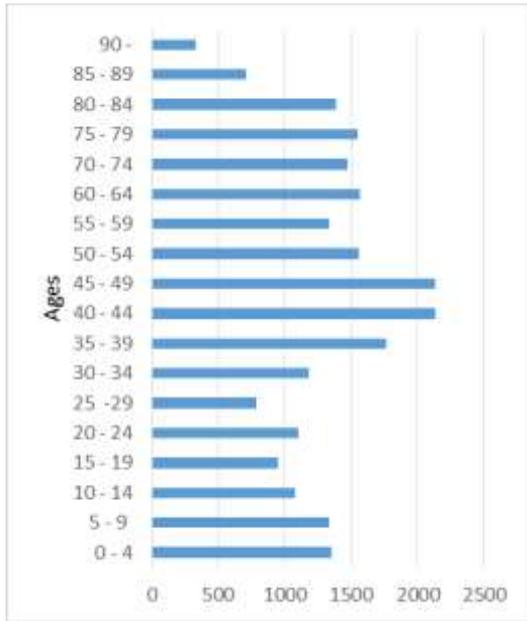

Figure 3 New Town area's population by ages range

2.3 Sprawling Area

The Sprawling area investigated in this study was mostly covered by small detached houses. Gradients and many slopes characterize the topography. Houses were built without plans, and streets are narrow without pedestrian access. Further, there are only a few small parks for small children

There was no public transportation for a long time, but community buses could be used by residents. The nearest station is about 1000m from the opposite edge of the area. Near the station and along main streets outside the area are shops, restaurants, hospitals, and so on.

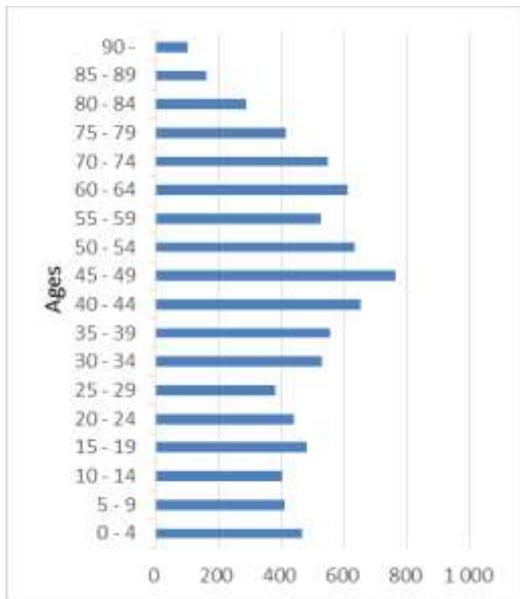

Figure 4 Sprawling area's population by age range

According to Figure 4, the Sprawling area's population is shaped similar to that of Suita City.

3. ACTUAL SITUATION

3.1 Survey Method

Collected reports and plans published by municipality and general trends for each area indicated by the results of the survey questionnaires were analyzed for each area. Questionnaires were dropped in mailboxes at individual dwellings. Dwellings for questionnaire distribution were selected randomly in both areas and included all kinds of residences. In total, 500 questionnaires each were distributed in the New Town and Sprawling areas.

As mentioned previously, the number of collected questionnaires was 378, including 203 from the New Town area and 175 from the Sprawling area.

3.2 Attributes of respondents

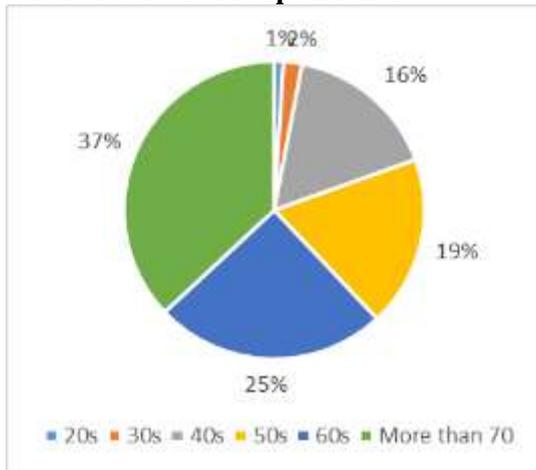

Figure 5 Ages of respondents in New Town area

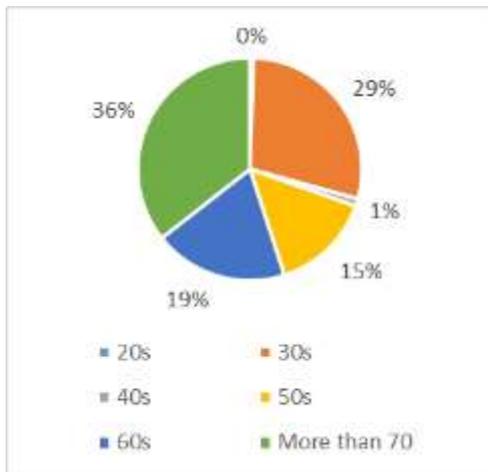

Figure 6 Ages of respondents in Sprawling Area

Regarding the New Town area, 16% of the residents were in their 40s, while in the Sprawling area, only 1% were in this age group. The comparison for people in their 30s living in each area was also revealing.

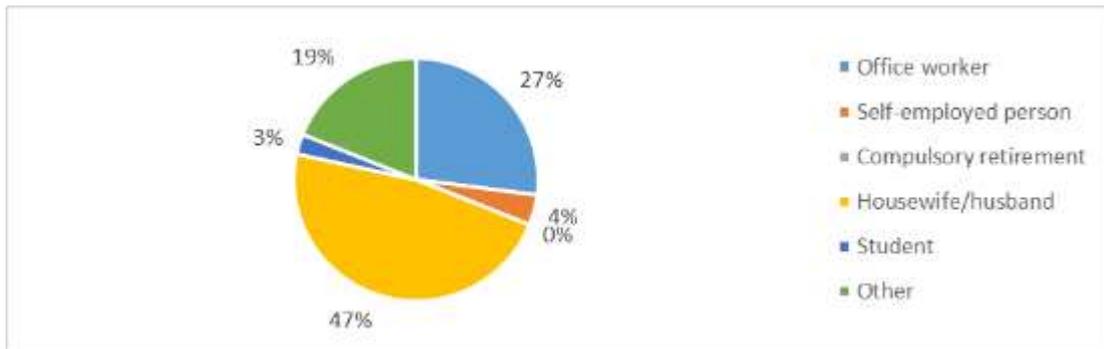

Figure 7 Occupation of respondents age below 59 years in the New Town area

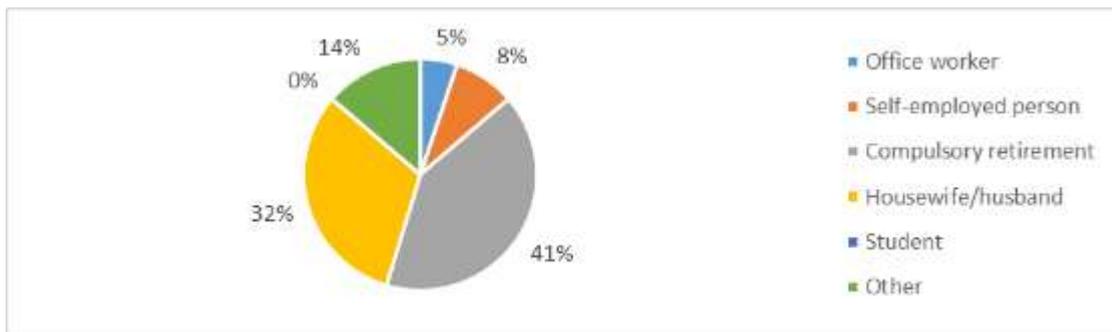

Figure 8 Occupation of respondents aged over 60 years in New Town area

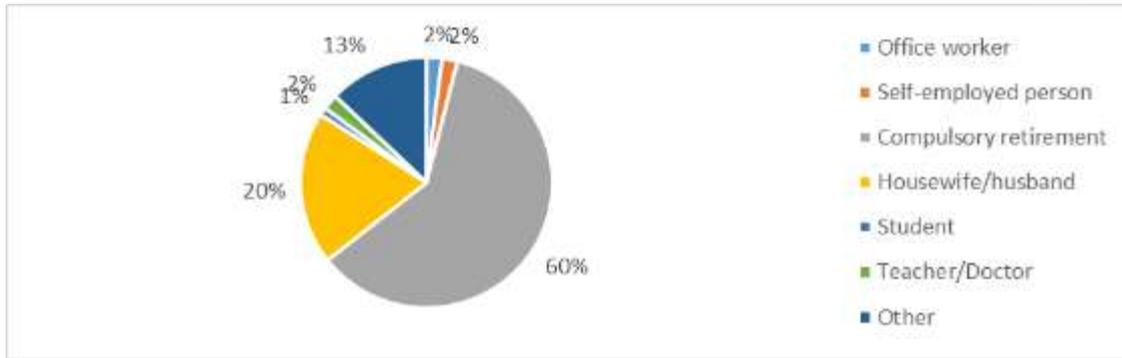

Figure 9 Occupation of respondents aged below 59 years in Sprawling area

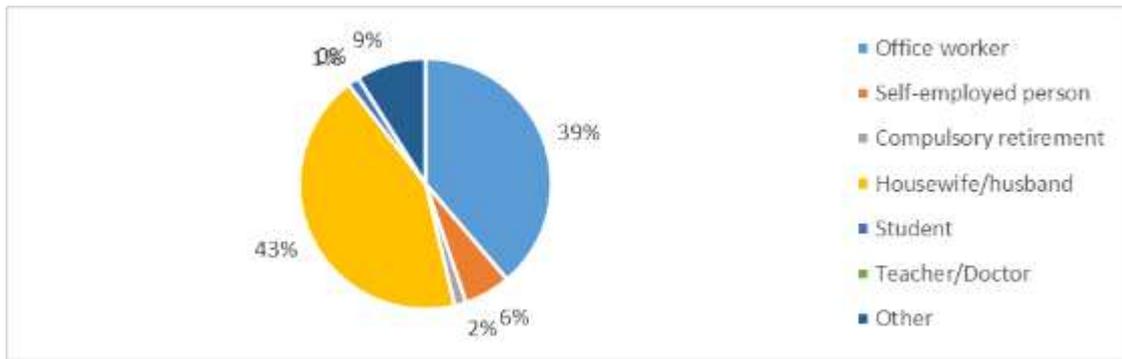

Figure 10 Occupation of respondents aged over 60 years in Sprawling area

The person from each family who spent the most time at home was asked to complete the questionnaire for this study. Regarding occupation, the respondents were affected by compulsory retirement. Moreover, 18% of respondents in the New Town area and 14% of respondents in Sprawling area chose “live alone.”

It should be noted that 32% of the respondents in the New Town area were living in public housing (apartment), whereas no respondents from the Sprawling area were living in public housing. The difference for house owners were also revealing.

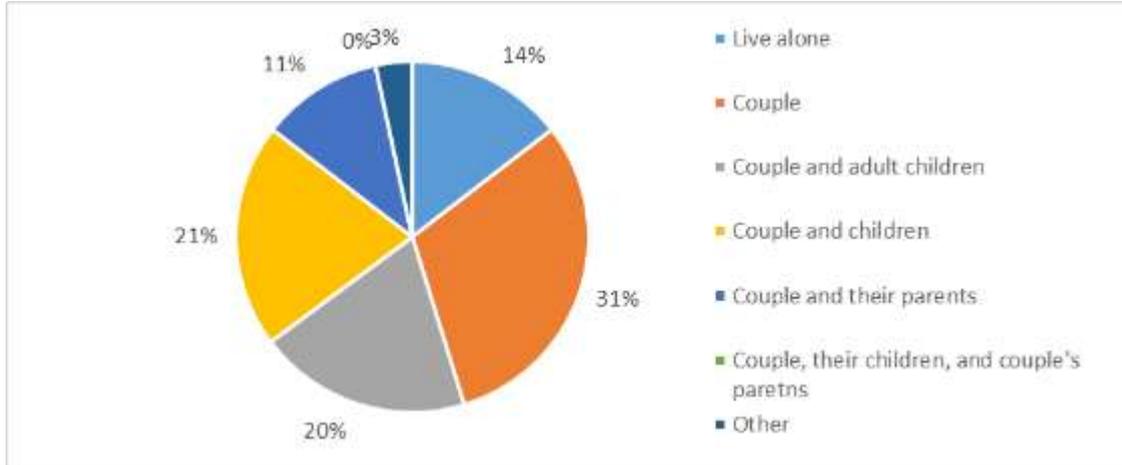

Figure 11 Family situation of respondents in New Town area

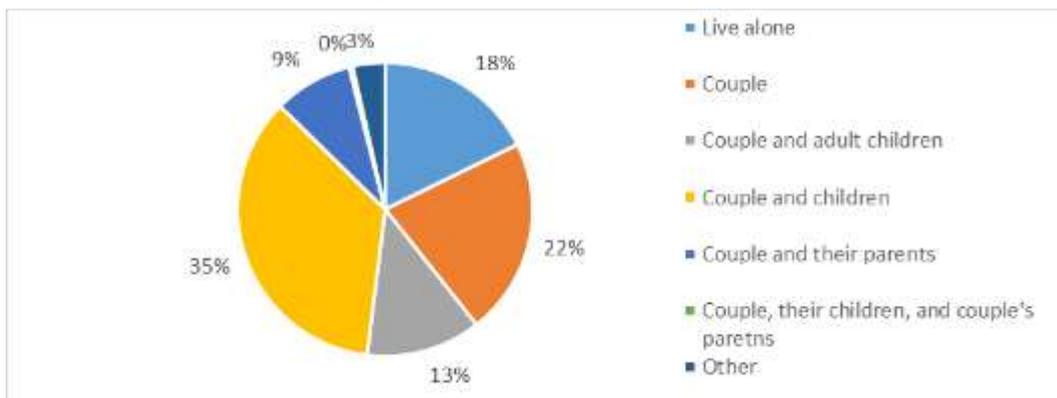

Figure 12 Family situation of respondents in sprawling area

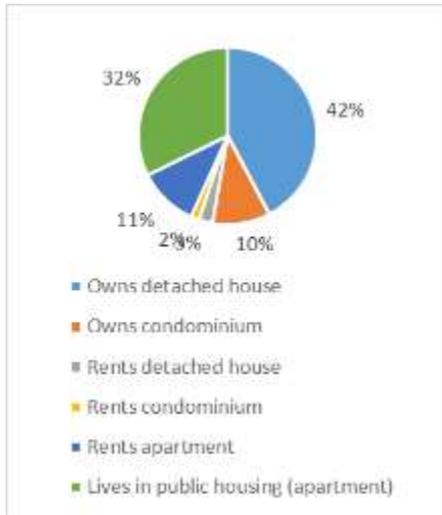

Figure 13 Housing situation in New Town area

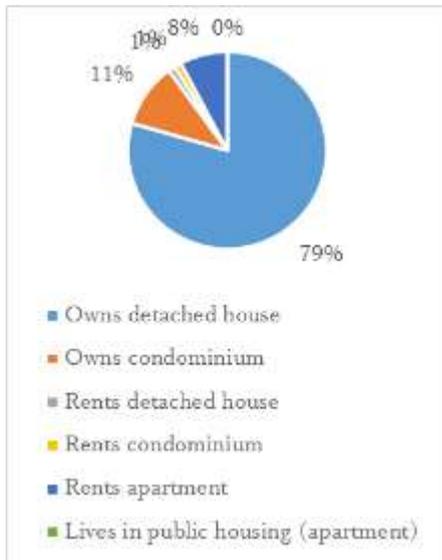

Figure 14 Housing situation in Sprawling area

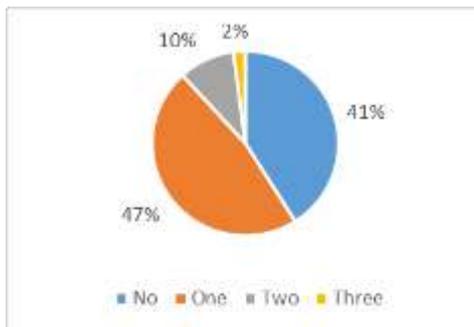

Figure 15 Respondents who own cars in the Figure New Town area

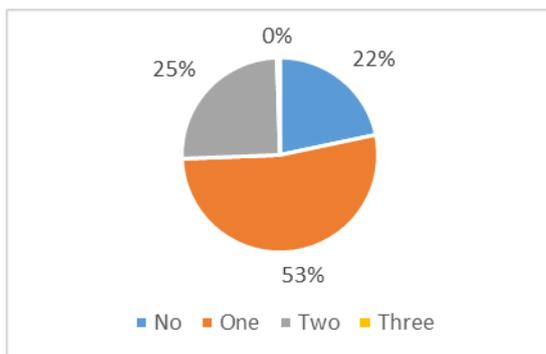

Figure 16 Respondents who own cars in the Sprawling area

In the New Town area, 41% of the respondents did not have their own cars. The percentage was almost twice as that in the Sprawling area.

3.3 Activities of leaving house

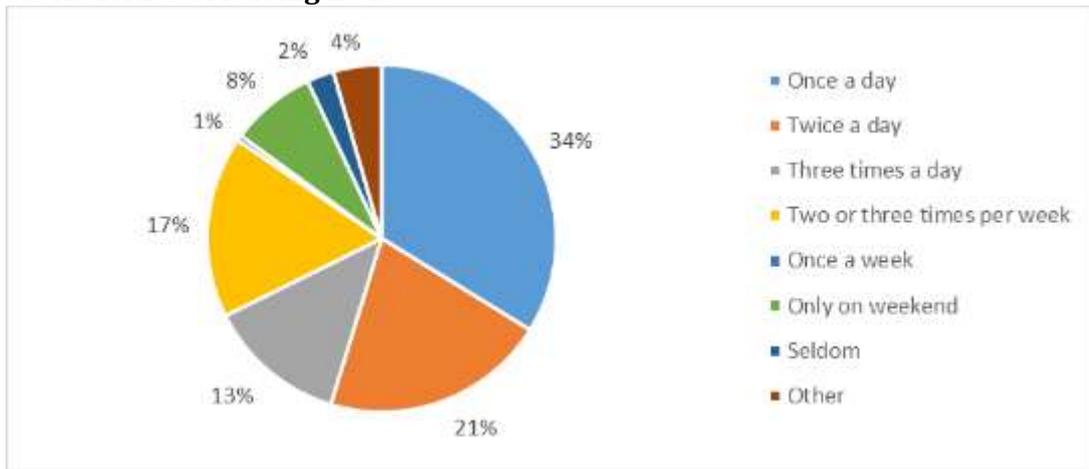

Figure 17 Frequency of leaving one's house in the New Town area

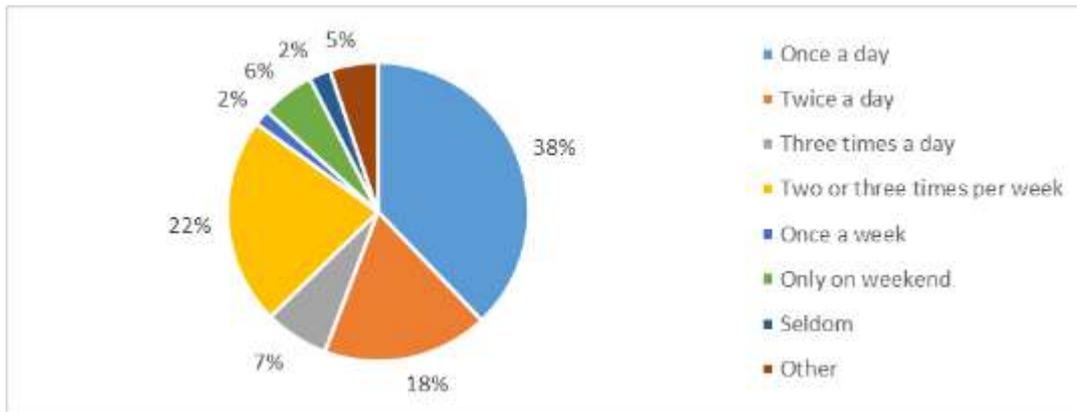

Figure 18 Frequency of leaving one's house in the Sprawling area

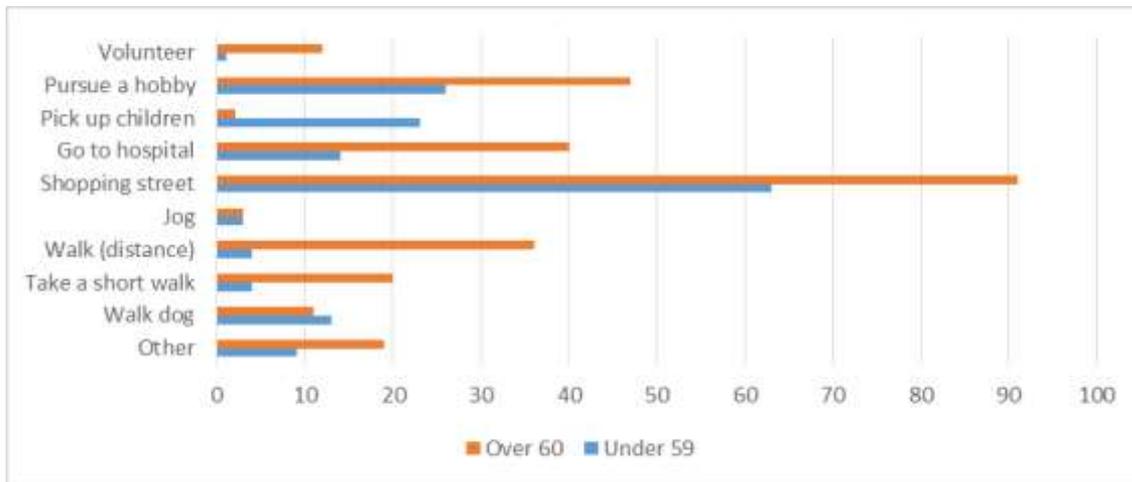

Figure 19 Reasons for going out in the New Town area (comparative graph by ages)

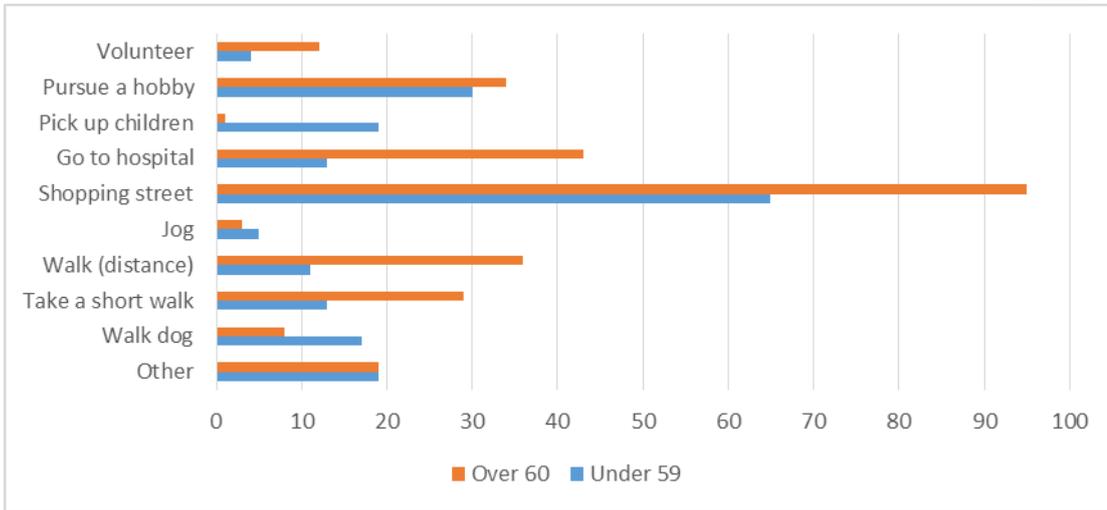

Figure 20 Reasons for going out in Sprawling area (comparative graph by ages)

The most frequent reason for going out was to “Shop,” and they go shopping on foot or in their own cars or bicycles.

Figures 19 and 20 show different reasons for going out based on age (i.e., below 59 years and over 60 years); the outstanding difference is that the respondents over 60 years chose “go to hospital” more often, whereas those aged below 59 years chose “pick up children” frequently. According to the results of this survey, 60 years is a critical age associated with retirement (Figures 7 to 10).

In the questionnaire, respondents were asked to identify the place when they customarily walked. According to Figures 21 and 22, parks were more often destinations for walkers in the New Town area, whereas streets were more popular destinations in the Sprawling area. According to the map and guidebook edited by Suita City, there are almost no parks in the Sprawling area.

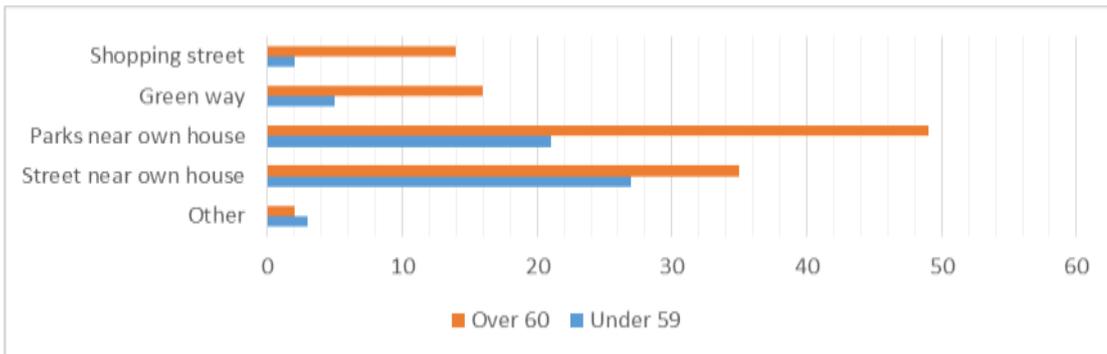

Figure 21 Walking site in New Town area

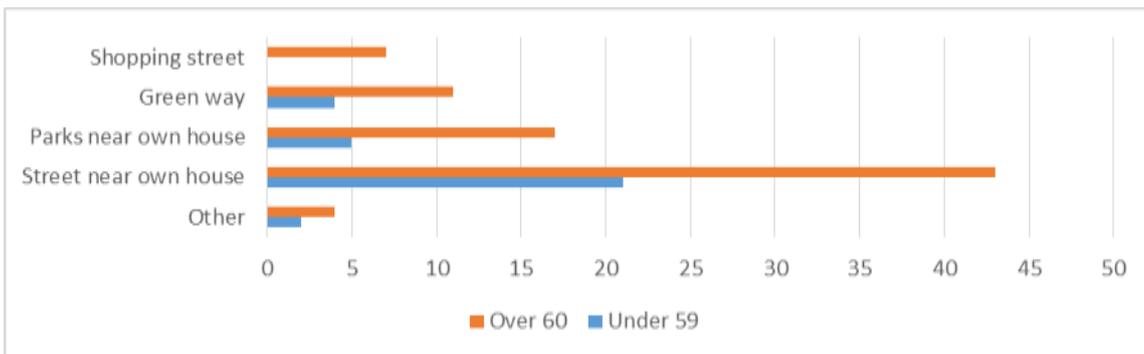

Figure 22 Walking site in Sprawling area

Respondents to the questionnaire were asked to explain their criteria for choosing where they typically walked, and safety was the primary condition.

3.4 Dogs

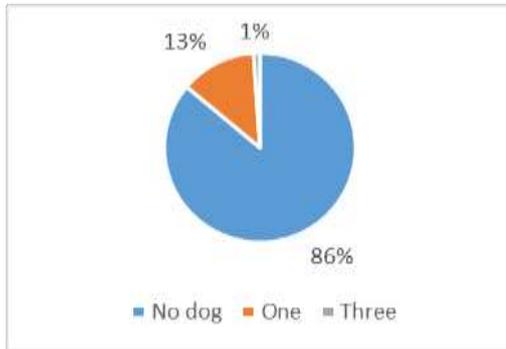

Figure 23 Respondents who keep dogs in New Town area

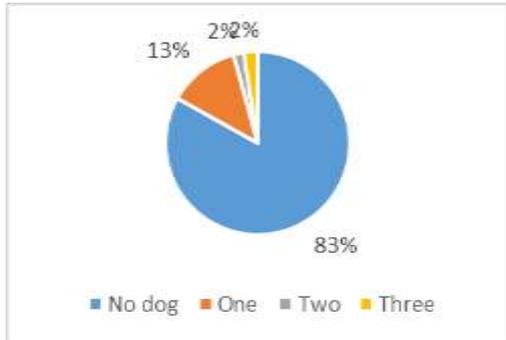

Figure 24 Respondents who keep dogs in the Sprawling area

In the New Town area, 32% of the respondents lived in public housing, which did not allow keeping dogs. However, compared with the Sprawling area residents, the New Town area residents kept more dogs than usual. In the latter area, dog owners lived in their own detached houses or rent detached houses, while in the Sprawling area, dog owners lived in their own detached houses or condominiums or rent condominiums.

The dog owners in the New Town area used streets for walking dogs more than parks. This result was different from the general respondents in the New Town area. The reason is worth examining.

According to questionnaire results, the breeds of dogs kept in the New Town area comprise 77% small-size breed, 15% medium-size breed, and 8% large-size breed whereas in the Sprawling area, it is 56% small-size breed, 37% medium-size breed and 7% large-size breed. Thus, there was a difference in the breeds owned has difference.

Regarding the ownership of cars, 96% of dog owners in the New Town area and 89% of dog owners in the Sprawling area had their own car. The percentages had a substantial difference from the ownership of one’s own car (Figure 15 and 16).

Only few dog owners used dog parks or dog cafes in both areas; and there were no such facilities near each area. To bring the dogs to the vet, it was popular for dog owners to use their own car; they made friends while walking their dogs.

4. COMPARISON OF NEIGHBORHOOD WALKABILITY

WHO’s age-friendly cities guideline provides five criteria for evaluating the physical environment for accessibility:

1. Neighborhood walkability
2. Accessibility of public spaces and buildings
3. Accessibility of public transportation vehicles
4. Accessibility of public transportation stops
5. Affordability of housing

This study addressed “neighborhood walkability,” “accessibility of public spaces,” “accessibility of public transportation vehicles,” and “accessibility of public transportation stops.”

In the questionnaire, “neighborhood walkability,” was linked to shopping, and “accessibility of public spaces” was associated with taking a walk. “Accessibility of public transportation” and “accessibility of public transportation vehicle” were examined using a map. The guideline cites the distance for evaluating “accessibility of public transportation” as 500m.

According to the survey results, respondents went shopping on foot or in their own cars. The reason to choose these two ways should be examined to evaluate whether their living areas were walkable neighborhoods or not. The survey results revealed that public open spaces were rather scarce in the Sprawling area.

Access to public transportation in the New Town area was not so bad considering on the map, although there were many slopes and a probability for these slopes to become a difficulty. Access to the Sprawling area was bad because the train station was located far on the edge of this area and there were only community buses.

5. CONCLUSION

This study revealed that the younger generation undertook trips to pick up their children, although this was not mentioned in the previous studies on elderly people.

In the New Town area, the younger generation has been increasing but because of the development, public open spaces have been decreasing. The shopping center is outdated making it difficult to develop a walkable neighborhood. In the Sprawling area, there are almost no public open spaces, and residents of this area use street without pedestrian for their walking. This area is covered with small detached houses and is undergoing a changes of population balance.

Dog owners comprise a small percentages and it was difficult to extract concrete results; however, there are many points on which precise surveys should be conducted, such whether it is standard for residents to not use parks for walking dogs or whether in general, cars and use them to go somewhere with their dogs as well as have a walkable neighborhood since the population of dog owners is currently increasing in Japan.

This study clarifies many points that require more precise investigation and they are parts to make sustainable community.

ACKNOWLEDGEMENTS

Surveys were supported by the Japan Society of Lifology in 2017.

1224 ENERGY TRANSITION AND NEOLIBERALISM, AGREEMENT IS POSSIBLE? THE CASE OF GREEN BUILDING IN GURUGRAM, DELHI, INDIA

ABSTRACT

This present proposal discusses how stakeholders understanding energy transition. Energy transition is often reduced to a new political program to develop green energy including economic and social transformation. Thus we interest to focus about energy policies, particularly in a Region engaged in a development of urbanization program included energy transition. India is involved in these issues on the international stage. India government initiatives conducted among other to create “International solar tears”. This program is social implication, build green and develop renewable energy is also a purpose to create job and raise the standard of living. However, the “key economic stakeholders” of those green programs became dominant in the process of negotiation. They are social consequences remote of sustainable approach but relevant neoliberalism process. In the present study, a green building was analysed using the entrepreneurial approach. The result show that energy policies be operatives and challenging economic and social transformation if local stakeholders will be capable in the process of sustainable urbanism. Though economic globalization influenced our capacities to shoulder a regulatory role in “making of the territories”. It is the result of including more and more stakeholders where the active roles are in the hand of few individuals, those dominated other stakeholders and put a spin horizontal governance. Sustainable development was largely broadcast in political discourse since three decades. Gradually this term is substituted in climate change discourses by “energy transition”. In human science, particularly in France (Verdeil E., Jaglin S., 2015; Rocher L., 2015; Burger C.,2014) there is agreement to rethinking what energy transition it means for research. In this paper, we don’t used transition management studies approach because they are don’t care spatial and political aspects (Coutard O., Rutford J., 2014, Bridge G). Our research is aligned with approach that considers energy transition is multiple and are interested in spatial issues. If they are not agreements to know how exactly this term cover, it’s was interesting to analysed how this term is usually used by political stakeholders and how it is field for citizens. This article focuses on the India government’s policy for “new energy paradigm”. In this way, a lot of political programs emerge to “transform” the city. For example, development of green energy (International Solar tears), green construction (GRIHA) and smart cities. Focusing to Gurgaon which is a typical example of new urban planning. The city was built since 1980 by private companies without global plan of urbanization and are is considered as a “modern city” with “innovative program” of development but we assumed that this urbanization is “geomarketing”. Key words: energy transition, neoliberalism, sustainable urbanism, energy policies, greenbuilding.

SS02.3. Smart Cities Initiatives for the 21st Century: Myth or Reality

1426 ACHIEVEMENTS OF NATIONAL MISSIONS IN DEVELOPING URBAN INFRASTRUCTURE: INTROSPECTION THROUGH RESPONSES OF CITIES TOWARDS SMART CITIES MISSION

Subhrangsu Goswami¹, Sreenandini Banerjee²

¹ Asst. Professor & Area Chair, Environmental Planning I Faculty of Planning - CEPT University

² Urban Planner – Chandigarh Smart City Project (EGIS India), Chandigarh, Punjab, INDIA

ABSTRACT

An evident reality in the 21st century is the pressure on the infrastructure, created in Indian cities due to the increasing population. In large cities the problem of weak infrastructural situation and its importance in overall development, was highlighted in the Eleventh Plan. The High Powered Expert Committee constituted by Government of India, on urban infrastructure and services was among the first to assess the demands and the immediate attention to be given to the infrastructure deficits and state of poor service delivery. Although there have been various national missions initiated by the Government of India since last ten years focusing on urban infrastructure in India, the latest one is the Smart Cities Mission. However, it is important to examine how this mission is different from other missions and more importantly what is the response from cities. Therefore, the primary objective of this paper is to study the perspective of the national government about infrastructure needs of Indian cities as reflected in general in the National Missions and in specific in smart cities mission. The study also examines the pattern in responses of the cities, in terms of type of projects and scale of investments, as an indicator, which may explain the priority of cities. The guideline of smart cities mission was studied along with other two recent national missions namely JNNURM and AMRUT. The overlaps between three of these missions were observed on the basis of Objectives, Duration, Selection of cities and Coverage, Admissible components and Fund allocation. On the other hand, the responses of nineteen sample cities (selected on basis of their recurrence in the three missions) have been analyzed through the lens of projects with the help of City Development Plans (CDPs) submitted during JNNURM, State Annual Action Plan (SAAP) before AMRUT and the Smart City Proposals submitted during the Stage 2 of the SMART City challenge. Two of these eighteen cities, Ahmedabad and Bhubaneswar were then selected as case cities where all proposed projects were reviewed through data collected from key municipal officials during interview. Major findings of the study are that, although a new strategy was made to make the cities smart, it is evident that national government failed to understand the priority of cities. Almost all mission cities have repeatedly proposed projects related to water supply, sewerage and transportation, during JnNURM, AMRUT and Smart cities mission. It is interesting to note that cities have suitably repackaged the same old project in order to avail the funds.

Keywords: Smart Cities, Urban Infrastructure, National Missions, JnNURM, AMRUT

1 BACKGROUND TO THE STUDY

1.1 Introduction

Each city has its own particular history, culture and character (Agentschap NL, 2015). With the evolving times there is a need to sustain, protect and re-establish the urban texture of these cities. At the rate of 2.47%, India is urbanizing. About 31.3% or 37.71 million of its aggregate is currently urban (Chandramouli, 2011). As indicated by McKinsey Global (2010), by 2025 it will add 215 million to its urban areas which will increase the urban population to 38%. As a result, the key actors of the cities need to operate holistically, using the majority of their assets, to face the difficulties and also handle the potentialities that the city has (ISO/IEC JTC 1, 2014).

The increasing population and its relocation will put enormous weight on its megacities, 7395 towns and 1456 urban agglomeration (according to Census of India, 2011) for enhanced infrastructure and better service delivery. The enormous pressure on civic infrastructure like water supply, drainage, solid waste management etc. has also resulted in inadequate investment for the same or vice-versa. This can have two direct impacts; *firstly*, almost the entire urban poor living in slums and unauthorized colonies in the cities, are deprived of the basic utilities like water, sanitation, education and also health services. *Secondly*, inadequate infrastructure has a negative economic growth rate of India by reducing its Gross Domestic Product (GDP) by 1-2% annually (Rani, 2015).

1.2 Issues faced by ULBs

Lack of critical urban infrastructure being a severe foundational challenge of cities and towns includes inadequate provision and maintenance of infrastructure, lack of finances for the same, uneven development and low quality of infrastructure and most importantly the governance of infrastructure.

Governance of infrastructure primarily depends on the capacity of urban local bodies to raise taxes. Specifically, in India urban local bodies largely depend on grants from government (Kumar, 2017). After the 74th Constitutional Amendment Act³¹⁵, Municipalities have been regarded agencies responsible for provision and maintenance of services. But history says that the ULBs of almost all the cities have been very weak in the efficient collection of revenue and also in imposing

³¹⁵ To make decentralization strong, the 74th Constitutional Amendment Act came into being in June 1993. The main factors of this Act are structure and composition, formation of wards committees, seats reservation, functions and powers, finances, elections and planning committees of district and metropolitan areas. The ULBs will take up responsibilities for urban planning, water supply, social and economic planning, upgradation of slums, public health.

low user charges (Gupta, 2016). Therefore, the consequent shrinkage of local resource base and fiscal incapability has deteriorated the situation of these civic bodies (Kim, 2003). The High Powered Expert Committee (HPEC 2011) on urban infrastructure and services after the Eleventh Plan defined the demands and the immediate attention required to be given to the infrastructure deficits and urban state service delivery. Therefore, the focus of the infrastructural development strategy should be on the accumulation of higher tax and non-tax revenue through internal sources, external borrowing, private-public partnerships, mobilizing funds through bonds and other innovative financial instruments (Kundu, Politics and Economics of Economic Growth, 2011).

1.3 Missions and Programs on Urban Infrastructure in the Last Decade

If an effort is taken to list down the issues from various sources, then there would be broadly three issues with regard to urban infrastructure--- poor governance, low capacity of local bodies, and also financial challenges. In the light of these problems, the Central Government has launched various missions and programs on Urban Infrastructure, the latest being the Smart Cities Mission.

Starting from the year 1979, Integrated Development of Small and Medium Towns (IDSMT) was the first Urban Development Scheme, which continued till 2005, with a time period of 26 years. During this same time period, another program, 'Mega City' started in the year 1993 with duration of 12 years. In the last decade, starting from 2005, the Jawaharlal Nehru National Urban Renewal Mission (JnNURM) continued till 2014 after which in 2015, Atal Mission for Rejuvenation and Urban Transformation (AMRUT) was announced along with The Smart Cities Mission by the present Government.

2 AIM AND RESEARCH OBJECTIVES

Although there have been a lot of Initiatives, Missions and Programs throwing a light on Urban Infrastructure in India, by the Government it is important to see that how Smart Cities Mission being the latest one is important from others and moreover what is the response from the cities. Therefore, this exploratory study leads us to the following aim and research objectives.

2.1 Aim

To understand the responses of the cities towards the National Missions in the Infrastructure Sector

2.2 Research Objectives

- ❖ To study the perspective of the national government about infrastructure need of Indian Cities as it is reflected from the National Missions
- ❖ To explore the pattern in responses of projects and investments in the urban infrastructure sectors as perceived by Indian cities in the context of National Missions

3 SELECTION OF SAMPLE CITIES AND CASE CITIES

To understand the perspective of the National Government in the formulation of guidelines, the three missions (JnNURM, AMRUT and SMART Cities Mission) focusing entirely on urban infrastructure have been studied, to observe the overlaps and differences with the help of their Mission Statement and Guidelines. On the other hand, to understand the pattern of responses of the cities through the lens of project and investments, 19 sample cities and 2 case cities were selected. For the purpose of selection of the sample, the recurrence of the smart cities in the earlier two missions i.e. JnNURM and AMRUT has been selected. It was noticed that 19 out of the 61 Cities (considered till the Second Round of Smart City Challenge for this study³¹⁶- 61 SMART cities out of the total 100) have been selected in all the three missions. Two case cities--Bhubaneswar and Ahmedabad were selected for interviewing the key Municipal Officials on the basis of the above objectives.

Table 1: List Of Complete 100 Smart Cities.

³¹⁶ The complete round of 100 selected Smart Cities has been announced in January 2018, but for this study, only cities declared up to the Second Round have been considered. Also, two case cities out of the 19 Sample Cities had to be selected for Primary interviews with the officials.

	Cities selected under 3 Missions

4 APPROACH AND METHODOLOGY

In order to fulfill the above two objectives, the following two paragraphs focus on the approach and the detailed methodology adopted for it.

- ❖ **To study the perspective of the national government about infrastructure need of Indian cities as it is reflected from the National Missions**

There were two sub-tasks which had been identified for establishing this particular objective. *Firstly*, the Mission Statement and Guidelines of the three missions (JnNURM, AMRUT and SMART Cities Mission) were reviewed on the basis of four parameters--- i) aim, objectives and duration ii) selection of the cities and coverage iii) focus areas / admissible components and iv) fund allocation. *Secondly*, the common areas on the basis of these four parameters were observed by preparing tables and matrices, in which the overlaps and the differences were highlighted with different shades of color.

- ❖ **To explore the pattern in sectors of urban infrastructure as perceived by Indian cities in the context of National Missions**

For analyzing these missions from the perspective of the Indian cities, two sub tasks had been chalked out in order to understand their responses. *Firstly*, patterns in the projects were tried to be studied in the proposal documents prepared by the 19 sample cities after the announcement of the Missions--- City Development Plans (CDPs) submitted in the JnNURM phase and the Smart City Proposal (SCP) documents submitted by the cities in the Stage 2 of SMART City Challenge. The projects appearing in both the missions were highlighted and a final Matrix has been prepared for the Infrastructure Sectors across Cities and Missions. *Secondly*, the pattern in the investments for these infrastructure projects by the 19 cities were studied similarly by preparing Scatter Diagrams through CDPs in the JnNURM Mission and Bar Graphs for the investments made on the infrastructure projects through SCPs in the SMART City Mission and State Annual Action Plans (SAAPs) submitted by the cities for the AMRUT Mission.

5 INFRASTRUCTURE NEEDS OF CITIES: PERSPECTIVE AND APPROACH OF NATIONAL GOVERNMENT

To understand the perspective of the government, the Mission Statement and Guidelines of the three Missions --- JNNURM, AMRUT and SMART Cities Mission have been studied to observe the overlaps and differences. The following

four parameters have been selected for this purpose and to see how the Smart Cities Mission is different from the other two.

- Aims, Objectives and Duration
- Selection of Cities and Coverage
- Focus Areas / Admissible Components
- Fund Allocation

5.1 Aims Objectives and Duration

All the three missions mentioned above have taken place in the course of ten years but are of varied durations. Starting with the JNNURM Mission, the first large scale mission on urban infrastructure, took place in the year 2005-06 and continued for seven years. After the year 2012, there were 2 more years of extension up to the year of 2014 (MoUD, 2011). In June 2015 two missions on urban infrastructure were announced by the present government--- AMRUT and SMART City Mission having a time duration of five years which means it would continue till 2019-20. However, these missions had a specific aim and a clear set of objectives which are shown in the table according to their Mission Statement and Guidelines.

Table 33: Overlaps For Aim Objectives And Duration Among The Three Missions

Parameters	Missions		
	JnNURM	AMRUT	SMART
Aim	To “encourage reforms and fast track planned development of identified cities. Focus is to be on efficiency in urban infrastructure and service delivery mechanisms , and accountability of ULBs towards citizens.”	“Providing basic services (e.g. water supply, sewerage, urban transport) to households and build amenities in cities which will improve the quality of life for all, especially the poor and the disadvantaged is a national priority.”	
Objectives	a) Integrated development on city infrastructure b) linkages between creation and management of assets c) adequate funds for meeting deficiencies in urban infrastructural services d) Dispersed urban settlements e) To increase the delivery of civic amenities f) More focus on urban renewal programme g) Providing the urban poor with basic services	a) ensuring that every household should have tapped water supply and also a sewerage connection b) Scaling-up the aesthetic and amenity value of cities by developing greenery and properly maintained open spaces c) Decreasing pollution by adopting public transport or constructing facilities for non- motorized transport	To basically promote those cities that would provide the basic infrastructure by giving a decent quality of life to its people, and also a clean and sustainable environment by using ‘Smart’ solutions.
Duration	(2005-12), with 2 years of extension	Financial Year 2015-16 to 2019-20	Financial Year 2015-16 to 2019-20

Source: Author, Data based on Mission Statement and Guidelines of JnNURM (2005), AMRUT (2015) and SMART City Mission (2015)

The above table points at three important observations. *Firstly*, the basic aim of two out of the three missions, focuses on basic civic infrastructure. *Secondly*, the SMART Cities Mission does not have any particular aim mentioned in the Mission Statement and Guidelines, however the objective clearly indicates basic infrastructure. *Thirdly*, if the duration of the missions is considered, then excepting the JNNURM Mission, both AMRUT and SMART are ongoing and they have almost the same time duration.

5.2 Selection of Cities and Coverage:

The cities selected for all the three Missions have a different criterion but the basis is population for both JnNURM and AMRUT Mission. The Selection Process of Smart Cities Mission however was altogether different.

Table 34: Selection Criteria Of Cities Among The Three Missions

JnNURM	AMRUT	SMART
A) Cities/ UAs with 4 million plus population as per 2001 census- 7 B) Cities/ UAs with 1 million plus but less than 4 million populations as per 2001 census- 28	Five hundred cities will be taken up: i. All Cities and Towns with a population of over one lakh with notified Municipalities, including Cantonment Boards (Civilian areas). ii. All Capital Cities/Towns of States/ UTs, not covered in (i) ,	A) Intra-State Competition after letter sent to the State Governments B) On the basis of responses from the states 100 potential smart Cities are announced C) Each potential Smart City prepares its proposal with the help of a Consultant.

JnNURM	AMRUT	SMART
C] Selected Cities/ UAs (State Capitals and other cities/ UA of religious/ historic and tourist importance- 28	iii. All Cities/ Towns classified as Heritage Cities by MoUD under the HRIDAY Scheme , iv. Thirteen Cities and Towns with a population above 75,000 and less than 1 lakh , on the stem of the main rivers v. Ten Cities from hill states, islands and tourist destinations (not more than one from each State)	D] Stage 2 proposals submitted which are evaluated by experts E] Selected Cities declared as Round 1 Smart Cities

Source: Author, Data based on Mission Statement and Guidelines of JnNURM (2005), AMRUT (2015) and SMART City Mission (2015)

To understand the overlaps in the coverage areas, the following table has been prepared for the three missions.

Table 35: Recurrence Among 61 Smart Cities (Declared Upto The Second Round) Across The Three Missions Along With Population And Class Sizes

STATES	CITIES	SMART (2015)	AMRUT (2015)	JNNURM (2005-12)	POPULATION	CLASS SIZE	STATES	CITIES	SMART (2015)	AMRUT (2015)	JNNURM (2005-12)	POPULATION	CLASS SIZE

TRIPURA	Agartala				400004	I							
	Cities selected under 1 Mission												
	Cities selected under 2 Missions												
	Cities selected under 3 Missions												

Source: Author, Data Based On Mission Statement and Guidelines of Jnnurm (2005), AMRUT (2015) And SMART City Mission (2015), Population Records from Census of India, 2011

From the above table 19 out of 61 cities have a recurrence of all the three missions, 27 out of 61 cities show a recurrence of two missions and the remaining i.e. 15 cities have appeared only as Smart Cities. Population along with class sizes (according to Census of India, 2011) have also been shown for all the 61 cities in order to understand that almost all are of Class I Size.

5.3 Focus Areas / Admissible Components

The table below shows the mission components in brief, with the idea that the overlapped components and Focus Areas can be observed. It is seen that Water Supply, Sewerage and Sanitation, Solid Waste Management, Urban Transport are actually the focus areas of all the three missions. Similarly, Storm Water Drainage and Slums are also important as they have been the admissible components in two missions. In the JnNURM Mission, heritage areas development has also been

one of the Admissible Components. Focus on IT Connectivity and Digitalization is the most unique component in the Smart City Mission.

Table 6: Comparison Of The Three Mission Components

JNNURM	AMRUT	SMART
Water Supply & Sanitation	Water supply	Adequate water supply
Sewerage & SWM	Sewerage facilities and septage management	Sanitation including Solid Waste Management
Storm water drainage	Storm water drains to reduce flooding	
Urban Transport	Pedestrian, non-motorized and public transport facilities, parking spaces, creating and upgrading green spaces, parks and recreation centers, especially for children.	Efficient urban mobility and transport
Parking Lots on PPP Basis		
Development of heritage areas		Safety and Security of Citizens
Prevention & rehabilitation of soil erosion/landslide areas		Sustainable environment
Preservation of water bodies		
Basic Services for Urban Poor (BSUP)		Affordable housing, especially for the poor
Redevelopment of inner city areas		Assured electric supply
		Robust IT Connectivity and digitalisation
		Health and education

	1 Mission
	2 Missions
	3 Missions

SOURCE: Author, Data Based On Mission Statement and Guidelines of JnNURM (2005), AMRUT (2015) And SMART City Mission (2015)

5.4 Fund Allocation

For getting an idea about the proportion of funds for each mission under each head, the guidelines of the three missions have been referred. The structure of JNNURM fund allocation was somewhat different therefore a separate table has been analyzed for it.

Table 8: Comparison of The Three Mission Components

MISSIONS	PROJECT FUNDS	A & OE	A & OE (MoUD)	REFORMS
AMRUT	93	5	2	
SMART	80	8	2	10

Category of Cities/Towns/UAs	Grant		ULB or Para-State Share/Loan from Financial Institutions
	Centre	State	
Cities/UAs with 4 million plus population as per 2001 census	35 %	15 %	50 %
Cities/UAs with million plus but less than 4 million population as per 2001 census	50%	20%	30%
Cities/towns/UAs in North Eastern States and Jammu & Kashmir	90%	10%	-
Cities/UAs other than those mentioned above	80%	10%	10%
For setting up de-salination plants within 20 Kms. from sea-shore and other urban areas predominantly facing water scarcity due to brackish water and non-availability of surface source.	80%	10%	10%

Source: Author, Data Based On Mission Statement and Guidelines of JnNURM (2005), AMRUT (2015) And SMART City Mission (2015)

The proportion of Funds are different for AMRUT and SMART City Mission but the heads under which funds are allocated, are the same.

6 PERSPECTIVE AND RESPONSE FROM CITIES TOWARDS NATIONAL GOVERNMENT

6.1 Concept of Sectors

Before getting into the actual scenario of the cities a National Assessment tool was required to study, to understand the investment requirements due to the construction of projects in the past years. There are mainly four broad sectors which the HPEC Committee had recognized (HPEC, 2011).

- ❖ Water Supply
- ❖ Sewerage and Sanitation
- ❖ Solid Waste Management

❖ Urban Transport and Roads

Figure 1: Capital Expenditure Of The Sectors Of Urban Infrastructure

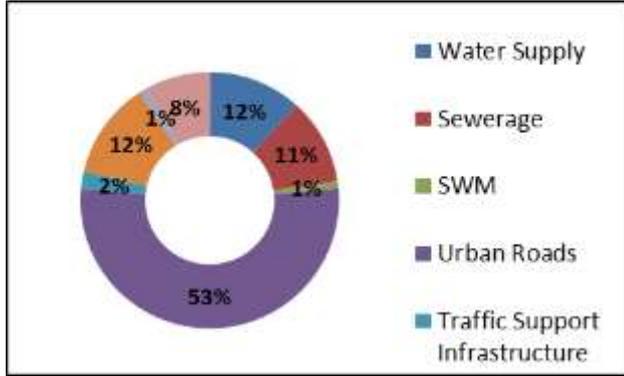

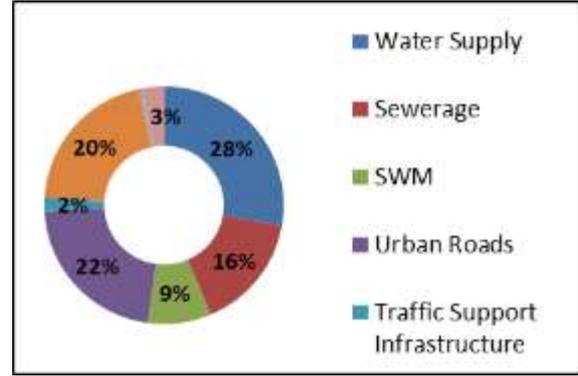

Figure 2: Operation Expenditure Of The Sectors Of Urban Infrastructure

Source: HPEC Report, 2011

It is seen that the maximum capex is allocated for urban transport which is 53%. If the sectors of water supply, sewerage and Sanitation and SWM can be clubbed, then it can be observed that the second in position would be the sector of Water Supply and Sanitation. However, in the case of Opex it is the reverse. Water Supply and Sanitation has the maximum investment allocated for it and second in position is urban transport.

6.2 Analyzing City Responses through Projects and Investments

To understand the responses of the Cities, the development proposals submitted during the three missions were studied through the lens of Projects and Investments. In this case, CDPs (City Development Plans) and SMART City proposals have been taken into consideration as in the State Annual Action Plans (SAAPs) of AMRUT Projects do not have the detailed projects but the costing per sector is there which will be used in analysis of investments later.

6.2.1 Water Supply

From the CDPs and SMART Proposals the list of projects can be categorized into the above heads. If the projects of JNNURM are considered first, then it is observed that the project of Augmentation has got the maximum importance, as it has got multiple sub- projects under it.

Table 9: Comparison of Water Supply Projects Through CDPs & Smart City Proposals

CITIES	JNNURM							SMART					
	AUGMENTATION	METERING	WTP/UGROHT & TUBEWELLS	MONITORING/ MANAGEMENT	RAINWATER HARVESTING	GIS	CAPACITY BUILDING	SMART METERING	AUGMENTATION	ASSURED WATER SUPPLY	MANAGEMENT	IUWM	RAINWATER HARVESTING
AJMER	✓ 5	✓	✓ 4		✓			✓		✓			✓
BHUBANESWAR	✓ 5										✓		✓
IMPHAL	✓ 2	✓	✓ 2				✓						
KOCHI	✓ 3		✓ 2								✓		
KOHIMA	✓ 5	✓	✓ 2										✓
PANAJI	✓			✓ 5			✓	✓					✓
UJJAIN	✓ 2								✓				
AGRA	✓ 2		✓										
CHANDIGARH	✓		✓					✓	✓	✓			✓
AMRITSAR	✓ 2	✓ 3	✓ 2	✓									
JASALPUR	✓ 2												
KANPUR	✓ 2	✓ 2											
MADURAI	✓ 2		✓ 5						✓		✓		
NAGPUR	✓									✓			
RABPUR	✓ 3		✓							✓			
VADODARA	✓ 4	✓						✓				✓	✓
VARANASI	✓ 6				✓		✓	✓					✓
AHMEDABAD	✓ 2		✓ 2				✓		✓			✓	✓
DELHI	✓		✓	✓ 2							✓		✓

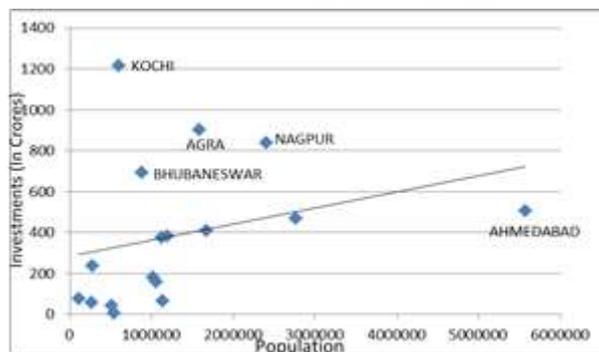

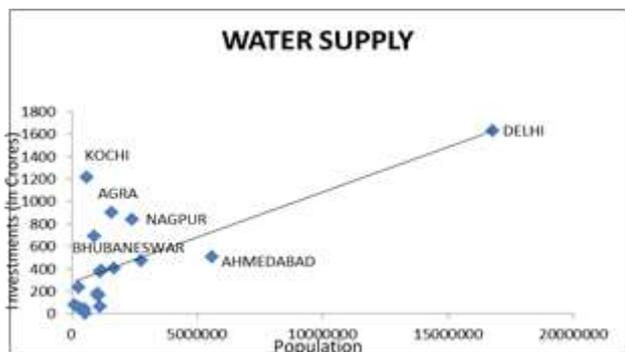

Source: Author, Data from CDPs and SMART City Proposals

Looking into the SMART City proposals, the project of Augmentation has been repeated. And Madurai and Ahmedabad are unique cases, as in spite of having 2 projects in JNNURM, it again has projects of similar nature in the SMART City Proposals. Similarly, is the case of the projects of Monitoring / Management and also Rainwater Harvesting as both have got priorities. Metering has however been named as 'Smart Metering' in the SMART City Proposals. However, as discussed in the literature review section, the concept of 'smartness' is not defined. If we look into the projects of the SMART Cities Mission--- IUWM and Assured Water Supply have been the new type of projects which can be included as smart solutions but has been implemented in only fewer cities.

Investment pattern for the water supply projects has also been studied, in which in this case scatter diagrams have been made from CDPs. Investment figures of CDPs have only been taken into account as it is the only completed mission. A relation is tried to be established between population numbers of the 19 sample cities and their investment figures.

Figure 3: Investment by Cities on Water Supply for JnNURM

Figure 4: Investment by Cities on Water Supply for JnNURM by excluding Delhi

Source: Author, Data from CDPs

As evident from the scatter diagram, there is a positive relationship between the two which means as the population rises, investments should also be higher. However, some cities like Kochi and Bhubaneswar not follow this relation. If their population figures are considered, it is seen that in comparison to the other cities, the investments for the water supply projects are extremely high. Agra and Nagpur can also be marked, but they have a comparatively higher population than Kochi and Bhubaneswar. In all the scatter diagrams, Delhi is being kept out of consideration because it has a population incomparable to the 19 other sample cities, being the national capital.

6.2.2 Sewerage and Sanitation

It is interesting to see that in this sector of sewerage and sanitation, which is one of the most important basic civic services, there is no smart element in the projects of the SMART Cities Mission if compared with the JNNURM Mission.

Table 36: Comparison Of Sewerage And Sanitation Projects Through CDPs & Smart City Proposals

CITIES	JNNURM						SMART						
	AUGMENTATION	STP/PUMPING STATIONS/ OXIDATION PONDS	PUBLIC TOILETS	DISPOSAL	MANAGE MENT	GIS	CAPACITY BUILDING	AUGMENTATION	SMART UTILITY DUCT	STP/PUMPING STATIONS	PUBLIC TOILETS	MANAGE MENT	TERTIARY WATER
AJMER	✓ 3	✓ 2	✓ 2										
BHUBANESWAR		✓			✓ 2					✓			
IMPHAL	✓												
KOCHI	✓												
KOHIMA	✓ 2	✓											
PANAJI	✓ 2			✓ 2	✓	✓							
UJJAIN	✓ 2										✓		
AGRA	✓	✓	✓	✓									
AMRITSAR	✓ 4	✓ 6			✓								
CHANDIGARH	✓	✓		✓								✓	✓
JABALPUR	✓			✓ 2									
KANPUR	✓ 2	✓			✓								
MADURAI	✓ 2	✓ 3											
HAAGPUR	✓			✓				✓	✓				
RAIPUR	✓ 2	✓									✓		
VADODARA	✓ 2	✓ 3											
VARANASI	✓ 3			✓			✓				✓	✓	✓
AHMEDABAD	✓ 2	✓ 2						✓					
DELHI	✓	✓							✓		✓		

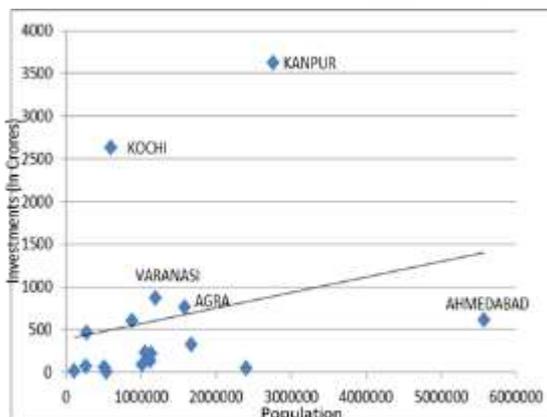

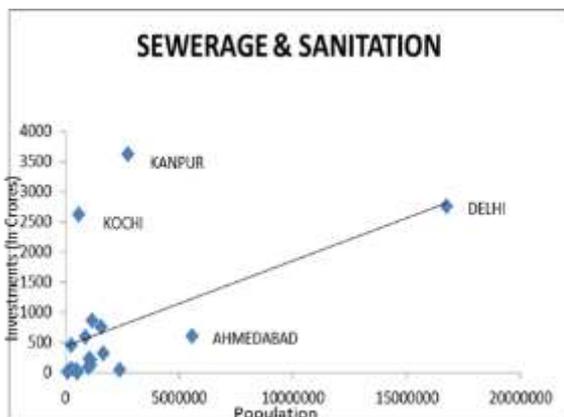

Source: Author, Data from CDPs, SMART City Proposals

If observed, the projects in both the missions are exactly similar in nature which question’s the meaning of the phrase ‘Smart Solutions’. If we just look at the JNNURM Proposals, the project of Augmentation has the maximum amount of projects and Ahmedabad is a unique case as in spite of having two projects in JNNURM, it was repeated in SMART City Proposals too.

From the scatter diagram, it is evident that although there is a positive relationship between the two variables, Kochi and Kanpur has an incomparable investment with respect to the other cities. However, Kanpur can still be justified as it has a very high population (third highest among the sample cities).

Figure 5: Investment by Cities on Sewerage and Sanitation for JnNURM

Figure 6: Investment by Cities on Sewerage and Sanitation for JnNURM by excluding Delhi

Source: Author, Data from CDPs

Among the low population cities, Kochi had extreme high the highest investment. As a matter of fact, Delhi which has a population of more than 1.5 Cr, has spent an almost equal amount in the same type of projects.

6.2.3 Solid Waste Management

In general, the basic projects of Solid Waste Management are almost similar for both the missions except the concept of RFID Bins, GIS Sensor Vehicles and the Management part

Table 37: Comparison Of Solid Waste Management Projects Through CDPs & Smart City Proposals

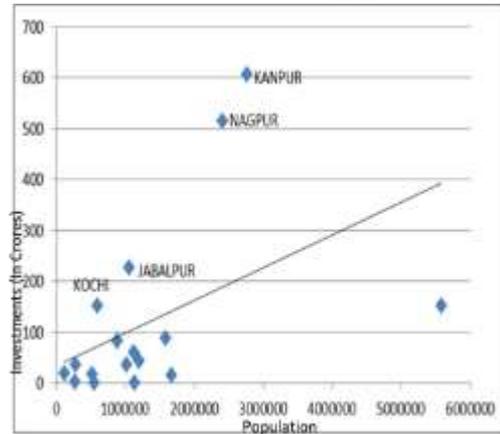

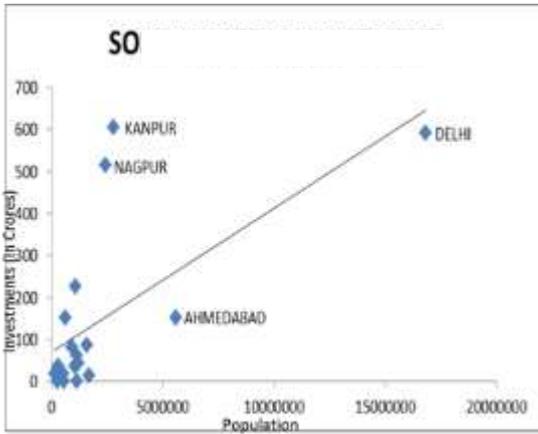

CITIES	JNNURM								SMART				
	SEGREGATION	COLLECTION	TRANSPORTATION	PROCESSING	DISPOSAL & LANDFILL	EQUIPMENTS	CAPACITY BUILDING	MANAGEMENT	GIS/RFID BINS/VEHICLES	MANAGEMENT	TRANSPORTATION	PROCESSING	DISPOSAL
AJMER				✓		✓		✓	✓ 3	✓			
BHUBANESWAR	✓	✓	✓ 2	✓	✓	✓						✓	
IMPHAL								✓				✓	
KOCHI	✓	✓		✓ 2	✓			✓

VADODARA		✓	✓	✓	✓				✓	✓		✓ 2	
VARANASI				✓	✓	✓ 5	✓	✓		✓			
AHMEDABAD		✓	✓		✓	✓ 2				✓			
DELHI				✓ 2	✓					✓		✓	

Source: Author, Data from CDPs, SMART City Proposals

where there is an intervention of some smart techniques. From the highlighted areas, it is seen that four projects in JNNURM--- Transportation, Processing, Disposal and landfill and Management has been of similar nature in the SMART City Proposals. Delhi, Panaji and Vadodara are unique cases, as for Delhi having 2 projects in JNNURM under processing got repeated in the SMART Cities Mission. In the SMART City Mission there are 2 projects in processing, in spite of having a project in JNNURM.

Figure 7: Investment by Cities on Solid Waste Management for JnNURM

Figure 8: Investment by Cities on Solid Waste Management for JnNURM by excluding Delhi

Source: Author, Data from CDPs

Even if Kanpur and Nagpur has a very high population, their investments had been very high as compared to the other cities of medium range population class cities. This is the reason, in the scatter diagram that Kanpur and Nagpur are extremely deviating from the trend line. Kochi and Jabalpur can also be considered as exceptions, as compared to the other cities in their respective classes, but their deviation is less from the trend line. This indicates that they do not show much an abnormality as the amount invested was almost at par with the demands of these cities.

6.2.4 Drainage

Excepting re-use of storm water, the projects of augmentation and construction of drains are absolutely similar if SMART City projects are compared with those in the JnNURM Projects.

Table 38: Comparison Of Drainage Projects Through CDPs & Smart City Proposals

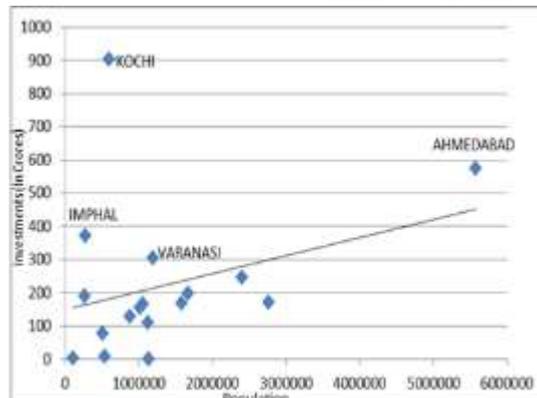

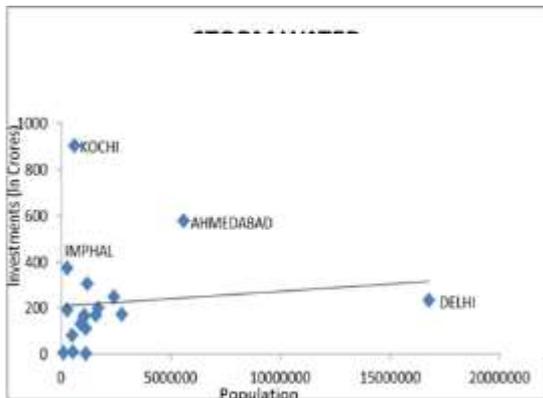

CITIES	JnNURM						SMART		
	AUGMENTATION	RIVER	DRAINS	O&M-MANAGEMENT	PUMPING STATION/OXIDATION PONDS	EQUIPMENTS	AUGMENTATION	DRAINS	RE-USE
AJMER	✓		✓ 3		✓	✓			
BHUBANESWAR			✓ 5						
IMPHAL		✓							
KOCHI	✓	✓			✓ 2				
KOHIMA	✓	✓							
PANAJI	✓			✓ 2					
UJJAIN			✓ 2				✓

AMRITSAR	✓						✓		
CHANDIGARH	✓		✓						✓
JABALPUR			✓ 2						
KANPUR									
MADURAI	✓ 2				✓				
NAGPUR	✓		✓					✓	
RAIPUR			✓ 2						✓
VADODARA	✓		✓ 3						
VARANASI	✓		✓ 2	✓ 2	✓	✓			
AHMEDABAD	✓	✓ 2							
DELHI	✓								

Source: Author, Data from CDPs, SMART City Proposals

Although Re-use of Storm water is a novel project it has been used only in two cities, Nagpur and Amritsar. However, there are no unique cities where more than one project has been repeated under a project head.

Figure 9: Investment by Cities on Storm Water Drainage for JnNURM

Figure 10: Investment by Cities on Storm Water Drainage for JnNURM by excluding Delhi

Source: Author, Data from CDPs

In this case the trend line is almost constant in the first scatter diagram which means that there is a very weak relationship between the two variables. This is somewhat not possible, so the zoomed image of the scatters on the right image shows that. A positive relationship can be somewhat established in this image between the two variables. Excepting for Kochi, Ahmedabad, Imphal and Varanasi, where there is no positive relationship. It is more abnormal for Kochi and Imphal as they have less population falling in the small sized cities. Although Ahmedabad has very high population, it is showing as an exception because compared to the other cities in this sector, its investment for storm water drainage had been very high. If it can be compared to Delhi, which has a much higher population than Ahmedabad, the investment was much lesser.

6.2.5 Urban Transport

The sector of Urban Transport is perhaps the most interesting sector, as all the project heads in the JNNURM Mission has been repeated in the SMART City Mission. If only the JNNURM Mission is considered, construction of roads had the maximum amount of projects and has the similar projects in SMART Mission. Bhubaneswar, Imphal, Jabalpur, Kanpur, Madurai, Nagpur and Raipur are unique cases here as there is more than one project in JNNURM for these cities and they have been again taken up in SMART. Bhubaneswar and Panaji are two other unique cities as not only the construction of roads have been taken up twice, but along with it more project heads like monitoring, motorized and parking have also been repeated.

Table 39: Comparison Of Urban Transport Projects Through CDPs & Smart City Proposals

CITIES	JNNURM						SMART					
	MOTORIZED	NON-MOTORIZED	PARKING	MONITORING MANAGEMENT	ROADS	FLYOVERS/STB/WAYS BUS TERMINUS	URBAN MOBILITY & PARKING	GIS/MANA GEMENT	SSIT & PEDEST PLAN	MOTORIZED	ROADS	FOOTPATHS/FLYOVERS/ BUS TERMINUS

8 out of 19 cities have repetition of the project--- roads, signifying that accessibility network within the cities are the real needs of the people. Traffic Management has been the priority project for four cities which highlights the fact of proper managerial expertise of the city. It is very shocking to city that only one city has taken the project of NMT as priority, wherein the country is trying to promote pollution-free transport.

The first scatter diagram on the left shows a perfectly positive relation between the two variables.

Figure 10: Investment by Cities on Urban Transport for JnNURM

Figure 11: Investment by Cities on Urban Transport for JnNURM by excluding Delhi

Source: Author, Data from CDPs

In the enlarged scatter diagram, there are distinctly four cities which can be seen as an exception. At least Kochi and Agra can be considered, as their investments are comparatively higher. Kochi can be a specific case, as it has less population and demand should be less. In the case of Agra and Nagpur, their population is on the higher side, which can still be considered. Out of the 19 cities, Delhi has the maximum investment, which is justifiable as its population is highest as compared to the others. In general, looking at the cost figures, it can be said that almost all the cities have tried to focus on roads and public transport, considering accessibility as a very important parameter in improving the quality of life.

6.2.6 Slums and Related Projects

In the JnNURM Mission there was a separate program for the LIG (Low Income Group) section known as Basic Services for Urban Poor (BSUP) which aimed at providing the basic infrastructure for the slums. However, in the SMART Cities Mission there was no separate program but one of the mission components was affordable housing for the poor. It is surprising to notice that if we look into the category of projects, for both the missions, then there is absolutely no difference in them. The projects for JNNURM have been repeated in the SMART Cities Mission and the major focus is on basic services for both the missions which encompassed physical and Social Infrastructure for the JNNURM Mission. Kochi is a unique case here as there is more than one project in both physical and social infrastructures in the JNNURM Mission, which has been again taken up in the SMART Cities. On the contrary, Ujjain and Chandigarh are also unique as they have not focused on slums in any of the missions.

Figure 12: Investment by Cities on Slums for JnNURM

Figure 13: Investment by Cities on Slums for JnNURM by excluding Delhi

Source: Author, Data from CDPs

There is a strongly positive relationship as in the scatter diagram, the points are extremely clustered towards the left. Kanpur and Nagpur had invested much in housing for the weaker sections. Although they have population on the higher side, but the costing for slums have been quite high as compared to the medium class sized cities. However, in the case of Jabalpur, Kohima and Kochi, their exceptionality is not much as they are closer to the trend line, and their margin is quite lower from that of Nagpur and Kanpur. If Delhi’s population is compared to Kanpur, then it is much higher, but their investment figures in slums have been equal.

6.3 City wise Priority of Sectors across the Missions on the basis of Projects:

If all the sectors are tried to be combined, with all the nineteen cities in one matrix across the three sectors, then the priority of the cities would look like the above matrix. The cities with their population and ranks have also been indicated so that it is easier to understand which population range class size city has focused on which sector. If it is looked at holistically, then Ajmer is the only city which has focused on four sectors. Bhubaneswar, Nagpur and Ahmedabad shows a priority in three sectors.

Table 41: Final Matrix Showing The Priority Sectors Of The Cities

Cities	Population	Urban Transport	SWM	Water Supply	Sewerage & Sanitation	Storm Water Drains	Slums
PANAJI	114759						
KOHIMA	267988						
IMPHAL	277196						
UJJAIN	515215						
AJMER	542321						
KOCHI	595575						
BHUBANESWAR	885363						
MADURAI	1017865						
CHANDIGARH	1055450						
JABALPUR	1055525						
RAIPUR	1123558						
AMRITSAR	1132383						
VARANASI	1198491						
AGRA	1585704						
VADODARA	1670806						
NAGPUR	2405665						
KANPUR	2765348						
AHMEDABAD	5577940						
DELHI	16787941						

	WATER
	SEWERAGE
	SWM
	STORM WATER
	URBAN TRANSPORT
	SLUMS

Source: Author

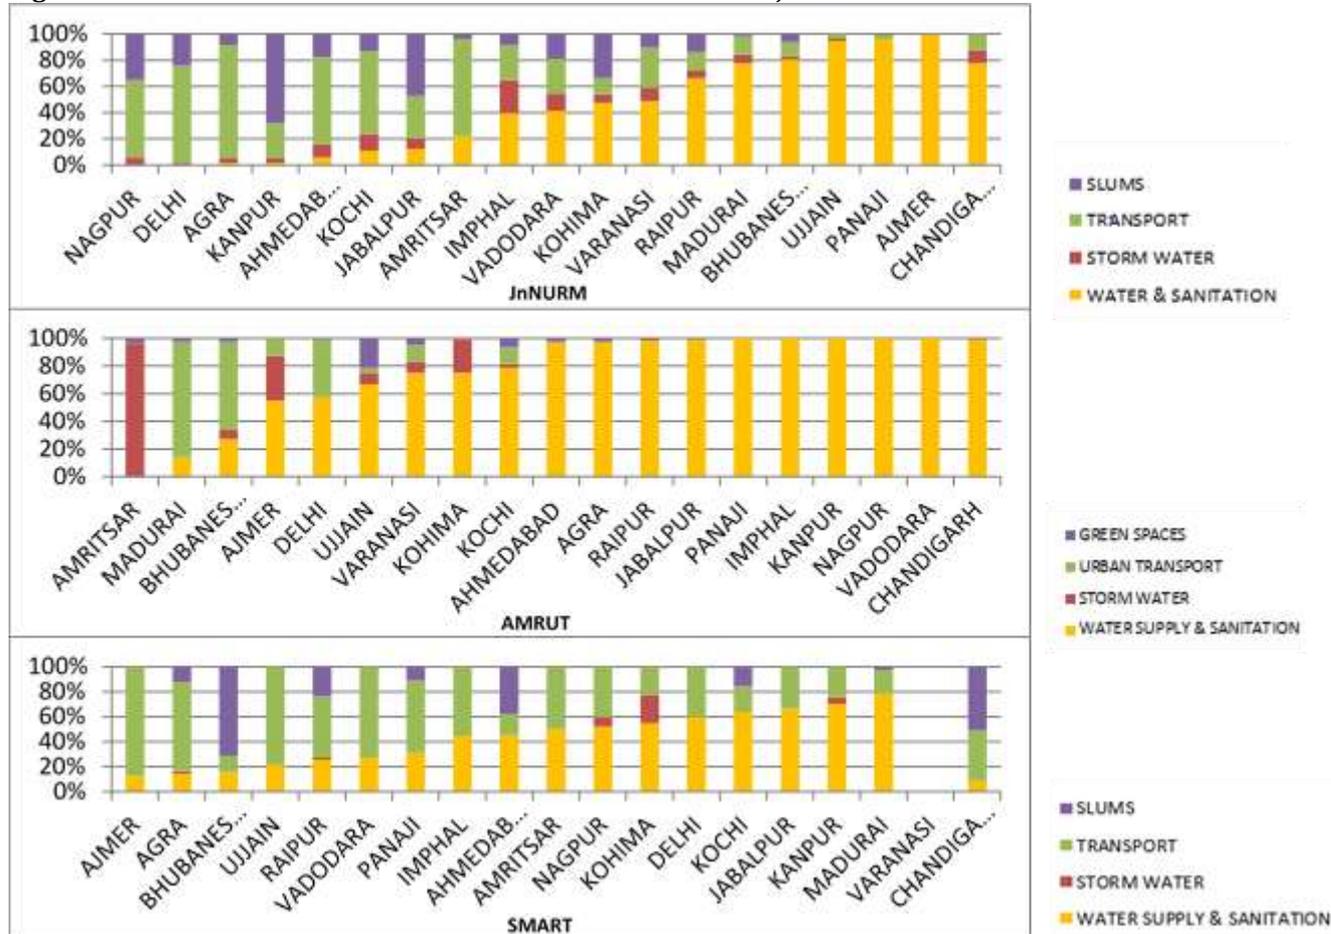

If the sectors are looked at as a whole, then it is seen that urban transport is the most important sector having the maximum requirement of investments due to the construction of projects, second in position is Solid waste management followed by water supply sector and then sewerage and sanitation. However, if all these sectors are combined into one, as water supply and sanitation, then it is seen that it falls into the second position requiring investments. Therefore, if

the HPEC Report can be compared with the scenario observed from these planning documents of the cities, then Water Supply and Sanitation along with Urban Transport seem to be still the priority sectors of all the Indian cities.

6.3 City wise Priority of Sectors across the Missions on the basis of Investments:

As seen from the three graphs, the yellow and green color signifies water supply and sanitation and urban transport respectively, across all the three missions. Firstly, if the yellow color is observed, an increasing trend is noticed as one comes down the graphs. This means in JNNURM, there was the least amount of cities taking water supply and sanitation as their projects.

Figure 14: Trend of Investments Seen for Urban Infrastructure Projects Across the Three Missions

Source: Author

However, in SMART Cities Mission the color looks more distributed. If the maximum priority of water supply and sanitation as a sector in the cities is considered, then it is observed that the AMRUT Mission has the highest number of cities taking it as their priority. Secondly, there is a clear trade-off between the sectors of water supply and sanitation (clubbed together) and urban transport. The cities having the less amount of yellow color has more amount of green color. This means wherever water supply and sanitation is not taken up as a priority in the cities, urban transport is taken as a priority, excepting a few in which slums is seen as a priority. Therefore, the fact, that urban transport and water supply and sanitation, can be considered the two most significant sectors of urban infrastructure becomes evident once again.

7 CONCLUSIONS DRAWN FROM THE STUDY

If the two objectives of this study are considered, then there are some interesting observations which can be noted and summarized. Looking from the perspective of the National Government, it is important to note that how are the Mission Statement and Guidelines of each Program / Mission / Policy different from each other or they have a similar approach and outlook behind the framing of the same. In this study, the basic aim and objective of all the three missions are, providing basic infrastructure in the cities with a duration of five years for two missions. Even if the Selection Criteria of the cities have been different in the three Missions, population has been the most important basis behind the same for all the three. 19 out of 61 Cities have occurred repeatedly in all the three Missions. The basis Focus Areas and Admissible Components for all the three Missions is Water Supply, Sewerage and Sanitation, Solid Waste Management and Urban Transport. In terms of Fund Allocation, the mechanism was different for only the JnNURM Mission but have absolutely the same heads for AMRUT and the Smart City Mission.

If the responses of the Cities are tried to be understood then it is seen that across all the three Missions the Cities have mainly tried to focus on Water Supply, Sewerage and Sanitation, Solid Waste Management and Urban Transport. This

means before upgrading the basic Civic Services, the nineteen Cities have competed for the Smart Cities Mission just in order to utilize the funds before analyzing their priority Sectors. As seen in the earlier section, through the comparisons of the City Development Plans (CDPs) and the Smart City Proposals, the cities have suitably repackaged the same old Projects in order to utilize the funds. The Smart Cities Mission therefore, remains a mere myth if both the perspectives are looked into.

Primary informal interviews and discussions have also been conducted with the key city officials of Bhubaneswar and Ahmedabad in order to validate this study. Their responses indicate that before knowing the proper basis and understanding of the Smart Cities Mission, both the cities had simply oriented their proposals according to the admissible components in order to win the Second Stage of the Smart City Challenge.

1484 E-GOVERNANCE, AN INITIATIVE TOWARDS BETTER GOVERNANCE: A CASE STUDY OF DURGAPUR MUNICIPAL CORPORATION

Rituparna Ghosh

Assistant Professor of Geography, Raniganj Girls' College

ABSTRACT

E-governance or electronic governance is basically associated with carrying out the functions and achieving the results of governance through the utilization of Information and Communication Technology (ICT). ICT provides efficient storing and retrieval of data, instantaneous transmission of information, processing information and data faster than the earlier manual systems, speeding up governmental processes, taking decisions expeditiously and judiciously, increasing transparency and enforcing accountability. It helps in increasing the reach of government- both geographically and demographically. National E-governance Plan (NeGP) has been formulated by the Department of Administrative Reforms and Public Grievances (DARPG) in 2006. The NeGP aims at improving delivery of Government services to citizens and businesses. E-governance in Municipalities is one of the most important Mission Mode Projects and a unique initiative of the Government of India conceptualized under the umbrella of the overall National e-Governance Plan (NeGP) and the Jawaharlal Nehru National Urban Renewal Mission (JNNURM) aimed at improving operational efficiencies within Urban Local Bodies (ULB's). Local governments serve as the first interface between the citizen and the government. E-governance in these institutions will cater to the needs of the citizens by bringing in efficiency, transparency, and improvement in service delivery. The hassles of standing in a queue for payment of property taxes, issue, and renewal of trade license etc can be avoided and the same services can be obtained by just a click of a mouse, at any time, anywhere. The implementation of e-governance requires capacity building of the ULB's as well as creation of awareness among the citizens about the process and benefits of e-governance. Durgapur Municipal Corporation with an area of 154.20 square kilometres and a population of 566937 persons as per Census 2011 is the second largest Municipal Corporation in West Bengal in terms of its area after Kolkata Municipal Corporation (187.33 square kilometres) and ranks third in terms of its population after Kolkata (44,86,679 persons) and Howrah Municipal Corporation (10,72,161 persons). The status of Durgapur has changed over the years from a police station under Asansol sub-division in 1961 to a Notified Area Authority in 1962 to Municipal Corporation in 1996. As an initiative towards e-governance, the website of Durgapur Municipal Corporation has been launched recently. Only a few services are being provided online such as birth and death registration, trade license, social welfare schemes etc. The other services are soon to be provided online. In this paper, an attempt has been made to analyse the initiatives of the Urban Local Body in introducing E-governance. Since citizens are the consumer of these services provided by the Urban Local Body, their perception of the effects of e-governance has been taken into consideration.

Keywords: Urban E-Governance, People's participation and perception

INTRODUCTION

Urbanisation results in increasing concentration of people in the urban areas. This increasing population exerts a tremendous pressure on the infrastructure of the urban areas leading to increasing complexities in the city life and deterioration of the urban environment. Among the urban areas, the Class I cities are in an alarming situation as they growing faster than the other categories of urban areas. These cities offer several pull factors in the form of employment opportunities, educational opportunities etc due to which people are attracted to these cities. These cities often attract people far in excess of their capacity. The cities are contributors to Gross Domestic Product (GDP) so they assume great importance. Their importance has increased enormously after globalisation. The cities have become hub of economic activities. The management of the huge population compounded by the increasing importance of the urban areas necessitate an effective system of governance and thus governance of urban areas has gained importance. Durgapur is a Class I city with a population of 566937 persons in 2011. Population has increased steadily from 41696 persons in 1961 to 566937 persons in 2011. Governance of Durgapur thus assumes importance. The 74th Constitutional Amendment Act, 1992 has recognised the urban local bodies as the third tier of government. The urban local bodies are entrusted with the responsibility of provision of various services. Introduction of e-governance is also one of the important responsibilities of the urban local bodies This introduction of the system of e-governance is one of the 23 reforms of Jawaharlal Nehru National Urban Renewal Mission (JNNURM). E-governance tends to bring the government closer to the people through easy access to and fast and efficient delivery of services.

GOVERNANCE

The concept of governance denotes the use of political authority and exercise of control in a society in relation to the management of its resources for social and economic development (*Organization for Economic Cooperation and Development, 1995, n.pg.*). According to United Nations Development Programme, 1997, "Governance is viewed as the exercise of economic, political and administrative authority to manage a country's affairs at all levels. It comprises mechanisms, processes and institutions, through which citizens and groups articulate their interests exercise their legal rights, meet their obligations and mediate their differences" (*Human Development Report, 1999, 29*). In other words, it denotes the process of administration of an area.

E-GOVERNANCE

E-governance or electronic governance is basically associated with carrying out the functions and achieving the results of governance through the utilization of Information and Communication Technology (ICT). E-governance is the use of ICT by government to provide easy and improved service to the citizens. According to UNESCO E-governance is "Governance refers to the exercise of political, economic and administrative authority in the management of a country's affairs, including citizens articulation of their interests and exercise of their legal rights and obligations. E-governance may be understood as the performance of this governance via the electronic medium in order to facilitate an efficient, speedy and transparent process of disseminating information to the public and other agencies and for performing government administration activities" (*Gandhi and Kumbharana, 2017,122*).

One of the 23 reforms which form part of the reform agenda of the Jawaharlal Nehru National Urban Renewal Mission (JNNURM) was the introduction of a system of e-governance using IT applications like GIS and MIS for various services provided by Urban Local Bodies (ULBs)/parastatals. National E-Governance Plan (NeGP) intends to institute and enable mechanisms to improve the system of governance and thus provide better services to citizens by effective use of ICT. E-governance in municipalities is one of the Mission Mode projects under NeGP, which is expected to result in improved service delivery by local governments for the citizen.

THE STUDY AREA

Durgapur is one of the six Municipal Corporations in the district of Paschim Barddhaman, in the state of West Bengal. It is located between 87°13'E to 87°22'E longitude and 23°28'N to 23°36'N latitude. It is situated on the banks of river Damodar at a distance of about 160 kilometres from Kolkata. It is bounded by Community Development Blocks, Kanksa on the east, Faridpur-Durgapur on the north, Andal and Pandabeswar on the west and river Damodar forms its southern boundary. Durgapur, a post-independent industrial new town was constituted as a Notified Area Authority in 1962 and was upgraded to the status of a Municipal Corporation in 1996. The total area (154.20 square kilometres) of Durgapur Municipal Corporation is divided into forty-three wards and five boroughs. As per Census 2011 it is the second largest Municipal Corporation in terms of its area after Kolkata Municipal Corporation and ranks third in terms of its population after Kolkata and Howrah Municipal Corporation.

OBJECTIVES OF STUDY

- To study the growth and development of Durgapur.
- To study the evolution of governance in Durgapur.
- To study the initiatives of the Urban Local Body in introducing e-governance
- To study the perception of the people with regard to awareness about the process of e-governance and its implementation.

METHODOLOGY

The study is based on both primary and secondary data. The primary data has been collected through household survey carried out in the sample wards of Durgapur Municipal Corporation. The wards have been chosen keeping in mind their location in the Municipal Corporation. Ward Nos. 1 and 22 have been selected for the study. Ward No. 1 is a peripheral ward and Ward No. 22 is a centrally located ward forming the City Centre. The survey has been conducted with the help of a structured questionnaire.

EVOLUTION OF DURGAPUR

Durgapur has grown out of an area which was under forest cover. The first nucleus for urban development came into existence in the year 1854 when East Indian Railway (now Eastern Railway) passed through this area on its way to Raniganj coalfields (*Singh, A.K., 1990*). In 1955 the barrage across the Damodar River at Durgapur was constructed. Due to its locational advantage it was an ideal choice for locating a major Industrial Complex. Durgapur is situated on the fringe of coal fields, which is West Bengal's chief source of energy but was itself outside the coal belt. It also did not encroach on the agriculturally rich alluvial plains of West Bengal toward its southeast. Due to the presence of the barrage, water was also available to support industry and urbanisation. The factors which influenced the government's decision to locate industries here were nearness to the source of raw material particularly iron ore, coal and limestone, good transportation facilities to transport the finished products to the large wholesale

markets at Calcutta and labour supply from the neighbouring states. Due to these advantages a major programme of industrial promotion was undertaken by the Government of West Bengal. Several industries were developed such as steel plants, mining machinery plant, power stations and a complex of coke ovens, by products and intermediate chemicals. Due to the location of the major steel industry Durgapur came to be recognised as the single largest concentration of heavy industry in the country and West Bengal.

At present Durgapur is a Municipal Corporation beside its distinctive status of being an Industrial Complex. It is an "Urban Industrial Complex." Industrialisation has been the causative factor behind its urbanisation.

EVOLUTION OF GOVERNANCE IN DURGAPUR

The advantageous location of Durgapur made it an ideal choice for locating a major Industrial Complex. It was State Governments' decision of setting up of industries in Durgapur during the Second Five Year Plan (1956-61). It was a post-independent industrial town. It was developed with an aim to promote the growth and development of the surrounding

regions. The first industry to be set up here was the Cove Oven Plant, followed by the Durgapur Steel Plant. Two townships were established to accommodate the workers of both the plants. The two industrial townships - the Steel Township (63.67 square kilometres) and Coke Oven Plant Township (10.02 square kilometres) were spatially separated from each other by the G.T. road (now NH 2) with a total area of 73.69 square kilometres as per the 1961 Census. Durgapur had no distinct boundary at that time and consisted of the two townships. The 1961 Census mentions Durgapur to be a Non-Municipality included under Asansol Sub-Division as a Police Station. These two walled townships of their respective plants were provided with all kinds of urban amenities. The intermediate and surrounding non-company areas were deprived of services. The first form of evolution of urban government took place in 1958 when Durgapur Development Authority (DDA) was formed. It was formed to initiate and coordinate the development works for Durgapur and provide amenities and public utility services to the non-township people. Durgapur was constituted as a Notified Area Authority on 1st October 1962. The administration was then headed by a chairman who was generally an Indian Administrative Service (IAS) officer. Under him was a vice chairman who was nominated by the State Government. The boundary of Durgapur Notified Area Authority (DNAA) was formed at this time which included 3 police stations with their 40 mouzas along with the two plant townships. After the delineation of the DNAA boundary it encompassed an area of 154.20 square kilometres. The West Bengal Town and Country (Planning and Development) Act 1979 amalgamated the Asansol Planning Organization (APO, established in 1964) and Durgapur Development Authority (DDA, established in 1958) to form a new Development Authority namely Asansol Durgapur Development Authority (ADDA) in 1980. Durgapur Notified Area Authority was upgraded to the status of a Municipal Corporation on 7th October 1996. The total area of 154.20 square kilometres however remained same and was divided into 43 wards and 5 boroughs.

The Corporation functions under the Mayor-in-Council system which has eight members excluding the Mayor. They are responsible for various services such as water supply, solid waste management, education, health service, electricity etc. After the formation of Municipal Corporation in 1996 the first municipal elections took place in 1997 and after that municipal elections are held regularly at an interval of five years i.e. in 2002, 2007, 2012 and in 2017.

The total area of Durgapur Municipal Corporation is divided into forty-three wards and five boroughs. Ward is the smallest administrative unit in a Municipal Corporation. A borough is above the ward and is formed by a group of wards. Ward Committees have been constituted in all the 43 wards. Apart from the ward committees, borough committees have also been formed. Ward committees are headed by a councillor and borough committees are headed by a chairman. Ward committees supervise and monitor the development works at the ward level and borough committees supervise the conservancy services of the wards under them. Borough committees mainly supervise and monitor the overall services and developmental works of the wards grouped under them.

The management of cities is not an exclusive responsibility of municipal governments; parastatal is also responsible for it. Parastatals are interdisciplinary bodies responsible for planning; coordinating, implementing, funding and supervising urban development works (*Mukhopadhyay, 1999*). Parastatals/Development Authorities are nominated by the state governments, bureaucratic in composition and unaccountable to the local people while the Municipal Corporations are elected bodies, accountable to the people. These bodies play an important part in urban governance but they are far away from people's participation and response. Their functioning is insulated from local politics but are heavily influenced by the state level politics. They function in an authoritarian manner while making decisions on capital budgeting (*Mathur, 1999*). The 74th Constitution Amendment Act, 1992 provides constitutional status to the urban local bodies but does not specify the role of the development authorities. The development authorities are concerned with development and capital works, while the municipal bodies are responsible for operation and maintenance of services. Asansol Durgapur Development Authority is the development authority set up for planned and scientific management of growth of the planning area. It is responsible for spearheading the cause of industrial, infrastructural and other development activities in the area under its jurisdiction which extends from Panagarh to Barakar with a total area of 1615.90 square kilometres covering about 30 lakhs of both rural and urban population. Its planning area includes two Municipal Corporations - Asansol and Durgapur and three Municipalities - Raniganj, Jamuria and Kulti. Among the two Municipal Corporations, Asansol Municipal Corporation is the older one formed in 1994.

E-GOVERNANCE INITIATIVES IN DURGAPUR MUNICIPAL CORPORATION

As a pan-city initiative, DMC has a plan to introduce crowd mapping. It is an alternative civic engagement strategy which is not bound by time and location and can be performed on the web, mobile phones or other media. Crowd mapping has the following advantages:

- It builds real-time social change network and an online community to address city's needs.
- City centric problems can be posted by citizens
- It provides citizens useful information on various issues- public works, maintenance, traffic, events etc
- It records complaints posted with a unique number and sends grievance redressal send to the concerned authority.
- Application of GIS technology to locate the exact point of issue
- It is a mobile sms and app-based platform reaching out to larger number of citizens.

The crowd mapping data can be accessed through various means, one such means is websites.

The website of Durgapur Municipal Corporation has been launched. It has been designed by West Bengal Electronic Industry Development Corporation Limited (Webel) Technology Limited. On-line Trade license, Social Beneficiary

Scheme and Birth and Death Registration services are available online. Other services like Building Plan, Property Tax, Water Tax etc would soon be made on-line. The City Development Plan (CDP) prepared by ADDA envisages to implement e-governance in the ULBs under its jurisdiction. It plans at computerisation of entire systems and records. Thus, DMC is in the initial stage of introduction of E-Governance measures. It has only made its web presence.

Durgapur is one of the cities in West Bengal included under the 'Green City Mission'. It is a project of Urban Development and Municipal Affairs, Government of West Bengal. Durgapur Municipal Corporation and Asansol Durgapur Development Authority are entrusted with the responsibility of execution of the project. Different works are included under the mission such as urban afforestation, conservation of water bodies, improvement of solid waste management, installation of solar panels etc. Making the city technologically efficient is also one of the important programme under the 'Green City Mission'

SOCIO-ECONOMIC SCENARIO OF DURGAPUR

Social and economic scenario of the study area has been taken into consideration to provide an idea of the population of the same who are affected by the process of governance. They are one of the stakeholders in the governance process. Census data has been considered to study the socio-economic profile of Durgapur. Population of Durgapur has increased steadily increased from 41696 persons in 1961 to 566937 persons in 2011. The growth rate of population has decreased from 395.58 per cent during 1961-1971 to 14.90 per cent during 2001-2011. The maximum increase of population has taken place between 1961 and 1971. In 1971 the boundary of Durgapur Notified Area Authority was delineated which included population of 3 police stations of 40 mouzas along with the two townships. The number of households has also increased from 10401 in 1961 to 163916 in 2011. This indicates the pressure on the infrastructure or services provided by the urban local body. Population density has also increased from 566 persons per square kilometres in 1961 to 3677 persons per square kilometres in 2011. Literacy rate has also increased from 64.03 per cent in 1961 to 80.01 per cent in 2011. Sex ratio has increased constantly from 338 in 1961 to 926 in 2011. Work participation has declined from 62.48 per cent in 1961 to 35.13 per cent in 2011. Non-workers has increased from 37.52 per cent in 1961 to 64.87 per cent in 2011.

PEOPLE’S PARTICIPATION

Effective and successful implementation of any system lies on the receptivity of those for whom it is being implemented. E-governance aims to bring the government closer to the people. The receptors of the advantages of e-governance is the people. To have an idea about the recipients of e-governance services, household survey has been carried out in two wards i.e. 1 and 22 keeping in view their location within Durgapur Municipal Corporation. Ward No. 22 is a centrally located ward, the City Centre, and Ward No. 1 is a peripheral ward.

AGE STRUCTURE OF THE SAMPLE POPULATION

Age structure has a bearing on the perception and participation of the people in the process of urban e-governance. It is assumed that perception and participation of people about e-governance varies among different age groups. To have an idea of the people residing in the sample wards, age of the household population has been taken into consideration. The age has been grouped into the categories, 0 to 30 years, 30 to 60 years, and 60 years and above. The age group of 0 to 30 years includes the mobile and young population who have little time and experience to involve in decision making. The age group of 30 to 60 years includes the mature population who have the capacity to actively participate in the decision-making process and the age group of 60 years and above includes the elderly and experienced population who can devote most of their time in the same.

Ward No. 1 is a peripheral ward and Ward No. 22 is the City Centre. In Ward No. 1, 51.52 per cent of the sample population belong to the age group of 0-30 years, 41.52 per cent of the sample population belong to the age group of 30-60 years and 6.97 per cent of the sample population belong to the age group of 60 years and above. In Ward No.22, 41.20 per cent of the sample population belong to the age group of 30-60 years, 30.81 per cent of the sample population belong to the age group of 0-30 years and 27.99 per cent of the sample population belong to the age group of 60 years and above (Table No.1)

Table No.1: Age Groups (Figures are in percentage)

Sample ward no.	0-30	30-60	60 and above
1	51.52	41.52	6.97
22	30.81	41.20	27.99

Source: Field Survey, December 2017.

MALE-FEMALE RATIO

Male female ratio indicates the status of women residing in an area. It is also an indicator of the level of social development of the area. Gender effects the adoption and use of e-government. Generally, knowledge of computers is more among males than females. In Ward Nos. 1 and 22 males outnumber females as shown in Table No 2.

Table No. 2: Male-Female Ratio (Figures are in percentage)

Sample ward no.	Male	Female
1	52.12	47.88
22	51.58	48.42

LITERACY RATE

Literacy is an important indicator of the level of development of an area. Literacy rate of Durgapur Municipal Corporation is 80.01 per cent as per Census 2011. It can be seen that 85.06 per cent and 91.14 per cent of the sample population are literates in Ward No. 1 and 22 respectively. In Ward No. 1 and 22, 14.94 per cent and 8.86 per cent of the sample population are illiterates respectively.

Table No.3: Literate-Illiterate (Figures are in percentage)

Sample ward no.	Literate	Illiterate
1	85.06	14.94
22	91.14	8.86

Source: Field Survey, December 2017.

LEVEL OF EDUCATION

Perception and participation of the people in the process of urban e-governance depends on their level of education. Adoption of new technologies is dependent upon the level of education. The level of education of the sample population in the selected wards has been grouped into primary, secondary, higher secondary, graduation, post- graduation, above post-graduation and technical. Primary education indicates education up to class five, secondary education indicates education from class six to class ten, higher secondary indicates the plus two level, graduation indicates the three- year degree course, - graduation includes only the general post graduate courses, above post graduate level indicates persons pursuing research on any field after post -graduation. In Ward No.1, 60.31 per cent of the sample population belong to the secondary level of education, 20.23 per cent of the sample population are educated up to the primary level. Only a meagre per cent i.e. 0.38 have technical education. In Ward No.22, 39.84 per cent and 15.43 per cent of the sample population are graduates and belong to the secondary level of education respectively. About 12.89 per cent of the sample population have technical education.

Table No.4: Level of Education (Figures are in percentages)

Sample ward no.	Primary	Secondary	Higher Secondary	Graduation	Post Graduation	Above Post Graduation	Technical
1	20.23	60.31	9.54	8.78	0.76	0	0.38
22	10.74	15.43	9.57	39.84	10.55	0.98	12.89

Source: Field Survey, December 2017.

OCCUPATIONAL PATTERN

Occupational pattern helps to understand the employment opportunities generated by the urban local body. Perception and participation of the people in the process of e-governance depends on the type of occupation. Generally, people engaged in the public sector are satisfied with the government services than those working in the private sector. The household survey (Table No.5) reveals that in Ward No.1, 33.17 per cent of the sample population are workers and 66.83 per cent are non-workers. In Ward No. 22, 28.57 per cent and 71.43 per cent of the sample population are workers and non-workers respectively. Table No. 6 shows the occupational pattern of the sample population. The survey reveals that in Ward No. 1, 29.41 per cent of the working population are engaged in service, 19.61 per cent are engaged in business, 11.76 per cent are agricultural worker and 39.22 per cent are non-agricultural workers. In Ward No.22, 69.38 per cent of the working population are engaged in service, 10 per cent are engaged in business and 20.63 per cent are non-agricultural workers.

Table No.5: Work Participation (Figures are in percentages)

Sample ward no.	Worker	Non-Worker
1	33.17	66.83
22	28.57	71.43

PEOPLE'S PERCEPTION

Perception of the people are most important for judging the quality of service being provided by the municipal administration as they are the consumer of such services. Thus, people's perception on two important aspects of e-

governance; e-openness and e-participation (Rahim Alaa-Aldin Abdul and A. Al Athmay, 2015) been taken into consideration.

E-OPENNESS

It means the ease with which information on the government website can be obtained. It helps the people to know about the activities undertaken by the ULB. The respondents were enquired about their opinion on e-openness. The study reveals that in Ward Nos. 1 and 22, 27.03 per cent and 35.90 per cent of the respondents respectively are satisfied with the information provided on the website. About 20.27 per cent and 28.85 per cent of the respondents respectively in Ward Nos. 1 and 2 are not satisfied with the same. About 47.30 per cent and 12.82 per cent of the respondents in Ward Nos. 1 and 2 are not aware of e-governance. The category NA (Not Applicable) includes rented households. About 5.41 per cent of the respondents live in rented houses in Ward No.1 and 22.44 per cent of the respondents live in rented houses and office quarters.

Table No.7: People's Perception on E-Openness (Figures are in percentage)

Sample ward no.	Satisfactory	Not satisfactory	Not Aware	NA
1	27.03	20.27	47.30	5.41
22	35.90	28.85	12.82	22.44

Source: Field Survey, December 2017.

E-PARTICIPATION

It means the use of internet technology by the citizens to access the services provided by the urban local body. Citizens participation in policy and decision-making processes forms the core of electronic participation. E-participation increases citizens involvement with the government. The study reveals that in Ward No. 1, 37.84 per cent of the respondents uses e-services, 9.46 per cent follow traditional methods and 47.30 per cent are not aware about e-services. In Ward No.22, 48.72 per cent of the respondents uses e-services, 16.03 per cent do not use e-services and 12.82 per cent are not aware about the same.

Table No.8: People's Perception on E-Participation (Figures are in percentage)

Sample ward no.	E-services	Traditional Methods	Not Aware	NA
1	37.84	9.46	47.30	5.41
22	48.72	16.03	12.82	22.44

Source: Field Survey, December 2017.

CONCLUSION

Durgapur Municipal Corporation is in the initial stage of the introduction of e-governance measures. The website has been launched. Only a few services are being provided on-line. The study reveals that the citizens are also not aware about the e-services. They mostly prefer the traditional methods of accessing the services provided by the urban local body. Awareness about e-services are more in the centrally located ward than in the peripheral ward. Infrastructure must be developed to make the services easily available to the citizens. Thus DMC has to go a long way for introduction and effective implementation of e-governance measures.

Email address: eeshanbhaduri@gmail.com**ABSTRACT**

In modern world transport researchers are vehemently emphasizing the use of mass transits over other modes for their distinct advantages in various aspects, from congestion reduction to being environment friendly. This paper discusses about the probability of modal shift to bus mode from non-mass transit modes on introduction of different service improvement measures applicable to Indian road condition. A multinomial logit mode choice model is developed based on revealed preference dataset consisting peoples travel behaviour in existing traffic scenario where three mass transit modes – train, subway & bus and one intermediate public transit mode – auto-rickshaw is available. Further the model is used to predict policy impacts, broadly considering two service improvement domains (a) travel time and (b) frequency & reliability, attainable through three major strategies (1) network improvement facilities (2) lane management and (3) introduction of bus rapid transit system. Finally, the probability of modal shift is assessed to evaluate the best potential strategy for mass transit sustainability. These results can be used as a policy making tool by the concerned authorities for future smart cities.

Keywords: modal shift, logit, alternative, policy, transit**1 INTRODUCTION****1.1 Present scenario**

Indian cities have been traditionally dependent on buses as dominant mode of transport because of its advantages to carry more people at a time and being economical as well. Unfortunately though, the bus fleet size is degrading fast (20%-40% drop from 2000-2008) even in big metros like Delhi, Mumbai, Kolkata (Ministry of Urban Development, Handbook of Urban Statistics, 2016) whereas the private vehicle (PV) and intermediate public transport (IPT) is increasing to fill the void. However, existing performance evaluation reports of traffic condition done by Indian Government itself clearly shows a huge gap in 'mass transport' (MT) infrastructure, plagued by inadequate capacity and financial reasons, specifically in Kolkata which includes (a) Depleting fleet size of MT (b) Unreliable service of most MT services, and (c) Less or no coordination between different MT modes (National Transport Development Policy Committee, 2014). The poor state of MT modes in cities like Kolkata have been further magnified by IPT modes which act as a competitor rather being an ideal feeder service which perhaps could be a solution to last mile connectivity problem. In the absence of adequate provision of MT infrastructure especially in cities like Kolkata, including public transport, congestion diseconomies outweigh the benefits of agglomeration forcing people to switch to PV and IPT like auto-rickshaw. The goal is therefore to build a sustainable MT system to solve the fundamental issues like congestion, pollution, high energy demand etc. as it has been predicted that in a do-nothing scenario MT share will drop by 50% whereas PV & IPT share increases by almost equivalent proportion in the period 2007-2031 (Ministry of Urban Development, Handbook of Urban Statistics, 2016).

One approach to achieve this goal is to enhance the level of service (LOS) for bus mode to attract captive IPT users back to MT. This study is intended to estimate the probable shift from IPT modes to bus mode using an appropriate modeling technique. At the same time assessment of different MT service improvement measures has been done based on the modal shift those can incur considering Indian traffic condition.

2 REVIEW OF THE PREVIOUS STUDIES

As this study focuses on modal shift from IPT to bus mode, the review of literature presented here considers the choice behaviour of urban commuters where more than two modes are available as well as different types of transportation policies related to bus LOS improvement. Alvinsyah *et al.* (2005) developed a binomial logit model based on Stated Preference (SP) data, to study the response of the travellers in using the proposed Jakarta bus-way system. Travel time and travel cost were considered as the main variables to develop utility functions. Chakrabarti (2017) shows that any major strategy to attract discretionary PV users to MT should include three service measures i.e. Speed, Frequency and Reliability. Fatima & Kumar (2014) further explains the impact of BRTS in million plus cities in India in terms of speed and travel time but the discussion strictly considers only BRTS option. Anwar and Yang (2017) show with help of binary logistics model that a direct bus service with hourly interval is more efficient strategy compared to Park & Ride service, causing approximately five times higher modal shift to MT.

All of these studies, in summary, are focused towards identifying factors that influence the way individuals decide to choose their modes of travel and their ability to respond to shift to buses. At the same time, it can be argued that there are very few studies which clearly deal with multiple MT modes and multiple policies, which resembles better with our actual mode choice behaviour. This study attempts to fulfil this need.

3 Methodology

As different literature suggests, there are predominantly two approaches to analyse modal shift – (1) revealed preference (RP) approach and (2) stated preference (SP) approach. Here RP approach has been followed as it is based on actual mode choice behaviour which suits better for building a mode choice model and thereafter one or two key variables were changed to estimate peoples’ response to bus LOS improvement. The aim of the study is to analyse how modal shift occurs to bus from IPT as well as other MT modes simultaneously, based on introduction of different transit development measures. Hence a multinomial logit model (MNL) was mostly used along with incremental logit model (ILM) in some specific cases considering the fact that logit model is easily interpretable than probit model.

In the second stage, development of scenarios was done through transit speed which was in turn used as an input to calculate transit capacity in the study stretch. The factors those were used and altered as well to build up different scenarios were – mean dwell time, dwell time variability, average stop spacing, average dwell time, scheduled number of buses at critical stop, traffic signal phasing and bus facility type (Kittelsohn & Associates, Inc.; Parsons Brinckerhoff; KFH Group, Inc; Texas A&M Transportation Institute; ARUP, 2013).

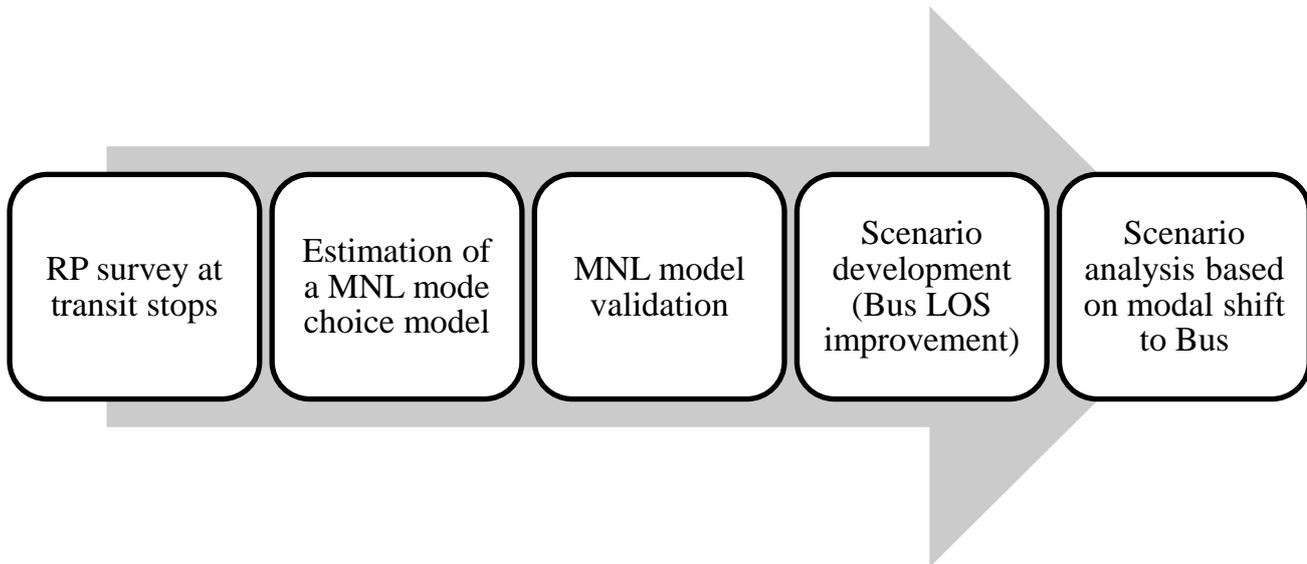

Figure 107: Flow chart of methodology

4 SURVEY DESIGN AND ANALYSIS

Study area

In this study survey data was used to build a valid mode choice model. To identify the mode choice factors for urban commuters, a RP questionnaire was prepared. All those data were collected through bus station survey, conducted along a particular stretch (Tollygunje to Kalighat metro/ Rashbehari crossing) on a three-lane busy arterial road (Deshapran Sasmal Road) in Kolkata, India where reasonable accessibility to all four modes (train, subway, bus and auto-rickshaw) is co-exist.

Survey dataset (Response elicitation)

During the survey the respondents were asked to base their response on the trips they were making or about to make. The questionnaire had two major sections –

General data – (a) socio-economic data and (b) household data

Travel data – (a) trip related information

In the same line of explanation, the explanatory variables can also be subdivided in three categories –

- (1) Individual specific variables (age, gender, occupation etc.)
- (2) Journey specific variables (origin-destination, trip purposes, time of day etc.)
- (3) Transport facility specific variables (travel time, travel cost etc.)

A total two hundred and eleven (211) trips with detailed information about trip legs were extracted from the available survey dataset out of which seven (7) nos. of trip records were neglected for errors or insufficient data.

5 MODEL DEVELOPMENT

Model specification

The correlation between different variables are analysed in R-Studio to identify the variables in the mode choice equation. The correlation threshold has been set as 0.5 to consider highly correlated variables. It’s also worth noting that there are no such variables in the final mode choice model which are correlated by any manner. and Table 1 provides descriptions about the variables considered for modeling.

Table 42: Variable correlation square plot

I d	Variables	Variables with high correlation (>0.50)	Remarks
1	Age		'age' has been grouped into 4 categories - (1) 0 - <20 years, (2) 20 - 35 years, (3) 35 - 60 years and (4) >60 years based on in general education and retirement age. The variable will be assigned value 1, if it's in one category and 0, otherwise.
2	Gender		The variable will be assigned value 1, if male and 0, if Female.
3	income_class		Individual income has been considered instead of household which gives a wrong interpretation of those who can afford high travel cost despite earning less.
4	hh_size		Number of people in a single household.
5	whh_size		Number of earning member in a single household.
6	veh_ownership		Vehicle ownership = Number of household vehicles (2 wheelers + 4 wheelers) / Number of household members possessing driver's license
7	peak_hr		Trips made in time groups 08:00 to 11:00 Hrs and 17:00 to 20:00 Hrs were marked as peak-hour trips, represented by 1, and trips made during 14:00 to 17:00 Hrs was marked 0.
8	trip_purpose		A binary variable where there are three types of trip purposes considered (1) Home based work (HBW), (2) Home based education (HBE) and (3) Home based other (HBO). If the person has made the trip in one of the mentioned purposes then it is coded as 1 otherwise as 0.
9	trip_length	tcost TT_hr	Total distance travelled in kilometres adding up individual trip leg distances.
10	n_transfer	tcost TT_hr	Number of transfer = Total number of trip legs - 1
11	TT_time_hr	tcost n_transfer trip_length	Total travel time in hours adding up individual trip leg travel time.
12	Tcost	TT_hr n_transfer trip_length	Total travel cost in rupees adding up individual trip leg travel cost.

Model estimation

The variables, selected for the final mode choice model, are not at all correlated because such correlated variables do not augment well for MNL model. The model was estimated by maximum-likelihood estimation using Newton-Raphson method as it picks the values of model parameter which make the observed data more likely to occur than any other values. For model estimation statistical software platform 'R-Studio' was used.

The variables those are in the final mode choice equation are shown in table 2 along with their statistical significance and coefficients. It is worth mentioning that auto-rickshaw has been considered as the base mode i.e. auto-rickshaw has a zero intercept value. As the full dataset size was considerably small compared to dataset size used in similar research work, 100% of it was taken for estimation purpose. Simultaneously some variables (eg. trip_HBW) come to be statistically significant only for selected alternatives (mode) out of four modes in consideration for the logit model. Those are represented as (mode_i * variable_k).

However, one should be careful about the fact that the model does not consider 'Car' mode although one's general intuition indicates that 'Bus' mode will only attract more ridership from 'Car' with further improvement in service quality. The estimation results are shown in table 2.

Table 43: MNL estimation results (R - 'mlogit' package)

Variable(s)	Estimate	Pr(> t)	Significance
bus:(intercept)	2.61449	5.87e-07	***
subway:(intercept)	-1.01066	0.13611	
train:(intercept)	-2.24903	2.70e-09	***
TT_hr	-6.93211	< 2.2e-16	***
bus * peak_hr	-0.95616	0.08372	.
subway * peak_hr	-1.04916	0.0667	.
subway * (veh_ownership)^2	-1.06393	0.20352	
bus * age_2	0.9606	0.06526	.
subway * age_2	1.17498	0.04921	*
subway * trip_HBW	-1.14735	0.03807	*

There are mainly two ways to judge the explanatory ability of the mode choice model in the development stage. First of those are the value of McFadden R²(similar to normal R²) and second one is Log-likelihood value.³¹⁷

The goodness-of-fit measure for the model during model development stage can be assessed by likelihood ratio index, $(\rho^2) = [LL(0) - LL(P)] / LL(0)$

Where, LL(P) = Log-likelihood of estimated model; LL(0) = Log-likelihood of zero-coefficient model. The summary of the model estimation is shown in table 3.

The value of (ρ^2) index varies between 0 (no fit) and 1 (perfect fit) in order to compare alternative models. Although its meaning is clear in the limits (0 and 1), values around 0.4 are usually considered excellent fits (Ortúzar & Willumsen, 2011). It can be observed from different literatures that the value of McFadden R² also varies from 0.30 - 0.50 in similar mode choice models (Anwar & Yang, 2017) (Chakrabarti, 2017) (Alvinsyah, Soehodho, & Nainggolan, 2005). Hence it can be claimed that the model performs considerably good with respect to both of these index (Log-likelihood & McFadden R²).

Table 44: Statistical summary of the MNL estimation (R - 'mlogit' package)

No. of Observations	211
No. of iterations	6
Log-Likelihood:	-134.19
McFadden R ² :	0.39928
Likelihood ratio index (ρ^2)	0.39927

Model validation

Re-estimation of model

As already mentioned, due to less number of data it was not possible to set aside a certain number of the data for validation purpose. Although to gain confidence in the signs and magnitudes of constant as well as variables those were selected in the mode choice model, built based on the full dataset (211 nos. data), an attempt was taken to re-estimate 20 times, as shown in table 3 (first 10 attempts shown), with same variables for 80% of full dataset size (169 nos. out of 211 data). In each of the attempts the survey records were selected randomly with help of MS-excel random number generation.

Table 45: Re-estimation with first 10 random set comprising 80% of full dataset

Model run id	R ²	Log-Likelihood	Intercept/Constant			Alt. specific coeff.	Individual specific coefficient		Trip specific coefficient	
			bus	subway	train	Total Travel time (TT_hr)	Age (age_2)	Vehicle Occupancy (veh_occupancy^2)	Peak Hour (peak_hr)	Trip purpose (trip_HBW)
						Coeff. = Negative	Coeff. = Positive		Coeff. = Negative	
						all modes	bus	subway	bus	subway
1	0.384	-107.95	2.89	-1.7	-2.34					
2	0.388	-105.65	2.38	-1.52	-2.75					
3	0.390	-113.51	2.51	-0.91	-2.26					
4	0.383	-113.06	2.53	-0.6	-2.07					
5	0.397	-106.12	2.71	-0.94	-2.21					
6	0.393	-106.01	2.51	-1.14	-2.22					
7	0.411	-105.03	2.54	-1.21	-2.48					
8	0.391	-110.8	2.83	-0.32	-1.97					
9	0.361	-116.82	2.41	-0.85	-2.1					
10	0.428	-92.838	2.59	-1.35	-2.71					

Table 46: MNL estimation results for all (20) attempts (R - 'mlogit' package)

Pr(> t)<0.25	Frequency for high sig.	20	17	15	6	14	11	15
Pr(> t)<0.10	Frequency for medium sig.	0	2	3	10	6	7	3
Pr(> t)=Insignificant	Insignificance	0	1	2	4	0	2	2

It was found that in each case, the signs and the mean value is consistent with the full dataset model. Simultaneously the choice of the variables set in the full model can be justified through analysing all the attempts by the frequency of variables in terms of statistical significance. For this purpose, three different significance threshold level as shown in Table 5 are used instead of general levels as suggested by default in R statistical software because of small dataset size. As it is found 'Travel time' is highly significant and all other variables is significant combined high and medium threshold for at least 80% of times. This underlines the fact that the choice of variable set in full model dataset is not random in nature rather consistent enough.

Validation by trip length fit approach

The number of trips per mode per distance is aggregated in 5 km distance brackets, up to maximum 25 km. The predicted modal shares are graphed against the observed modal shares.

317 *** 99.9% significance level, ** 99% significance level, * 95% significance level, . 90% significance level

Figure 2 indicates that the predicted modal shares grossly follow the overall pattern of the observed modal shares (*observed mode share of train, subway, bus and auto-rickshaw are 6.16%, 15.16%, 61.61% and 18% respectively whereas predicted mode share are 4.51%, 19.11%, 58.95% and 17.39%*), especially for shorter distances and for all the modes. The pattern is not so closely matched at longer distances specifically between the modes 'Subway' and 'Train' because there are very few actual trips made at such distances. That is why most of the 'Train' trips are misclassified as 'Subway' trips. It should be taken into consideration that most trips are short to medium-distance 'Bus' trips, and the model captures that behaviour well.

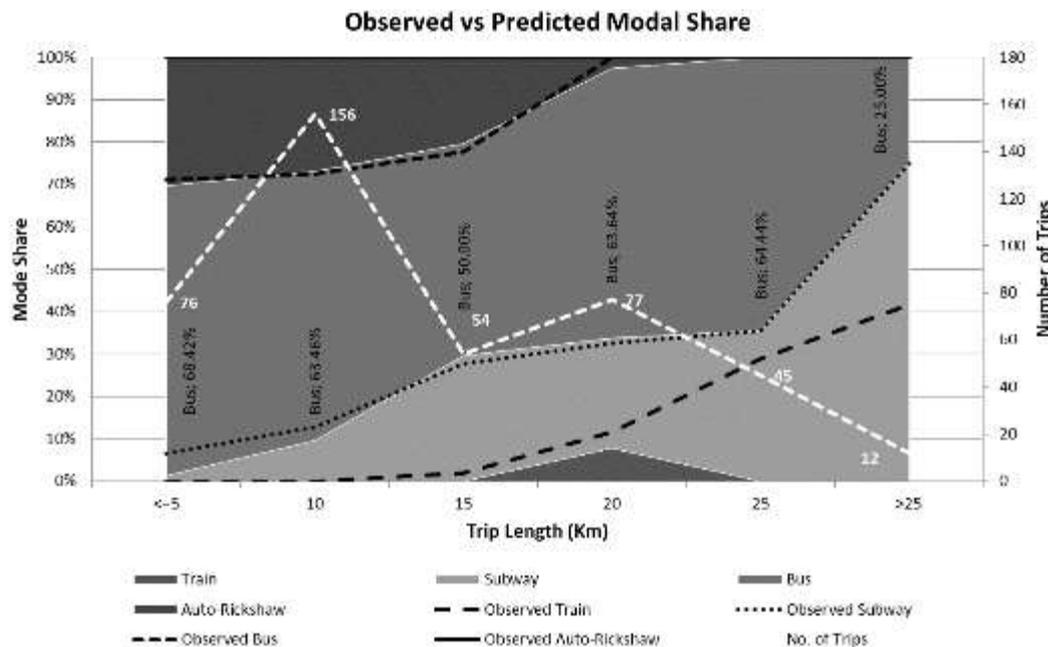

Figure 2: Distribution of modal share by trip length (observed vs. predicted)

6 SCENARIO ANALYSIS

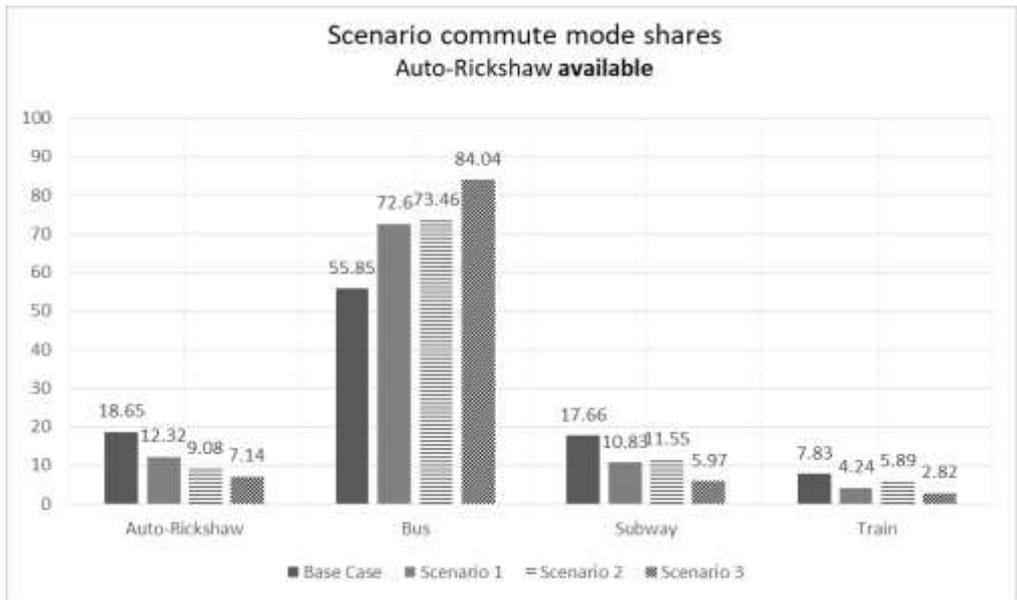

6.1 Scenario development

To build up different scenarios and to find out which variables could be changed to alter the travel speed a detailed literature study was done which resulted in estimation of transit capacity and speed in the study corridor separately based on the methods published in the reports by Transportation Research Board. As an output of this the scenarios were broadly classified into three categories –

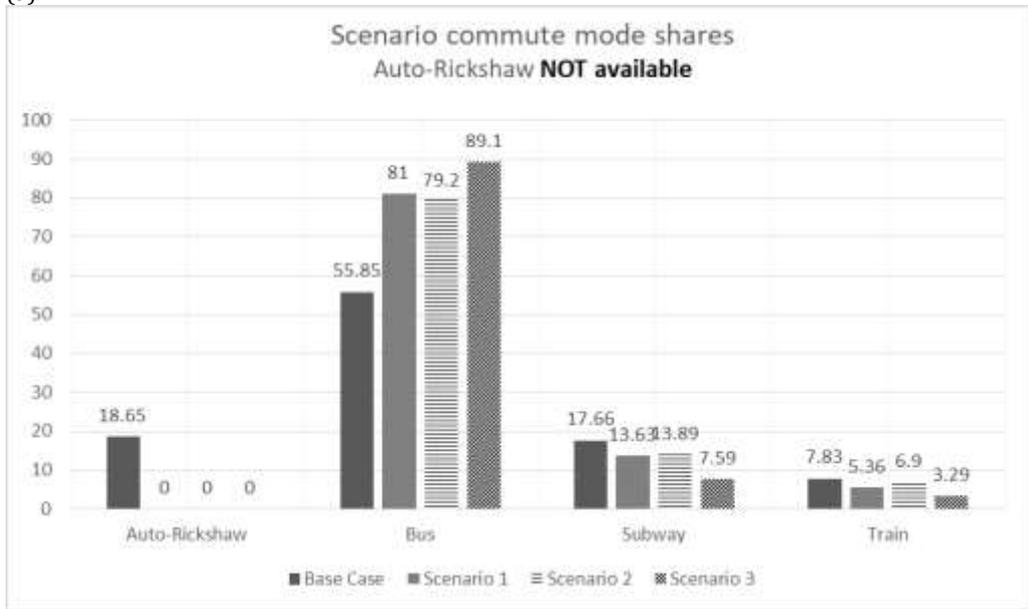

- 1) Scenario 1 - Network characteristics improvement (capacity and speed constraints)
- 2) Scenario 2 - Improvement in lane management & operational hours
- 3) Scenario 3 - Introduction of a new BRTS service

Analysis of scenarios

Here the prediction results are analysed to find out the impact of availability of auto-rickshaw on mass transit commuter mode share as well as to assess the impact of three major service improvement strategies.

(a)

(b)

Figure 3: Mode share predicted for scenarios (a) auto-rickshaw available and (b) auto-rickshaw not available

As a output of this scenario analysis, scenario 3- introduction of BRTS is found to be most influential strategy causing highest modal shift to bus mode. It is an expected result as grade separated bus way leads to maximum amount of travel time saving out of proposed three scenarios. Interestingly there are couple of more points which can also be inferred from figure 2 (a) and (b) – (i) increase in mode choice through simple speed & capacity improvement techniques (scenario 1) are almost equal or even greater than comparatively cost & time intensive lane management techniques (scenario 2) and (ii) removal of auto-rickshaw from the arterial lane to feeder network increases significantly mode share for ‘bus’ across all the scenarios (scenario 1, 2 and 3).

The model being a multinomial logit model suffers from red bus-blue bus syndrome, drawing share proportionate to the original mode share whereas originally increasing utility of bus will be drawing more share from auto-rickshaw compared to other MT modes and the model also does not consider car mode. So, in reality the modal shift will be better than this model could represent and we should also consider that the model is not based on city wide survey therefore the modal shift may be somewhat exaggerated.

7 CONCLUSIONS

This study focuses on the rationality of huge investment on high yielding ‘transit improvement strategies’ whereas we often overlook fundamental ones. The model results, in terms of modal shift each category of strategy incurs, can be used as a planning tool for policy formulation as the categories are divided in an increasing order of time and cost budget. It clearly suggests that fundamental improvements in transit service e.g. planned stop spacing, uniformity in dwell time, schedule reliability, skip-stop operation, bus priority signalling, bus preferential intersection etc. can act as quite impactful strategies for facilitating higher modal share for ‘bus’.

The result gives an indication to travellers' sensitivity or response to system changes. Considering the modal shift shown in section 0 upon implementing scenario 1, 2, 3), some major inferences can be drawn upon:

- i. For scenario 1, it can be observed that there is a modal shift to bus by 16.75% when auto-rickshaw is allowed on the arterial street and an equivalent modal shift by 17.61% for scenario 2. Similarly, comparable modal shifts are seen for Scenario 1 and 2 (25.15% and 23.35% modal shift respectively) when auto-rickshaw is not allowed on the arterial street. Network improvement measures (scenario 1) require less time and cost compared to scenario 2 and 3. Whereas scenario 2 is more time complicated in implementation when compared to 1. Thus we can infer that scenario 1 could be a better strategy than 2.
- ii. For BRTS strategy (scenario 3), it can be observed that there is a modal shift to bus by 28.19% when auto-rickshaw is allowed on the arterial street and a modal shift by 16.75% for scenario 1. Similarly, the modal shares are found to be 33.25% and 25.15% respectively for Scenario 3 and 1 when auto-rickshaw is not allowed on the arterial street. Scenario 3 proves to be the most effective strategy of the lot but the modal shift incurred by it does not differ largely from the modal shift caused by network improvement measures (scenario 1) Thus, evaluation of the trade-off between time, cost and ease of implementation is of great importance to the policy makers while selecting such strategies.
- iii. Auto-rickshaw removal from arterial streets can prove to be more advantageous strategy in case of scenario 1 compared to scenario 2 and scenario 3 which anyway frees up exclusive lane (space) for 'bus'. The modal share difference are 8.4%, 5.74% and 5.06% between situations when auto-rickshaw is available or not respectively for scenario 1, 2 and 3.

Moreover, the research work also helps to identify the causal factors e.g. 'travel time', 'age', 'gender' etc. which play important role in modal shift behaviour of urban commuter to bus consequent on the bus LOS improvement under Indian traffic scenario.

At the same time, this shows us an alternative way to work with relatively small dataset. It can be observed that the model, in spite of being based on small number of records, performs average to well in re-estimation and somewhat in validation too. A certain level of confidence on the model can be built upon based on iterative (10 times in this case) re-estimation exercise as well as validation attempts can also be done on various aspects to evaluate model performance.

8 RECOMMENDATIONS

As the traffic characteristics has been already analysed in section 0 and modal shift in section 0 acts as an indicator for policy making with respect to the study corridor the policies that could be formulated are as follows:

1. Use of site specific bus preferential treatments (capacity constraints improvements) like queue jumps and curb extension can be very much effective when applied to major junctions in the corridor.
2. Use of auto-rickshaw as a feeder network rather than a competitor for 'bus' on arterial street seems to be a better effective strategy than parking removal from streets.
3. Proper scheduling of bus routes through discontinuation of overlapping routes and parallel introduction of skip-stop service causes significant rise in 'bus' attractiveness. Total 11 no. of stops can be planned as per travel demand analysis, in this study 6 major stops selected.
4. Bus priority signalling should be introduced in all stops for better transit service rather than using it only for major intersections.
5. Instead of full-fledged BRTS, express Bus (lane reservation) along with improved 'bus' service seems to be an ideal combination.

SS02.4. Smart Cities Initiatives for the 21st Century: Myth or Reality

1571 SMART INITIATIVES FOR SMART LIVING - SHOWCASING BENGALURU'S EXPERIENCES

S. Manasi

Associate Professor, Centre for Research in Urban Affairs, Institute for Social and Economic Change, Bangalore-72

ABSTRACT

Rapid growth of urbanization is expected to increase further and it is estimated that by the year 2025, 34 cities worldwide will have a population of more than 10 million people. At present, 54 per cent of the world's population live in urban areas and expected to augment to 66 per cent by 2050. Urban population has increased from 746 million in 1950 to 3.9 billion in 2014. Asia accounts for 53 per cent of the world's population. World Urbanization prospects by UN DESA's (2014) Population Division has pointed that most urbanization will happen in India, China and Nigeria.

Cities demands and pressures on resources like energy, water, housing, and transportation will increase further. All linked infrastructure to sustain these services will have to be met with enormous infrastructure costs in addition to maintaining adequate, timely and quality services. The quality of life will depend on the quality of air, access to clean drinking water and sanitation facilities, reliability of power supply and other services like education and health. Thus, 21st century faces one of the critical development challenges of governing urban areas.

Cities are working to get smart all over the world and adopt various ways to achieve it. Internet of Things (IoT) is one of the significant approaches which focus on intelligence to help cities use resources more efficiently holistically by improving water use, transportation, energy, air quality, energy and communication systems, thus aiding in changing the overall quality of life of the populace.

Although such initiatives are yet to take off in a holistic way in Indian cities, there are several initiatives taken up towards understanding challenges in cities like Bengaluru and making Cities smarter in managing their resources and improving the quality of life. Bengaluru is the IT hub/capital of India and one of the fastest growing cities of the 21st century. It is referred to as the 'million plus city' with its population growing at an enormous rate. Bengaluru witnesses several pressures and challenges in providing a good quality of life to its citizens.

However, it is important to highlight the smart initiatives that have led to positive changes in the city environs. It matters most to find pathways to upscale these initiatives by and make them work in an effective way with suitable modifications in other cities as well. The current paper is based on a review and some research studies that have used technology to change Bengaluru city. Urban resilience through improving urban governance and resources management in the city has showcased interesting initiatives that needs appreciation. Some of the popular smart solution initiatives may be broadly categorised into – (i) IT based solutions for improving governance (ii) Technology based solutions for improving resources management. These cases will be discussed in detail in the paper.

INTRODUCTION

The continuing growth of urbanization is expected to increase further and it is estimated that by the year 2025, 34 cities worldwide will have a population of more than 10 million people. Currently, 54 per cent of the world's population lives in urban areas and expected to increase to 66 per cent by 2050. Urban population has increased from 746 million in 1950 to 3.9 billion in 2014. Asia alone accounts for 53 per cent of the world's world population. United Nations report projects that urbanization and population growth together would contribute to further add 2.5 billion people to urban population by 2050 and 90 per cent of the concentration would be in Asia and Africa. World Urbanization prospects by UN DESA's (2014) Population Division indicate that most urbanization will take place in India, China and Nigeria. It is projected that India will add 404 million urban dwellers, China 292 million and Nigeria 212 million by 2050. Among the UNs ranking of most populous cities, Delhi and Mumbai are listed.

Cities consume majority of the resources and the demands and pressures on energy, water, housing, transportation are bound to increase. Associated infrastructure to support these services will have to be met with huge infrastructure costs besides maintaining quality of providing these services through timely access and adequacy. The quality of life will depend on the quality of air, access to clean drinking water and sanitation facilities, reliability of power supply and other services like education and health. Given this situation, 21st century faces one of the most important development challenges of managing urban areas. According to John Wilmoth, Director of UN DESA's Population Division, "Our success or failure in building sustainable cities will be a major factor in the success of the post 2015 UN development agenda".

Cities have to work towards getting smarter and there are several approaches adopted towards achieving smartness in city management around the world. One of them is the Internet of Things (IoT) wherein smart cities technology aids in cutting edge intelligence to help cities use resources more efficiently wherein it improves and takes care of all aspects-improving water use, transportation, energy, air quality, energy and communication systems. This would help in transforming the quality of life of citizens. The US will be investing around \$ 41trillion over the coming 20 years to upgrade their infrastructure in line with IoT. In this regard, Intel and the City of San Jose, CA are working on a public-private partnership project which aims to provide an Intel's IoT Smart City Demonstration Platform to further improve the city's Green Vision initiative. Their aim is to provide 25,000 Clean Tech jobs, create environmental sustainability and enhance the quality of life for its citizens. Installations of network on Air quality Sound and Micro Climate sensors will be creating a 'sustainability lens' for the city. The sustainability lens would use IoT technology to measure characteristics

such as noise pollution levels, traffic flows wherein the city management will later use the information/ data to improve air quality, transport efficiency etc.

Although such initiatives are yet to take off in a holistic way in Indian cities, there are several initiatives taken up towards understanding challenges in cities like Bengaluru and making Cities smarter in managing their resources and improving the quality of life. Bengaluru is the IT hub/capital of India and one of the fastest growing cities of the 21st century and has witnessed significant expansion spatially and has grown more than 10 times since 1949. It is referred to as the 'million plus city' with its population growing at an enormous rate. Bengaluru witnesses several pressures and challenges in providing a good quality of life to its citizens. To describe a few implications, Bengaluru is ranked as one the most highly polluted cities according to a report by the Centre for Science and Environment. Based on the air quality analysis data of the Karnataka State Pollution Control Board, Bengaluru has been identified as one of the 14 cities that have high levels of particulate matter, increase in benzene levels, increasing nitrogen dioxide levels entering the dangerous zone (The Hindu, March 23, 2013), garbage menace and conflict which brought the world's attention in 2012, still remains unresolved although Rs. 405 crores are spent only on disposing garbage by the Municipal Corporation. Dumping unsegregated garbage into landfills would mean disaster in the long run. The landfill areas around Bengaluru have shown high ground water and air contamination making villagers the victims (Deccan Herald, 25th May 2015).

However, it would still be interesting to showcase some of the positive inventiveness that highlight the various smart initiatives undertaken in the city. It is a matter of finding ways and ascertaining processes about how we upscale these smart solutions and work towards making Bengaluru a smart city in the true sense. Some of the popular smart solution initiatives include – (i) IT based solutions for improving Governance (ii) Technology based solutions for improving resources management, etc.

SMART LAND GOVERNANCE

It requires an accurate and efficient maintenance of the land record system in order to carry out any land related transactions in a hassle free environment. Increased urbanization has created complex land transactions associated issues like- an aberrant increase in the demand for urban property, creation of bogus documents, 'benami' and deceptive land transactions, coupled with inadequate checks/control at various levels for monitoring irregularities taking place - all these serve to increase public insecurity. Given this situation, the initiative of the 'Urban Property Ownership Records' (UPOR) intends to ensure transparency in land administration procedures, simplify the process of registration, provide greater access to information, centralize land records data and thereby improve accountability. Thus, the core objective of UPOR is to issue ownership title to urban households and the creation of a fresh data base for urban mapping. It is expected that UPOR will result in the elimination of corruption and middlemen in the process and promote good governance. One of the primary aims of UPOR is also to create an approved land record system of documents by a statutory authority in order to enable the other stakeholders to make use of this database.

A robust system of UPOR is created for every property with a view to documenting accurately both spatial characteristics of properties and record of rights data in respect of (i) land parcels (ii) structures /buildings (iii) roads etc. This property record will serve as a trusted record for all land related transactions. The property card thus, created under UPOR would serve as evidence for property ownership for regulatory and legal purposes. The property card issued will continue to remain valid and will not become obsolete or inaccurate. All the property record related transactions and services are intended to be fulfilled through this project (UPOR webpage)³¹⁸. The project is to be launched in 50 of the 198 wards in Bengaluru by the Survey Settlement and Land Records Department in the first phase and is under process (Manasi, et.al 2013).

SMART CITIZEN SERVICE CENTRES – 'BENGALURU ONE'

'Bangalore One' or B1 is based on PPP and aims at delivering citizen-centric services to common people. It is a 'One-Stop-Shop' for all C2G (Citizen to Government) facility to ensure accountability, convenience, certainty and speed through easy access to a chain of computerized Integrated Citizen Service Centres and also multiple delivery channels like Electronic Kiosks, mobile phones and the Internet. B1 also aims to provide cost-effective methods of service provision to the department/agencies and efficient and real time MIS and EIS to the departments which would enable them to work on core functions and free them from routine operations.

'Bangalore One' is being implemented in a phased manner. The estimated number of these Centres required is about 100 G2B (Government to Business), G2C (Government to Citizens) and G2C (Business to Citizens) services in the city. Government of Karnataka has decided to establish 15 service centres and 24 basic services of 9 Government Departments in the B1 project. Eventually, they plan to bring all the G2C and G2B services within the purview of B1 project to see that citizens and business people could avail all services at the centres except for specialized services. Currently, there are 23 B1 centres and 82 Mini B1 centres. Services offered by B1 centres include both B2C (telephone bill payments, insurance premiums payments, government job notifications etc), G2C (Bengaluru Electricity Supply Company- BESCO, Bruhat Bengaluru Mahanagara Palike (BBMP), Bengaluru Police Service (BPS), Regional Transport Office (RTO) etc) have integrated with the B1 centres to provide various services to the citizens. B1 project will also be evaluated periodically through independent agencies to ensure its efficiency in attaining the set objectives.

MANAGING TRAFFIC SMARTLY

³¹⁸UPOR objectives are listed out in City Survey Department-UPOR webpage www.upor.karnataka.gov.in.

Bengaluru's vehicular population has grown immensely resulting in traffic congestion and reducing the average speed as low as 10 kmph during peak hours. 'Bengaluru Traffic Improvement Project'- B-TRAC 2010 was initiated to improve the traffic management systems with the aim to reduce traffic congestion by 30 per cent in central area, accidents by 30 per cent, pollution levels and improve compliance of Traffic laws and rules and set up an effective Trauma Care System. Many components are being incorporated in the plan like road markings, signage, enforcement cameras, surveillance cameras, upgradation of signals including vehicle actuation and will be integrated into the Interim Traffic Management Centre. The information from traffic signal system, signal timings and traffic flow data will be real time data that will be processed instantly to ensure harmonized results.

Bengaluru Police has provided 612 Blackberry phones and wireless printers to traffic sub-inspectors and inspectors to levy on-spot fine collection and receipt. For those who cannot pay the fines on-spot, details are provided and will be put on the server. The system also aids in booking cases and is storing in the server the cases of repeated offenders. Registration data base from the transport department is linked up to Automated Enforcement Centre. Currently, there are 175 surveillance cameras watching violation of various traffic rules. Besides this, the traffic violations have been recognized by the interceptor effectively. Interceptors are used for deployment of traffic violations by surprise since it is not possible to install enforcement/surveillance cameras at all junctions. For instance in 2014 the total number of cases recorded were 1,34,835 collecting a fine of Rs.3,72,11,600.

SMART WAYS IN TRANSPORT SERVICES

Private transport services are working towards providing good service to citizens of Bengaluru. Taxi services in Bengaluru city are aiming at ensuring services by incorporating smart devices to guarantee accuracy in billing and safety features. Several taxi companies come with a tablet and a smart blue tooth enabled digital meter to ensure that the fare is calculated with accuracy and providing an e-receipt that would be e-mailed to the user of the cab, thus enabling them to pay the prescribed fare structure. Other innovative services that are making women feel safe while travel are launch of the SMS based trip tracker service by Meru Cabs where women can designate a family member to receive SMS alerts about the location of their journey throughout their travel in the taxi till they reach the destination. The updates are sent at fifteen minutes interval. There are several taxi companies that have equipped their vehicles with tracking devices. The cab is connected with a 5000 smart phone that acts as a GPS locator and the driver has to keep it on since that is the only way that he can undertake business. Recording of bookings are also done which doubly ensures safety. Some companies also have plans to add video surveillance to scale up security measures.

SMART ENERGY CONSERVATION

Given the importance of reducing the usage of fossil fuels and increasing the use of natural resources, the efforts in the recent times towards the application of the eventual renewable resource, the solar energy assumes greater significance particularly in the context of climate change concerns. Energy efficient technology based initiatives by the BESCOCOM has worked towards several programmes to reduce power consumption and usage of renewable energy options, specifically solar energy. Under the BESCOCOM Efficient Lighting Programme (BELP), Government of Karnataka has made it mandatory for use of Solar Water Heaters for buildings constructed in sites measuring more than 600 sq ft and above for residential buildings and sites measuring 1200 sq ft area and above within the limits of Municipalities/Corporations and Bengaluru Development Authority sectors. It details about the users – Industries where hot water is required for processing, Hospitals and Nursing homes, Jail Barracks, Canteens, Universities, Training Institutions, Housing complexes and positions field officers to create awareness in the area. Approved source for supply and installation of solar water heating systems is assigned to Aditya Solar shop of Karnataka Renewable Energy Development Limited to ensure installation of optimally designated quality systems. Besides, it also directs all the Departments like Urban Development Department, Public Works Department, Housing Department etc. to amend their rules to make use of the solar water heating systems as mandatory.

Another initiative has been the mandatory use of Compact Florescent Lamp (CFL) in government buildings and aided institutions/Boards/Corporations. BESCOCOM has also included the promotion of energy efficient buildings to be constructed by the government. The number of solar water heating systems installed in BESCOCOM have increased from 6187 in 2008-09 to 1,20,791 in 2013. BESCOCOM's initiative of replacement of existing copper chokes in fluorescent tube light fittings of BESCOCOM buildings by energy efficient electronic ballast has resulted in saving of energy of about 0.35 million units annually. Bengaluru is one of largest usage of rooftop solar water heaters in India. These heaters generate energy equivalent to 200 MW every day. Bengaluru is also the first city in the country to have introduced an incentive mechanism by providing a rebate of 50 paise per unit of electricity consumed for residents who have rooftop thermal systems installed. These systems have been made mandatory for all new structures. In respect of bulk Solar Water Heater installations, solar rebates are extended to each of the individual installations, provided, the minimum capacity of a Solar Water Heater is 100lt per household. Similarly, the Bengaluru Metropolitan Transport Corporation has taken the initiative of using bio- fuel from pongamiapinnata seeds in 25 buses of its fleet. In addition to this, the Doddaballapur Depot of KSRTC operates 81buses on a 90:10 ratio mix of diesel and pongamia oil. Bengaluru Metro Rail reduces energy consumption through traffic decongestion and fuel savings in the city of Bengaluru.

SMART 'E- TOILETS'

In view of the increasing demand and need for public toilets in Bengaluru, BBMP's initiative on installing e-toilets is welcome. Thee-toilets are designed state-of-the-art toilets; the striking feature of thee-toilet is that it flushes

automatically even if a person fails to flush and after five uses, the unit automatically cleans up the entire toilet. Intelligent fans and lights turn on and off with the entry and exit of the user. E-toilets are unique as it does not require manpower to maintain the toilets as the in-built technology takes care of it. To prevent damage and encroachment of public toilets, the e-Toilets are equipped with GPRS devices to alert the officials concerned in case of theft or trespassing. It is equipped with a Bio Membrane Reactor that helps recycle the water and reuse it for flushing and cleaning. Solar panels are available for alternate energy needs. In the areas where drainage tank facility is not available 'Delight' a Green Eco Friendly solution is provided to manage the waste and its disposal like the Bio Membrane tank system and the Water recycling unit.

In 2013, three e-toilets were launched in the city on a pilot basis and the BBMP plans to expand the services to other locations. BBMP is funding the project with a total cost of Rs. 4 crores and has engaged Eram Scientific Solutions Pvt Ltd, a Kerala based company to install e-toilets at 75 major locations of the city. Each e-toilet including civil works like sewage, water and power costs Rs. 5.0 lakhs. E-toilets are popular and are used by large number of users-street vendors, auto drivers and customers.

RAIN WATER HARVESTING INITIATIVE – A SMART INITIATIVE

Smart assets management will help address obstacles in the way to conserve and protect water. One such initiative is the RWH that has been made mandatory for households in Bengaluru city. The amended Act made rainwater harvesting compulsory for home and offices with an area of more than 2,400 sq. ft. in the heart of Bengaluru. The Bangalore Water Supply and Sewerage Board (BWSSB) (Amendment) Act passed in August 2009, states that every owner or occupier of a building having an area of 2,400 sq. ft. and above, or every owner who proposes to construct a building on an area of 1,200 sq. ft. and above, should install rainwater harvesting structures. So far, of the 60,000 buildings there with BWSSB water connections, more than 43,000 have adopted harvesting techniques (BWSSB 2013). Theme park, information and research centre on RWH have been established in co-ordination with BWSSB and KSCST which showcases RWH models. Major benefits include a compliance with the law, recharge of the aquifer and prevention of urban flooding (Manasi, Umamani, 2013).

Bengaluru's water demand from the river Cauvery located about 100 km away and 500 mts below, incurring huge financial costs has remained unfulfilled and the city still faces an acute shortage of water supply. Other ways to meet water demands especially from ground water sources also cannot fulfill the city's demand leaving the water sources depleted or polluted. Increasing bore wells both private and public have resulted in overexploitation of ground water. Besides, encroachments of tanks have affected the city's drainage system making urban flooding a serious concern. Bengaluru gets about 70 rainy days spread over the year and the drainage system can handle only 30mm of rainfall in one hour.

WASTE MANAGEMENT – SMART ECO INNOVATION

The problem of solid waste management in Bengaluru continues to grow exponentially. The production of solid waste is growing enormously and the Corporation's capacity to transport, dispose and treat waste has become a challenging task. Only a part of the ordinary solid waste is removed and treated completely. 'Daily Dump' is green entrepreneurship initiative that works towards managing compost locally at the household level. They design earthen pots to compost waste which can be used in gardening. Daily dump provides the technology, advice and service for households/institutions. Daily Dump provides business opportunities to people to network and contribute at various levels. Daily Dump customers keep away 14,589 kgs waste away from landfills turning it into valuable compost each day. This can be an interesting option for responsible citizenship and managing our city environs.

Toxic wastes are also a matter of serious concern in Bengaluru. Increased E-Waste, one of the recent outcomes of the IT boom, is seen as a major threat to the already deteriorating environment in Bengaluru. E- Waste pollution is one of the most serious management challenges in the recent times. As estimated by E-Parisara, Bengaluru generates 12,000 tonnes of E-waste per year. E-Parisara, the first formal e-waste recycling unit in India is spread over an area of 1.5 acre and established with a capital cost of 2.5 crores in 2005. E-waste at E-Parisara is derived from different kinds of electronic materials, especially computer components. Approximately 194 companies and three government sector firms have registered with E-Parisara. Once registered with E-Parisara, the institutions have to abide by certain terms and conditions. Its main aim is to work towards maximum material recovery, non-incineration, minimum power and water use and also minimum landfill (E-Parisara, 2014). There are more than 16 formal e-waste recycling units which are processing waste scientifically, however at various levels of expertise and registered with the Karnataka State Pollution Control Board. Still, there is a long way to go to ensure efficient management of e-waste scientifically.

GREEN BUILDINGS – SMART LIVING

Green Buildings are getting popular in Bengaluru with several projects initiated in the city with more than 15 residential projects and 14 commercial projects by reputed builders. They are eco-friendly structures that consume less energy during and post construction. Green buildings utilize less water, optimize energy efficiency, preserve natural resources, produce less waste and offer healthier spaces for occupants in contrast to conventional buildings. The building is assessed based on its predicted performance over its entire lifecycle. The Leadership in Energy and Environmental Design (LEED India) Green Building Rating System is a nationally and internationally accepted benchmark for the design, construction and operation of high performance green buildings. In India, Indian Green Building Council Green Homes is the first rating

programme developed exclusively for the residential sector. GRIHA- Green Rating for Integrated Habitat Assessment is another popular system for evaluation of green buildings.

CONCLUSION

Besides these various interesting initiatives taken up in Bengaluru city, it is important that the data be effectively converted to information that can aid further decision making processes to fine-tune the system. Some of the initiatives are yet to achieve its desired potential. Smart information and understanding will offer structures and tools to moderate situations that utilities have struggled to proactively address in the past. All these initiatives can bestow benefits that can be translated into economic benefits besides providing opportunities for green jobs in cities. There is a large scope for further learning from experiences of other cities within and outside India and to localise it to the city context.

1618 THE MOTIVATIONS OF SMART CITY PROJECTS

Tamás Dusek

Professor, Széchenyi István University, Győr, Hungary, 9026 Egyetem tér 1. dusekt@sze.hu

ABSTRACT

Smart city initiatives, plans, missions have mushroomed in every continent in recent years. These projects want to apply the information technology for improving the efficiency and quality of local services and for providing new services for the inhabitants, visitors and the entrepreneurs of the settlements, or more safety, leisure and less pollution. Areas of applications are manifold, such as transportation (vehicle routing, road pricing, parking systems, traffic patterns, congestion reduction, smart traffic lights and so on), mobile workforce enablement (city surveyors, park maintenance, inspectors, health and social services), energy (street lighting, building control, demand for electricity, energy theft detection), utilities (smart meters, field service, customer service, maintenance optimization and so on), healthcare (reduction of waiting times, forecast of visit and admission rates, real-time alerting, telemedicine and so on), education, security and others.

These projects have mainly positive impact from technological point of view (for example, more information, quality improvement, more safety is engendered). However, in the evaluation of the projects, the cost benefit analysis, the comparison of implementation and maintenance costs and the realization of benefits is either missing or use doubtful, questionable nonmonetary categories for benefits. Moreover, it typically neglects the displacement effect and opportunity costs, therefore systematically biased toward greater positive impacts. The dominant rhetoric and propaganda is strongly influenced by the big information technology companies, which set its sights on local governments as a huge, untapped market.

The paper deals with the reason and consequences of this situation, presenting some real and controversial cost benefit analysis and smart city projects. The main source of enthusiastic literature is the affected institution, company (in information technology industry), which is active in smart city and big data business and therefore interested to demonstrate large positive effects. Beside some useful and effective projects, there are smart city initiatives motivated by the self-advertisement of settlements, and/or by the biased proposals of big IT companies. The danger of this type of projects are the implementation of wasteful, low impact, costly, spectacular, prestige projects, which represent a form of detrimental rent seeking and income transfer instead of a real improvement in the quality of life. Only the minority of the local government can be supported by central governments in the frame of pilot projects grants, but the majority cannot, which system is equal with a spatial tax redistribution mechanism among local governments.

Keywords: smart city, cost benefit analysis, rent seeking, information technology

INTRODUCTION

Smart city became a key term or rather a buzzword in the city planning and city strategy literature, sometimes used parallel with digital city or intelligent city, in the same or similar meaning. Plethora of other phrases emphasize the technological side of the concept: telecity, urban cybernetics, informational city, knowledge-based city, wired city, virtual city, metered city, real-time city, smart urbanism and others. These terms, but most frequently the term smart city, are used by the researchers, planners, technocrats, public media, government administrators, politicians and IT (information technology) companies. In every continent, in every settlement size category, from the very small towns to the global megacities, more and more participants want to use more and more information technology and digital solutions, preferably not by the expense of their own budget, but by the expense of some outer sources, for example, grants and supports of the central governments.

Smart city projects became popular research topics, supported by both the interested cities and IT companies. The proportion of corporate research is unusually high in the area. Company materials, published not only in company propaganda materials (biased, subjective product descriptions by the IBM, Cisco, SAP, Intel, ABB, Siemens, Ericsson, Dunlop, Fujitsu, Google, Huawei, Hitachi, Microsoft, Oracle, General Electric for example), but in academical journals too, is quite common. Similarly, biased governmental marketing materials are also very frequent. These self-congratulatory materials focus mainly only to the technological side of the projects, without mentioning such issues as costs and economic efficiency, sustainability of developments, uneven spatial development, unfairness and injustice of high tech islands.

I think, an important element in the success and rapid spread of smart city programs is that policy makers and practitioners could create new jobs for themselves as a service class for implementing smart city projects. The risk of the projects is low: there are some improvement in something, which can be demonstrated, with forgetting to mention the costs and the possible alternative use of resources. The aim of this paper is to call attention to the neglected cost-benefit analysis of the smart city projects. While lots of complex indicators were suggested for the measuring of smartness of the cities (see for example Giffinger et al., 2007; Zygiaris, 2013; Lazaroiu-Roscia, 2012; Lombardi et al., 2012; Carli et al., 2013), the true efficiency measures, assessment of costs and benefits is not typical.

In ideal situation, every smart city projects, as public projects financed by the taxpayers, would have a public and accessible cost-benefit analysis. In this case the task of a researcher would be easy, just a meta-analysis should be conducted, demonstrating which type of projects are the most successful and efficient. Maybe, determining success and efficiency would be hard and problematic due to the character of this project, but at least there would be some results.

However, in the reality, the source of the problem is that only the very general and mostly technical features of the projects are publicly available, the most interesting and detailed cost elements are treated as business secrets. The only possible way to analyse of efficiency is the unique data gathering about the individual projects, which is often impossible due to the privacy matters. Therefore, this paper discusses mostly the conceptual problems of cost-benefit analysis of smart city projects.

TERMINOLOGY AND TYPICAL APPROACHES TO SMART CITY

The term smart city has been variously defined within the literature, but can broadly be divided into two distinct but related understandings as to what makes a city smart. The first approach stresses on the technological elements: sensors, cameras, digitalisation, big data, wireless technologies, applications, grids, buildings, infrastructures, networks system integration and so on. The second approach has an emphasis on the knowledge economy aspects, innovation and creativity. Local democracy, participation of citizens, quality of life plays also an important role in these definitions. The mix of the two approaches is also frequent, the stressing on synergies between new technology and social structure. These concepts are mainly positive, desirable, attractive. As many authors point out, the term is brilliant from the marketing point of view: smartness is a more user-friendly, positive term than the more elitist term intelligent (Nam-Pardo, 2011),

I do not want to give a new definition. Instead of this I collected some definitions, organized into Table 1, which shows the huge diversity. Most of the papers deal in the beginnings with the problem of the definition, moreover, there are papers, which deal only with this conceptual problem; see for example Allwinkle–Cruickshank, 2011; Albino et al, 2015; Mora et al, 2017.

Table 1 Definitions of smart city

Definition	Author(s)	Year
We believe a city to be smart when investments in human and social capital and traditional (transport) and modern (ICT) communication infrastructure fuel sustainable economic growth and a high quality of life, with a wise management of natural resources, through participatory governance.	Caragliu, A.; De Bo, C.; Nijkamp, P.	2011
A smart city infuses information into its physical infrastructure to improve conveniences, facilitate mobility, add efficiencies, conserve energy, improve the quality of air and water, identify problems and fix them quickly, recover rapidly from disasters, collect data to make better decisions, deploy resources effectively, and share data to enable collaboration across entities and domains.	Nam, T.; Pardo, T. A.	2011
A smart city is a well-defined geographical area, in which high technologies such as ICT, logistic, energy production, and so on, cooperate to create benefits for citizens in terms of well-being, inclusion and participation, environmental quality, intelligent development; it is governed by a well-defined pool of subjects, able to state the rules and policy for the city government and development.	Dameri, R. P.	2013
Smart cities are presented as the object of a wide range of technologically mediated practices of management at a distance, based on orchestrated assemblages of computerised systems that act as conduits for multiple crosscutting forms of data collection, transfer, and analysis. At their core, efforts towards smart cities thus imply a world of optimised ordering and regulation that relies fundamentally on the coding of social life into software	Klauser, F.; Paasche, T.; Söderström, O.	2012
Smart City is the product of Digital City combined with the Internet of Things.	Su, K.; Li, J.; Fu, H.	2011
A city that monitors and integrates conditions of all of its critical infrastructures, including roads, bridges, tunnels, rails, subways, airports, seaports, communications, water, power, even major buildings, can better optimize its resources, plan its preventive maintenance activities, and monitor security aspects while maximizing services to its citizens	Hall, P.	2000
Two main streams of research ideas: 1) smart cities should do everything related to governance and economy using new thinking paradigms and 2) smart cities are all about networks of sensors, smart devices, real-time data, and ICT integration in every aspect of human life.	Cretu, G. L.	2012
A Smart City is a city well performing in a forward-looking way in [...] six characteristics [...], built on the smart combination of endowments and activities of self-decisive, independent and aware citizens.	Giffinger, R.	2007
'Smart city' seems like a textbook example of an 'empty signifier' in urban planning; that is, a concept virtually void of any substantive meaning.	Haarstad, H.	2017

From technological point of view, the approach toward smart cities lies on a scale of which one endpoint is the technoutopian vision, the optimistic view of future, where all problems are solved by the help of technology. Sustainability, energy efficiency, infrastructure optimization, quality of life, social initiatives, e-government safety, security, intelligence, citizens are keywords in this enthusiastic literature. The other extremists have an anti-technology attitude, Smart city for them is equal with control of the society by the authorities and greedy corporations (Greenfield, 2013; Krivy, 2018). The starting point of both supporters and critics is often not the normal experiences of “ordinary” towns and cities, but the planned or semi-finished greenfield megaprojects of IT multinationals financed by the government (see some of them in Table 2), or the high-tech islands of megacities (such as Sao Paulo, Kuala Lumpur, Singapore).

TYPES OF SMART CITY PROJECTS FROM ECONOMIC POINT OF VIEW

Different typologies exist about the areas of smart city projects. The following list shows the wide array of categories:

- Transportation (vehicle routing, road pricing, parking systems, traffic patterns, congestion reduction, smart traffic lights and so on)
- Mobile workforce enablement (city surveyors, park maintenance, inspectors, health and social services)
- Energy (street lighting, building control, demand for electricity, energy theft detection)
- Utilities (smart meters, field service, customer service, maintenance optimization and so on)
- Healthcare (reduction of waiting times, forecast of visit and admission rates, real-time alerting, telemedicine and so on)
- Education, smart people
- Living lab
- Environment (environmental protection)
- Security
- Living conditions (cultural facilities, housing quality, touristic attractiveness)
- Governance (participation in decision making, transparency)

From the economic point of view, it is crucial, what is the cost and revenue impact of the project on the budget of the city. The wrong side of the projects, that each has some initial investment costs; the worse side, that almost every project has significant maintenance costs too. On the good side one can find rarely plus revenue. There can be new or better services, more safety, less pollution, energy saving, better process of urban governance. Cost restructuring can be dramatical: cost of information technology and the dependence of the city from IT company became much larger. The common features of these projects, that they are not profitable. It is not like Amazon, Uber or Airbnb, users of new technologies, which as profit oriented companies cannot be operated without revenues. Smart city projects can be maintained only by the support of local or central government.

The typical smart city project is financed by grants, supports of non-local authorities: regional government, central government, international government. For example, India's 100 Smart Cities Mission was prepared by the Government of India, Ministry of Urban Development in an amount US\$15 billion; Chinese National New-type Urbanisation plan, 2016-2020; The European Innovation Partnership on Smart Cities and Communities (EIP-SCC); JESSICA (Joint European Support for Sustainable Investment in City Areas) (European Commission); SMART (Singapore - MIT Alliance for Research and Technology); The White House Smart Cities Initiative; Smart Cities Plan of Australia, and others.

FINANCING OF THE SMART CITY PROJECTS

According to an estimation, the global market size of Smart city projects was USD 425 Billion in 2016 and is expected to grow to USD 1202 Billion by 2022 (marketsandmarkets.com). The exact market size cannot be given, but the important thing is that this is a huge and rapidly growing market for the IT companies. Therefore, IT companies have a vigorous lobby activity toward (local and central) government for projects, programs, and special privileges, grants, supports, benefits. This is a form of bad rents according to Tullock's terminology. Some local government is supported by central government, but the vast majority of them cannot, which means an unfair spatial tax redistribution among local governments. Thanks to these projects a new form of spatial inequality is created, not by the market mechanism, but by the forced spatial redistribution of incomes by the state.

As I already mentioned, it is very hard to find cost-benefit analysis of concrete project, and virtually impossible to find or get a detailed one. Of course, originally I wanted to present different real cost-benefit analyses, assumed that there are a lot of successful projects and some pointless prestige investments too. My data and information request to the public authorities was not successful until now. Informally I was enlightened that this is a sensitive area. Therefore I can present only partial examples with not too much information, published in business journals.

According to the president of General Electric and many other experts, streetlights will be the network for the future of connected cities. By connecting streetlights to the internet and embedding sensors in them, GE is working with cities to gain loads of new data on vehicle and pedestrian traffic along their roadways. Smart LED street lights are equipped with video monitors. The city can use the video monitors to track parking spaces in the city, and can launch new mobile app for residents to find the nearest parking spaces. Data from the video monitors is sent back to GE's Predix cloud platform, which applies detection algorithms that tell when a car parks in a space and when it leaves. GE has invested more than

USD\$1 billion in the platform, and is looking to open it up to developers to create new apps for smart city solutions (businessinsider.com). GE had two pilot projects, one in San Diego (California), the other in Jacksonville (Florida). San Diego has already deployed 4,000 smart LED street lights equipped with video monitors. The smart LED streetlights also provide better energy efficiency, the 4,000 deployed in San Diego are saving the city USD 250,000 annually on electricity. However, the investment cost of the project was USD 30 million; yearly maintenance cost was not publicized. Investment cost shows, that the project can never be profitable in economic terms. In Jacksonville the cost of intelligent LED conversion would be USD 50.1 million. However, before the realization of the project, in March 2017, the city abandoned the projects. The cost of standard LED conversion (which is also energy saving) is just USD 1.4 million – huge differences. “It is not clear exactly what discouraged Jacksonville from proceeding. The spokesperson declined to elaborate when LEDs asked if costs or operability stymied the smart lighting project, or whether Jacksonville was concerned with things like data protection, data ownership, privacy, and security. The spokesperson would only say that the city pulled the plug in early 2016 because it ‘had other priorities that took precedence.’ That’s hardly how Mayor Brown characterized the project at its kickoff, when he enthused, ‘This technology has the potential to transform how our city solves problems by allowing us to use the power of data to drive outcomes that give us flexibility, efficiency, and new, creative actions to enhance life in our city.’” (ledsmagazine.com)

CONCLUSION

The whole discussion about smart city projects has a very serious deficit, the almost total absence of economic reasoning. The biased rhetoric is shaped by the interested multinational information technology companies and government technocrats. Information technology solutions are treated almost as a free goods, investment and maintenance cost plays an unimportant element. As there will be more and more experiences about the success or failures of pilot projects, the problems of maintenance, the situation must be changed. The changing emphasis from technological to economical side would be favourable the sooner the better.

1158 IMPACTS OF MULTI-FUNCTIONALITY OF URBAN AGRICULTURE ON THE CREATIVE CLASSES IN GLOBAL MEGA CITIES: FOCUSING ON SHANGHAI MEGA REGION IN CHINA

Lily Kiminami¹, Shinichi Furuzawa¹ Akira Kiminami²

¹Niigata University

²The University of Tokyo

ABSTRACT

the purpose of this study is to clarify the relationship between multi-functionality of urban agriculture (MFUA) and the creative classes (CCs) through examining Shanghai mega region in China. Based on the existing researches in the fields of the CCs, MFA and social capital, we will firstly introduce spatial econometrics analysis on published statistical data of the cities in the Yangtze River Delta Economic Zone to clarify the effects of MFA on the utility of the CCs in these cities. Secondly, we will conduct structural equation modeling (SEM) based on the results from authors' original questionnaire survey targeting at the residents in Shanghai City to identify the perception formation process of the CCs (including those who are thinking creatively) towards MFA and lifestyle. Finally, policy implication for the sustainable development of cities by enhancing the impacts of multi-functionality of urban agriculture on the CCs will be derived from the analytical results.

Keywords: Multi-functionality of agriculture (MFA), Creative Class (CC), Social Capital (SC), Shanghai

1. INTRODUCTION

China's cities have enjoyed several decades of explosive growth. The country passed the 50% urbanization threshold in 2010, and the urbanization rate had already exceeded 54% by 2014. However, cross-national comparisons suggest that when countries pass a level of urbanization of around 50%, the relationship between urbanization and economic growth becomes less automatic and depends critically on how urbanization processes are managed.

Nowadays, creativity is considered to be one of the most important driving forces for the development of cities in so called "knowledge-based economy", although the global creativity index (GCI) for China was 0.462 (14th for technology; 87th for talent; 96th for tolerance) ranked as 62th among 139 countries and regions in the world (Florida et al., 2015). and Shanghai was ranked as the 74th among the 100 global sustainable cities³¹⁹ scored highest among all the mainland China cities on the people sub-index ranking in 2016.

On the other hand, multi-functionality of agriculture (MFA) composed of economic, environmental, and social aspects supplies not only food but also service such as environmental conservation, good scenery and farm experience etc. can also be one of the factors attract the creative classes (CCs) to reside in the region. However, these functions and relationships might have specific characteristics according to the context of countries and regions (cities), and might be changing in the processes of development of cities under the urban policy and planning such as the land taxation and zoning system. Although some researchers have started to pay attention to the relationship between regional factors attracting the CCs and multi-functionality of urban agriculture (Kiminami et al, 2018), they are far from sufficient, especially researches on the impacts of multi-functionality of urban agriculture on the creative classes in global mega cities are scarce.

Therefore, the purpose of this study is to clarify the relationship between multi-functionality of urban agriculture (MFUA) and the creative classes (CCs) through examining Shanghai mega region in China. Based on the existing researches in the fields of the CCs, MFA and social capital, we will firstly introduce spatial econometrics analysis on published statistical data of the cities in the Yangtze River Delta Economic Zone to clarify the effects of MFA on the utility of the CCs in these cities. Secondly, we will conduct structural equation modeling (SEM) based on the results from authors' original questionnaire survey targeting at the residents in Shanghai City to identify the perception formation process of the CCs (including those who are thinking creatively) towards MFA and lifestyle. Finally, policy implication for the sustainable development of cities by enhancing the impacts of multi-functionality of urban agriculture on the CCs will be derived from the analytical results.

2. A SELECTIVE LITERATURE REVIEW

2.1 Creative occupation or creative thinking?

Since focused by Florida (2002), the CCs who are engaged in the work of "creating meaningful new forms" classified into "super creative core" (the likes of scientists, technicians, university professors, poets, novelists, artists, entertainers, actors, designers and architects) and "creative professionals" (the likes of tech or finance workers, lawyers, doctors, managers and so forth) has been thought to be a key driving force for economic growth in the deindustrialized cities through innovation (Batabyal and Nijkamp, 2013).

However, the occupation classification on the CCs is not fixed, while Schoales (2006) included clothing and jewelry industry employees, Westlund and Calidoni (2014) used "High-Tech" industry employees. On the other hand, McGranahan and Wojan (2007) showed that some occupations in Florida's creative class don't have high creativity using

³¹⁹ See "Sustainable Cities Index 2016: Putting people at the heart of city sustainability", Arcadis.

“thinking creatively” element of 2004 O*NET content model. Moreover Kiminami et al. (2018) clarified that although a stronger positive correlation between thinking creatively and creative occupations comparing to other occupations was testified, “thinking creatively” was also found to be important in other occupations³²⁰. Therefore, it is thought to be necessary to grasp the creative class both from the views of “creative occupation” and “thinking creatively”.

On the other hand, studies on the CCs in large cities (Florida et al. 2008; Boschma and Fritsch 2009) clarified that the CCs were attracted by tolerance, university, consumer services, and openness of the regions. However, Marlet and van Woerkens (2005) argued that urban amenities, job opportunities and esthetics of cities attracted the CCs, but tolerance didn't do it in Netherland. Furthermore, the research on Hong Kong creative workers in Shanghai and Beijing by Chow (2017) clarified that the possibility of creating a job or project determined where they went implied that Florida's ideas on city attractiveness predominantly situated in the cities in Europe, the United States and Australia should be reserved critically as a reminder to policy-makers and urban planners in the Asian cities, particularly in Chinese cities (He et al. 2018). Nevertheless, researches on the CCs in China were generally followed with Florida's creative occupation so far (Rao and Dai, 2017).

2.2 Whether the CCs prefer multi-functionality of agriculture in mega cities?

Although many studies have pointed out the benefits of urban agriculture, including increased food access, job creation, educational opportunities, and green space, a focus on its social benefits has fed an association of urban agriculture with social justice. Reynolds (2015) argues that a failure to examine urban agriculture's role in either supporting or dismantling unjust structures may perpetuate an inequitable system based on the findings from a 2-year study of urban agriculture in New York City, which found race-and class-based disparities among practitioners citywide. Clearly, arguments for and against urban agriculture will always have a strong element of context specificity. However, in response to the massive population growth in developing world, new cities are being planned and built and existing cities drastically be modified, so the opportunity exists for urban agriculture to be included in food systems in an organized rather than reactionary manner (Hamilton et al. 2014).

The results from Kiminami and Kiminami (2006, 2007) on the awareness of urban residents regarding urban agriculture in Tokyo and Shanghai showed that residents' subjective impressions towards urban agriculture influence their consciousness of settlement in large cities. The study evaluated the multi-functionality of urban agriculture by showing that it enhances the quality of urban life and settlement of its residents. Furthermore, by using the authors' original questionnaire survey targeting at the residents in Tokyo, Kiminami et al. (2018) clarified that multi-functionality of urban agriculture was more preferred by the CCs, especially those who are thinking creatively across occupations have higher preference than others in the mega city.

2.3 Whether social capital (SC) matters for the CCs?

Which theory has stronger explanatory power among social capital (SC), human capital (HC) and creative class (CC) on regional economic development has been discussed for some years (Florida 2003; Hoyman and Faricy 2009), despite the debates on the question of how to define the core of these factors. Especially, there are arguments both for and against the role of Bonding SC in the regional economic development. Although Westlund and Calidoni (2014) could not find a clear impact of civil society on regional development from the empirical study on the relationship between the CCs and social capital in Japan, Rich (2012) pointed out that small cities attempting to achieve economic growth and population stability should focus on their strengths: city livability and the thick social ties that maintain communities. Furthermore, based on the questionnaire survey targeting at the residents in Tokyo, Kiminami et al. (2018) clarified that among the CCs who are “thinking creatively” also have a high level of social capital and are favorable to diversified lifestyles that is thought to contribute to the development of cities.

On the other hand, by using the data of 16,253 participants from 29 provinces/municipalities in China based on Labor-force Dynamics Survey (CLDS), Li (2017)'s results showed that the positive role of generalized trust in promoting success was less sensitive to the influence of societal residential mobility. In this study, we would like to testify the relationships among multi-functionality of urban agriculture (MFA), the CCs and social capital (SC) in Shanghai to make contributions to the debates on the issues.

3. THEORETICAL MODEL AND HYPOTHESES

In accordance with Kiminami and Kiminami (2006) and Kiminami et al. (2018), the multi-functionality of urban agriculture can be regarded as supply of private goods and public goods with externality. And, the utility function of the residents can be expressed as follows.

$$U = U(C, N, A, G, MFA) \cdot \cdot \cdot (1)$$

Here, U is the utility function of residents; C is consumer goods; N is housing service; A is pure amenity; G is public goods; MFA is multi-functionality of Urban Agriculture.

If the multi-functionality of urban agriculture is classified into three categories of economic function (EC), environmental function (EN) and social function (SO), the equation (1) can be expressed as follows.

³²⁰ See Table 3 in Kiminami et al. (2018) for detail.

$$U = U \{ C, N, A, G, MFA (EC, EN, SO) \} \dots (2)$$

When the utility functions of the CC (creative class) and non-CC are UC and UN respectively, and the multi-functionality of urban agriculture has a positive influence on the utility of residents, we obtain the following conditional expression.

$$\partial UC / \partial MFA > 0 \dots (3a)$$

$$\partial UN / \partial MFA > 0 \dots (3b)$$

Population growth rate will increase in the areas where the level of multi-functionality of urban agriculture demanded by residents is high under the assumption that the mobility cost among regions is zero. Furthermore, if the CCs prefer multi-functionality of agriculture more than non-CC, we obtain the following formula from the utility function.

$$\partial UC / \partial MFA > \partial UN / \partial MFA \dots (4)$$

Then the increase rate of CC is higher than that of non-CC in the region where the level of multi-functionality of urban agriculture demanded by residents is high.

To clarify the relationship between the multi-functionality of urban agriculture and the CCs in the development of cities, the analytical framework of our research is shown in Figure 1 and the following hypotheses are put forth.

H1: Multi-functionality of urban agriculture (MFA) has a positive influence on the utility of the CCs.

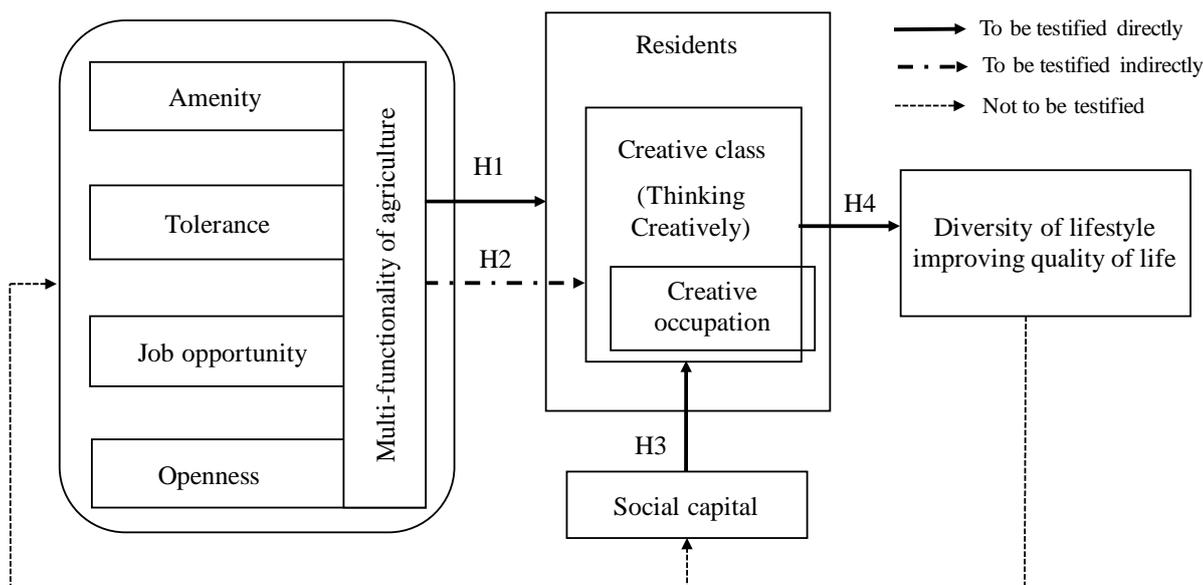

H2: The CCs prefer MFA more than that of non-CC.

Furthermore, based on the discussion on the relationship between CC and SC in the regional development in the previous section and Kiminami et al. (2018), we add the following hypotheses to make contribution to this issue.

H3: The CCs have a high level of social capital as well.

H4: The CCs prefer diversified lifestyles and contribute to the development of cities.

In the following, we will firstly verify the hypothesis H1 through space metric analysis on published statistical data of the cities in the Yangtze River Delta Economic Zone, and next verify the hypotheses H2, H3 and H4 through the analysis on the results from questionnaire survey targeting at the residents of Shanghai in Section 4.

Figure 1. Analytical framework of this study

4. EMPIRICAL ANALYSIS

4.1 Target areas

The target areas in the analysis are centered on Shanghai mega region. The cities in the Yangtze River Delta Economic Zone (Figure 2) including Shanghai City, Jiangsu province, Zhejiang province and Anhui province accounts for 16.1% of China's total population and 22.6% of GDP in 2010. In the economic zone, the mega city Shanghai is the largest city and its population growth rate and CC growth rate are the highest from 2000 to 2010, and its CC rate in 2010 is also the second highest after Beijing City in the whole country. Therefore, the mega city Shanghai and the its enlarged Yangtze River Delta Economic Zone (YRDEZ) is one of the most dynamic regions in the country.

Growth rate of population CC (2010)	GP	Growth rate of total population (%)	PC	
	CC2010	Ratio of CC in total number of employed person (%) in 2010	PC	
Independent variables				
Urbanization	Population Density	PD	Population density (person / km ²)	PC
Amenity	Nature	PPAGREEN	Area of park green space per person (m ² /person)	CSY
	Culture	PTHEATER	The number of theater and cinema per population (number/million person)	CSY
Food Education		PCHEF	Ratio of chef in total number of employed person (%)	PC
		EDUC	The average year of education (years)	PC
House		HOUSE_AME	Ratio of house with water supply facility in total number of house (%)	PC
	Minority	MINORITY	Ratio of ethnic minority in total number of population (%)	PC
MFA	Economy	ECO	Output value of agriculture (excluding livestock) / Total sown area (million yuan/ha)	AC
Environment		ENV	Ratio of village with treatment facility of livestock manure in total number of village with livestock concentrated area (%)	AC
	Sociality (Tourism)	SOC_T	The number of village with farm household accommodation in the total number of village (%)	AC
Sociality (Job)		SOC_J	The number of employed person in the primary industry / Total sown area (person / 1,000 ha)	AC
	CC	CC2000	Ratio of CC in total number of employed person (%) in 2000	PC

Notes: District level data in Shanghai city and city level data in other three provinces are used.

The nine wards in the central part of Shanghai where agriculture related data cannot be obtained are excluded from the sample. Professional and technical workers who used as CCs are those who are classified into the occupational classification 206-219 (medium classification).

Observations		50	9	13	11	17	

As shown by Table 3, the presence or absence of spatial autocorrelation was checked on four variables of CC, GCC (CC rate), DGCC (CC increase rate minus non-CC increase rate) and GP (the growth rate of population), and Moran's I was calculated as well. Due to a positive spatial autocorrelation was confirmed for the three variables of GCC, CC, GP, spatial error model was used for the estimations in our analysis.

Table 3. Results of Spatial Auto-correlation (Moran's I)

4.2.2 Results of estimation

Two models of Basic Model and MFA Model (by adding variables of multi-functionality of urban agriculture to basic model) were estimated as shown in Table 4. In order for our object to clarify the relationships between multi-functionality of urban agriculture and CC, we will analyze the results based on MFA model in the following.

First, the significance of the whole model was confirmed in all three estimations except for DGCC and the sign of the explanatory variables and the significance were generally in agreement with the theoretical prediction except for some explanatory variables. It was confirmed that there was a positive correlation between population density (PD), GCC (growth rate of CC), CC2010 (population of CC in 2010) and DGCC (GCC – Growth rate of non-CC) but a negative correlation with GP (growth rate of population). As for the amenity of cities, the statistical significance of the variables for the amenities of nature, food, education and living were all confirmed, and the statistical significance of minority variables for the tolerance of the cities was also confirmed in GCC with a positive correlation.

Next, the variables of multi-functionality of urban agriculture in the estimations were confirmed as follows.

-A positive correlation of economic indicators (ECO) with GCC and GP was confirmed.

-A positive correlation of environmental index (ENV) with GCC and GP, and a negative correlation of it with CC2010 was confirmed.

-A positive correlation of social indicators (SCO) with CC and DGCC, and a negative correlation of it with GP was confirmed for tourism but no significant results for employment.

Furthermore, a positive correlation of CC2000 (the ratio of CC in the population in 2000) with GP (the population growth rate) was confirmed.

Therefore, our hypothesis of “Multi-functionality of urban agriculture (MFA) has a positive influence on the utility of the CCs” (H1) was verified in the case of YREB (among the MFA, a higher level of economic efficiency and a more environment-friendly urban agriculture were positive to a higher rate of growth in the CCs were clarified). On the other hand, a higher level of social function positively influence the ratio of the CCs was consistent with the results of questionnaire survey in the next part, but a higher level of environmental function negatively influence the ratio of the CCs could be explained that the degree of controlled negative externality as non-commodity outputs of livestock farming has greater influence on non-CC than CC.

4.3 Results of the structural equation modeling (SEM)

4.3.1 Basic outline of the questionnaire survey and variable setting

In order to verify our hypotheses of “The CCs prefer MFA more than that of non-CC”(H2), “The CCs have a high level of social capital as well” (H3) and “The CCs prefer diversified lifestyles and contribute to the development of cities” (H4), we carried out a questionnaire survey targeting at the residents in Shanghai. Internet usage survey was conducted on January 24-27, 2018 through Macromill Co., Ltd. The number of collected samples is 1029. To clarify the different influences between creative occupation (CC) and non-CC on the results of answer, the condition of assignment including “managers and executives”, “professionals/technical workers”, and “company officers who are neither manager nor professional or technical work” are equally allocated.

Table 5 shows the profile of respondents in the questionnaire survey. The results of population census on the distribution of male-female ratio and age hierarchy in 2010 are shown in parentheses. It is obvious that survey respondents are

almost equal to population census in terms of gender ratio, but in terms of age “30 - 39 years old” accounted for the largest and about half while in other age groups the proportion of respondents was small though the percentage of responses of “40 to 49 years old” almost agree with each other.

As for creative thinking, 44.2% is “very important”, followed by 38.9% “extremely employing” and 14.0% “important”. Furthermore, as shown in Table 6, thinking creatively is also considered to be important in non-professional/technical worker although there is a stronger positive correlation between creative occupation (CO) and thinking creatively (TC).

Table 5. Socio-economic attributes and basic results of the questionnaire (%)

	Item	Distribution of the ratio of respondents					
		Male	Female	Total			
Socio-economic attributes	Sex	50.7 (57.1)	49.3 (42.9)	100.0 (100.0)			
		18-19	20-29	30-39	40-49		
	Age (years old)	1.1	18.0 (26.1)	47.1 (20.3)	18.3 (18.5)		
		-	50-59	60-69	70 and above	Total	
		9.6 (17.7)	5.7 (9.1)	0.2 (8.4)	100.0 (100.0)		
	Household income (1,000 yuan)	< 10	10 to <12	12 to < 14	14 to < 16	16 to < 18	
		1.5	2.7	4.7	7.1	7.4	
		18 to < 20	20 to < 30	30 to < 40	40 and above	Don't Know	Total
		12.6	25.8	19.7	18.5	0.1	100.0
	Farmland	There is a lot	There is a bit	There is not much	There is not any	Total	
12.0		40.5	36.2	11.4	100.0		
Creative class	Occupation	Executive in a company	Professional / technical worker	The other worker	Total		
		33.3	33.3	33.3	100.0		
	Thinking creatively	Extremely important	Very important	Important	Somewhat important	Not important	Total
		38.9	44.2	14.0	2.7	0.2	100.0

Notes: The value in parenthesis of sex item indicates the ratio calculated from the *Population Census 2010* (the age of 20 and above: Shanghai).

The value in parenthesis of age item indicates the ratio calculated from the *Population Census: 2010* (the age of 20 and above: Shanghai).

Null hypotheses that ‘the ratio of the response by the questionnaire survey is equivalent to the ratio calculated from a population’ was not rejected in sex ratio and was rejected in the age structure as a result of the test of the goodness of fit.

Sex ratio: Chi-square = 0.148 (p-value =0.701)

Age structure: Chi-square = 527.508 (p-value =0.000)

Table 6. Occupational CC and Thinking Creatively

		Total	Executives in a company	Professional /technical worker	Non-professional/technical worker

	Somewhat important (1)	2.7	2.0	2.0	4.1
	Not important (0)	0.2	0.0	0.3	0.3
Average score (0-4)		3.19	3.37	3.24	2.95

4.3.2 Results of the structural equation modeling (SEM)

Here, we apply the covariance structure analysis to the results obtained from the questionnaire survey to clarify the formation process of the relationships among the multi-functionality of urban agriculture, social capital, and the diversity of lifestyle.

Table 7 summarizes the basic statistics of variables used for SEM. Variables of socioeconomic attributes and farmland existence are set for layer 1, variables of CC and social capital (SC) are set for layer 2 and variables relating to diversity of lifestyle and multi-functionality of urban agriculture (MFA) are set for layer 3. Detailed information on the variable setting concerning multi-functionality of urban agriculture, social capital, and diversity of lifestyle is shown in Appendix.

In the estimation, correlation of error term of each variable in layer 1, layer 2 and layer 3 is assumed. Also, estimation method of Maximum-likelihood with missing value is used because there are missing variables for household income among socioeconomic attributes. In the following, we will testify three models (creative occupation, thinking creatively, and twin analysis) for analysis.

Table 7. Descriptive statistics of variables

Variables	Layer	Number. of Obs.	Average	S.D.	Min.	Max.	
Socio-economic attributes	Sex	(1)	1,029	0.51	0.50	0.00	1.00
	Age	(1)	1,029	2.35	1.10	0.00	6.00
	Household Income	(1)	1,028	5.67	1.96	0.00	8.00
Farmland	(1)	1,029	1.53	0.85	0.00	3.00	
Creative class	Creative thinking	(2)	1,029	3.19	0.79	0.00	4.00
	Executive	(2)	1,029	0.33	0.47	0.00	1.00
	Prof./Tech. worker	(2)	1,029	0.33	0.47	0.00	1.00
Social capital	(2)	1,029	1.58	0.68	0.00	2.00	
Diversity of lifestyle	Self-actualization(high-low)	(3)	1,029	0.98	0.58	0.04	3.55
	Self-investment(high-low)	(3)	1,029	0.06	0.46	-1.04	1.51
	Altruism (low-high)	(3)	1,029	-0.03	0.41	-1.24	1.47
Multi-functionality of agriculture	Economic function	(3)	1,029	0.63	0.68	0.00	2.00
	Environmental function	(3)	1,029	0.93	0.71	0.00	2.00
	Social function	(3)	1,029	2.27	1.51	0.00	8.00

Notes: Details of each variable are as follows. Values in parentheses are given when applicable.

Sex: Male (1), Female (0)

Age: 18-19(0), 20-29 (1), 30-39(2), 40-49(3), 50-59(4), 60-69(5), 70 years old and above(6)

Income: < 10 (0), 10 to < 12 (1), 12 to < 14 (2), 14 to < 16 (3), 16 to < 18 (4), 18 to < 20 (5), 20 to < 30 (6), 30 to < 40 (7), 40 thousand yuan above (8)

Farmland: There is a lot (3); There is a bit (2); There is not much (1); There is not any (0)

Thinking Creatively: Extremely important (4); Very important (3); Important (2); Somewhat important (1); Not important (0)

Executive: Executive in a company (1); Others (0)

Professional/technical worker: Professional/technical worker (1); Others (0)

Model of creative occupation

Figure 3 and Table 8 are the path diagram and path coefficient obtained from the result of covariance structure analysis for the model of creative occupation. The main goodness of fit indicator is Chi 2 (7) = 437.210 (p-value: 0.000), RMSEA = 0.244, CFI = 0.735 which is a good result. According to the analysis results, the formation process of consciousness about the diversity of lifestyle such as the types of “Self-actualization”, “Self-investment” and “Altruism” is complicatedly influenced by occupation, social capital, socioeconomic attributes, farm land, evaluation on multifunctional function of urban agriculture. Below we will look at the items that were significant at 1% level.

First, for socioeconomic attributes, “gender (+)”, “age (+)” and “income (+)” have positive correlation with “executive” but age has negative correlation with “professional and technical workers” and “self-investment”, which clearly presented the image that creative occupations in Shanghai with the aged, high income and male “executive” on one side, and younger “professional/technical worker” who prefer the lifestyle of “self-actualization” and the environmental and social functions of urban agriculture on the other. However, it is also clarified that women prefer the lifestyle of “self-actualization” and social function of urban agriculture than man and young people prefer “self-investment” than elderly one in Shanghai.

Next, neither correlation between “creative occupation” and “social capital”, nor variables of socioeconomic attributes affecting “social capital” was confirmed in the model, though those who have high level of social capital prefer the lifestyle of “self-actualization” and environmental function of urban agriculture was confirmed. Subsequently, regarding the relationship between the diversity of lifestyle and the multi- functionality of urban agriculture in layer 3, “self-actualization” was positively correlated with all dimensions of MFA and “altruism” was negatively correlated with social function, but there was no confirmed correlation with self-investment. However, looking at the factors affecting the diversity of lifestyle in layer 2, only “professional/technical worker” in creative occupation and those who have higher level of “social capital” prefer the lifestyle of “self-actualization”. Furthermore, among creative occupations, professional/technical workers and those who have higher level of social capital prefer environmental and social functions while those who are living in the place with more farm land prefer economic function of urban agriculture.

Model of Thinking Creatively

Figure 4 and Table 9 are the path diagram and path coefficient obtained from the result of covariance structure analysis on the model of thinking creatively. The main goodness of fit indicator is Chi 2 (6) = 139.678 (p-value: 0.000), RMSEA = 0.147, CFI = 0.860, which is a good result.

Initially, the factors that influence “thinking creatively” are the such as “income (+)” and “farmland ()” among social economic attributes. Next, regarding the relationship between “thinking creatively” and “social capital”, a positive correlation was confirmed according to the result of assuming covariance of error terms. Subsequently, the relationships between diversity of the lifestyle and multi-functionality of urban agriculture were almost similar to the model of creative occupation. Furthermore, it is clarified that those who are “thinking creatively” positively evaluate the social function of MFA and prefer the lifestyle of “self-actualization”, and those who have higher level of “social capital” positively evaluate the environmental function of MFA. In addition, those who are living in the place with more farmland prefer more economic function of urban agriculture.

Twin Analysis (Creative occupation and Thinking Creatively)

Figure 5 and Table 10 are the path diagram and path coefficient obtained from the result of covariance structure analysis on the twin model. The main goodness of fit indicator is Chi2(7)=434.21(p-value: 0.000), RMSEA=0.244、CFI=0.751, which is a good result. According to the analysis results, the formation process of consciousness about the diversity of lifestyle and multi-functionality of urban agriculture in Shanghai is clarified as below.

First, as for the effective socioeconomic attributes on the creative occupations and thinking creatively, sex, age and income were positive for the executive, but age was negative for professional and technical workers while income and farmland were positive for thinking creatively. Therefore, the characteristics of CCs in Shanghai could be described as follows. They are aged men with high income executives and young professional and technical workers for occupational CC on one side, and high income of living in the place with more farmland for thinking creatively on the other.

Next, although there are positive correlations among executive, professional/technical worker and thinking creatively, the executives don't prefer MFA and give negative evaluation on social function while the young professionals prefer environmental function and those who are thinking creatively with higher level of social capital prefer social function.

Furthermore, there are positive correlations among lifestyles and MFA, especially the lifestyle of self-actualization is positive to all the functions of urban agriculture while altruism is positive to social function.

Finally, it is interesting that the CCs in Shanghai (both creative occupation and thinking creatively) prefer the same lifestyle of self-actualization which is quite different from the result of our survey on Tokyo. Additionally, women in Shanghai prefer self-actualization and social function of urban agriculture than men, and younger prefer the lifestyle of self-investment than elder are clarified as well.

Table 11 summarizes the results of questioning about what items of the MFA are important or not, and what items they are enjoying about. It is clarified that the items thought to be important are also the items to be enjoyed about, although there are 4.8% responded “No function seemed important” and 5.4% responded “I don’t enjoy any role of urban agriculture” among the respondents.

Table 11. Importance and Enjoyment about Functions of Urban Agriculture (Ratio of response: %)

	Important (A)	Enjoyment (B)	(A)-(B)
Supply of fresh and safe agricultural and livestock products	47.5	41.4	6.0
Providing the employment	56.6	26.2	30.4
Conservation of the green and environment	93.8	50.7	43.1
Education functions such as farming experience and food education	51.0	24.8	26.2
Revitalization of regional industry	55.4	24.2	31.1
Disaster prevention function such as evacuation place in case of disaster	42.9	18.6	24.2
Making a life tasteful and peaceful	63.0	33.2	29.8
Succession of local tradition and culture	45.4	24.6	20.8
Formation of good scenery	54.3	31.6	22.7
Place for local community	35.4	19.5	15.9
Medical and welfare functions such as horticulture therapy	29.7	15.2	14.5
Place of familiar recreation	21.4	9.2	12.2
Other	0.1	0.0	0.1
No function seemed important (I don’t enjoy any role of urban agriculture)	4.8	5.4	-0.5

Note: The bold emphasizes are added to the top three items with the largest point in each column. Respondents where there isn’t any farmland of urban agriculture in their residence are excluded.

5. CONCLUDING REMARKS

The above-mentioned analytical results clarified that our hypothesis of “Multi-functionality of urban agriculture (MFA) has a positive influence on the utility of the CCs” (H1) was verified in the case of Shanghai mega region. “The CCs prefer MFA more than non-CC” (H2) was verified in the case of Shanghai City. Additionally, “The CCs (especially those who are young professional/ technical workers) prefer the social and environmental functions of urban agriculture more than others” was also verified as a complementary hypothesis (H2-a). Furthermore, our hypothesis of “The CCs have a high level of social capital as well” (H3) was verified besides “those who have high level of social capital prefer the environmental function of urban agriculture” was verified as a complementary hypothesis (H3-a). Although, our hypothesis of “The CCs prefer diversified lifestyles and contribute to the development of cities” (H4) could not be verified directly in the case of Shanghai City because all the CCs (including creative occupation and thinking creatively) prefer the same lifestyle of ‘self-actualization’. However, women evaluate social function of MFA and prefer the lifestyle of “Altruism” than men, and the younger prefer self-investment than the elder in Shanghai were also clarified from the results.

Although, urbanization in China was long underpinned by cheap labor, cheap land, the underpricing of environmental externalities and rising export demand, Chinese policy makers recently have therefore begun to place greater emphasis

on domestic consumption, efficient resource use and productivity in order to shift to a new model of urbanization so called “people-centered urbanization” (OECD, 2015). Therefore, policy implication from this research encourages the city leaders to pay more attention to the multi-functionality of urban agriculture in order to realize an efficient, inclusive and sustainable urbanization (The World Bank, 2014).

However, a uniform policy for improving MFA without considering the regional diversification might bring on the results of the concentration of the CCs in urban central areas and the declination in suburban areas under the circumstance of globalization as pointed out by the existing research on Tokyo (Kiminami et al. 2018), because the economic advantage of agriculture in land endowment in suburban areas comparing to that in urban central areas has obviously resulted in a decrease of the CCs in there. To lead to a more universally applied study, international comparative study will be taken into account in our next research agenda.

ACKNOWLEDGEMENTS

This study was supported by JSPS KAKENHI Grant Number 17K07989 (study on the creativity of cities through improving agriculture amenity: comparative analysis between Japan and China), 15K18750 (study on the entrepreneurship of social business in rural and agricultural sector). We wish to express our gratitude for the support.

APPENDIX

Diversity of lifestyle

Table 12 is the results of principal component analysis about the answer of “Please select all that apply as your ideal life”. In order to compare with the results in Tokyo (the same questions in Japanese), we used the data obtained by summing

the two survey results. The cumulative contribution rate of eigenvalue that is 1st, 2nd and 3rd principal component is 28.7%. When interpreting each principal component based on the principal component score, the first principal component is “self-actualization type (high - low)”, the second principal component is “self-investment type (high - low)”, the 3rd principal component is “altruism (low - high)”.

Table 12. Results of the principal component analysis about the ideal life style

		Ratio of response (%)			PC1	PC2	PC3
		Total	Tokyo	Shanghai			
1	Living while enjoying comfortable living space in the suburbs with moderate convenience.	36.1	35.3	36.9	0.257	-0.184	0.308
2	Living while being surrounded by nature in rural areas and countryside.	22.0	14.2	29.7	0.220	-0.356	0.154
3	Living while enjoying various activities in urban areas with high convenience.	27.7	24.8	30.7	0.186	0.452	-0.117
4	Living a life to be devoted to a hobby while working.	43.4	42.0	44.8	0.303	0.053	0.167
5	Living a simple life with having less things as much as possible.	24.6	27.1	22.2	0.179	-0.135	0.073
6	Living a life to be devoted to a hobby while working.	33.3	33.4	33.2	0.290	-0.151	0.219
7	Living a highest convenient life using IT apparatus and service.	22.3	15.7	28.8	0.135	0.405	-0.093
8	Living and working in abroad for a long time.	9.1	12.1	6.0	0.122	0.316	0.380
9	Addressing energy-saving, recycling and other environmentally-friendly life and activity	29.3	12.1	46.5	0.361	-0.158	-0.402
10	Addressing activities that contribute to society such as a volunteer.	20.5	8.9	32.0	0.350	-0.179	-0.304
11	Building family life with bearing housework and childcare regardless of gender.	27.4	18.5	36.2	0.393	-0.077	-0.155
12	Doing the work that can be only done by oneself utilizing one's skill and sense.	31.6	27.9	35.4	0.210	0.282	0.068
13	Enjoying various art works such as fine art and architecture.	23.5	17.2	29.7	0.336	0.152	-0.024
14	Spending one's time on what one likes by retiring work before one's retirement age.	18.3	19.1	17.4	0.181	-0.012	0.443
15	Devoting oneself to work for promotion in one's company.	13.9	8.5	19.3	0.105	0.261	-0.336
16	Living a life in a luxurious house, wearing high grade jewelry and brand goods.	7.0	5.2	8.9	0.044	0.308	0.203
Number of items selected (average)		3.90	3.23	4.58			
Eigenvalue					1.895	1.438	1.252
Ratio of accumulated contribution					11.84	20.83	28.66
Interpretation of each component					Self-actualization	Self-investment	Altruism

Notes: The sentence of the question is “Please choose all that apply as your ideal living.” The answer of “Other” is not used in the analysis.

Importance of multifaceted function of urban agriculture

Table 13 shows the result of classifying the item of multi-functionality of urban agriculture into economic, environmental, and social categories based on the answers to the role they think about in their urban life. The simple accumulation value of each selection item is sued as a variable.

Table 13. Classification of multi-functionality of agriculture

		Ratio of response (%)	Economic function	Environmental function	Social function
1	Supply of fresh and safe agricultural and livestock products	60.4			✓
2	Providing the employment	31.9	✓		
3	Conservation of the green and environment	63.3		✓	
4	Education functions such as farming experience and food education	38.1			✓
5	Revitalization of regional industry	41.4	✓		
6	Disaster prevention function such as evacuation place in case of disaster	28.4			✓
7	Making a life tasteful and peaceful	41.8			✓
8	Succession of local tradition and culture	32.8			✓
9	Formation of good scenery	41.7		✓	
10	Place for local community	30.9			✓
11	Medical and welfare functions such as horticulture therapy	32.8			✓
12	Place of familiar recreation	28.5			✓
	Total		2	2	8

Notes: The sentence of the question is “It is told that urban agriculture has various role for urban life. Please choose all that you think to be important from the roles of urban agriculture below.” The answers of “Other” and “No function seemed important” are not used in the classification.

Social Capital

Table 14 shows the results concerning the social capita (SC) and its variable creation. The answer of "Most people try to be helpful" in Q2 and "Most people can be trusted" in Q3 are judged to have social capital and used as a variable.

Table 14. Results concerning the social capital

Question	Answer	Ration of response (%)	Social capital
Q2. Would you say that most of time, people try to be helpful, or that they are mostly just looking out for themselves?	Try to be helpful	80.8	✓
	Look out for themselves	19.2	
Q3. Generally speaking, would you say that most people can be trusted or that you had better to be careful in dealing with people?	Can be trusted	77.6	✓
	Had better to be careful	22.4	
	Total		2

ABSTRACT

Since the early 1990s, the number of nongovernmental organizations (NGOs) has been growing rapidly in Nepal but Nepal remains a very poor country. In examining the distribution of NGOs, this study finds that districts with higher poverty levels have fewer local NGOs. Although NGOs play an important role in poverty reduction, poverty itself limits their growth in various districts in Nepal. While local NGOs provide an important contribution to the margin of poverty reduction, they alone cannot engineer national poverty reduction. This paper suggests that the Government of Nepal expand its poverty reduction program, streamline foreign aid and infrastructure development, but continue to attract both national and international NGOs for help in reducing poverty.

Keywords: poverty, nongovernmental organizations, two-stage least-squares regression, Nepal

1 INTRODUCTION

This is a preliminary study of the distribution of nongovernmental organizations (NGOs) and poverty in Nepal. As such it is limited in scope and exploratory in nature but some associations are identified that may be helpful to local authorities in managing these internal and external resources in regard to their contribution to poverty reduction.

NGOs as service providers, innovators, collaborators, activists, advocates, and change agents, are capable of positively transforming a society (see Korten, 1987; Price, 1998; van Tuijl, 1999; Mitlin, Hickey, & Bebbington, 2007; Werker & Ahmed, 2008). NGOs contribute to various sectors including health care, education, farming, and sanitation and their number is also dramatically increasing (see Werker & Ahmed, 2008). Overall, they have been extremely beneficial, but not free from criticism. For instance, Hearn (2007, 1102) noted that “husband- and-wife NGOs” or “briefcase NGOs” are often self-serving and even fake; Nega & Schneider (2014) found that NGOs are unable to contribute to development because of various factors, such as their inability to promote certain kind of changes and that they sometimes support corrupt dictatorships; and Banks, Hulme, & Edwards (2015) suggested that NGOs have not been able to adopt new tools and approaches that are necessary for reducing poverty and inequality.

The number of NGOs affiliated with the Social Welfare Council (SWC), Government of Nepal (GoN) has been increasing since the early 1990s (SWC, 2015a) and poverty is declining. In spite of this positive trend there are people and regions that continue to suffer even in areas directly affected by these organizations (GoN & United Nations Country Team of Nepal, 2013; Poverty Alleviation Fund, 2015; Mitra, 2016). Since NGOs are playing an important and significant role in poverty reduction in Nepal, this paper proposes to examine the relationship between the number of NGOs and poverty at the district level.

The rest of the paper is arranged in the following manner. Section 2 provides an overall introduction to NGOs in Nepal and introduces the research issue. Methodology and data are discussed in Section 3 and empirical findings are presented in Section 4. Section 5 includes concluding remarks, policy recommendations, and the direction of future research.

2 NONGOVERNMENTAL ORGANIZATIONS IN NEPAL

The linkages between NGO's and poverty alleviation strategies are multi-faceted. They include support for minimum levels of health, shelter, nutrition and safety that need to be met in order for people to function effectively. They extend to helping with human capital development including literacy, numeracy and skill development. They are important on the output side in helping with participation in the market economy. This includes access to finance and micro- finance and development of productive skills that generate products and crafts that can be marketed thus creating remunerations can flow back into the community. They also include groups that help with institution building including local empowerment to ensure that individual and community needs are articulated and communicate to the government and ensuring that the government responds appropriately. It is often thought that NGO's can help deliver these support activities more efficiency and effectively than over stretched and often politicized government agencies. In this way NGO's often expand or complement government programs in these areas.

Further NGO's provide access to new resources to help support these critical areas of service delivery and institution building. Last but not least, they are often important in addressing issues of crime and corruption as well as reducing or ameliorating victimization. The result is a wide variety of NGO's with different short term purposes and aims but all clearly related directly and indirectly to the huge problem of poverty alleviation. It seems reasonable to expect NGO's are located close to their clients so that their contributions will directly impact poverty reduction.

The emergence and growth of civic institutions in Nepal has been attributed to its religious, social, cultural, economic, and political constructs. From the nation's early period to mid-20th century, local entities, such as *Arya Samaj* (civic society), *Nepal Nagrik Adhikar Samiti* (Committee for Citizens' Rights), and *Paropakar Sansthan* (Charity Association), took active roles in fighting against prejudice, inspiring public consciousness, demanding political freedom, and improving public life (Dahal, 2001).

In the 1960s and 1970s, welfare-oriented NGOs, such as the Family Planning Association of Nepal, Nepal Red Cross Society, and National Anti-Tuberculosis Association, had already started operating on a national scale through regional frameworks (Ghimire, 2003). In addition, various regulatory frameworks, such as the *Society Registration Act of 1960*, *Association Registration Act of 1977*, and *Social Service National Coordination Council Act of 1977*, were adopted to streamline the activities and legitimize the participative involvement of the Third Sector in economic development (see Dahal, 2001; Uprety, 2011).

During the absolute monarchical Panchayat era, Queen consort Aishwarya was the patron of the Social Welfare Coordination Council (SWCC). At that time there were less than 250 NGOs registered with the central government. According to Whelpton (2005), NGOs of this period behaved more like consulting companies instead of advocacy bodies, which was commonly observed in the West. The international donor agencies often by passed government and cooperated directly with the NGOs in the development process. Some NGOs were more advocacy-oriented. Basnet (2012) noted that some not-for-profit organizations, such as the Human Rights Organizations of Nepal and Forum for Protection of Human Rights, played an important role in coercing the monocratic government to adopt human rights measures. Such organizations also contributed to the political movement that ended the Panchayat regime and established a multiparty democratic system with a constitutional monarchy in 1990.

The new political milieu created an environment conducive to the growth of NGOs. The *Social Welfare Council Act of 1992* was promulgated to repeal the *Social Service National Co-ordination Council Act of 1977* and to dissolve the SWCC. Under the provision of the Act of 1992 the SWC was created and made responsible for coordinating, cooperating, mobilizing, and promoting social organizations and institutions. The *Cooperatives Act of 1992*, *Forest Act of 1993*, *Local Self-governance Act of 1999*, and *Good Governance Act of 2007* were also enacted to further the role of NGO's as cooperatives, community user groups, ethnic and indigenous communities, and to support civil society participation in Nepal's development (see Uprety, 2011).

Since 1990, NGOs in Nepal have assumed these various roles to support a wide range of activities. For instance, Bhatta (2001) noted that many NGOs often act as intermediaries to disburse government credit that target rural micro-entrepreneurs as well as connect rural clients to commercial banks. They are also involved in creating self-reliance and augmenting knowledge of community forest projects (Ito et al., 2005) and contributing to upward social mobility through education (Whelpton, 2005). Anti-trafficking NGOs combat human trafficking, help to reduce the stigma on trafficking victims, rescue and integrate trafficked survivors back into the communities, and provide income-generating skills (Crawford & Kaufman, 2008; Thapa, 2015).

The implementation of water supply and sanitation projects and the promotion of sanitation and hygiene campaigns in rural areas by NGOs are well developed in Nepal (Barrington, Fuller, & McMillan, 2013). They have also contributed to domestic human rights and conservation issues (Bhandari, 2014). According to the Poverty Alleviation Fund (2015), NGOs facilitate the government's poverty reduction programs that target marginalized and vulnerable communities living below the national poverty line. In Nepal, NGOs are also known for creating international alliances, advocating for laws, and contributing to public policies (Forbes, 1999; Jones, Oven, Manyena, & Aryal, 2014; Thapa, 2015).

NGOs in Nepal are playing an important role in strengthening institution in civil society, but they are also, as in other parts of the world, not free from criticism. Rademacher & Tamang (1993) argued that while NGOs have proliferated, they have not been able to prove their worthiness and effectiveness to the government and the general public. They also noted that NGOs are highly politicalized. Further, Roka (2012) suggested that NGOs generally do not address local issues and cater to the needs of donors and politicians. Ulvila & Hossain (2002) and Risal (2014) have also reached similar conclusions.

Controversies (Forbes, 1999), lack of professionalism, transparency, accountability, and commitment (Ghimire, 2003; Dhakal, 2007), and failure to set priorities and reach the targeted individuals (Sajjad, 2016) under cut the legitimacy and integrity of NGOs. Often, NGOs are not even registered with the SWC or District Administration Offices (DAOs) (C. D. Bhatta, 2012) which makes it difficult for the government to monitor, coordinate and facilitate their activities. Such limitations could be the reasons why Roka (2012) noted that rural communities often prefer government to NGOs in implementing rural development projects and Karkee & Comfort (2016) proposed that NGOs should focus on advocacy issues instead of becoming service providers.

Poverty is associated with various factors, such as inherent human weaknesses, poor government structure, topographic isolation, health and diseases, corruption, conflicts, and weak civil institutions (Hine & Montiel, 1999; Sachs, Mellinger, & Gallup, 2001). Moreover, the poverty trap is self-reinforcing suggesting that poverty is endogenous (Bird, 1999; Azariadis & Stachurski, 2005). Since NGOs have been playing an important role in the fight against poverty (Riddell & Robinson, 1992; Poverty Alleviation Fund, 2015) does this imply that districts with higher poverty should have more local NGOs to tackle the problem? This study does not answer this question but it does propose to assess this issue.

3 METHODOLOGY AND DATA

The instrumental variable (IV) approach is a commonly used econometric technique to examine the effect of an endogenous explanatory variable on the dependent variable. The IV is not directly associated with the dependent variable, but operates through the endogenous variable and is not associated with the error term (Cameron & Trivedi, 2005).

Following Cameron & Trivedi (2005), a multiple regression model is written as:

$$y = \mathbf{x}'\boldsymbol{\beta} + u$$

with K regressor variables, so that \mathbf{x} and $\boldsymbol{\beta}$ are $K \times 1$ vectors. It is assumed that an $r \times 1$ vector of instruments \mathbf{z} , with $r \geq K$, exists. The regressor vector $\mathbf{x} = [\mathbf{x}'_1, \mathbf{x}'_2]'$ is the combination of endogenous regressors (\mathbf{x}_1) and exogenous regressors (\mathbf{x}_2). Then a valid instrument is $\mathbf{z} = [\mathbf{z}'_1, \mathbf{x}'_2]'$. While \mathbf{x}_2 can be its own instrument, there must be as many instruments \mathbf{z}_1 as there are endogenous variables \mathbf{x}_1 . The instruments \mathbf{z} must satisfy the conditional moment restriction:

$$E(u|\mathbf{z}) = 0$$

A common IV estimation procedure is the two-stage least-squares (2SLS) approach that involves two consecutive ordinary least-squares (OLS) regressions. The first-stage regression involves the OLS regression of \mathbf{x} on \mathbf{z} to obtain the fitted values of \mathbf{x} . In the second-stage regression, y is regressed on the fitted \mathbf{x} to obtain the 2SLS $\boldsymbol{\beta}$ estimates.

Data for this study come from various sources. The number of NGOs at the district level is obtained from the SWC (2016). The Human Poverty Index (HPI) is a multidimensional index that is based on the percentage of people not expected to survive beyond age 40, adult illiteracy rate, deprivation of economic provisioning, percentage of people without access to safe water, and percentage of malnourished children under age five. The larger the HPI value, the higher is the level of poverty. The HPI is obtained from the National Planning Commission and United Nations Development Programme (2014). Population density gives the number of individuals per square kilometer and comes from the Central Bureau of Statistics (2013). Foreign aid disbursement per capita (in US dollars) and road density (road length in kilometer per 100 square kilometer) are from the Ministry of Finance (2013) and the Department of Roads (2012), respectively. Finally, per capita income, purchasing power parity (in US dollars) is obtained from the National Planning Commission and United Nations Development Programme (2014).

4 FINDINGS

Figure 1 shows the annual and cumulative number of NGOs registered with the SWC. From the late 1970s through the late 1980s, there were less than 200 NGOs affiliated with the SWC. Since the early 1990s, the number of NGOs started to increase and by mid-2014, there were about 40,000 NGOs registered with the Council.

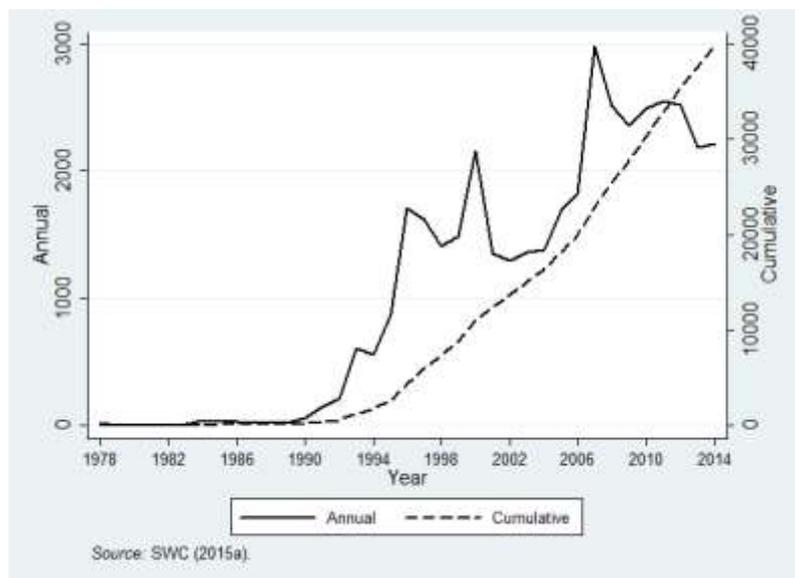

Figure 1: NGOs registered with the SWC

According to the SWC (2015b), more than 25,000 NGOs are involved in the community and rural development services sector. The remaining are in sectors, such as youth services, women services, and health services. Less than 100 NGOs are working in the area of AIDS and abuse control (see Figure 2).

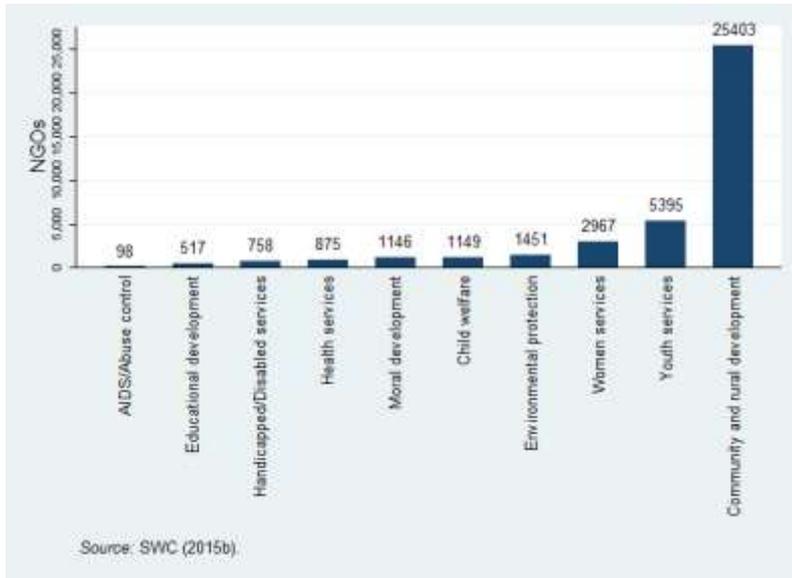

Figure 2: NGOs by sector

The distribution of NGOs in Nepal is uneven and is shown in Figure 3. While more than 12,500 NGOs are registered in Kathmandu, less than 20 NGOs are in Manang (SWC, 2016). In general, moving northward from the southern Terai, the number of NGOs declines.

Source: SWC (2016).

Figure 3: Distribution of NGOs by district

The summary statistics of all variables (in logarithm) are shown in Table 1.

Table 1: Summary statistics

Variable	Observation	Mean	Std. Deviation	Minimum	Maximum
Nongovernmental organizations (Ingo)	73	5.6295	0.9730	2.8332	9.4467
Human Poverty Index (Ihpi)	73	3.4851	0.2355	2.8034	3.8971
Population density (Ipopden)	73	5.0915	1.1971	1.0685	8.3929
Road density (Irden)	73	2.1300	0.8615	0.0000	4.5433
Foreign aid disbursement per capita (Ifaidpc)	73	2.8565	1.0890	0.6931	6.2265
Per capita income, purchasing power parity (Ipcinc)	73	6.9210	0.3556	6.1883	8.0602

Source: Authors' calculations.

As shown in Figure 4, the HPI and number of NGOs are negative related. That is, as poverty increases, the number of NGOs decreases at the district level in Nepal.

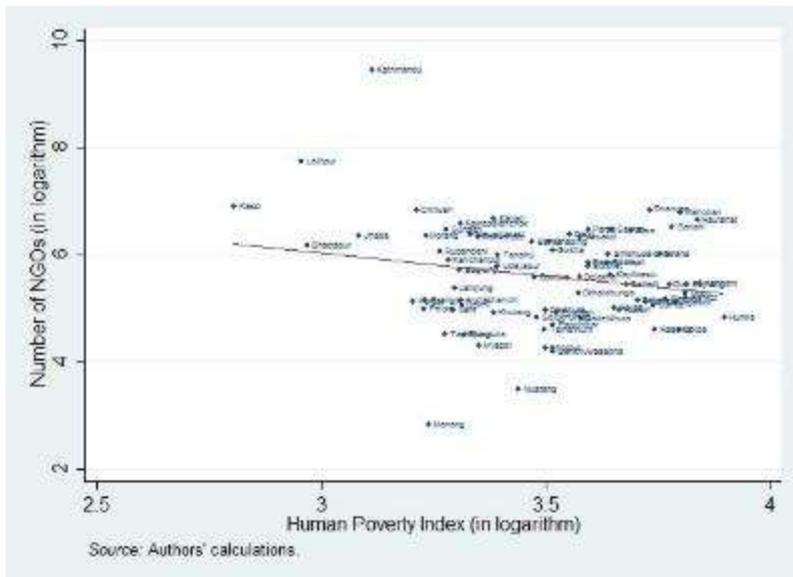

Figure 4: Relationship between poverty and NGOs

Table 2 shows the results of the first-stage and second-stage regression models. As poverty is endogenous, it is instrumented with per capita income in the 2SLS regression model. The correlation between per capita income and the HPI is -0.6522 . As the correlation coefficient between the endogenous variable and its instrument is large, there should not be efficiency loss using IV compared to OLS (see Cameron & Trivedi, 2005, 195).

According to Staiger & Stock (1997), if there is one endogenous variable, the F -statistic in the first-stage should be at least 10. If $F \geq 10$, there is no weak IV and the single instrument enters the first-stage of the 2SLS model. Here, $F(1, 68)$ is equal to 53.35, which suggests that per capita income is not a weak instrument. Further, Shea's partial R -squared (Shea, 1997) is 0.4396 which also indicates that the instrument is not weak.

In the first-stage model, foreign aid per capita and road density (measure of infrastructure and access) are not significantly associated with poverty. While the association between population density and poverty is negative and statistically significant, the relationship is weak compared to per capita income. Per capita income and the HPI are strongly negatively associated with poverty and are statistically significant at the 1% significance level, *ceteris paribus* and can be introduced in the 2SLS model.

Next, the estimated coefficient of poverty is -0.8220 and is statistically significant at the 10% significance level. The estimate implies that for a 10% increase in the HPI, the number of NGOs decreases by 8.22%, *ceteris paribus*. Further, the number of NGOs is positively associated with population density and is negatively associated with foreign aid disbursement per capita as well as road density.

The HPI is treated as an endogenous variable. If it was exogenous, the OLS estimator is more efficient. The Durbin-Wu-Hausman test is used to examine the endogeneity of the poverty variable. The Chi-squared value with one degree of freedom is 6.89 (p -value = 0.009), which is significant at the 1% significance level. Thus, the null that the HPI is exogenous is rejected.

Table 2: 2SLS regression results

Variable	First-stage regression (Dependent variable: lhpi)	Second-stage regression (Dependent variable: lngo)
lpopden	-0.0641* (-1.87)	0.6844*** (5.90)
lfaidpc	-0.0233 (-0.87)	-0.1560* (-1.73)
lrden	-0.0074 (-0.19)	-0.3126** (-2.34)
lpcinc (instrument)	-0.4226*** (-7.30)	
lhpi (endogenous)		-0.8220* (-1.79)
constant	6.8189*** (15.08)	6.1214** (3.27)
Observations	73	73
R-squared	0.4891	0.6384

* 10% significance level, ** 5% significance level, and *** 1% significance level; t -values in parentheses

5 CONCLUSION

This paper examined the relationship between poverty and the number of NGOs registered with the SWC at the district level in Nepal. Based on the 2SLS approach, it was found that the HPI is negatively associated with the number of NGOs. Note that the poverty index is multidimensional in nature and is based on survivability, illiteracy, economic deprivation, inaccessibility to safe water, and child malnourishment. With larger incomes, individuals are more likely to live long and healthy lives as they can access healthcare facilities, invest in education, provide themselves and their family nutritional food and safe drinking water as well as create economic opportunities. Once people are self-sufficient and live a decent life, they are capable of contributing to development activities through NGOs. On the contrary, poorer individuals are possibly more focused on making their “ends meet” including seeking economic opportunities for uplifting their socio-economic conditions. As survivability and sustenance become more important and as people are not well educated, NGOs are less likely to be established in the poverty-stricken districts.

Although the number of NGOs in Nepal has dramatically increased since the early 1990s, in general, regions with higher poverty have a smaller number of local NGOs compared to regions with lower poverty. This could be attributed to the fact that poverty is endogenous and that poverty inhibits the establishment of local NGOs. Thus, while NGOs can play an important role, they cannot reduce poverty single-handedly. In such a situation, government intervention is essential. First, the GoN has its own poverty alleviation program, but its reach is limited (Poverty Alleviation Fund, 2015). Thus, the Government should consider expanding the program. Second, as foreign aid and road density are negatively associated with the number of NGOs, the positive externalities associated with government investment and infrastructure could help in supplementing the role of NGOs in poverty reduction. Third, the GoN should consider supporting the creation of an environment conducive for both national and international NGOs to actively contribute to poverty reduction programs, especially in areas that have high poverty rates, but have a limited number of local NGOs.

This study focused on the number of locally registered NGOs, but it was not possible to recognize their operational status. While some of them might be actively involved in various programs, others could be nonoperational. This should be assessed and taken into account in future studies. In addition, NGOs that are registered only with the DAOs have not been taken into considerations and should be included in succeeding studies.

1018 UNDER WHAT MANAGEMENT PRACTICES THE LAND USE CONFLICTS ON LARGE CONSTRUCTION PROJECTS CAN BE MINIMIZED IN PAKISTAN?

ABSTRACT

Previous studies show that blemished infrastructural development projects dispossessed local population and degraded natural resources to a greater extent in developing countries like Pakistan. Therefore, this research is aimed to determine that how land use decision affect local habitats and the resources in various part of Pakistan. Thus, we use data from Chotiari water reservoir and Diamer Bhasah Dam projects, which were constructed in the country, where we emphasize the impacts of the projects on socioeconomic and natural resources in the respective regions. Our findings show that forceful displacement with no proper rehabilitation plan propagated the confrontations at local, regional and national level. The project is hampered by local actors' nonparticipation in decision-making, deceptive information dissemination by the authorities, misuse of funds, power relations, diverse interests and unequal access to natural resources. We paid attention to the actors' network over land and property rights violations, which have created a dissimilar power distribution. We assess the root causes of conflicts with response to land use decision in the light of international rules and laws. It is recommended that for natural resource governance and land use conflict management is imperative to take all stakeholders on board during feasibility of any water sector development project. We also suggest to the government that the awareness campaigns regarding the environmental importance and valuation of natural resources must be on its topmost agenda.

1052 HOUSEHOLD WATER SUPPLY IN THE GREATER ACCRA REGION, GHANA

ABSTRACT

The Greater Accra Region is generally tropical and humid in nature, and is facing insufficient water supply in the majority of the towns in the region. In recent years, access to safe and reliable water supply in the region has received increased government attention. As a result, the region’s water coverage rate has gradually improved. Yet 75% of the households are without 24-hour access to improved water and 10% with no access at all. The purpose of this study is to investigate the causes of the current water supply situation in the Greater Accra Region using the method of secondary analysis. The paper analyzes various annual reports from the Ghana Water Company Limited (GWCL), Community Water and Supply Agency (CWSA) and various other published works on the water sector in the region to review the availability of water resources, water quality and the characteristics of the water provision sector. It furthermore discusses the causes of the water situation and how it affects the health of millions of residents in the region. The findings of the paper reveal that the water provision problems in the region are mostly due to high population growth, the contamination of the drinking water, effects of climatic change and lack of effective and efficient management of the Ghana Water Company Limited (GWCL). Given these realities, GWCL will have to develop strategies to address the water issues in the region. For instance, the paper recommends that the capacity of Kpong and Weija water plant in the region needs to be expanded and regularly maintained to catch up with the sprawling city’s expansion to meet consumers demand and expectations. Thus government should endeavour to enter into more public private partnership water projects to improve on water infrastructure and consequently water quality and quantity supply in the region.

1143 SPATIAL VARIATION IN TENURE SECURITY PREMIUM: EVIDENCE FROM INDONESIA

ABSTRACT

This paper estimates the spatial variation of resident’s willingness-to-pay for secure property rights within Indonesia. Previous studies have examined the tenure security premium in developing countries; however, it remains unknown the extent to which this premium is constant across regions and what local factors explain variation in the premium. Using a spatially rich dataset of property prices across the country, we estimate the premium for secure property rights using spatial hedonic and geographically weighted regressions. We find the premium ranges regionally from less than 10% to over 45% of the property price. We then explore this spatial variation to understand the relationship between the tenure security premium and local governance characteristics, socioeconomic factors, and strength of traditional cultural values. Larger premiums for secure property rights are found in areas with higher levels of local corruption. Additionally, local governments that spend less and have a lower percentage of their spending financed through transfer payments have higher premiums, particularly relevant given pushes toward fiscal decentralization in many developing countries. Literacy rates, immunization coverage, poverty rates, and the share of the population living in urban areas are also all correlated with the tenure premium. Understanding these driving forces underlying the tenure security premiums explains the challenges of effective land registration programs. Furthermore, our findings provide direction for potential property rights’ policies that can better align incentives of local governments with the interests of the general public.

SS03.2. Territorial Governance and Local Development in Developing Countries

1343 GOVERNANCE AND THE QUALITY OF INFRASTRUCTURES AT VILLAGE LEVEL: ANALYSIS USING THE INDONESIA FAMILY LIFE SURVEYS

ABSTRACT

The quality of local infrastructures is important for economic development. One of the crucial policies to improve the quality of local infrastructures is decentralisation, in which local governance is involved. It is known that many developing countries promote self-governance at the local level in order to gain positive impacts on the quality of local infrastructures. In Indonesia, self-governance is also promoted at village level. Granting village autonomy and creating for democratic institutions indicate that the aim of decentralisation is basically to improve village development and as an expected result is an improvement in the the quality of infrastructures at village level. However, empirical investigation on the relationship between governance and the quality of infrastructure at the lowest level of government in Indonesia is still less well documented. This paper contributes with a study of Indonesia using the Indonesia Family Life Surveys (IFLS). Therefore, our analysis employs IFLS data at community level to explore the impact of governance on the quality of several public services and infrastructures. These local public services and infractructre include sanitation, road, drainage, irrigation, public lighting, and clean water. Our regression analysis also includes two group of control variables, the first is geographical or locational characteristics of the village, and the second one is local community participation.

1386 INCOME INEQUALITY AND QUALITY OF LOCAL GOVERNANCE ACROSS INDONESIA

ABSTRACT

This paper analyzes the relationship between income inequality and the quality of local governance in Indonesia at the district level during the period 2000-2014. Specifically, we test for the hypothesis that across districts better local governance reduces income inequality. We also search for main driving forces and spatial patterns of changes in the relationship between governance quality and inequality. Indonesia is the 4th most populous country in the world and currently undergoes rapid socio-economic changes. The big bang decentralization in 2001 and the introduction of direct elections of president and local district heads since 2004 has led to an emerging role for more than five hundred districts in local and national governance processes. In recent years, economic development in Indonesia is characterized by high economic growth and a rapid increase of overall income inequality. Our analysis makes intensive use of secondary data from various sources and levels such as Central Bureau Statistics Indonesia (BPS) for household and village level, Audit Board Indonesia (BPK), Ministry of Finance, and Regional Autonomy Watch (Kppod) for district level. We measure the quality of local governance in different ways. First, we use quality of institution in terms of budget efficiency and as presented in audit results. Second, we use governance outcomes by developing a public service delivery index and a local regulation index. In our analysis, we include local economic performance (GDP per capita), urban population, infrastructure, and education as control variables. We employ a GMM-system estimator as our empirical strategy and focus on the dynamic relationship in order to test our hypothesis (i) if institutions are strong, inequality remains constant, (ii) if governance is good, income inequality will be low. We expect governance variables will have a negative relationship with the inequality as hypothesized. If budget is spent efficiently in terms of disbursement and absorption as resulted from a strong institution, income inequality will be stable. This paper will contribute to understanding the mechanism how governance affecting inequality and vice versa, especially in the Indonesian context. We find that local audit result is strongly positively related to increasing income inequality while the quality of local public service delivery is strongly negative to increasing income inequality. In contrast, local budget efficiency and the regulatory index both are weakly and oppositely related to income inequality. In other words, our findings suggest that income inequality across Indonesia could be lowered by improving local public service delivery. Meanwhile, improving transparency of local administrative government practices, as captured by local audit result, may help in attracting more firms to local districts – hereby contributing to increasing income inequality.

1447 ADMINISTRATIVE SYSTEM OF SRI LANKA: CHALLENGES AND PROSPECTS

ABSTRACT

In Sri Lanka administrative system has been expanded gradually to four levels: the central, provincial, district and divisional levels. With the socio-economic and political changes of the country mainly occurred after the 1970's, as a new emerging state, Sri Lanka introduced some constitutional changes and administrative reforms with the main objectives of gaining rapid socio- economic development and an efficient administration. As a result of these reforms, a number of administrative institutions have been proliferated and the public administrative system of Sri Lanka has become extremely complicated. However, regarding these administrative reforms, their implications, and performance, managerial issues and recent reform initiatives of these institutions have not been fully examined academically, though a few researches have been done by using mainly the historical descriptive approach (Warnapala (1974), Bandara (2010, 2013), Navaratna (1989), Wanasinghe (1994), Somasundaram (1997), Leitan (1983). These studies have been done on some specific areas such as: District Political Authority system, District Ministerial System, and Provincial Council system. Therefore, in our view, it is fundamentally necessary to examine through scholarly research whether the objectives of these constitutional and administrative reforms have been fruitfully achieved during the period of last three decades or whether they have created new problems and challenges to the Sri Lankan administrative system and made it complicated. This study will also shed light on emerging issues in the administrative system and its implications for public sector management. The objectives of this study are to describe briefly the historical background and evolution of the Sri Lankan administrative system, the existing institutional structure of the Sri Lankan administration, the recent constitutional and administrative reforms introduced after the 1970's, the objectives behind these reforms, adjustment of administrative system, proliferation of administrative institutions, changing relations of the administrative institutions in various levels and with the centre, their roles and performance in practice and how the new systems have created constraints such as politicization, centralization, lack of administrative efficiency and professionalism etc. and how they destructed legitimate institutions of public administration and how they have become corrupted, less effective and less efficient. The study will be mainly based on the review of relevant documents and literature survey. This paper flows on six aspects: i) Historical overview and evolution of Sri Lankan administrative system, ii) The existing central, provincial, district and divisional structures, the functions and powers are given to these institutions, iii) Constitutional and administrative reforms introduced mainly after the 1970's, the objectives behind them, iv) Implications of these reforms and v) lessons for future with recommendations, VI) emerging issues in the administrative system.

1455 COEXISTENCE AND HYBRIDIZATION OF AGRICULTURAL MODELS IN ORIENTAL AMAZON. THE DAIRY PRODUCTION EXAMPLE IN TWO VILLAGES OF THE “GREEN MUNICIPALITY” OF PARAGOMINAS (BRAZIL)

ABSTRACT

The coexistence of agricultural models arise as an issue when several types of farming systems meet within the same territory or supply chain. In our communication, we evaluate the effect of this type of coexistence on the evolution of socio-technical systems and development of a given territory. We conducted our study in the Brazilian amazon municipality of Paragominas, spearhead of the green municipality program led by the federated state of Pará. This municipality sealed a territorial pact against deforestation practices with the local stakeholders, but the originally significant effects became to slowdown. We present primary data collected on an emerging milk supply chain within two villages of the municipality and the interpret our results by means of social network analysis. We demonstrate that beyond the temporary adoption of practices considered as eco-efficient by specialized producers, the sustainability of productive systems at territorial scale depend above all on the management of the coexistence of farming systems and the power relationship that lie behind it.

1501 DURBAN AND RECIFE URBAN DEVELOPMENT PROCESS: CRITICALLY COMPARING PLANNING APPROACHES AND TREATMENT OF SOCIAL JUSTICE IN EACH CASES

Rumeysa Bayar

Istanbul Technical University, Turkey

ABSTRACT

Although all cities in the world aim to provide socially, economically and politically equal environment to their citizens; there are major differences among cities in terms of living standard and accessibility to quality life. Durban and Recife are significant example to examine poverty and social exclusion. This paper aims to provide a critical review of development process of these two cities. Since they aspire to provide basic needs, enhance quality of life and improving political structure. In this paper, two different development approaches to interventions of social justice is critically analyse based on planning approaches criteria. Consisted of two parts starts with explaining different planning approaches which can be used for establishing city strategies and also their changes through time. The paper proceeds to exploring how Durban and Recife have addressed distribution of social justice in their interventions on the basis of social justice definition and criteria.

All cities in the World consist of unique combinations of social, political and economic environment. Yet, some cities have variant cases in terms of equality and living standards. Durban and Recife are two different cities which have been suffering from poverty and social exclusion. Durban, or the municipality of eThekweni, is the largest urban area in the province of KwaZulu-Natal, South Africa and the largest port city on the east coast of Africa with 3.5 million populations (Local Agenda 21, 2001) and Recife is the fifth largest metropolitan influence area in Brazil and the capital and largest city of the state of Pernambuco with 1.4 million populations (Cabral and Moura, 1996). Both cities have been experiencing development planning process in order to improve the quality of life, access to basic needs and enhance a strong political structure. The aim of this paper is to compare these two cities' interventions within the context of planning approach and treatment of social justice. The paper will be composed of two parts. It prefaces with identifying which planning approaches are implemented during the process of establishing city strategies and illuminates whether or not these approaches have been changed over time and the paper will continue to explore, through provision of a social justice definition and criteria, how local governments in these two cities have addressed distribution of social justice in their intervention periods.

To begin with planning approaches, it can be said that both Durban and Recife local governments considered public participation as a fundamental strategy in order to establish good government communication with citizens. As Davidoff (1965) stated the process has to include all community, if the primary agenda is to promote democratic urban government. Citizens 'inclusion' means not only to be heard but also to be informed about the planning process with inferable language (Davidoff, 1965).

In Durban, Long Term Development Framework (LTDF) has been constituted by the municipality for 20 years long term city-wide planning and implemented by council in 2002, after a society participation process. Continually, as a medium term plan, with purpose of accommodating a system for the activities of council, which would be updated every five year, Integrated Development Plan (IDP) was conducted in June 2003. These developments are significant for generating democracy in the city. Since 'not only did it involve substantial process of participation, widening the decision-making process beyond formal realm of politicians and officials, it is also highlights the range of intuitional and informal process which are substantially shaping the kind of democracy' (Ballard et.al. n.d., p. 3). As it is seen, participation was pivotal factor of the process and one of the underlying assumptions of advocacy planning is pluralism and participation (Mazziotti, 1974). According to Davidoff (1965), intention of pluralism and advocacy is to raise concern about future conditions among all different groups in society. At first Durban was sub-divided into 100 wards and a large scale of participation process so meetings and workshops with stakeholders, councils and locals was developed in all wards and established a draft of IDP. However, this process conveyed the impression as participative but it was more consultative and politically-driven and city's development strategies were dominant (Ballard et.al. n.d.). Therefore, tenor and contexts of LTDF and IDP were shaped by 'a complex process of participation, informal influences and political contestation' (Ballard et.al. n.d., p.5). Moreover, the IDP process was not only collecting data and community expectations, but so was vitiating expectations, such as unfeasible or realistic demands. The main reason for that, community participation was problematic in some cases because citizens tented to concentrate on their immediate environment changes rather than metropolitan-scale problems. On the other hand, there were two key actors in Durban: the one being local business interest and the other local, regional and national political party interests (Ballard et.al. n.d.) and according to Logie Naidoo, Deputy Mayor and chair of the council's Economic Development Committee, these main players were interested in 'building a closer bond between the political leadership and the business sector' (interview, 25 November 2003 ; Ballard et.al. no date) through development of LTDF and IDP. Whereupon, participatory process diverged from democracy became more market-driven and closely related to politics. In 2004 an IDP review was published and suggested that economic development strategies had still not been accomplished; consequently, the review started to be evolved from individual and household focus to a particular pro-growth orientation (World Bank, 2005). As things stand, it can be indicated that development process in Durban had been changed from participatory to entrepreneurial planning

overtime. This means that planners need to support the market and increase city competitiveness. Because former industrial cities like Durban has to restructure its economy. For instance, Durban Growth Coalition encouraged economic growth and realise city's potential as a world-class port and leisure centre. The local and city government started to focus on partnership with companies and put community engagement into the back burner.

Recife had also experienced a development process based on participation and master plan was a planning tool. Namely, the approach was the same yet participation process was different from Durban. Compare to Durban's participatory process, case of Recife is a very positive example of this process in such a deprived and dynamic urban area.

Tenure was the key problem and slum upgrading was the key issue of master plan. In the late 1970s, a strong popular movement was expressed by slum-called *mocambos*- dweller for squatters' rights and this was supported by political decentralization and growing local democracy in the early 1980s. As a result citizens were ensured for the institution of a system for security of tenure (Jones and Carmona, 2002). After establishing the planning law of 1983 by the mayor of right wing Gustavo Krause, 27 land use zoning areas, called ZEIS (Zonas Especiais de Interesse / Zones of Special Interest) was formulated for the city and now there are 65 such ZEIS in various states of formation (Guide of good practise in Urban Development, 2001). These were consisted of extempore the popular settlement, formed by the occupations of public or private areas, lacking basic infrastructure, urbanization and legalisation. In 1987, Plan of Regularisation of the Zones of Social Interest, known as PREZEIS, was confirmed in order to legitimise the process of legalisation of land of those settlements and be a national guide for implementation of public policies and it particularly emphases on fortification of the occupations in those settlements instead of relocation or eviction them (Guide of good practise in Urban Development, 2001). The Urbanisation and Legalisation Commissions – COMUL's and the FORUM of PREZEIS are two components of PREZEIS. Firstly, with its two representatives, COMUL's main goal is to determine the priorities for the areas, negotiate with authority to tackle conflictual cases and planning strategies. On the other hand, the FORUM of PREZEIS is a forum to control the process of urban development, bureaucratic and legislative, related with the ZEIS. Inarguably, it can be said that participation and transformation of planning process was dominantly contributed by this mechanisms of ZEIS and PREZEIS between squatters and authority. In 1991, a master plan was written by three private consulting groups of planner, who were hired by the city. This plan was focused on decentralisation and all land-use issues, such as fees, taxes, valuation. Also it was a protection for squatter settlement in terms of displacement and recognition of informal settlements (Cabral and Moura, 1996). In this stage, with purpose to citizen participation in planning process three advisory committees were set up. Firstly, Government Organisation Committee presented different city agencies. Secondly, the Civil Society Committee was mainly consisted of citizens and NGO representatives. The last one is Popular Representatives Committee was representative of squatter settlements and *mocombos* (Cabral and Moura, 1996). In spite of the fact that this process was well organised, meetings worked as advisory rather than integrating community into master plan. Additionally, governments did not embrace NGOs or NGOs criticisms and Popular Representative's Committee also did not engage with the process because their representatives were not expert or did not have sufficient knowledge; therefore, they did not play a strong role in this process. However, in 1991 a series of debates was started among the NGOs and city's professional associations. These debates strengthened not only the community engagement but also political representation of community at the level of governance.

To reach the conclusions, it can be said that participation process in Durban started as a core strategy yet, in the course of events, in order to strength the economy, group of officials, 'councillors, consultants, ward level representatives, traditional authorities, business leaders, and senior ruling party members' (Ballard et.al. no date) have change the direction of LTDFs and IDPs policies. Hence, participation has become solely consultation session. As in the interview TC Chetty (July, 2004 ; Ballard et.al. no date) stated 'it tried to make ever body happy' but at the end of the day 'it was a political rather than a planning process'. On the other hand, Recife development process showed a successful participation process and master plan was explicit with advocacy approach.

There is no doubt that planning and participation are two key components that need to be linked; however, in terms of distribution of social justice, the key question is how can a plan make a city more just? The answer depends on how to define social justice. This should be pointed out that social justice within the context of planning does not only mean accessing material goods equally but also receiving, as Young stated (1990), nonmaterial social goods. There is a tendency to define social justice as a distribution of primary urban needs, such as wealth, income and resources yet Young (1990) emphasised on social justice need to be considered into a wider context with regard to an individual as a consumer of goods, which are included action, rights, opportunity and self respect. For instance, Rawls said that 'the way in which the major social institutions distribute fundamental rights and duties' (Rawls, 1971, p.7) and he explicitly underlies these rights and duties are related to decision making, social positions and power (Young, 1990). Runciman (1978) and Ackerman (1980) emphasised on problems of social justice in terms of distribution of *which* social good in society and determining and converting resources into social good (Young, 1990).

As we can understand the issue of defining social justice, there are considerable amount of theory addressing this notion. I should say that, as indicated above, although many theories address social justice as individual posses only material goods, I take the similar approach to Young (1990, p.16 and p.248) 'the concept of social justice includes all aspects of institutional rules and relations...' such as decision -making, rights and self-respect as well as income and other goods and also 'involves equality among groups who recognise and affirm one another on their specificity'. As Smith (2002, p.69) expressed ' ...everyone should be guaranteed a minimum level of material well-being...to remain a normal functioning human being' only then social justice can be distributed equally. Consequently, social justice means that a

person should access basic needs equally and also receive social rights, regardless of person's income, age, ethnicity or culture.

Whatever all these theories explore, social exclusion is the main problem of many countries such as Durban and Recife. The development process experienced in each city was aimed to address this problem through participation process. Durban, in its LTDFs and IDPSs, mainly focused on three criteria. Building skills, meeting basic needs and strength the economy were the key strategies of improving quality of life (LTDF, 2001). Regrettably, neither LTDFs nor IDPs did not advert social justice within the concept of the three criteria decision-making, rights and self-respect. Development process concerned only improving spatial and economic perspectives; therefore, participation and planning process has turned its ways to economic perspective rather than upgrading social developments. Individuals should be able to contribute decision-making process; however, as indicated earlier, this process was not engaging citizen's expectation and listening voice of all groups in society. On the other hand in Recife, during master plan process, citizens had right to elect their own representatives and create Popular Representatives Committee and communicate with authority. Recife had been suffering from social exclusion, the primary agenda of master plan was eliminate this problem, reduce socio-political issue about clientism and protect rights of the squatters in informal settlements, so it can be seen social inclusion interventions were made. Also, in order to include women and increase community engagement in the process, gender and the participatory budget strategy was set up (Women's International Network News, 2003). This intervention provides community to receive social goods equally and helps develop self respect. In theory this notion can be well-organised yet in practice it is hard to implement

To evaluate, both cities attempted to implement advocacy approach in their development process. As we discussed earlier, advocacy planning mainly consist of participation and political interference. In both cases, improving quality of life through participation process was the major goal; however, Durban has changed the approach to entrepreneurial planning since the informal economy had a significant effect on contribution to the Durban's social and economy. Although, there was a commitment to improve economic development set up new strategies tackling with safety healthy and investor friendly (Durban Economy Policy, 2001). On the other hand, in Recife, participatory process was conducted through political interventions. The mayor promised a master plan with well-organised community engagement and advisor committees in order to eliminate social exclusion and the master plan was became a law. Due to these legal approaches, it was easy to distribute social equality. It can be said that legal attempts strength the process.

In conclusion, I should say that planning is a complex process and includes different elements. Yet the most important two factors are participation and equality in all groups of society. In order to achieve a successful development, these key elements must be considered. Durban and Recife had clear visions in theory but in practice Recife had been successful in terms of social inclusion. Governments in developing countries usually are mistaken prioritising economic developments. This is the first mistake Durban authority. Briefly, if cities are living organism then it cannot be separated from human life.

SS03.3. Territorial Governance and Local Development in Developing Countries

1512 DOES FISCAL EFFICIENCY SUPPORT POVERTY ALLEVIATION IN THE INDONESIAN REGIONS?

ABSTRACT

Poverty alleviation in the decentralization era has been faced with new challenges in coordinating policies and programs between central and local government. The effectiveness of poverty alleviation program is not only the responsibility of central government since it also greatly depends on the local government participation. This is inline with the goal of decentralization to improve wealth and wellbeing of the local residents. This paper focuses on the impact of state fiscal efficiency on poverty rate of the Indonesian regions, particularly after the implementation of decentralization in 2001. An expenditure efficiency score of each state government is computed using a non-parametric method of Data Envelopment Analysis (DEA) and a Panel Data is constructed to measure the effect of expenditure efficiency on poverty rate. This study finds that the correlation between state fiscalefficiency and poverty reduction is not significant. There is an indication that the utilization of public expenditure to reduce the poverty rate has not been optimal despite the expansion of the social transfer program.

1526 CONCEPTUALIZING ECONOMIC UNDERDEVELOPMENT AND INSURGENCY NEXUS: CASE STUDIES OF ASSAM, MANIPUR AND NAGALAND

Dona Ganguly, Debasis Patnaik

INTRODUCTION

The last half of the twentieth century marked the inception and the expansion of the waves of globalization and its adjuncts- democratization, liberalization, privatization and free market principles. Its spill over effect is now realized in the twenty first century as well. Unfortunately these much hyped processes seem to be serving the interests of the developed nations only, whereas the developing countries and the least developed countries together known as the Third World countries, are suffering from gross inequities in terms of political and economic power coupled with minimal opportunities for political reforms and upward economic mobility. In 1985, according to the World Bank's classification one out of every three persons, some 1,116 million men, women, and children, in the poorly or least/less developed countries were extremely poor having less than the equivalent of about \$1 a day per person to meet their needs. By 2002, this number fell slightly to 1015 million persons in poverty. Former World Bank president Robert McNamara called these people the absolute poor human beings who suffer a condition of life so degraded by disease, illiteracy, malnutrition, and squalor as to deny its victims basic human necessities. In other words under the influence of globalization, what is observed in this part of the world is the inversely proportional relationship between the ever increasing demands of the masses and the slow pace of politico-administrative and socio-economic modernization. Consequently the popular grievances are finding expressions through violence, extremism and insurgent conflicts. Therefore insurgent warfare, which has now become a fact of life in most of the third world countries feeds on instability as well as breeds in instability, volatility and flux which in turn give birth to failed or failing states, often struggling to recover from bloody civil or interstate wars. Failed states further create a vicious cycle of political, economic, and social unpredictability in which deep-seated maladies related to economic underdevelopment, undemocratic institutions and social inequality fester and then erupt into insurgency violence once more. Against the above background, the present study makes an attempt to assess the delicate and vulnerable relationship that exists between the economic underdevelopment and insurgency conflicts in the context of Assam, Manipur and Nagaland-India's three most insurgency-prone states located in the Northeastern region- the area which is infamous for being the breeding ground of the violent secessionist movements, intense ethnic insurgency insurrections coupled with massive underdevelopment and chronic poverty.

THEORIZING UNDERDEVELOPMENT

The idea of underdevelopment is a much contested and debated topic. There are two broad paradigms that have offered different theoretical perspectives on the idea. One is the theory of Modernization and the other is the Dependency theory. However modernisation has failed to explain the process of underdevelopment in the way dependency theory does. According to Hopkins whereas modernization has attributed the economic backwardness to the internal constraints in "traditional" societies and presumed that external contacts would be instrumental in removing them, the dependency thesis argues that it is the external links which have created the economic backwardness by forging chains of dependence and inequality between a privileged core and an exploited periphery.³²¹ Broadly there are two intellectual strands of thinking involved in dependency theory: Emmanuel Wallerstein and Andre Gunder Frank. According to Emmanuel Wallerstein, the global system is characterized by unequal but simultaneous development of its component national units. The new capitalist world system was based on an international division of labor that determine relationships between different regions as well as the types of labor conditions within each region. In this model, the type of political system is also directly related to each region's placement within the world economy. As a basis for comparison, Wallerstein proposes four different categories, core, semiperiphery, periphery, and external, into which all regions of the world can be placed. The categories describe each region's relative position within the world economy as well as certain internal political and economic characteristics. The Core regions benefit the most from the capitalist world economy. Politically, the states develop strong central governments, extensive bureaucracies, and large mercenary armies. This permit the local bourgeoisie to obtain control over international commerce and extract capital surpluses from this trade for their own benefit. On the other end of the scale lay the peripheral zones. These areas lack strong central governments or are controlled by other states, export raw materials to the core, and rely on coercive labour practices. The core expropriate much of the capital surplus generated by the periphery through unequal trade relations. Between the two extremes lie the semi-peripheries. These areas represent either core regions in decline or peripheries attempting to improve their relative position in the world economic system. They often also served as buffers between the core and the peripheries. As such, semi-peripheries exhibit tensions between the central government and a strong local landed class. Economically, these regions retain limited but declining access to international banking and the production of high cost high quality manufactured goods. Unlike the core, however, they fail to predominate in international trade and thus do not benefit to the same extent as the core.³²²

According to Andre Gunder Frank the present capitalist system has enforced a rigid international division of labour which is responsible for the underdevelopment of the many areas of the world. The dependent states supply cheap minerals,

³²¹A.G. Hopkins, Two essays on Underdevelopment: From Underdevelopment to Modernization, Geneva Institut Universitaire de Hautes Etudes Internationales, 1979, p.27

³²² Immanuel Wallerstein, The Modern World System: Capitalist Agriculture and the Origins of the European World Economy in the Sixteenth Century, New York: Academic Press, 1974

agricultural commodities, and cheap labour, and also serve as the repositories of surplus capital, obsolescent technologies, and manufactured goods. These functions orient the economies of the dependent states towards the outside for money, goods and services. However the allocation of these resources are determined by the economic interests of the dominant states and not by the dependent states. This pattern of unequal exchange ultimately explains the causes of underdevelopment of the dependent states: a situation in which the resources are being actively used, but used in a way which benefits dominant states and not the poorer states in which the resources are found.³²³

MEASURING ECONOMIC UNDERDEVELOPMENT

The level of economic underdevelopment of any country can be determined by studying and analysing the level of economic development and growth, which in turn is measured by the growth of total income gained by the country in question. The two most common methods used for measuring economic growth are *gross national income* (GNI) and *gross domestic product* (GDP). **GNI** is the annual total value of all income *accruing to* residents of a country, regardless of the source of that income, that is, irrespective of whether such income is derived from sources within or outside the country. **GDP** is the annual total value of all income (= value of final output) *created within* the borders of a country, regardless of whether the ultimate recipient of that income resides within or outside the country. Therefore based on these developments, a country can be declared to be economically underdeveloped if it shows:

- Low GDP/SDP (in case of individual states within a country)
- High poverty rate
- High Literacy Rate but High Unemployment Rate
- Low Industrialization
- Low Female Education Rate

UNDERSTANDING INSURGENCY AND ITS CRADLES

The last half of the twentieth century marked the inception and the expansion of the waves of globalization and its adjuncts- liberalization, privatization, free market principles and democratization. Its spill over effect is now realized in the twenty first century as well. Unfortunately these much hyped processes seem to be serving the interests of the developed nations only, whereas the third world countries are suffering from gross inequities in political and economic power, combined with the perception of minimal opportunities for political reform and economic upward mobility. In other words under the influence of globalization, what is observed in this parts of the world is the inversely proportional relationship between the ever increasing demands of the masses and the slow pace of politico-administrative and socio-economic modernization. Consequently the popular grievances are finding expressions through insurgent conflicts. It is notable here that during the colonial era, such protests often combined with nationalistic stirrings were manifested in anticolonial movements, but in the postcolonial period, the same have led to struggles to overthrow regimes ruled by wealthy elites often far more incompetent, fraudulent, and tyrannical than their colonial predecessors. The end result is that insurgent warfare has become a fact of life in most of the third world countries.

Insurgency as a concept frequently engages widely disparate interpretations and conceptual confusions. Insurgency falls within the genre of irregular, unconventional, revolutionary and guerrilla warfare but it cannot be used interchangeably with terrorism. Although insurgents employ guerrilla and terrorist tactics, espouse revolutionary and radical causes, pose asymmetric threats to modern conventional forces, operate on the legal and moral margins of societies and blur distinctions between civilians and combatants, yet insurgency is different from terrorism. Insurgency, unlike terrorism, is characterized by the support and mobilization of a significant proportion of the population. According to Mao insurgency operates at three Stages - **Stage I/Strategic Defensive** is characterized by avoidance at all costs of pitched, set-piece battles and the moral superiority of the guerrillas is established with the local population, political indoctrination is carried out and new recruits are trained to fight as irregulars in remote, safe bases; **Stage II/Stalemate** begins the prolonged battle to attrite thenemy's physical and moral strength and government control, in the form of local officials, is targeted and its representatives are either killed or forced to leave, with government presence in rural areas neutralized, the population is drawn upon for moral and physical support channelled into building capable, conventional *main forces*; **Stage III/Strategic Offensive** is the end game of the conflict, in which popular and main forces conduct the battle of manoeuvre and use overwhelming force to destroy decimated enemy forces in their defensive positions.³²⁴ From the above interpretation it can be concluded that an insurgency is a prolonged violent conflict based on popular support in which one or more groups strive for overthrowing or profoundly changing the existing political or social order in a state or region through the use of sustained violence, insurrection, social disruption and political action.

It is to be borne in mind that although all the successful insurgencies have common characteristic features yet the causes behind the emergence of each insurgency movement vary from one another. Debates over the causes of insurgencies often focus on issues, usually related to modernization, globalization, poverty, or political ineptitude. Scholars like Thomas Barnett identifies the failure of the states and regions to tap into globalization and its economic and political

324 James D Kiras , Irregular Warfare: Terrorism and Insurgency in Baylis John et al (eds), Strategy in the Contemporary World: An Introduction to Strategic Studies, Second Edition, Oxford University Press, 2007, p.190

benefits as the cause of insurgency.³²⁵ Others, such as Samuel Huntington, cite the violent disruptiveness of competing cultures, embodied in religious and ethno-nationalism and exemplified by Islamist radicalism and al Qaeda to be at the roots of insurgent upheavals.³²⁶ Still others focus on repression, terrorism, crime and corruption, and discrimination, actions that incite popular unrest and feed insurgency. However insurgency is the spontaneous interactions between actions, structures and beliefs which explode into sustained violence. Structurally, insurgencies most often occur in poorly developed and unstable states or regions, unwilling or unable to address their endemic problems of inequitable political, social and economic conditions characterized by poverty combined with inadequate services, lack of education and crime; oppressive or corrupt regimes; ethnically exclusive enclaves leading to factionalism; lack of natural resources or disparities in their distribution; and social exclusion and stratification or military occupation. The discontents rooted in the discriminatory and undemocratic socio-economic and political structures of the poorly developed nations are further aggravated by the extremist and exclusionary beliefs about identity, especially ethno-nationalism, cultural exclusiveness, religion, or a combination of the three which dominate the socio-economic and political life of these countries. Individual and group identity, radical worldviews, attitudes, and historical myths (particularly if they involve past tragedies) promoted and sustained by charismatic leaders who offer insurgency as an alternative to the current intolerable situation (as was the case of Mao, Castro, Issac Muivah and many others) barely leave room for conciliation and compromise. The structural inequities coupled with fanatical beliefs and radical attitudes, in turn, are powered and exploded by the catalysing actions inclusive of state violence and repression against a particular segment of the population, economic exclusion either by existing governments or by one political or ethnic group against another, acts of corruption and crime that no longer can be tolerated, or even single acts, such as arrests, political assassinations or overreactions to protests. Therefore it may be observed that insurgency feeds on instability as well as breeds in instability, volatility and flux which in turn give birth to failed or failing states, often struggling to recover from bloody civil or interstate wars. Failed states further create a vicious cycle of political, economic, and social unpredictability in which deep-seated maladies related to economic underdevelopment, undemocratic institutions and social inequality fester and then erupt into insurgency violence in turn.

ECONOMIC UNDERDEVELOPMENT AND INSURGENCY NEXUS: THEORETICAL UNDERPINNINGS

In 1985, according to the World Bank's classification one out of every three persons, some 1,116 million men, women, and children, in the poorly or least/less developed countries were *extremely poor* having less than the equivalent of about \$1 a day per person to meet their needs.³²⁷ Former World Bank president Robert McNamara called these people the *absolute poor* human beings who suffer a condition of life so degraded by disease, illiteracy, malnutrition, and squalor as to deny its victims basic human necessities.³²⁸ Therefore very often both the national and international policy makers as well as academicians and scholars across the wide political spectrum prefer to consider insurgency and other forms of political violence affecting the third world nations, to be a product of poverty and poor distribution of income and resources leading to a widening gap between the rich and poor. The link between political extremism, violence and instability and socioeconomic discontent and desperation can be understood from three economic explanations as follows:³²⁹

- a) **Group Motivation:** Groups engaged in internal conflict are often united by a common ethnic or religious identity and fight for a common cause/ purpose. The conflict occurs where there are significant underlying differences in access to economic or political resources among ethnic or religious groups, providing both leaders and followers with a strong motive to fight. Ted Robert Gurr terms such group differences *relative deprivation*; Frances Stewart defines differences in groups' access to economic, social, and political resources as *horizontal inequalities*, in contrast to the traditional *vertical inequalities* that apply to individuals rather than groups. Horizontal inequalities (HIs) are multidimensional, involving access to a variety of resources along economic, social, and political dimensions. Along the economic vector, not only income is important, but access to employment and to a variety of assets (e.g., land, credit, education) comes into play. The social vector includes decisions on official languages, religion, or cultural events that favor one group or another, access to services (e.g., health care, water) and to assets (e.g., housing). The political vector includes power at the top (e.g., the presidency, the cabinet), at lower levels (e.g., parliamentary assemblies, local government), in the bureaucracy at all levels, and in the army and the police. For example, in Zimbabwe unequal access to land is important, while in Northern Ireland conflict concerned HIs in housing, education, and jobs.
- b) **Failure of the Social Contract:** The second explanation of violent conflict points directly to grievances. It derives from the view that social stability is premised on an implicit social contract between the people and the government. According to this contract, people accept state authority as long as the state delivers services and provides reasonable economic conditions in terms of employment and incomes. With economic stagnation or decline and worsening state services, the social contract breaks down and violence results. Thus, high (and rising) levels of poverty and a decline in state services would be expected to cause conflict.

- c) **Green War (Environmental Scarcity):** The third explanation of violent conflict, associated with the work of Thomas Homer-Dixon, is the *green war*, or *environmental scarcity*, argument. The essence of this perspective is that the contest for control over declining natural resources, often intensified by population pressures, is a major cause of violent conflict around the world. Poorer societies are more at risk because they are less able to buffer themselves from environmental pressures. Three dimensions of environmental scarcity that may lead to conflict are: supply-induced scarcity, linked to the depletion and degradation of an environmental resource; demand-induced scarcity, linked to population growth and the consequent extra pressures on existing resources; and structural scarcity, which arises from an unequal distribution of a resource that concentrates it in the hands of a relatively few people.

Violent conflicts result into the destruction or removal of physical capital, including bridges, buildings, and communications and energy sector infrastructure. A fall in investment (especially private rather than public investment) is also observed because the investors are discouraged by the unstable political and economic situation of the country. The skills and abilities of labour force alter as a result of conflict. During conflicts, schools are either closed or are destroyed and students and often teachers join rebellions and armies. These effects reduce investment in human capital. Production and trade is also interrupted by blocking freedom of movement. People become less productive when they are displaced or unable to access their workplaces due to landmines and other threats. Expectations of looting have implications for economic production, much like taxation; and the responses to looting, such as reduced travel, the closure of markets or the imposition of curfews hit production and trade.

OBJECTIVES OF THE PRESENT STUDY:

Against the above background, the present study makes an attempt to assess the delicate and vulnerable relationship that exists between the economic underdevelopment and insurgency situations in the North Eastern part of India. India's North Eastern region which is also recognized as a rainbow zone of the country, extraordinarily diverse, colourful and mysterious when seen through parted clouds, stretches from the foothills of the Himalayas in the eastern range and is surrounded by Bangladesh, Bhutan, China, Nepal and Myanmar. It includes the eight sisters - Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram, Nagaland, Tripura and Sikkim. The region is rich in natural resources, covered with dense forests, has the highest rainfall in the country, with large and small river systems nesting the land and is a treasure house of flora and fauna. It is marked by diversity in customs, cultures, traditions and languages, it is home to multifarious social, ethnic and linguistic groups. The troubled history and geo-politics, of the North East has been primarily responsible for the most backward status of the region by placing hurdles on its future economic progress. Further the evils of partition in 1947 isolated the region, sealed both land and sea routes for commerce and trade and severed access to traditional markets and the gateway to the East and South-East Asia- the Chittagong port in East Bengal (now Bangladesh). It also distanced the approach to the rest of India by confining connectivity to a narrow 27-km-wide Siliguri corridor popularly known as Chicken Neck, making it a remote land and constraining access for movement of goods and people. Moreover India's uneasy relationship with most of the neighbouring countries has not helped the cause of development of the region either: with 96 per cent of the boundary of the region forming international borders, private investment has shied away from the region. Poor infrastructure and governance is combined with low productivity and market access. Inability of governments to control floods and river bank erosion causes unmitigated damage to properties and lives of millions of people every year in the region. If the quest for ethnic and cultural identities has sowed the seeds, frustration and dissatisfaction from seclusion and remoteness then the problems of governance and economic backwardness have provided fertile ground for breeding armed insurgencies. Therefore out of the eight sister states in the North Eastern region, the present article focusses on the cases of Assam, Manipur and Nagaland which have been mostly plagued by the insurgency violence. The study seeks to project:

- That negligence of the Central government towards these three states since the very inception of the First Five Year Plan till the Ninth Five Year Plan has been responsible for a long period of economic underdevelopment of these states
- That the economic underdevelopment has triggered the insurgency situation in these three states
- That with the inception of Tenth Five Year Plan followed by the Eleventh and Twelfth Plan successively, the states of Assam, Manipur and Nagaland are recording fast economic growth and development
- That the economic development is gradually ameliorating the insurgency situation

METHODOLOGY

The study has been essentially based on the analysis of secondary data procured from the various government archives, statistical databases and annual reports of various ministerial departments of Government of India.

ECONOMIC UNDERDEVELOPMENT AND INSURGENCY NEXUS IN ASSAM, MANIPUR AND NAGALAND: THE PROBLEMATIQUE

In this part of the article an attempt has been made to analyse the correlation between economic backwardness and the growth of insurgency in Assam, Manipur and Nagaland. As already mentioned above that underdevelopment results from the exploitation of the dependent state by the dominating state which uses the resources of the former to further its economic interests. In case of North East India, the situation is bit tricky. The mainland India has never exploited the virgin reserve of the natural resources of the region and at the same time for almost 50-55 years after independence, New Delhi showed enough reluctance in addressing the paralysed economic situation of the region. The cultural

distinctiveness and the remoteness of the region coupled with the difficulty in accessing the region has been often cited as the cause behind the lack of attention towards the Northeast. The Central Government profusely influenced by the Nehruvian ideas of *leaving the North East on their own* somehow misinterpreted the economic requirements of the region. It can be argued that the negligence of the Central Government towards the North eastern region in general and Assam, Manipur and Nagaland in particular since the First Five Year Plan till the Ninth Five Year Plan, has been primarily responsible for the economic travails of these three states. However it is also important to note that since Nagaland could not become a state before 1963 due to its severe insurgency affected atmosphere, Kohima failed to reap the economic benefits of the first three five year plans and lagged behind the rest of the country in the process of development. Thus it is clear in case of Nagaland that the economic underdevelopment breeds in insurgency which in turn further provokes the former. **Table 1** below shows the central allocation of funds for these three states from the First (1951-56) to Ninth (1997-2002) Five Year Plan periods. It can be observed that from 1951 till 2000 the Central Government of India does not seem to have exhibited enough concern for these states. The statement can be justified by the fact that the Central allocation during this period for these three states had been fairly meagre. During the First Plan the percentage shares of the total allocation by the Centre for Assam and Manipur were 5.2% and 0.32% respectively. During the Second Plan the percentage shares of the total allocation by the Centre for Assam and Manipur were 5.31% and 0.35% respectively. During the Third Plan the percentage shares of the total allocation by the Centre for Assam and Manipur were 2.98% and 0.29% respectively. During the Fourth Plan the percentage shares of the total allocation by the Centre for Assam, Manipur and Nagaland were 3.12%, 0.43% and 0.49% respectively. During the Fifth Plan the percentage shares of the total allocation by the Centre for Assam, Manipur and Nagaland were 1.09%, 0.23% and 0.17% respectively. During the Sixth Plan the percentage shares of the total allocation by the Centre for Assam, Manipur and Nagaland were 2.29%, 0.49% and 0.43% respectively. During the Seventh Plan the percentage shares of the total allocation by the Centre for Assam, Manipur and Nagaland were 2.60%, 0.53% and 0.49% respectively. During the Eighth Plan the percentage shares of the total allocation by the Centre for Assam, Manipur and Nagaland were 1.07%, 0.22% and 0.21% respectively. During the Ninth Plan the percentage shares of the total allocation by the Centre for Assam, Manipur and Nagaland were 1.83%, 0.49% and 0.30% respectively. It is important to note here that while Assam has shown a decreasing trend from 5.2% to 1.07%, the fates of Manipur and Nagaland floated around 0.32% to 0.43%.

TABLE 1. FIVE YEAR PLAN OUTLAYS FOR ASSAM, MANIPUR AND NAGALAND (Rs in crores)

FIVE YEAR PLANS	ASSAM	MANIPUR	NAGALAND	TOTAL OUTLAY
First plan (1951-56)	75.9	4.8	NA*	1456.8
Second plan (1956-61)	119.0	7.9	NA*	2240.9
Third plan (1961-66)	120	12	NA*	4022.0
Fourth plan (1969-74)	220.0	30.25	35.0	7031.47
Fifth plan (1974-79)	429.0	92.86	70.15	39303.0
Sixth plan (198-85)	1115.00	240.00	210.00	48600.0
Seventh plan (1985-90)	2100.00	430.00	400.00	80698.00
Eighth plan (1992-97)	4672.00	979.00	939.80	434100.00
Ninth Plan (1997-2002)	8983.93	2426.69	1493.24	489361.00

Source: Compiled from the Five Year Plan Reports, Planning Commission, Government of India, <http://planningcommission.gov.in> (accessed on 09/01/2018)

*Since Nagaland attained statehood in 1963, therefore could not enjoy the benefits of the first three Five Year Plans.

The paucity of fund has been responsible for the increasing poverty accompanied by lack of employment and industrialization, all subsequently leading to the economic backwardness and underdevelopment in these three states. As per the sample surveys conducted by the National sample Survey (NSS) since 1973, **Table 2** below shows the percentage of population living below the poverty line in these three states during the entire period of First to Ninth Five Year Plans. When compared to the All India percentage of population below poverty line each of the three states have exhibited a decreasing trend in 1973-74 followed by increase in 1977-78, decrease in 1983, 1987-88 and then continuous increasing trend throughout 1993-94 and 1999-2000.

TABLE 2 PERCENTAGE OF POPULATION BELOW POVERTY LINE

STATE	1973-74	1977-78	1983	1987-88	1993-94	1999-2000
ASSAM	51.21	57.15	40.47	36.21	40.86	36.09
MANIPUR	49.96	53.72	37.02	31.35	33.78	28.54
NAGALAND	50.81	56.04	39.25	34.43	37.92	32.67
ALL INDIA	54.88	51.32	44.48	38.86	35.97	26.10

The increasing poverty level has resulted into poor education Table 3 below projects the ever increasing unemployment rates in Assam, Manipur and Nagaland when compared to the All India level. It is important to note here that the female unemployment rate in these three states is very alarming. Female empowerment being one of the important determinants of economic development, the situation in Assam, Manipur and Nagaland was not very encouraging. The situation was further aggravated by the lack of industrialization apart from the increasing level of

poverty and unemployment. **Table 4** below shows the poor development of small and medium size industries in Assam, Manipur and Nagaland from 1972-73 to 2006-07.

Table 3 Unemployment rates by sex 1993-94 to 1999-2000

The evils of economic backwardness and underdevelopment bred into violent secessionist and insurgency movements under the able leaderships of huge number of educated unemployed youths. **Table 5** below shows that compared to the All India statistics, there has been a continuous increase in the literacy level in these three states from 1961-2001. Unfortunately, despite of high literacy rate, as shown in Table 3 above, the corresponding increase in the rate of unemployment created frustration and anger among the youths of these three states. Therefore these youths sought to pursue the paths of violence and secessionism as a remedy to their economic plights and isolation from the mainstream Indian economic development.

TABLE 5 LITERACY RATES FOR MALE AND FEMALE 1961, 1981 AND 2001

STATES	1961		1981		2001

Resultantly, the insurgency situation in the states of Assam, Manipur and Nagaland, assumed a diabolical shape. **Table 6** below shows the intensity of the insurgency situation as evident in the number of insurgency related killings from 1992-2001. In case of Assam the number has increased from 133 in 1992 to 606 in 2001, in Manipur the number increased from 165 in 1992 to 256 in 2001 and in Nagaland it was 96 in 1992 and 103 in 2001. Therefore it can be concluded that with the increase in the rate of economic underdevelopment, the insurgency situation aggravated over the period of 1970 to 2001.

TABLE 6 INSURGENCY RELATED KILLINGS AND CASUALTIES FROM 1992 TO 2001

However, the economic situation in Assam, Manipur and Nagaland began to change since Tenth Five Year Plan (2002-2007) due to number of factors: **First**, recognizing the special requirements of the region and the need for significant levels of government investment, the North Eastern States have been categorized as Special Category States and Central Plan assistance to these States is provided on liberal terms. **Secondly**, in October 1996, the Central Government's announcement of 'New Initiatives for the North Eastern Region' included a number of measures for the development of the NER which covered policy changes, special area development and development projects in key sectors. In order to mobilize financial resources, a policy decision was taken to earmark at least 10% of the Plan Budget(s) of the Central ministries/departments for development of the North Eastern States. **Thirdly**, the Non-Lapsable Central Pool of Resources (NLCPR) created in 1997-98 (operationalized in 1998-

99) is the accrual of the unspent balance of the mandatory 10% budgetary allocation of the Ministries/Department. The broad objectives of the NLCPR Scheme is to ensure speedy development of infrastructure by way of filling the existing

infrastructural gaps (economic and social) in the region by making funds available from the pool. **Fourthly**, the Ministry of Development of North Eastern Region (DoNER) was set up in 2001 to coordinate and give impetus to the Centre's development efforts pertaining to socio-economic development of the region. **Fifthly**, the Central Government has also been announcing special packages for socio-economic development of the NER from time to time. Priority funding (both in the Central plan and State Plan) are being arranged from time to time for expeditious implementation of these packages. **Finally** and most importantly, in the second phase of Look East policy which is now rechristened as the Act East Policy under the Modi Government, India is now eager to involve North eastern region as the potential connectivity corridor towards the Southeast Asian markets. It will not only forge integration the East and Southeast Asian economies but will also promote a holistic development of the North Eastern region which is lagging far behind the overall national development, growth and prosperity. Although the North Eastern part of India suffers from geographical isolation, and socio-cultural asymmetries in relation to the mainland India, but it shares geographical contiguities and ethno-cultural continuities with the countries of Southeast Asia. Therefore North East India forms both a geographical gate way and a cultural linking bridge to ASEAN and countries of Southeast Asia. In this initiative the states of Assam, Manipur and recently Nagaland have gained prominence due to their geographical proximity to the Southeast Asian region.

With an aim to prepare the North eastern region a potential corridor to the Southeast Asia, it has become imperative for the Central Government of India to flood the states of Assam, Manipur and Nagaland with developmental projects and necessary funds required for the same. Resultantly, now the areas are experiencing a euphoria of economic development. It may be observed from the **Table 7** below, that from the 8th to 11th Plan periods, Assam, Manipur and Nagaland have shown considerable increase in the growth rates in State Domestic Product. Assam has registered an increase from 2.8% to 6.8%, Manipur shows an increase from 3.7% to 6.2% but Nagaland however has shown a decrease from 7.2% to 6.2%. The surge in growth rates is further validated by the developmental growth rates in industry and services sectors witnessed during the 12th Plan as shown in **Table 8** below. When compared to the all India growth rates in agriculture, industry and service sectors, all the three states of Assam, Manipur and Nagaland have recorded much higher growth rates with Nagaland having 9.0% growth rate in industrial sector. Further, the fast increasing level in female literacy rate in 2011 as shown in **Table 9** below also projects the development of these three states economically.

TABLE 7 Growth Rates in State Domestic Product (SDP) in Different States (% per annum)

STATE	8 TH PLAN (1992-97)	9 TH PLAN (1997-2002)	10 TH PLAN (2002-2007)	11 TH PLAN (2007-2012)

From the Tables above it can be concluded that these three states have been experiencing an economic developmental phase since 2002. Thanks to the Look East Policy, that Assam, Manipur and now also Nagaland are receiving due attention of the Central Government. Eventually, the insurgency situation in all these three states have also declined over the years barring one or two stray events. **Table 10** below shows the decreasing level of insurgency related violence in these three states since 2002.

CONCLUDING OBSERVATIONS

The end-objective of economic development is the development and growth of the human being. Therefore, any talk of trade and commerce and better livelihood options etc. are for the improvement of life of the people and increasing their happiness factor. However, the aim of developing the Northeast by facilitating increased regional and international trade with the neighbouring countries, aimed at providing the scope for industrialization and growth will have only marginal impact on the economy unless the region can be converted into a production hub. However in this context, it is to be noted that there are several challenges which need to be faced and solved accordingly. The **first** challenge is to overcome the general tribal mentality of subsistence economic production and transform into a market oriented one. There is as yet little concept of market forces and much learning is required. A few Border Haats and Land Customs Stations (LCS), where the trade is largely on barter, will not bring prosperity. **Secondly**, absence of proper communication infrastructure must be mitigated immediately by trained, skilled and enthusiastic manpower. **Thirdly**, the evils of corruption at various levels, illegal taxes, absence of coordinated official planning and concerted action, general indifferent attitude of the people etc need good governance and impartial administrative system. Fourthly, security and safety must be prioritized and for these law and order machinery must be fine-tuned through proper legislations. **Fourthly**, excessive industrialization and communication networks should not destroy the traditional resource base and the virgin environment of the region. Therefore care should be taken to ensure a sustainable development. **Fifthly**, draconian laws like AFSPA and many other undemocratic legislations should be repealed without further delay as it is endorsing more alienation and isolation.

Economic development should therefore encompass not only the material well being of any particular community but should also address the challenges of proper governance, environmental security and infrastructural bottlenecks. It is only possible then to mitigate both the evils of economic underdevelopment and insurgency situation.

ABSTRACT

Regional politics play a decisive role in national politics. When ethnic groups are regionally concentrated, the politics for regional autonomy not only challenges the territorial integrity of a country, but also controls the country's national political destiny. Similar to many developing countries, Sri Lanka has also severely suffered due to the political claims for self-rule, regional autonomy and separation by the regionally concentrated ethnic minorities. Sri Lanka's Eastern province has been highly influential in national politics as well as minority politics from the independence of the country, during civil war, and in the post-civil war era. Particularly, the province has continued to be a contested region in terms of state-building, national, and regional integration, and the integration of minority politics. The ethnic composition of the region has played an influential role in this regard. This study explores the ethnic group' competition for political control and autonomy, as well as its impact in Eastern Sri Lanka. This study has employed both qualitative and quantitative data, collected mainly through secondary sources such as literary books, journal articles, newspaper cuttings, and government documents, which are analyzed and presented through an interpretive and descriptive manner. The study reveals that the Eastern province has been a contested choice for the ethnic majority to extend their ethnic domination, and to implement ethno-centric development-cum settlement policies and programs, all of which are ultimately induced to change the ethnic composition of the region in favor of the ethnic majority and pushing ethnic minorities to mobilize and demand for more decentralized power and autonomy in the region. The thirty-year prolonged civil war made the region not only a war-torn one, but also the one that undermined regional democratic principles, including minorities' rights for autonomy. The study also reveals that the demerger of the Northern and the Eastern provinces, the establishment of the Eastern provincial council in 2006, and the end of the civil war in 2009 created hopes among the minorities that the region would return to a democratic system that ensures their self-rule and autonomy in the region. However, the new emerging political context at the provincial and national levels continues to undermine these hopes. Nevertheless, the region has emerged as one for ethnic cohesive politics.

Key Words: Regional politics, regional autonomy, ethnic minorities, Sri Lanka's Eastern province.

1 INTRODUCTION

Like many plural states, Sri Lanka has also been severely suffering due to claims and mobilization of ethnic minorities towards more autonomy and self-rule in their traditionally inhabited areas. Sri Lanka's Eastern province has been a contested region for ethnic and power politics, which brought the region to be important and politically influential in the post-independent era of regional development, administration, and governance. The settlement pattern of the ethnic groups in the region has induced the people of the region as well as the central governments to dominate the regional politics. Throughout history, Eastern province has been a Tamil-speaker predominant one with 'ethnic Tamils' formed the majority. Therefore, Tamils argue that the Eastern province is part of their traditional homeland with the Northern province. As a result, Tamil political leaders are claiming that Tamils should be given self-rule or more autonomy to be politically independent in order to control their inhabited areas. However, these claims and arguments have received little support from the country's ethnic majority, the Sinhalese, who form about 75 percent of the country's population and predominantly living in the country other than the Northern and the Eastern regions. However, when political power was transformed to Sinhalese from the British colonial, their immediate focus was on the Eastern province. As to sabotaging the minority claims for autonomy and power domination in the regional politics, Sinhalese-dominated successive governments made number of initiatives and implemented a number of policies and projects in the region, so as to ensure their dominance in the administrative and political affairs. Irrigation-based land settlement projects were the major target to make affective change in the region's ethnic composition and to control lands in the province.

Similarly, the Eastern province is one of the regions that continue to be under the control of Sinhalese bureaucrats and the dominance of their language, the Sinhala. This imposed a number of challenges for Tamil-speakers, the predominant linguistic communities living in the region. Even at the political level, the region has continued to be under the control of Sinhalese Governors, appointed by the country's President, and the major portfolios of the provincial government have also been controlled by the Sinhalese provincial councilors in the post-civil war era. All these socio-development and political contexts urge an academic investigation into why Eastern province has been important for ethnic majority and Sinhalese rulers and how it has undermined the political autonomy of minorities in the region. The existing literatures show a clear gap in answering the above research problem; therefore, this study attempts to fill this gap. The major objective of this study is to examine the nature of majoritarian dominance in politics, development, and administration in the Eastern province. The other objective is to examine the drive and challenges for political autonomy of minorities in the region and how their autonomy thirsts and demands were viewed and accommodated by the ethnic majority and their politics.

2. METHODOLOGY

This study is qualitative in nature and has used mostly secondary data collected from different sources such as literary books, book chapters, academic journals, newspaper articles, government departmental reports, and websites. These sources have recorded and reviewed many discourses and changing dynamics of ethnic and power politics for regional autonomy in the Eastern province and their recent developments. However, this study has taken a few thematic areas to test the ethnic and power politics for regional autonomy in the Eastern province. They are: (a) politics of development and the land-based rights of minorities, (b) politics of language and the denial of linguistic rights, and (c) the politics of representation and provincial autonomy in provincial governance. Also, this study has specially focused on the position of Muslims in regional autonomy discourse in the Eastern province, where they form a decisive majority in provincial population. The concerns and grievances of Muslims in the ethnic politics, and their autonomy proposals have influenced in the politics for regional autonomy of Tamils and ethnic dominance system of Sinhalese in the region. Therefore, Muslims and their demands have become the center of any kind of autonomy discourse in post-independence Sri Lanka. This context induces us to place a special focus on the Muslim part.

This paper is divided into eight major sections. After a brief introduction and methodology parts, the next section reviews the historical background of the Eastern province, its demography and political-administrative profiles. The next part examines the impact of politics of development and land settlement projects on the autonomy rights and concerns of minorities in the Eastern region, followed by a section examining the linguistic politics as a way to deny the linguistic rights of minorities in administration and as a means to dominate the provincial public administration. In the last part, before the discussion and conclusion sections, the representative politics and autonomy in the provincial governance are extensively reviewed through examining the provincial council system as a mean to accommodate political autonomy of minorities in the region. The discussion part views the rationales behind the minorities' autonomy concerns and claims and the reactions of the ethnic majority to those claims. The conclusion section summarizes the major findings of the study and proposes alternatives to accommodate the autonomy concerns of ethnic minorities in regional politics and governance.

3. EASTERN PROVINCE: DEMOGRAPHIC, ADMINISTRATIVE, AND POLITICAL PROFILES

The Eastern province covers an area of about 10,000 sq.km, which makes it the fourth biggest province in the country. According to the census of 2012, the Eastern province is a home for a population of 1,555,510, which comprises the country's three major ethnic groups in a competing manner. Accordingly, the Tamils are the majority ethnic group in the region forming 39.5 percent in the provincial population. The Muslims (Moors) form the second majority with 37 percent in provincial population, while Sinhalese forms the second minority with 23 percent in provincial population (See: DCS 2014 & Table-1). The settlement pattern of ethnic groups is also important in the context of ethnic competition and power politics in the Eastern province. The province is divided into three administrative districts in which the Tamils form the first majority in Batticaloa and the second majority in the Trincomalee district. The Muslims form the first majority in Amparai and Trincomalee districts and the second majority in the Batticaloa district. The Sinhalese forms the second majority in Amparai district and the second minority in Batticaloa and Trincomalee districts. However, this ethnic composition is artificially formed through a number of development-cum-settlement projects as extensively viewed in section four of this paper.

The Eastern province is one of the nine provinces, the first level administrative divisions in Sri Lanka. When the British gained control of the entire island of Ceylon in 1815, they divided the island into three ethnic-based administrative regions: one for low country Sinhalese, one for the Kandyan Sinhalese, and one for the Tamils, where the eastern province was part of the Tamil unit since it had predominantly Tamil-speakers (Tamils and Muslims). With the recommendation of Colebrooke-Cameron Commission in 1833, the ethnic-based administrative units were unified into a single central administration in which five provinces were created including the Eastern province in which Governors functioned as administrative heads. Later, these provinces further divided into nine (Ranasinge 2014; Yusoff et al. 2015a). For the administrative easiness, each province is now sub-divided into administrative districts and administered by the Government Agents (GA, also called as District Secretary). Both Governors and the Government Agent are directly appointed by the Head of the State. The Eastern province is divided into three administrative districts, namely Amparai, Batticaloa, and Trincomalee each are sub-divided into 43 Divisional Secretariat (DS) divisions. The province is politically divided into 45 Local Government units (3 Municipal Councils, 5 Urban Councils, and 37 Pradesiya Sabhas), three Electoral Districts and 10 Constituencies, which elect 16 members to the central Parliament, and 37 members to the Provincial Council.

The provinces gained political importance when United National Party (UNP) government introduced Provincial Council system based on the Thirteenth Amendment to the constitution made in 1987, as a mechanism to accommodate minorities claims for self-rule or autonomy. However, in this system, the Eastern province was merged with the Northern province on a temporary basis as to fulfil the autonomy demands of Tamils without the concern from the Eastern provincial population. This reduced the population strengthen of ethnic minorities in the region particularly of Muslims who formed 33 percent earlier and became 17 percent later. This also induced them to advocate for self-rule and a separate autonomous political unit for them in the region. However, the merger of these provinces continued till 2006 when the Supreme Court found the merger illegal and demerged the two provinces. The de-merger had a strategic importance for the Muslim community in the Eastern province, since they obtained the capability of living without the domination of any ethnic group and to ensure the attainment of their regional autonomy demand. However, the emerging ethnic context in the regional politics and the post-civil war political development little supported the Muslims [even the

Tamils] to experience self-rule or autonomy in the region. As history recorded, the province continue to be controlled by the central government authorities, ethnic majorities—the Sinhalese, and their language—Sinhala in the entire post-independent era, as extensively discussed in the following sections.

4. POLITICS OF DEVELOPMENT, LAND SETTLEMENT, AND THE QUESTION OF MINORITY RIGHTS FOR AUTONOMY

The land settlement projects implemented by the successive central government expecting to enhance regional development have also highly influenced in the demographic change, territorial demarcations, and ultimately territorial autonomy in the Eastern province. Historically, the most territories of the Eastern province were under the control of Sinhalese kingdoms and the region was rarely under the control of the North nor was it part of the traditional home rule of Tamils. However, even before independence, the Tamil politicians were claiming or advocating for a separate state or a federation covering the territories of the entire Northern and the Eastern provinces. This claim or advocacy is based on the argument that these regions are the traditional homeland of Tamils where Tamils experience a kind of self-rule. The formation of Federal Party (FP) under the leadership of SJV.Chelvenagayam was also partly based on the above argument and the party has continued to keep this as one of its major demands in its ethnic politics. This is a highly challenging concept and demand for the country's ethnic majority, the Sinhalese, as they have been advocating that Sri Lanka is a Sinhalese-Buddhist nation. Therefore, the Eastern province is the major target of Sinhalese rulers when they receive power from the British colonists. At the time of independence, the Eastern province was entirely a predominant Tamil-speaker region, but most of their settlements were in the coastal areas or belt. Targeting the inland areas, the successive governments initiated many irrigation-cum land settlement projects, and expecting to settle more Sinhalese and to challenge the ethnic dominance of Tamil-speakers in the region.

The successive governments policies with respect to population settlement and regional development in Eastern province have been characterized first by a regime of ethnic transmigration of Sinhalese populations, and second, by an effort to segregate all three ethnic groups into segregated zones of ethnic concentration (Routray and Singh 2007). In the immediate post-colonial period, the Sri Lankan governments engaged in a number of major irrigation and land settlement projects which provided preferential water access to upland Sinhalese populations and served as a platform for programs encouraging the systematic migration of Sinhalese populations into cleared jungle and populated Tamil-or Muslim-majority areas (Peebles 1990). Thereafter, the upland areas of Eastern province have always had a Sinhalese majority population. These Sinhalese settlements induced a rapid decline in the minority population in the region and also questioned the Tamil claim of continued or merged North-Eastern region as the autonomous or federal unit for them.

Starting from the Kantale irrigation-based settlement scheme in 1948 in the Trincomalee district, the land settlement project continued to other parts of the region; Gal Oya settlement project started in 1949 in the Southern part of the Batticaloa district (presently the Amparai district) and Alle and Morawewa in the Trincomalee district and Mahaweli-E scheme in the border of Batticaloa district from 1950 up to 1980s (See: Hasbullah et al. 205; Fonseka and Raheem 2010; Yusoff et al. 2015b). Under the auspices of the above various irrigation-based land settlement and development schemes, Sinhalese peasants were encouraged from the 1950s through the 1980s to move into many parts of the Eastern province by providing them with irrigable agricultural lands and basic amenities. According to the ICG (2008), by the late 1960s, the government had alienated more than 300,000 acres of land to 67,000 allottees in these major colonization schemes. The settlement of so many Sinhalese in these districts which were, at independence, almost entirely Tamil-speaking, was politically explosive and emerged as one of the major grievances expressed by the Tamil and Muslim public, their political leaders, and the Tamil militant groups fought for the liberation of Tamils in North-Eastern region. This process of state-aided colonization was seen not only as a threat to the political and autonomy status of Tamils [and Muslims] but also a threat to the existence of Tamils community with its linguistic and cultural identity (Reddy 2002).

These Sinhalese settlers were further empowered with the establishment of local government and administrative bodies, and electoral constituencies. Borders of these units were also redrawn, favoring them. The ultimate result of these projects was the progressive increase of Sinhalese and the decline of Tamil-speakers in the regional population. The review of the census reports reveals that the Sinhalese population of 4.23 percent in the Eastern province in 1921 has increased to 24.99 percent in 1981. On the other hand, the percentage of Tamils and Muslims has gone down progressively, as summarized in Table-1. Table-2 and Table-3 clearly summarizes the population changes in terms of ethnic groups in the districts of Amparai and the Trincomalee, respectively.

Table-1 Population of Eastern Province by Ethnic Groups (1921-2012)

One of the districts that was seriously affected by land-cum-irrigation-based settlement schemes in the Eastern province is the Amparai district. Before the district was formed in 1961, the Muslims and Tamils had been the predominant population in this area. However, due to the implementation of the Gal Oya project, thousands of acres of lands owned by Muslims and by Tamils were seized by government authorities in order to settle more Sinhalese. As a result, the Sinhalese population progressively increased in the district, reducing the strength of the Tamils and the Muslims (See: Table-2). According to Hasbullah et al. (2005), under the colonization project, beneficiaries were selected overwhelmingly from the Sinhalese rather than the Muslims and Tamils who formed a majority in the region at that time. Table-4 summarizes how the land was shared or allocated among the divisional administrative divisions predominated by ethnic groups in Amparai district.

Even in the post-civil war context, issues over land remain in the Eastern province. According to the Provincial Council Act, land is listed as one of the subjects under the provincial council list, and is under the control of the provincial administration. However, in many instances, according to MRGI (2011), the Chief Minister of the Eastern province has tried to intervene on issues where provincial land has been claimed by the State and/or where complaints have been made to him of individual lands taken over by various authorities, where he had failed to have his views considered by the central government authorities. Specific ways in which the central government authorities appears to be involved in land issues in the East were: taking over land for security purposes or under various ministries; and supporting or assisting and, and sponsoring families from the Sinhalese community of the other districts or provinces to settle in the province.

In fact, as Yusoff et al. (2015b) argues, the land policies and land settlement projects have further induced the emergence of territorial-based political claims (territorial autonomy, self-rule and separate state) in Sri Lankan ethnic conflict. Every land settlement in the dry zone of the Eastern province has been a major source of grievance among Tamil-speaking minorities, contributing to the demands of territorial autonomy among the Muslims, and a separate state among the Tamils. A systemic review of the minority demands in the discourse of ethnic conflict reveals that stopping land seizures and land settlements in the Eastern region, and granting more autonomy in terms of land affairs to the Northern and the Eastern provincial councils were the two major claims of ethnic minorities (See: Hasbullah et al. 2005; Uyangoda, 2009; Fonseka & Raheem 2010; Sarjoon 2011; Fonseka & Jegatheeswaran 2013). On the other hand, state-owned and state-controlled colonization programs, in particular, have been heavily criticized and often targeted by the Tamil fighters, accusing these programs as an effort to expand the Sinhala frontier into the so called 'Tamil homeland.' We discuss this matter extensively in the discussion section.

5. POLITICS OF OFFICIAL LANGUAGE, MINORITIES, AND LINGUISTIC DOMINANCE IN PROVINCIAL ADMINISTRATION

Language is one of the leading causes of ethnic conflict in Sri Lanka. The language problem has its roots in the 1956 Official Language Act, which substituted Sinhala alone for English as the official language. Although the 1957 Official Language Special Provision Act allowed public administration to be conducted in Tamil in the Northern and the Eastern provinces, Tamil legally became an official language with the adaptation of 13th and 16th amendments to the present (1978) constitution, in 1987 and 1988, respectively (See: Parliament Secretariat 2015). This status for Tamil is further ensured with the enactment of the Official Languages Commission Act (No.18) of 1991, as well as government directives through the number of gazette notifications and public administration circulars (See: FCE 2006; Yusoff et al. 2015a). However, the functioning of the public administration in Tamil in the Eastern province has always been a contested matter with regard to ethnic politics and provincial autonomy.

It is worth noting that about four-fifths of the regional population in the Eastern province are Tamil-speakers. However, Tamil-speaking public and public officers continue to receive letters, circulars, and letters from the ministries and the departments in Colombo in Sinhala language. In some districts, particularly in Amparai and Trincomalee in Eastern province, the District Secretaries (or Government Agents), who represent the central government in the administrative system and wield considerable authority, are always of Sinhalese with no or poor knowledge of Tamil. This has helped them to control the administrative affairs of Tamil-speaker predominant region in their hands. This clearly shows the violation of constitutional provisions in terms of minority rights accommodation—another means to undermine the linguistic identity and rights of minorities as part of undermining their self-rule or autonomy claims.

The progress increase of Sinhalese population in the region has led to increase their domination over the local administration in the region. The two Tamil-speakers' predominant districts, namely, Amparai and Trincomalee have continued to be administered by the Sinhalese District Secretary. Similarly, the head of the provincial administration, the Governor, was also appointed from the Sinhalese. It is found that six Governors were appointed for the merged North-Eastern province from 1988 to the end of 2006, and two Governors were appointed for the Eastern provincial council from 2007 to up to now, but none of them were appointed from Tamil-speaking communities while there were constant demands and expectations among them. The appointment of District Secretary and other administrative officers from the same ethnic groups (Sinhalese) over representing their ethnic ratio in the district population easily allowed them to violate the linguistic rights of Tamil-speakers in the region. Tamil-speaking minorities find it not only the violation of constitutionally guaranteed linguistic rights but also the rights to administer their affairs in their own or familiar language.

6. POLITICS OF REGIONAL [PROVINCIAL] COUNCILS, MINORITIES, AND THEIR AUTONOMY CONCERNS IN PROVINCIAL GOVERNANCE

The idea of granting autonomy or establishing autonomous political entity to regionally concentrated ethnic groups has evolved in Sri Lanka even before independence. In 1926, SWRD. Bandaranaike, who returned from British education proposed federalism as the best model to accommodate the autonomy claims of ethnic groups in Sri Lanka. After he became the country's Prime Minister, Bandaranaike offered the Tamil leaders the important concession of setting up regional authorities called 'regional councils' with powers on regional development, education, land, healthcare, water schemes, roads and colonization, through the popularly known Banda-Chelva Agreement. This agreement also agreed to adopt provision for establishing one 'Regional Council' for the Northern province, and two or more Councils for the Eastern province. The FP, while repeating its demands for federal autonomy accepted this agreement as 'an interim adjustment' (Nawarathna-Bandara (2000). However, this first initiative for granting regional autonomy for ethnic communities particularly in the Eastern province became unsuccessful due to the vehement opposition emanating from the imperative Sinhalese-Buddhist ethno-nationalism, which had dominated the Sri Lankan politics in 1950s. Although there were some initiatives on establishing territorial based autonomous councils as a political mechanism to resolve ethnic grievances of minorities, most of them have failed due to the oppositions emerged from the negative understanding of the concept of regional autonomy and because of the domination of majoritarian ethno-nationalism in national politics.

From the 1970s, the democratic political system and territorial integrity of the country came under threat. An insurrection in the Southern part of the country by the Sinhalese youth, known as Jantha Vimukthi Peramuna (JVP) and the youth movements in the North-Eastern regions called the Liberation Tigers of Tamil Eelam (LTTE) and others, influenced the state reform process significantly. During this period, there were some proposals for accommodating self-determination claims of Tamil-speaking people based on federal structure within the united Sri Lanka. However, they did not receive the focus of rulers. Therefore, from the early part of the 1980s, Sri Lanka experienced a gradual intensifying of civil war, and Tamil-speakers demanding more autonomy and self-rule, even separation in their traditional homeland. The LTTE and the other movements became increasingly violent due to lack of state mechanism to accommodate their autonomy claims and interest in regional governance structure.

From 1985 onward, the government of Sri Lanka was seen toward a military solution to separatist and terrorist campaigns of the LTTE and other militant groups. This induced the Indian intervention in Sri Lankan ethnic conflict. Faced with the possibility of an active Indian intervention, Sri Lanka government commenced negotiation with the Indian counterpart. This led eventually to the signing of Indo-Sri Lanka Accord on 29th July 1987 (Lakshman 2017). Accordingly, Thirteenth Amendment to the constitution was adopted on 14th November 1987 and provincial councils were established for every province, as specified in the 8th schedule of the constitution. The provincial council was expected to function as a politically decentralized institution.

The Indo-Sri Lanka Accord insisted the merging of the Eastern province with the Northern province to make it into one provincial council as an interim arrangement to accommodate the political autonomy claims of Tamil-speakers. The accord included a provision for a referendum to be conducted within the Eastern province by the end of 1989 in order to decide whether or not the Eastern province should continue to remain merged with the North. The merged North-Eastern province was declared by the President in 1988. Like other provincial councils, election to the newly formed North-Eastern provincial council was held on 19th November 1988. The referendum in the Eastern province, however, was never conducted and the successive Sri Lankan Presidents issued proclamations annually, extending the life of the temperately merged entity (Lackshman 2017).

In fact, the introduction of provincial councils was meant to ameliorate the demands particularly of the Tamil community, who sought a separate State or tangible autonomy for the Northern and Eastern provinces in Sri Lanka. However, the provincial councils, which fell far short of federalism, nevertheless, introduced the devolution of power. However, when it comes to practice, particularly in the Northern and the Eastern regions, the central government authorities strategically put mechanisms to control or undermine the exercise of devolved powers by the provincial council or the council of ministers. It is worth noting that the Provincial Council Act devolved land and police powers to the provincial councils, but the central government authorities denied those powers to exercise by the North-Eastern provincial council, and council of ministers. This was the major reason for the Chief Minister of the merged North-Eastern province and the leaders of Eelam People Revolutionary Liberation Front (EPRLF), A.Waradaraja Perumal to oppose the provincial council system and to pass a resolution in the provincial council in favour of a separate state for Tamils. This was ultimately led to dissolve the North-Eastern provincial council in one year survival.

The merger of Northern and the Eastern provinces together was bitterly opposed and campaigned negatively by the Sinhalese-Buddhist nationalist forces and parties. Ultimately, a Supreme Court ruling in October 2006, made a response to a case filed by the JVP, which eventually produced the de-merger of the two provinces permanently founding it unconstitutional, illegal, and invalid (Asian Tribune 2006). The de-merger came eventually in January 2007 and provision was made to set up the Provincial Council each in the Northern and the Eastern provinces. The Tamils view this as a major challenge to achieve their self-rule or autonomy claims in the traditional homeland of the merged North-East.

After the de-merger, the Eastern province has been functioning with democratically elected political bodies. However, the minorities worry about the dominance and rigid control of central government authorities, Sinhala language, and administrative elites mostly Sinhalese in the administrative, development, and political affairs of the province. This, in turn, in many ways helped undermine the minority expectations for exercising self-rule and autonomy in the region.

Politics of Representation and Regional Autonomy of Tamils and Muslims in the East

Self-determination and self-government have been in the critical demand of minority ethnic groups for over half a century in Sri Lanka. During the ethnic conflict and civil war, there have been attempts by successive Sri Lankan governments to discuss some form of political autonomy for minorities, mainly for the Tamils. However, the status of the Eastern province, and locating it within the power-sharing debates have continued to be a contested matter in the process of state-building and territorial autonomy discourse in Sri Lanka. This issue has continued even after the de-merger of the North-Eastern provinces and its influence in its electoral politics. The electoral politics has made the Eastern province the stage for power competition between the major ethnic groups. The Muslim community has become the special target of two ethnic majorities, the Sinhalese and the Tamils, as the major supporters to achieve control of the Eastern provincial council and experience a kind of self-rule and autonomy in the region.

In the last two decades, following a change in the electoral system to a proportional representation system, the minority political parties have played an influential role in Sri Lankan politics. Sri Lanka Muslim Congress (SLMC), which is the largest Muslim political party, has been in the position to make and break governments. The SLMC has emerged out of the political marginalization and grievances of Muslims of the Eastern [and the Northern] provinces in the early 1980s. The ethnic politics and the vulnerable position of the Muslim community due to violent civil war made the SLMC the major political voice and a representative body for Muslims in the national parliament and provincial councils (Yusoff et al. 2017). Therefore, though the SLMC opposed the merging of the Eastern province with the North, it contested the first election for the merged North-Eastern provincial council held in 1988 and has become the main opposition party in the council. During this election, ethnic sentiments have been highly motivated. Therefore, there have only been ethnic competition among three major ethnic groups. This led the SLMC to secure the highest Muslims votes and representations in the election although the Muslims in the region had a habit of supporting and voting the two major pro-Sinhalese parties, the UNP and the SLFP.

With the opposition leadership, the SLMC voiced the grievances of the Muslim community and advocated for their rights and privileges in the North-Eastern provincial council. Although this council was dissolved in one year period by the President, this electoral victory driven the SLMC became influenced in national politics. In successive elections, with the increase in public support and representations, the SLMC became the major political force that could influence to determine the destiny of national politics. This ultimately made the SLMC as the Queen-maker in 1994 and the successive general elections in the new millennium (Yusoff et al. 2017).

The more ethnic-based demands and their advocacy by the SLMC has brought more criticisms and oppositions to the SLMC in national politics. With the sudden demise of its founder, MHM.Ashraff, in September 2000, the SLMC became fragmented and more Muslims political parties mushroomed. When election was declared to the newly formed Eastern provincial council, it was winning the majority Muslim representations in the council, which has become the major target

of the SLMC. At that time, a tri-polar competition among Muslim political parties was existing. This has helped the-then President Rajapaksa and the UPFA leaders to convince the two major Muslim parties in his alliance while promising the CM post for Muslims. There were huge demands among the Muslim civil society urging all Muslim parties to unite and contest the election under a common symbol. The SLMC was not ready to conceal the tree symbol; therefore, unification failed and as usual it contested with the UNP, the main opposition party at that time. The SLMC leader, Rauff Hakeem, its chairman, Basheer Segu Davood, and its secretary general, Hasan Ali, resigned from their seats in the central parliament and contested the provincial council election as leading candidates under the UNP ticket in three districts of the Eastern province (Yusoff et al. 2014). Although the elections produced results favouring Muslims, due to disagreement and fragmentations within the Muslim parties, they could not achieve the CM post nor receive any influential provincial ministries.

On the other hand, the major Tamil political party, the Tamil National Alliance (TNA), had boycotted the 2008 provincial council election arguing that the de-merger of the North-Eastern provinces had undermined the self-determination rights of the Tamil people. This has helped the newly-formed Tamil Makkal Vidutalaip Puligal (TMVP) headed by Pillaiyan, alias Sivanesathurai Chandrakanthan to make an alliance with the ruling UPFA government. The UPFA had agreement with the TMVP to offer the CM post if they could receive more representatives in the council. Even though eight Muslims and six Tamils were elected from the UPFA list in the election indicating that the Muslims were the majority elected under the UPFA list, the UPFA leader, President Rajapaksa, after a long political turmoil, appointed Pillaiyan as the CM of the Eastern province (See: Yusoff et al. 2014). However, UPFA leaders strategically controlled the Eastern provincial council by appointing Sinhalese to the most important ministries such as land and education, expecting to expand their dominance in the province. This has helped them implement a number of policies and projects in the province favouring the Sinhalese and to extend their dominance in the post-war development and governance process. During this period of provincial council, both the Muslim and Tamil councillors expressed their disappointment in regard to their ministerial positions and expectations in provincial governance. Hisbullah, the then provincial minister of health, openly revealed the inefficiency of his ministerial position at one point. Although the UPFA-led government made number of initiatives for post-civil war development in the region, the control of the entire development and provincial administration was at the hand of central ministers and the provincial Governor, who was appointed by the President.

With the failure to control provincial administration in 2008, there have been continuous discourses among the Eastern Muslims on controlling the provincial council in the forthcoming election. Although election to the Eastern provincial council was due in 2013 only, President Rajapaksa dissolved it early and fixed the election on 8th September 2012. Both major political parties started to make an alliance with the influential parties in the East. An important change of the political context in the Eastern province was the TNA's announcement to contest the provincial council election. The TNA contested the election under The Ilankai Tamil Arasu Kadchi (ITAK).

Since Muslims formed a decisive majority in the provincial population (it was projected as 40 percent in 2007, but actually was 37 percent, according to the 2012 census (DCS, 2014)), both the UPFA and the TNA invited the SLMC for electoral coalition, while there were more demands from the Muslim community to contest the SLMC alone or with other Muslim parties. However, the SLMC was not in favour of conducting the election under a common symbol for the sake of Muslims but only favoured being with the UPFA alliance. When the coalition negotiation with the UPFA failed; mainly due disagreement on the matter of establishing a Muslim predominant administrative district in the coastal belt of Amparai district before the election, the SLMC decided to contest the election alone under its own symbol believing only in its traditional Muslim loyalties, while there were demands for Muslim coalition (Yusoff et al. 2014).

The 2012 provincial council election produced the SLMC again the 'King-maker' in forming the provincial government. While no party received any majority to form the government, the seven seats gained by the SLMC became a decisive number to form the government. The TNA openly announced that they are willing to concede the CM post to the Muslims if the SLMC agreed to form a provincial government with TNA (Colombo Telegraph 2012). However, believing that the consensus reached the UPFA, so as to fulfil the rightful rights of Muslims in the provincial administration, which would enable them to gain autonomy to some extent, the SLMC leaders supported the UPFA to form a provincial government. In fact, the UPFA leaders convinced the SLMC to make an alliance with them in the provincial government. However, not the SLMC nor any Muslim political party have been able to gain any important ministry in the provincial government, although two Chief Ministers were appointed from Muslim members, they acted as rappers, for which the central government authorities had major control over. The Sinhalese ministers with the provincial Governor extended their ultimate dominance in the affairs of the provincial administration, governance and development.

The defeat of Rajapaksa regime in early 2015 tremendously influenced Sri Lanka's national politics. Ethnic minorities played vital roles in defeating President Rajapaksa and his government in the elections held in 2015. This increased the importance of the minority political parties in Sri Lanka's national and regional politics as well. The TNA became the major opposition party in parliament after the 2015 general election. This regime change has also influenced the provincial politics and induced the Sinhalese rulers to initiate a coalition with the minorities, particularly with the Tamils, to survive and control the Eastern provincial council and governance. This time, the UPFA formed a coalition government with the TNA while merely accommodating the Muslims' interests to the so-called positions.

While keeping the SLMC and other Muslim parties as coalition partners in the Eastern provincial council, the UPFA-led central government was able to convince these parties to act in favour of their decisions or to endorse the provincial approval for many legal, political, and policy decisions taken to favouring the regime. Whenever the support of these parties were extended, and decisions were endorsed, these minority parties extended their supports believing on the

promise that they could enjoy a greater level of autonomy and control in the provincial governance and administration. However, up till now, the ethnic minorities' expectations in many matters related to ensuring their interests for autonomy has continued to be side-tracked or unsuccessful. The appointment of the provincial Governor from the Tamil-speaking communities, proper implementation of Tamil as official language, appointment of Tamil-speaking officers as District Secretaries in Amparai and Trincomalee districts, granting police and land power to the provincial council, establishing a Tamil-speakers' predominate administrative district in the coastal belt of the Amparai district for the administrative easiness of Tamil-speakers were some the continuous demands put forward by the Tamils and Muslims in the province, so as to ensure a kind of administrative and political autonomy in their part in the province. However, none of these demands were positively viewed and accommodated by the central government authorities, and therefore are always criticized and opposed on communal ground.

However, in terms of electoral politics in the Eastern province, with the results of the two elections not producing any single party absolute majority to form the provincial government, the Eastern provincial council has become a testing ground for political competency and maturity of any national and minority political party in their effort to establish a provincial government and administration with an absolute majority and to run them without any disruption. The election scenarios have also emphasized the importance of ethnic cohesive politics in the region rather than advocating ethnic group dominance or autonomy in the future.

7. DISCUSSION

The regional politics and governance in Eastern Sri Lanka has continued to be a contested matter due to the competing ethnic composition in the region and the power dominance of the ethnic majority over regional development, administration, and governance. Although the Tamil-speaking minorities, the Tamil and the Muslims, form the majority in the province, the provincial administration and governance continue to be controlled by the Sinhalese and their interests. The continuous claims of ethnic minorities for political autonomy and self-rule in the regional governance and administration were mostly responded negatively. There are fears among the majority Sinhalese and their leaders that granting regional autonomy will be merely a springboard to secession. However, autonomy and decentralization are seen by experts and governments as favourable tools in accommodating minority concerns and grievances in regional governance.

Therefore, there is a need for constitutional reform to provide more political and administrative autonomy for minorities in the Eastern province by examining the limitations of the existing legislative framework and analysing the most recent proposals. Although the existing devolution arrangement under the Thirteenth Amendment of the present constitution provides some level of devolved powers to the provinces [regions], this amendment is limited both on paper and in practice. Therefore, the Thirteenth Amendment is far from sufficient in fulfilling the minorities' aspirations to self-rule in the North and the East and there is a need to think and work beyond this limit so as to share more powers to the regions and to grant more autonomy to the regionally-concentrated ethnic groups in deciding their own regional affairs.

Tamil vs Muslim interests for regional autonomy in the East

There are different motives and aspirations among ethnic groups in terms of claims for regional autonomy and self-rule in the Eastern province. Although the Tamils and Muslims are living together, sharing a number of commonalities in the region, and having been collectively advocating for their rights and privileges from independence, including the equal status to Tamil language and for greater regional autonomy, where the two communities have a different perspective of autonomy for any minority in the region. Even before the independence, Tamils have been arguing that the Eastern province is part of their traditional homeland of merged North-East. In the 1977 election manifesto, the Tamil United Liberation Front declared an area slightly beyond the present borders of the combined Northern and Eastern provinces to be 'the exclusive homeland of the Tamils.' By the 1980s, the East was at the heart of the militant Tamil nationalist struggle to create a separate state of Tamil Eelam.

On the other hand, when the civil war became severe from 1980s onward, it negatively impacted the Muslim community and further increased their grievances as a result of the negligence of Tamil leaders. The government proposal to merge the Eastern province with the North also contributed to an increase in a sense of marginalization in the political settlement process among the Muslims in the East. These factors induced them to conceptualize and call for a Muslim predominant political autonomous unit for their security and ethnic identity. From 1980s onward, Muslim political forces, particularly the Sri Lanka Muslim Congress (SLMC), the party emerged as a response to severe ethnic conflict and ethnic politics, have been proposing a Muslim majority political autonomous unit and articulating it as a political mechanism on the Muslim part in the ethnic conflict resolution process (Yusoff et al. 2014; Sarjoon 2011; McGilvray and Raheem 2007). However, this was viewed by the Tamil nationalists and militant groups as opposed to their long-term demand of self-rule in their traditional homeland covering the entire and contiguous North-Eastern region. Therefore, Muslim autonomy demand was always criticized and challenged by the Tamil nationalists. However, both ethnic groups and their leaders continued to advocate their autonomy claims in the North-Eastern region in which the status of the Eastern region has always been a hot topic of debate during their advocacy.

It is worth noting that as noted earlier, the popular Sinhala and Tamil leaders SWRD.Bandaranaike and SJV.Chelvenayagam, in their agreement in 1957, have made an arrangement to form two or more autonomous units in the Eastern province to ensure the autonomy and self-rule of major ethnic groups living in the region (See: Ghosh 2003). As Jeyaraj (2016) argues, Chelvanayagam's approach is a recognition of regional and sub-national differences within the

North-Eastern region. This further indicates the importance of ensuring shared rule or self-rule for ethnic groups in the region.

When the demerger of the two provinces became successful in 2006, both Tamils and Muslims eagerly engaged in regional politics, expecting to form a provincial government that would give them autonomy in due time. Therefore, when the election was called for the Eastern provincial council, the SLMC, since it has been advocating for Muslim autonomous unit in the region, actively participated in the election. However, the more fragmentations and opportunisms in Muslim politics undermined the ability of Muslim political forces to gain influence in elections and control the provincial governance, as viewed earlier in this paper. However, it is worth noting that although the Tamil nationalist forces and liberal groups undermined the Muslim autonomy in the East, the Muslims leaders have been thorough in not opposing the demands and aspirations of Tamils on the matter of political autonomy. Only in the recent year, the political leaderships of the Tamil community have accepted the self-rule concept of Muslims in the East and expressed their willingness to establish an autonomous unit for Muslims when it comes to resolving the ethnic conflict by merging the Eastern province with the North. Similarly, many Muslims seem to have a realistic perspective that establishing an autonomous unit for Muslims by territorial merging of some kinds in the North-Eastern region must be an inevitable part of a political settlement to address Tamil grievances (McGilvray and Raheem 2007). However, there is a need for more mutual dialogs in this regard between the political and community leaders of both ethnic groups.

The Sinhalese criticisms and opposition to merge the Eastern region with the North, or to grant more autonomy to the Eastern provincial council has also arisen based on the arguments that the East was not always been part of, or under the control of the North. Accordingly, the major territories of the Eastern province are under the control of Sinhalese kingdoms of the so-called Dry Zones centred in Anuradhapura and later in Polonnaruwa. Today's Batticaloa and Amparai districts were under the control of the South-Eastern Sinhalese Ruhuna kingdom 300-200 BCE. However, the Sinhalese and Buddhist presence in the East had all but disappeared by the thirteenth century, except for a small number of widely scattered Sinhala settlements in the forested areas at the foothills of central hill country due to South Indian invasion and the expansion of Jaffna kingdom in the region. As McGilvray (2008) argues, the collapse of the Sinhala dry zone kingdoms in the thirteenth century opened the way for the slow 'Tamilisation' of the Eastern province.

Based on the above argument, in the post-independence era, the successive central governments attempted to equate the ethnic compositions in the districts of the Eastern province by implementing number of state-aided development-cum-land settlement projects. Sinhalese found that granting land to the Sinhalese is a positive process aimed at distributing land to the landless. There is also a perception among the Sinhalese that they are not stealing land from minorities but are merely re-claiming land that they abandoned centuries ago. They further claim that the process of land settlements in the North-Eastern region is to establish inter-racial equity (Marga 1985). Therefore, the settlement of more Sinhalese through state-sponsored land settlement programs, and the control of central government authorities in opposition to autonomy for Tamils and Muslims in the region were justified in this line. In fact, as Yusoff et al. (2015b) argues, the Tamil separate state (homeland) demand and the Muslim demand for an autonomous political unit, to a considerable extent, have challenged the ability of the central government authorities to control land in the Eastern province.

Similarly, the pro-Sinhalese governments have also used land settlement schemes to undermine the Tamils' claims of merged North-East as their traditional homeland. The settlements of more Sinhalese on the borders of districts in the Eastern provinces were motivated towards this line. There was no initial plan to turn the Mahaveli river to the North-Eastern region, but later, the UNP government purposively turned it in two areas to settle more Sinhalese as buffer zones in diving the concept of traditional homelands for Tamils. Settling the Sinhalese at the border of the Eastern province with the North (at Weli Oya), and between the Trincomalee and Batticaloa boarder (at Weliganda area) was designed in this regard. The Tamil nationalists claim that this is an attempt at bifurcating the North from the East with a string of Sinhalese settlements and to undermine their autonomy demands in the East.

On the other hand, there are other motives for government authorities and majority Sinhalese to keep the control of the Eastern province in their hand. Eastern province is enriched with natural resources valuable to the country's national economic benefits. Forests, agricultural lands, wetlands, lagoons, sea ports, and attractive beaches are prominent among these resources. Above all, there has been a well-established ancient irrigation system in the province, which supports the full potential of agricultural production. The Trincomalee district has a natural harbour, which played a strategic role during the world wars, and the civil war period in Sri Lanka. The state-aided settlements of the Sinhalese are mainly located in these resource basins and other strategic locations in the province. These settlers have been controlling the economic and administrative affairs of districts and province to a considerable extent. There is a fear among Sinhalese and rulers that granting more autonomy in the hand of ethnic minorities, the Tamils and the Muslims, may directly and indirectly challenge the interests and dominance of Sinhalese. There is no assurance that the regional autonomy to the Tamils and Muslims will ensure the rights and interests of Sinhalese living as pockets in the regions. This can be one of the major reasons that opposing or unfulfilling the Tamil-speakers' demands to appoint Provincial Governor, and District Secretaries for Amparai and Trincomalee from Tamil-speaking communities. Because these officers are the major pillars and guardians of fulfilling the central government's expectations in the districts of these region.

Similarly, Sinhalese leaders feel that granting autonomy for minorities in the North-East would easily promote regionalism and secession that will ultimately challenge the territorial integrity of the country. This feeling ultimately helps mobilise the Sinhalese masses to challenge any minority demand for autonomy as a threat to territorial integrity through which minorities will attempt to establish new states easily. These feelings and fears progressively motivated

the central government authorities and the Sinhalese easily undermine any claim coming from ethnic minorities in the region for regional autonomy and self-rule.

8. CONCLUSIONS

Self-determination and self-government expecting to exercise more autonomy in political and administrative affairs have been the critical demands of minority groups for over half a century in Sri Lanka. The Eastern province has been a contested region in terms of ethnic and minority politics and politics for autonomy compared to other regions in Sri Lanka. The ethnic composition in the region has been highly influential in ethnic relations, ethnic conflict, ethnic politics, development, and governance in the region. Ethnic minorities, though they possess the majority in the provincial population, could not enjoy autonomy and devolved power in the affairs of regional governance and administration. They have always been controlled by the central government authorities or regimes, which have used them as periodic tools for fulfilling their political interests and agendas in the province. Therefore, from the beginning of independence, the pro-Sinhalese political parties and regimes easily implemented a number of policies and projects to settle more Sinhalese in the region, targeting to undermine ethnic composition of minorities in the region, failing to implement the policy recognizing Tamil as the official language equal to Sinhala in public administration, but allowing the domination of Sinhalese and Sinhala language at an extreme level, refusing to grant constitutionally-guaranteed devolved power in the affairs of provincial police and land, and expanding the dominance of the central regime in the political and administrative apparatuses of the provincial government.

In fact, all of the above identified factors have motivated the intensified ethnic conflict and civil war in the region that has further challenged the influence, power exercise, and autonomy of minorities in the region in one hand, and induced the claims for autonomy, self-rule, and separation on the other hand. Since the civil war has ended, and all the minority political parties and civil forces have abandoned the separatist claims, ensuring regional autonomy for minorities has become important in the process of post-civil war transformation and the political settlement process. Autonomy and decentralization are seen as the best tools to accommodate minority concerns and claims for self- and shared-rule within the unitary system of government. There are a number of successful cases around the world in which minorities are given more autonomy to decide their political and administrative affairs while maintaining their ethnic and regional identities.

When the state faces autonomy demands from competing ethnic groups from a multi-ethnic region, granting more autonomy to the regional-based political council can accommodate the minorities' concerns within the united country, to a considerable extent. Therefore, in the post-civil war context, implementation of the regional autonomy policy is critically important to enhance the relationship of equality, unity, and mutual assistance among different ethnic groups, to uphold national integration, and to accelerate the development of places within the region and prosperity for all ethnic groups. However, in Sri Lanka, political autonomy, power-sharing, and decentralization still remain largely debated subjects. Initiatives for conceptual clarification and understanding among ethnic majority, national political leaders, and regional minorities together with mass education are highly needed in this regard.

1681 REGENERATIVE LANDSCAPING IN RETROFITTING AND RECREATING TROPICAL CITIES USING COMMUNITY BASED APPROACH

Hema Rallapalli, Jagadeesh Gorle

CEPT University, INDIA

ABSTRACT

Climate change is a phenomenon that is currently a threat to all the living species on our planet. It particularly poses challenges for cities with frequent flooding, heat waves, droughts and other extreme weather conditions which have direct impact on urban neighbourhoods and infrastructure, and consequently affect the health and mortality of urban population. Due to the unique geographical location, the tropical cities emerge from the life supporting elements such as hills, forests, lakes and rivers. However unplanned urbanisation is bringing biophysical changes in the environment making cities vulnerable to disasters. Understanding the cities and the interactions between natural and built environment help us in making cities more resilient to natural disasters and creating a healthy atmosphere to the urban population. There is a need for regenerative development with the involvement of communities to work with the natural systems through productive landscaping in urban built environment. Urban farming, where food is grown and maintained by the public in various vacant plots, parks, gardens, streets, building rooftops etc. have multiple social, economic and environmental benefits. Transforming the dead spaces into active and productive areas through a regenerative process will conserve the natural ecosystem values and functions and provides associated benefits to urban population. This paper discusses a conceptual review of local and micro scale approaches that incorporate the techniques of modifying the urban fabric and designing vegetative areas in a sustainable approach through the concept of productive and regenerative landscaping and other mitigating strategies to improve urban built environment. The paper focuses on solving the socio-economic and ecological issues concerned with the urban spaces through productive gardening as one approach. A study of the inflow and outflow of energies to the cities in the form of food and waste is presented in the paper discussing the issues that are linked and possible solutions. Various ecological solutions are suggested for improving air quality, conserving the top soil, improving ground water recharge, saving the water bodies from excess nutrient load, providing green patches to act as carbon sinks etc. A case study of the implementation of regenerative landscaping in Indian coastal city, Visakhapatnam is done and the inferences are discussed, identifying the models that were successful on microscale and the possibility of expanding the same on a macro level along with anticipated challenges and solutions. The findings of this paper are hoped to guide the practitioners in architecture, landscape architecture, urban design and policy making to incorporate sustainable landscape design approach towards building resilient cities, improving the microclimate and providing a better quality of life.

INTRODUCTION

Humanity is currently depleting the natural capital stocks of the planet and eroding its resilience. That is evident from the increasing problems and calamities we are facing today. According to WWF Living Planet 2012¹, "We are using 50 per cent more resources than the Earth can provide, and unless we change course that number will grow very fast. By 2030, even two planets will not be enough." Cities and urban areas were major contributors to this trend. It is clear, then, that in order for cities to develop sustainably, they must not only stop their extraction of natural resources faster than ecosystems can recover but reverse the trend by improving the regenerative capacity of ecosystems. This is the only way cities can be sustained in the long term.

Regenerative urban development requires a switch from the old linear metabolic system to a circular metabolic system that can be found in nature. In nature there are no landfills; all waste becomes organic nutrients for new growth. Closing the urban resource cycle means finding value in outputs that are conventionally regarded as waste and using them as resource inputs in local and regional production systems. A regenerative city reintroduces treated water into the hydrology cycle, increasingly sources food from urban and peri-urban producers, captures the nutrients from its waste and reduces its dependence on non-renewable energy. Closing resource loops in this way is the first step toward regenerative development. This entails returning organic nutrients to soils, growing plants and trees, replenishing watersheds and developing ecosystem infrastructures within the city to encourage urban biodiversity. Doing so helps to strengthen the regenerative capacity of ecosystems on the local, regional and global levels.

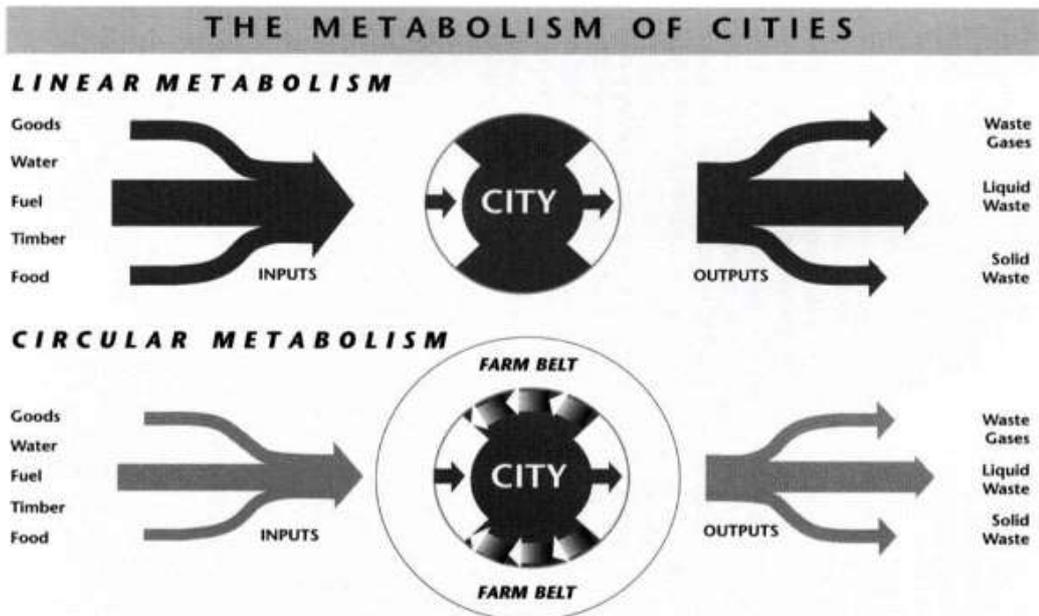

Figure 1: Linear metabolic system vs Circular metabolic system in Cities²

One advantage cities have is high concentration of human capital, that have tremendous potential to be an asset in tackling the pressing challenges we face today. Therefore, involving the community and providing a solution through the community involvement is the way to transform our cities into regenerative cities. Cities that close their resource loops and source an increasing share of the resources they consume from their own territory create social, economic and environmental value in their communities (See figure 1). Promoting urban and peri-urban farming to feed the urban population results in increased efficiency in water and nutrient use as well as have a smaller energy demand through a lesser need for food transportation, storage and packaging.

WHAT IS URBAN FARMING?

Urban farming, refers to growing food in various spaces in the city - the backyards and balconies of houses, vacant lots, parking lots, rooftops, parks, private or public spaces for the urban consumers. Urban farming is a practice that ensures the community where their food comes from, how is it grown, how safe is it to be consumed, and what to do with the food waste. This is a sustainable practice that improves community activity, improves the quality of public and semi-public spaces, decreases the distance that food is transported, increases food security and awareness about healthy food and provides facilities for organic waste recovery through composting.

Urban farming is not an entirely new concept. Since most of our ancestors have agrarian roots, they used to have the practice of maintaining kitchen garden in which they used to grow food. However, over the years due to industrialization and urbanisation, this system has declined. Today, due to various problems the city dwellers are facing like food insecurity, air water and land pollution, food contamination, etc it is important to practice urban farming. Urban farming will help the city to adapt to climate change and reduce its ecological foot print. It contributes to disaster risk reduction and adaptation to climate change by reducing runoff, reducing urban temperatures, sequestering CO₂ etc.

Table 1: Potential areas for growing food based on landuse and land availability

Natural Forest Area	Rural Area	Peri-urban Area	Urban Area	Core Urban Area
	Agriculture	Agriculture	Public Farms	Front yard and backyard
		Industrial Area Farms	Community Farms	Garden Balconies
		Institutional Farms	Institutional Farms	Roof tops
		Green houses	School Farms	Window Sill
			Front yard and backyard gardens	Walls
			Green houses	Vertical farms
			Roof tops	Streets

Growing fresh food close to consumers reduces energy spent in transport, cooling, processing and packaging, and in productive reuse of urban organic wastes and wastewater thereby reducing the load on landfills.

WHY DO WE NEED URBAN FARMING?

- Provide food and nutrition to the community.
- Reduces the distance food has to travel giving access to fresh produce and
- Filter and purify the air and water in the community, especially important in urban areas.
- Provide habitat for local wildlife like birds, rabbits, and butterflies.

- Beautify the community.
- Allow for social interaction within a community. Community gardens also promote intergenerational interactions.
- Provide a location for social activities like gardening demos, harvest parties, and potlucks.
- Remove carbon dioxide and other greenhouse gases from the air.
- Provide opportunities to exercise and engage in physical activity.
- Keep the community active, which encourages social interaction and deters crime.
- Urban revitalisation: Urban farms developed in under-utilized urban spaces such as vacant lots or under-used parks will turn into lush green space and hub of activity for the community and urban farmers.
- Crops: Use of indigenous seeds and native plants and trees will decrease the attraction to pest and disease and increase the resilience in extreme weather conditions in the farm and help in saving and propagating the seeds. Sharing seeds and produce with the neighbours will build the community.

URBAN FARMING AS A SOCIALLY INCLUSIVE ACTIVITY.

The stakeholder in Urban Farming are the government, the NGOs working in this area and citizens who can be divided into active and passive users. Active users refers to those who take active interest in Urban Farming, attend workshops and learn about urban farming and work towards building their community Farm. Passive users are ones who are not keen on learning and developing the farm but will use the spaces after it has been established. It is hoped that once the farm is established and there is activity on the farm, it would attract the passive users to become active users and motivate them to work on the farm. As opposed to formal city parks, urban community farms refers to the leadership and active participation of city residents who take it upon themselves to build healthier sustainable communities through farming and enjoy the ‘socio-ecological spaces’ and the associated flora, fauna, and facilities (See figure 2 and 4).

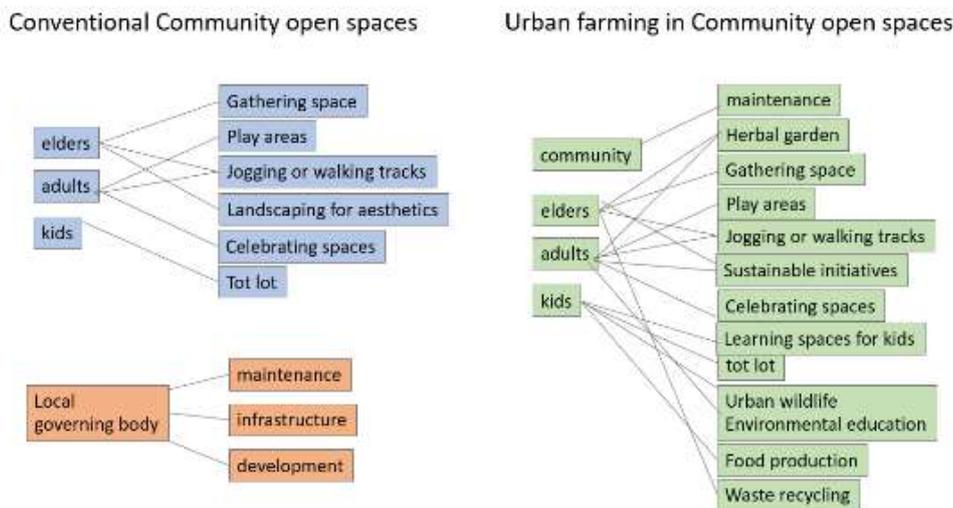

Figure 2: Showing various social-economic activities of Conventional community spaces vs. Urban community farms

Urban farming with community involvement is healthy and socially productive (See figure 3). Linkages in the food chain become stronger when the food is grown locally and sustainably. Farming can be a fun activity that families or communities can do together. Working with soil on the farm connects people with the nature. This outdoor activity allows kids to learn about where food comes from, how is it produced and allows them to learn about bees, butterflies, ladybugs, birds, squirrels etc. Once children start understanding the ecosystem and that they are a part of this ecosystem which has different elements that are interdependent, they will start respecting the environment and grow up to become responsible adults.

Community farms also become a safe space where youth and adults come to socialize, participate in cultural events (e.g. meetings, festival celebrations, harvest celebrations), relax, learn about gardening, exercise, and enjoy nature. Given that individuals engaged in urban community farming organize, and learn together, often gives them a sense of empowerment and self-efficacy therefore it can be viewed as an institution that contributes to social learning related to community development and food security. Children involved in growing their own food will learn about the importance of food, how many resources, work and time it takes to grow they will learn to respect food. A matrix showing the health, social and ecological benefits of Urban Farming are shown in Figure 5.

Figure 3: Showing various social-economic activities of Urban community farms

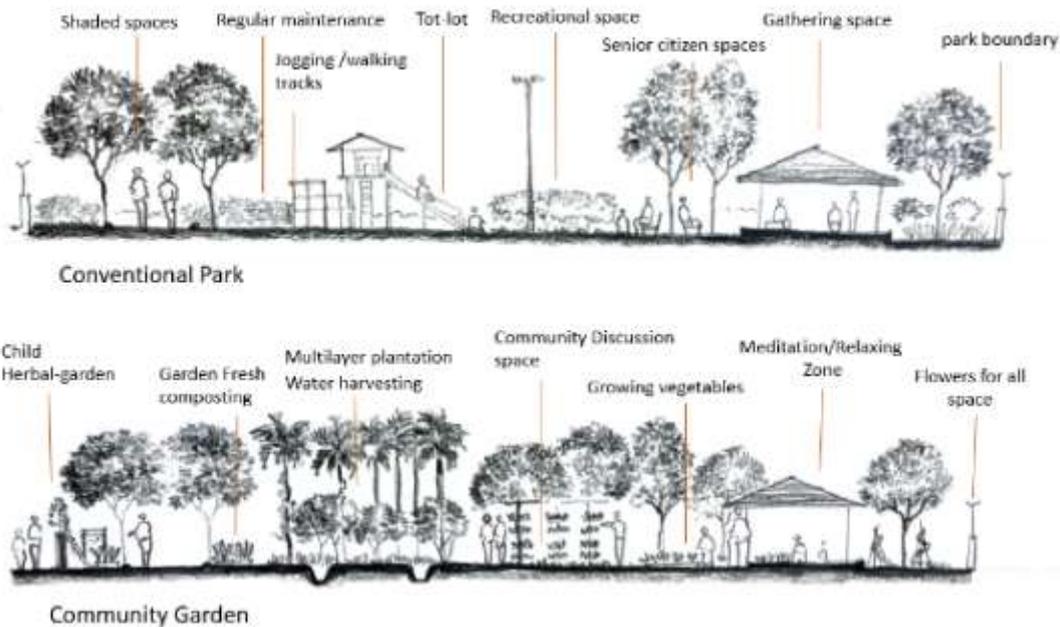

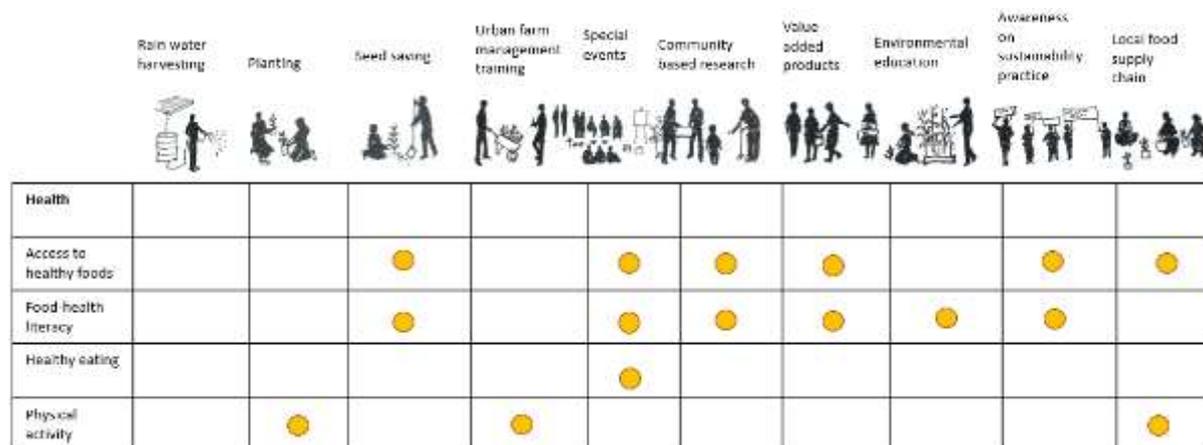

Figure 4: Shows the Conventional park design vs Community Farm design

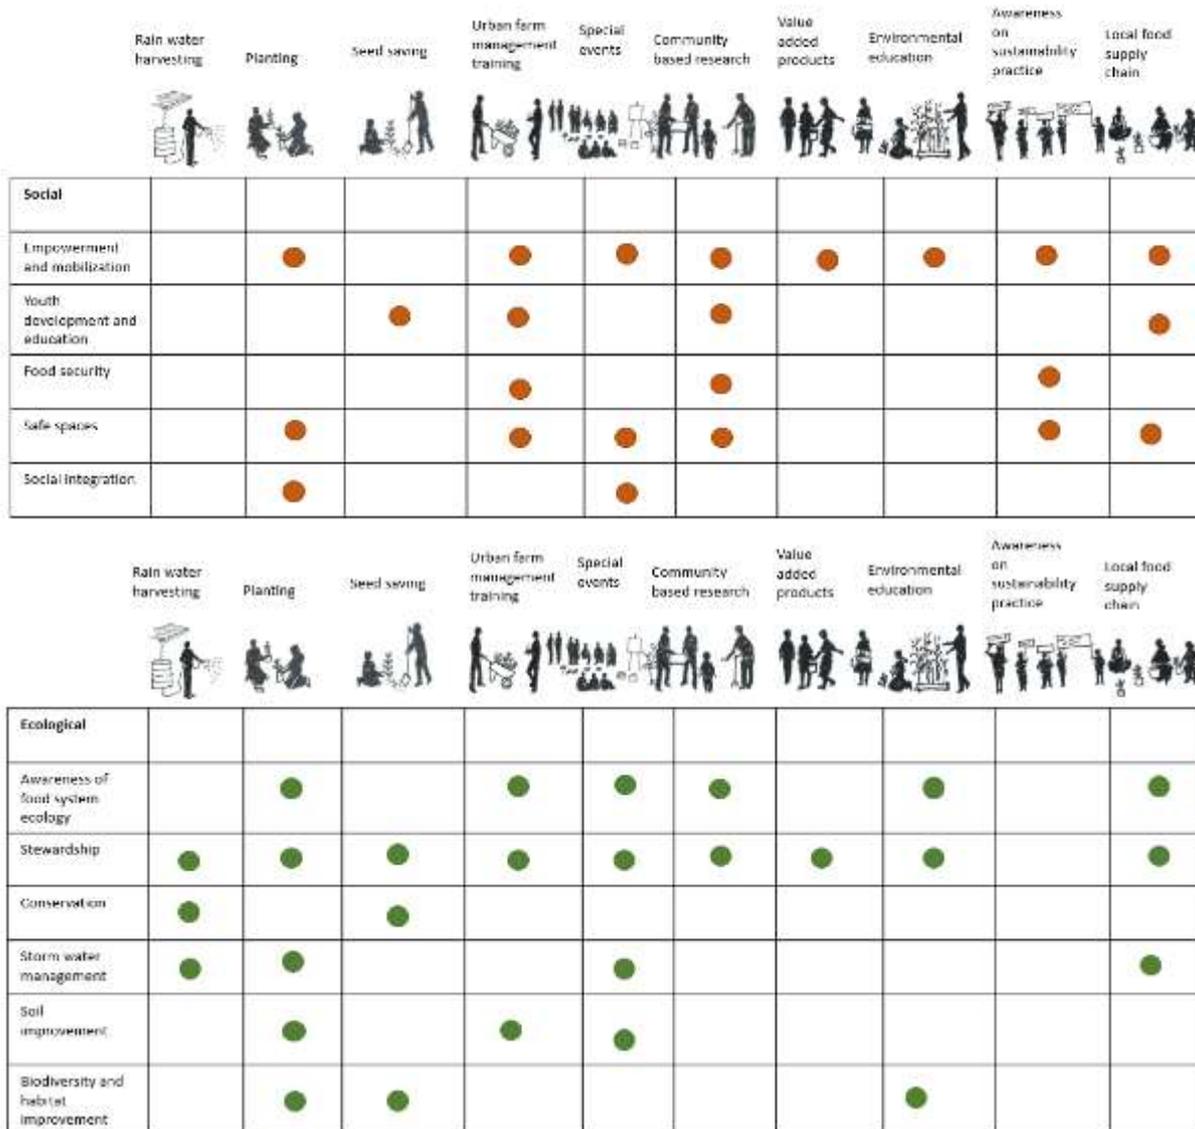

Figure 5: Matrix showing the Health, Social and ecological benefits of various activities in a community farm.

HOW TO DO URBAN FARMING?

Resources required for urban farming:

- Land/space – Open spaces, parks, vacant plots, rooftops, balconies, property setbacks, etc
- Growing medium – soil, cocopeat, compost, water (hydroponics)
- Crops – Seeds and saplings
- Water supply - municipal water, ground water, waste water recovered from household, harvested rainwater
- Electricity – for irrigation and night lighting
- Waste management - The reuse of urban organic solid wastes (composting, vermiculture) and waste water (for irrigation and nutrients)
- Manpower -Community members and helpers - supporting garden organization, leadership, outreach, and maintenance
- Equipment – Handtools, small machinery like tillers
- Facilities – Storage sheds

CASE STUDY - LEARNING FROM THE EXISTING

Urban farming activities in the city of Visakhapatnam, India

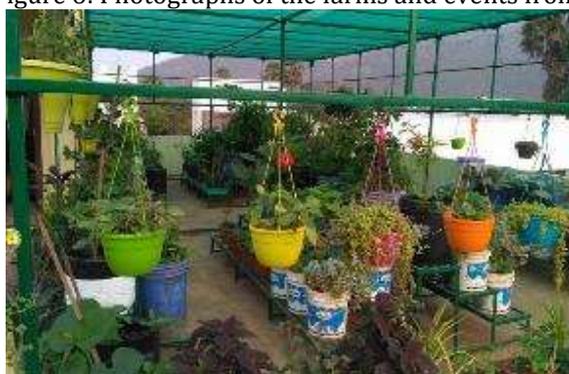

There is a small but active group of urban farmers in the city of Visakhapatnam who have been practicing urban farming in vacant plots, roof tops etc and helping in educating the city dwellers by demonstrating how urban farming can be done in the spaces available to them. A Non-government organisation (NGO) which is an active part of this group aims at educating the city dwellers on how to do farming in their premises in a sustainable way using zero budget natural farming techniques.

The NGO developed a model roof top kitchen garden, a farm on vacant plot and a food park in a semi urban area which they use to conduct workshops and awareness sessions on a weekly basis reaching out to more and more citizens. They

encourage and guide the city dwellers in developing their own farms and also train them in activities like composting on a household level and community level. These spaces help in creating a dialogue, encourage community engagement and empowerment as well as introduce city-dwellers to fresh, safe, healthy home grown produce. They engage with schools and colleges to educate students on farming and healthy eating and encourage institutions to develop urban farms in their premises. The organisation also educates city dwellers about nutrition, healthy eating and treating diseases through herbal plants with a motto 'Eat food as medicine, otherwise you have to eat medicine as food'.

The NGO helps various farmers and gardeners in urban and peri-urban areas of Visakhapatnam in selling their produce through specific stores and arrange local farmers markets over the weekends in public spaces (See figure 6). The organic farmers market has been attracting many city dwellers and encouraging them to shift to natural food and food products and motivating them to start their own kitchen garden. The group uses the web and social media for a wider outreach by sharing pictures of the farming activities and demonstrations videos. Through social media they encourage the members to post their farm updates, queries and share their challenges and problems and help them by providing solutions to their problems. The network on the social media provides a platform for marketing and sharing details of events related to Urban farms. This kind of a motivated group with a strong support system is a great advantage for the city to adopt urban farming on a large scale.

Urban farmers sharing the pictures of their farm produce

Lessons learnt from the existing urban farming activities in Visakhapatnam.

The experience of the group of urban farmers confirmed that urban farming has a number of benefits. Apart from food production for the urban population, the social value of bringing a community together, education and training on how food is produced and provision of space for recreation and physical activity remains important. The following are the take-aways from the case study.

- A voluntary organisation having a good knowledge in Farming is an advantage for the city
- There are a few motivated citizens in the city who are interested to learn urban farming and start their own farms based on the space available to them.
- Organic Urban Farmers market is getting good response from the city dwellers which means that there is an increase in awareness about food adulteration and health safety.
- Urban farmers with small growing spaces are coming up with innovative ideas on how to produce high yields in small spaces. They are trying to adopt models such as aquaponics, vertical farming, micro-green operations, greenhouses on rooftops etc. in their own way.

- Intermittent workshops on organic waste composting and urban farming are increasing awareness among citizens and motivating them towards urban farming.
- Web and networking in Social media is acting as a powerful tool in bringing all the urban farmers in the city onto a single platform and is facilitating the learning process.

Challenges

The risks that are said to be associated with the promotion of urban agriculture must be recognised and addressed.

- Food produced in cities may be detrimental to human health if soils or irrigation water are contaminated by industries, if untreated urban waste water is used for irrigation of food crops or if hygiene is lacking in the processing and marketing of food.
- Cultivated areas in cities may attract or provide breeding grounds for rodents, mosquitoes and flies and therefore can contribute to the spread of diseases if proper precautions are not taken.
- Neighbours may complain of the dust, smell and noise created by urban farms.
- Lack of knowledge intimidates most city dwellers in setting up their own kitchen garden/farm.

However, such risks can be prevented and managed by proper knowledge and appropriate urban policies, including the provision of adequate support to urban farmers.

DEVELOPING A ROAD MAP FOR URBAN FARMS

Scope encompasses vision, goals, methodologies, boundaries and constraints. Scoping the study can be a powerful tool for engaging stakeholders in a common vision for understanding Urban Farming, working on the challenges and maximizing its benefits. From the case study we learnt how urban farming is being practiced in fragments. Now for a wholesome effort to expand it on a bigger scale, we can bring all the stakeholders onto one platform and work together. When the policy makers, urban planners, architects, urban farmers, enthusiastic citizens etc. come together and come up with a plan we can have great results (See figure 7).

Figure 7: Road map for decision making in Community-led urban farms

Before undertaking urban farming in any city a preliminary survey regarding the interest for it among the residents has to be conducted. Once some interest has been identified the availability of resources including the need and feasibility to set up waste water treatment facilities, composting facilities, etc has to be looked into. Identifying the sections of residents who are seriously interested in farming and providing them with support will ensure the success of the project. Availability of resources namely land, water for irrigation and support services including garden supplies, expert advice and support system are the prerequisites for success in urban agriculture in that city. Strategies and benefits of community farms in open areas is shown in figure 8 and 9.

Steps for designing a community farm in a neighbourhood.

- Identifying the variety of uses and amenities desired, including the potential to accommodate alternative uses in the garden such as hosting community events etc.
- Locating and allocating adequate space for the desired uses, and integrating those uses effectively
- Identifying key access points and predicted circulation through and around the farm,
- Integrating the neighborhood's unique history and character into the theme of the park
- Adding elements that enhance the space such as murals, sculptures, bird baths, etc.
- Designing boundary fence, entry and exit gates, walking tracks, space allocated for farm and other onsite activities.
- Designing the space allocated for farm dividing the area into smaller plots with workaround space.
- Test the soil for its fertility and treat it if required before cropping.
- Work out the water supply and drainage system. Considering the need for drip irrigation for some zones
- Find a convenient location for the garden's storage shed for tools, equipment and produce.
- Locating the community compost bin area in an accessible and functional location
- Considering the type, size and location for community gathering spaces such as areas for benches for relaxing, picnic tables, platform for farmers' market, a children's play area, a display and exhibition space, etc.)
- Identifying a location for shade elements in the garden (i.e. pergola, shade trees, etc.)
- A cabin or room for the gardener with toilets.
- Determine the need for security lighting
- Adding farm animals will enhance the dynamics of the space.

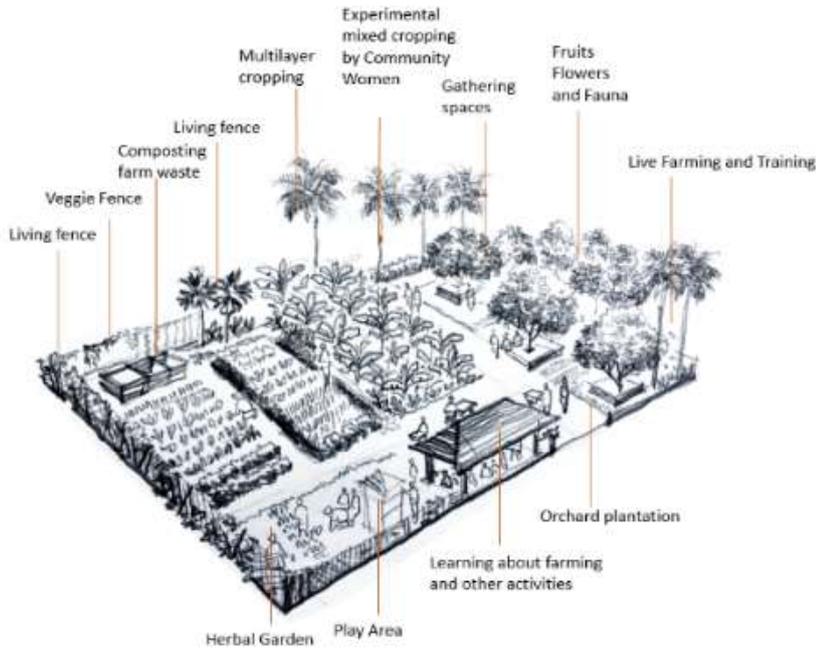

Figure 8: Showing a productive community farm along with the interactive social spaces and activities.

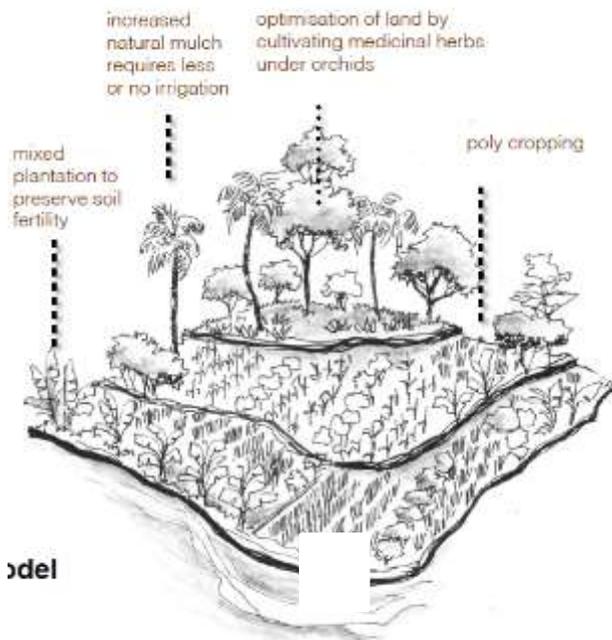

Figure 9: Diagram showing multi-layered cropping techniques for urban farming on vacant lands.

CONCLUSION

Urban farming is as an effective means to address global warming—by reducing the effects of UHIs and reducing flood risks while also fostering urban transitions to sustainability in many ways, such as creating common amenities, ecosystem services, reinventing urbanity and encouraging community building by growing local food, etc. Urban farming is and will continue to be a small but potential dimension of local food systems. One of the most direct benefits of growing food in or near towns and cities is the new source of products and people that adds value to local communities. Although it is not expected that urban farms have the potential to feed a whole city, they have great potential for increasing community health through providing secure access to fresh food for the community wellbeing. Urban farms have great potential for collaboration within the community by building partnerships with developers, the food service industry, schools, community organizations, and local governments. Some can also become educational hubs for growing and eating healthy food. Urban farms align with many of the food systems, green economy, and community development strategies being adopted by local governments. The findings of this paper are hoped to encourage city-dwellers, architects, urban designers and policy makers to adopt/incorporate urban farms and productive landscapes for building resilient cities and providing a better quality of life to the urban population.

SS04.1. Spatial Econometric Interaction Modelling

1019 CROSS-SECTIONAL DEPENDENCE MODEL SPECIFICATIONS IN A STATIC TRADE PANEL DATA SETTING

ABSTRACT

The focus is on cross-sectional dependence in panel trade flow models. We propose alternative specifications for modeling time invariant factors such as socio-cultural indicator variables, e.g., common language, common currency. These are typically treated as a source of heterogeneity eliminated using fixed effects transformations, but we find evidence of cross-sectional dependence after eliminating country-specific effects. These findings suggest use of alternative model specifications that accommodate cross-sectional dependence, which we set forth along with Bayesian estimation methods. Ignoring cross-sectional dependence implies biased estimates from panel trade flow models that rely on fixed effects.

1021 THE GRAVITY MODEL FOR INTERNATIONAL TRADE: SPECIFICATIONS AND ESTIMATION ISSUES

ABSTRACT

The Poisson gravity model along with pseudo maximum likelihood (ML) methods has become a popular way to model international trade flows. This approach has several econometric advantages that we outline in the paper. We argue that estimating the parameters by ML would only be justified statistically if the trade flows were independent. Such an assumption, however, is generally not valid, and a failure to account for spatial dependence may lead to biased parameter estimates and misleading inferences. To overcome this estimation problem we suggest eigenvector spatial filtering variants of the Poisson gravity model (without and with zero-inflation) along with pseudo ML estimation.

1023 A SPATIAL-FILTERING ZERO-INFLATED APPROACH TO THE ESTIMATION OF THE GRAVITY MODEL OF TRADE

ABSTRACT

Nonlinear estimation of the gravity model with Poisson/negative binomial methods has become popular to model international trade flows, because it permits a better accounting for zero flows and extreme values in the distribution tail. Nevertheless, as trade flows are not independent from each other due to spatial autocorrelation, these methods may lead to biased parameter estimates. To overcome this problem, eigenvector spatial filtering variants of the Poisson/negative binomial specification have been proposed in the literature of gravity modelling of trade. However, no specific treatment has been developed for cases in which many zero flows are present. This paper contributes to the literature in two ways. First, by employing a stepwise selection criterion for spatial filters that is based on robust (sandwich) p-values and does not require likelihood-based indicators. In this respect, we develop an ad hoc backward stepwise function in R. Second, using this function, we select a reduced set of spatial filters that properly accounts for importer-side and exporter-side specific spatial effects, both at the count and the logit processes of zero-inflated methods. Applying this estimation strategy to a cross-section of bilateral trade flows between a set of worldwide countries for the year 2000, we find that our specification adds further explanatory power to the benchmark models.

ABSTRACT

Using dynamic panel data estimation, this paper examines the effect of economic growth on venture capital investments in presence of other macroeconomic variables like innovation, R&D expenditure, tax rate, financial development, inflation rate and unemployment rate. The paper shows that economic growth has a positive effect on venture capital investment and hence, the results confirm that economic growth plays an important role for achieving high venture capital investment.

Keywords: Venture capital investment, economic growth, dynamic panel data estimates

1 INTRODUCTION

Venture capital³³⁰ investment (VCI) shows an important role in economic development (Pradhan et al., 2017; Gompers and Lerner, 2001; Florida et al., 1990). VCI is the source of funds that characteristically finance the new rapidly growing companies through equity participation (Gompers and Lerner, 2001, 1998; Wonglimpiyarat, 2009). It is also equally useful for many socio-economic activities such as innovation, job creation, industrial growth like small and medium-sized enterprises (SMEs), service sector growth (Carvell et al., 2013), financial development, infrastructure, and so forth (Hellmann and Puri, 2002). However, despite the vast utility of venture capital investment and especially for the attainment of economic development, little empirical research has examined the validity of these claims (Hasan and Wang, 2006). Hence, more empirical research on the relationship between VC investment and economic growth is urgently required.

In this study, we investigate the determinants of VC investment on economic growth in presence of other macroeconomic variables, which have both substitute and complementary effects on the VCI-growth nexus.

The paper is organized as follows. *Section II* describes our model and data. *Section III* describes the results. *Section IV* offers conclusion.

2 METHODS OF STUDY AND DATA

This paper arrays dynamic panel data modelling, suggested by Arellano and Bover [1991] and Blundell and Bond [1998], to investigate the effect of economic growth on VC investment.

The following regression model is set for this investigation

$$VCI_{it} = \lambda_1 VCI_{it-1} + \lambda_2 INN_{it} + \lambda_3 PEG_{it} + \sum_{j=1}^p \rho_j X_{jit} + \varepsilon_{1it} \quad (1)$$

Where, $\varepsilon_{1it} = \eta_i + \nu_t + \zeta_{it}$; η_i is country effect; ν_t is time effect and ζ_{it} is independent and identically distributed among countries (i) and years (t).

where, $i = 1, \dots, N$; $t = 1, \dots, T$; VCI_{it} is venture capital investments for country i over period t and is used as a proxy for VCE, VCL, and VCT; VCI_{it-1} entails the lagged value of venture capital investments for country i over period t ; INN_{it} is innovation activities for country i over period t and is used as a proxy for PAR, PAN, and RDE; PEG_{it} is per capita economic growth for country i over period t ; X_{jit} is the other determinants included in the model for country i over period t and for venture capital investments³³¹; λ_2 captures the effects of innovation activities on venture capital investments; λ_3 captures the effect of per capita economic growth on venture capital investments; λ_1 captures the lag of venture capital investments, ρ_j captures the impact of other macroeconomic variables on venture capital investments, and ε_{1it} is the error term.

We expect that venture capital investment is having a positive impact with economic growth and other macroeconomic determinants.

³³⁰ This is a specialized form of financial intermediation that provides funding to innovative new ventures with high-growth prospects (Da Rin et al., 2013).

³³¹ These macroeconomic determinants are per capita economic growth (PEG), patent by residents (PAR), patent by non-residents (PAN), R&D expenditure (RDE), long term interest rate (LIR), stock market capitalization (MAC), unemployment rate (UNE), income tax rate (ITR), and inflation rate (INF). These determinants are identified on the basis of past literature on venture capital investments.

The study uses a panel dataset covering the selected 19 countries for the period 1989-2016. The countries include in the analysis are Austria, Belgium, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Norway, Poland, Portugal, Romania, Spain, Sweden, the Netherlands, and the United Kingdom.

The data were obtained from the EVCA and *World Development Indicators* and Financial Development and Structure Dataset, published by the World Bank, Washington DC.

3 EMPIRICAL RESULTS

The dynamic panel data model specified in Eq. (1) is positioned to estimate the impact of venture capital investment on per capita economic growth. The estimated results are shown in Table 1. There are three specific model outcomes in Table 1 and it is different by the use of various VC investment indicators, namely, VCIE, VCIL, and VCIT.

From the estimated results, the study finds that the impact of economic growth on venture capital investments is positive and statistically significant, as expected, implying that higher level of economic growth promotes venture capital investments. For instance, a 1% increase in economic growth brings about the promotion of VC investments of about 8.0-26.2%. This finding is almost uniform for all the three models, particularly for all the three VC investment indicators, namely VCE, VCL, and VCT. The impact of innovation (particularly for PAR and PAN) on venture capital investments is statistically significant and positive, as expected, for the sample of 19 EEA countries and for all the three VC indicators. This implies that the higher level of innovation promotes VC investments in the EEA countries.

In case of R&D expenditure, the study finds a positive impact on VC investments; however, it is not statistically significant. The impact of stock market capitalization on VC investments is statistically significant and positive, as expected, implying that high level of stock market development promotes VC investments. For instance, a 1% increase in stock market capitalization brings about the promotion of VC investments of about 4.2-12.2%. The impact of lagged VC investments is also having significant positive impact on VC investments and is true for all the three models. It is observed that a 1% increase in lagged VC investments brings about the promotion of VC investments of about 0.4-3.8%. The impact of other macroeconomic determinants on VC investments are more or less non-uniform and have both positive and negative impact on VC investments. However, these are all not statically significant and is true for all the three models.

Over and above, the consistency of the model outputs depends upon the soundness of the instruments. The study employed three specification tests in order to justify the consistency of system GMM estimations. First, the Hansen test to know the over-identifying restrictions that report the p-values for the null hypothesis of validity of instrument set used by the estimator. The null hypothesis of this test is not rejected for any of the three estimations. Second, the Sargan test to verify independence between the instruments and the error term. The null hypothesis in this case is that the instruments and the error term are independent. Like the first case, the null hypothesis of this test is not rejected for any of the three estimations. Third, the Arellano-Bond test for serial correlations [i.e. the AR (2) test]. The null hypothesis of this test is that the errors in the first- difference regression exhibit no second-order serial correlation. As anticipated, the values of the test of second- order correlation present no evidence of model misspecification, indicating the acceptance of the null hypothesis of serial correlation in the first-differenced errors at order 2. The failure to reject the null hypothesis of all tests provides an evidence in support of the fact that the instruments are indeed valid. In brief, the overall performance of these model outputs are robust and consistent in terms of validity of instruments and the coefficients on variables.

To sum up, the effect of economic growth on per capita venture capital investment is positive and significant across the three selected venture capital indicators, namely VCIE, VCIL, and VCIT. Furthermore, the regression coefficients of other macroeconomic variables are mostly consistent with the standard results in the existing literature. That means the findings are consistent with theoretical arguments and quite robust to different measures of venture capital investment including the country and year fixed effects.

4 CONCLUSION AND POLICY IMPLICATIONS

The paper started with a conceptual question, "Does economic growth affect venture capital investment?" Our answer to this question is very much certain, as it affects the venture capital investment positively and is consistent with the earlier findings of Jeng and Well (2000) and Gompers and Lerner (1998). This study has examined the effect of economic growth on venture capital investment, a subject that has largely been neglected in the development literature. The findings of this study can give some clarity in existing debate on the causality between venture capital investments and economic growth.

RESEARCH HIGHLIGHTS

- Establishes the relationship between innovation, ICT infrastructure, and growth.
- The motivation is on G-20 countries from 1961 to 2016.
- Panel vector error correction model is used for establishing these relationships.
- Findings exhibit the presence of Granger causality between these variables.

GRAPHICAL ABSTRACT FOR REVIEW

Note: H1A, B: Innovation activities Granger-causes per capita economic growth, and vice versa. H2A, B: ICT infrastructure Granger-causes per capita economic growth, and vice versa. H3A, B: ICT infrastructure Granger-causes innovation activities, and vice versa.

ABSTRACT

This paper investigates the relationships among innovation, information and communication technology (ICT) infrastructure and economic growth for G-20 countries from 1961 to 2016. Using panel vector error-correction model, the study finds that in the long run both innovation and economic growth stimulate ICT infrastructure. However, in the short run, the causal links are mostly non-uniform and particularly due to different proxies that we use for both innovation and ICT infrastructure.

Keywords: Innovation, ICT infrastructure, economic growth, vector error-correction model

JEL Classification : O43, O16, E44, E31

1 INTRODUCTION

The nexus between information and communication technology (ICT) and economic growth provides an extensive literature for a large number of cases across the globe (see, for instance, Pradhan et al., 2016a). The previous studies have focused on different countries, time periods, modelling techniques, and proxies for innovation. The Granger causality test has been extensively utilized to study the direction of causality between the two. However, studies on the ICT infrastructure-growth nexus produced inconclusive results. These studies do not show consensus on either the existence or the direction of the Granger causality between the variables. One of the major reasons for the absence of consensus in the results of past studies is that the Granger causality test, in a bivariate framework, is likely to be biased due to the omission of relevant variables affecting the ICT infrastructure-growth nexus (see, for instance Pradhan et al., 2017a).

Similarly, the nexus between innovation and economic growth provides an extensive literature for a large number of cases across the globe (see, for instance, Pradhan et al., 2016b). Most of the studies have focused on different countries, time periods, modelling techniques, and proxies for innovation. The Granger causality test has been extensively utilized to study the direction of causality between the two. However, studies on the innovation-growth nexus produced inconclusive results. These studies do not show consensus on either the existence or the direction of the Granger causality between the variables. One of the major reasons for the absence of consensus in the results of past studies is that the Granger causality test, in a bivariate framework, is likely to be biased due to the omission of relevant variables affecting the innovation-growth nexus (see, for instance Maradana et al., 2017).

However, in reality, there is nexus among these three, i.e., the relationship between ICT infrastructure, innovation and economic growth. The importance and relevance of the innovation activities, ICT infrastructure and economic growth nexus arise from the potential high impact that ICT infrastructure might have on social and economic development (see, for instance, Cuervo and Menendez, 2006; OECD, 2005). Given this potential, ICT infrastructure might be valuable as innovation becomes increasingly important in modern economies, thus heightening the performance or prosperity of firms, industries, and nations (Arvanitis et al., 2013; OECD, 2010). The above discussion and reasoning indicate that ICT infrastructure¹ can enhance innovation and economic growth of an economy. In addition, the possibility of the existence of joint interdependence between these three variables needs to be researched.

The paper contains of six sections including introduction. The second section provides a concise survey of the related empirical literature and highlights the contributions of this study. The third section presents methodology. The fourth section presents the empirical results. The final section provides the derived conclusions.

2 LITERATURE REVIEW

The objective of the paper is to know the direction of causality among innovation, ICT infrastructure and economic growth. Hence, we can here three strands of literature.

The first strand of literature is between innovation and economic growth. There are four different ways we can explore this relationship: the *supply-leading hypothesis* (SLH³³²) of innovation-growth nexus, where innovation Granger causes economic growth; the *demand-following hypothesis* (DFH¹) of innovation-growth nexus, where economic growth Granger causes innovation; third, the *feedback hypothesis* (FBH¹) of innovation- growth nexus, suggests that both innovation and economic growth Granger cause each other; and the *neutrality hypothesis* (NEH¹) of innovation-growth nexus, where both innovation and economic growth do not Granger cause each other. Table 1 provides the brief summary of the studies where we find the support of these four hypotheses.

Table 1. Nexus between Innovation, ICT infrastructure, and Economic Growth

Part C : Innovation Activities and ICT Infrastructure			
Pradhan et al. (2017a)	OECD Countries	1970-2016	SLH ³ , DFH ³ , NEH ³

Note 1: SLH1: Supply-leading hypothesis: unidirectional causality from activities to economic growth; DFH1: Demand-following hypothesis: unidirectional causality from economic growth to innovation; FBH1: Feedback hypothesis: bidirectional causality between innovation and economic growth; and NLH1: Neutrality hypothesis: no causality between innovation and economic growth.

Note 2: SLH2: Supply-leading hypothesis: unidirectional causality from ICT infrastructure to economic growth; DFH2: Demand-following hypothesis: unidirectional causality from economic growth to ICT infrastructure; FBH2: Feedback hypothesis: bidirectional causality between ICT infrastructure and economic growth; and NLH2: Neutrality hypothesis: no causality between ICT infrastructure and economic growth.

Note 3: SLH3: Supply-leading hypothesis: unidirectional causality from ICT infrastructure to innovation; DFH3: Demand-following hypothesis: unidirectional causality from innovation to ICT infrastructure; FBH3: Feedback hypothesis: bidirectional causality between ICT infrastructure and innovation; and NLH3: Neutrality hypothesis: if no causality between ICT infrastructure and innovation.

Note 4: OECD is the organization for economic cooperation and development, DCs: Developing Countries; ACs: Asian Countries; and ICs: Industrialized Countries.

Note 5: ICT infrastructure does not have a uniform definition. It is captured by telephone mainlines, mobile phones, internet users, internet servers, or fixed broadband, depending on the study.

Note 6: Innovation activities is captured by patents, R&D expenditure, researchers in R&D activities, high technology exports, scientific and technical journal articles, or trademarks, depending on the study.

332 ICT mutually affects innovation and economic growth both at a micro-level and macro-level (Pradhan et al., 2017b; Zhang and Li, 2017; Sassi and Goaid, 2013; Vu, 2013).

The second strand of literature is between ICT infrastructure and economic growth. There are four different ways we can explore this relationship: the *supply-leading hypothesis* (SLH2) of ICT infrastructure-growth nexus, where ICT infrastructure Granger causes economic growth; the *demand-following hypothesis* (DFH2) of ICT infrastructure-growth nexus, where economic growth Granger causes ICT infrastructure; third, the *feedback hypothesis* (FBH2) of ICT infrastructure -growth nexus, suggests that both ICT infrastructure and economic growth Granger cause each other; and the *neutrality hypothesis* (NEH2) of ICT infrastructure -growth nexus, where both ICT infrastructure and economic growth do not Granger cause each other. Table 1 (Section B) provides the brief summary of the studies where we find the support of these four hypotheses.

The third strand of literature is between innovation and ICT infrastructure. There are four different ways we can explore this relationship: the *supply-leading hypothesis* (SLH3) of innovation- ICT infrastructure nexus, where ICT infrastructure Granger causes innovation; the *demand-following hypothesis* (DFH3) of innovation- ICT infrastructure nexus, where innovation Granger causes ICT infrastructure; third, the *feedback hypothesis* (FBH3) of innovation- ICT infrastructure nexus, suggests that both innovation and ICT infrastructure Granger cause each other; and the *neutrality hypothesis* (NEH3) of innovation- ICT infrastructure nexus, where both innovation and ICT infrastructure do not Granger cause each other. Table 1 (Section C) provides the brief summary of the studies where we find the support of these four hypotheses.

3 METHODS OF STUDY

The study deploys the following vector error correction modelling (VECM) to inspect the possible directions of causality among ICT infrastructure and innovation activities, and per capita economic growth.

$$\begin{bmatrix} \Delta PCEG_{it} \\ \Delta INNI_{it} \\ \Delta ICTI_{it} \end{bmatrix} = \begin{bmatrix} \eta_{1j} \\ \eta_{2j} \\ \eta_{3j} \end{bmatrix} + \sum_{k=1}^n \begin{bmatrix} \mu_{11ik}(L)\mu_{12ik}(L)\mu_{13ik}(L) \\ \mu_{21ik}(L)\mu_{22ik}(L)\mu_{23ik}(L) \\ \mu_{31ik}(L)\mu_{32ik}(L)\mu_{33ik}(L) \end{bmatrix} \begin{bmatrix} \Delta PCEG_{it-k} \\ \Delta INNI_{it-k} \\ \Delta ICTI_{it-k} \end{bmatrix} + \begin{bmatrix} \delta_{1i}ECT_{it-1} \\ \delta_{2i}ECT_{it-1} \\ \delta_{3i}ECT_{it-1} \end{bmatrix} + \begin{bmatrix} \varepsilon_{1it} \\ \varepsilon_{2it} \\ \varepsilon_{3it} \end{bmatrix} \tag{1}$$

where,

Δ is the first difference filter; i is country specification in the panel; t is time period; ε is the error term; *ICTI* is ICT infrastructure and represented by TELL, MOBP, INTU, INTS, FIXB or CIII; *INNI* is innovation activities and represented by PATE, RDEX, RRDA, HTEX, STJA, TRAD, or CIII; and PCEG is per capita economic growth.

The ECT-1's are the lagged error-correction terms. The above model provides robust results if the variables are integrated of order one [i.e. I (1)] and cointegrated³³³. The lagged error-correction terms are removed in the estimation process, if the variables used in the VECM are not cointegrated.

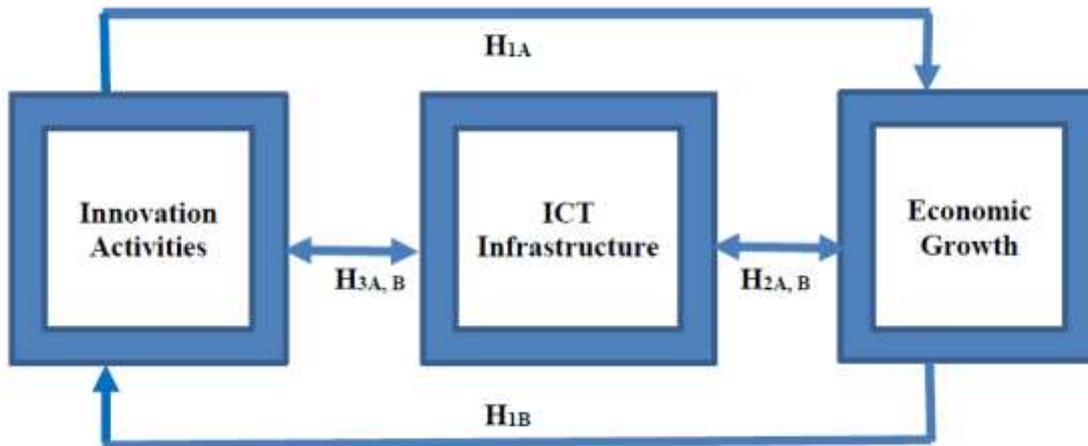

The study intends to test the followings:

- $H_{1A}^0: \mu_{12ik} = 0; \text{ and } \delta_{1i} = 0 \quad \text{for } k = 1, 2, \dots, m$
- $H_{1B}^0: \mu_{21ik} = 0; \text{ and } \delta_{2i} = 0 \quad \text{for } k = 1, 2, \dots, m$
- $H_{2A}^0: \mu_{13ik} = 0; \text{ and } \delta_{1i} = 0 \quad \text{for } k = 1, 2, \dots, m$
- $H_{2B}^0: \mu_{31ik} = 0; \text{ and } \delta_{3i} = 0 \quad \text{for } k = 1, 2, \dots, m$
- $H_{3A}^0: \mu_{32ik} = 0; \text{ and } \delta_{3i} = 0 \quad \text{for } k = 1, 2, \dots, m$
- $H_{3B}^0: \mu_{23ik} = 0; \text{ and } \delta_{2i} = 0 \quad \text{for } k = 1, 2, \dots, m$

333 It is claimed that long-run parameters are likely to demonstrate cointegrating relationships among a set of I (1) variables. In other words, it is anticipated that the macroeconomic variables in the model will be characterized by a unit root process. So examining the order of integration of the variables is the high priority in VECM estimation process and conducting unit root tests of all variables can achieve this objective.

There are numerous possible scenarios with respect to the direction of causality between ICT infrastructure, innovation activities, and per capita growth. For instance, if neither μ_{12ik} , μ_{13ik} , μ_{21ik} , nor μ_{31ik} are significantly different from zero, then we can deduce that ICT infrastructure, innovation activities, and per capita growth are not causally related. If only μ_{12ik} is statistically different from zero, then only innovation activities Granger-causes per capita economic growth. If only μ_{13ik} is statistically different from zero, then only ICT infrastructure Granger-causes per capita economic growth. If all μ_{12ik} , μ_{13ik} , μ_{21ik} , and μ_{31ik} are statistically different from zero, then this suggests feedback association between ICT infrastructure, innovation activities, and per capita growth.

Figure 1 presents a synopsis of the hypotheses that are tested in this empirical investigation.

Note: H1A, B: Innovation activities Granger-causes per capita economic growth, and vice versa. H2A, B: ICT infrastructure Granger-causes per capita economic growth, and vice versa. H3A, B: ICT infrastructure Granger-causes innovation activities, and vice versa.

Figure 1: Possible Causal Nexus among Innovation, ICT Infrastructure, and Economic Growth.

The choice of the lag length is an important consideration in a VECM estimation process, as the causality test results depend on the lag specification. This study uses Akaike information criterion to fix the optimum lag length. We use annual time series data obtained from *World Development Indicators* of the World Bank for the selected European countries over the period 1961-2016.³³⁴

The study uses six indicators for innovation (INNI), namely the number of patents by both residents and non-residents (PATE), research and development expenditure (RDEX), researchers in research and development activities (RRDA), high-technology exports (HTEX), scientific and technical journal articles (STJA), and trademark applications by both residents and non-residents (TRAD); five indicators of ICT infrastructure, namely, telephone landlines (TELL), mobile phones (MOBP), internet users (INTU), internet servers (INTS), and fixed broadband (FIXB); and real per capita economic growth (PCEG). Table 2 provides a detailed description of these variables.

Table 2. Definition of Variables

³³⁴ We have an unbalanced panel since data on the variables is not uniformly available for all the countries and for all the years over the period of our investigation.

Variable Acronym	Variable Definition
INNOVATION INDICATORS	
<i>PATE</i>	Patents total filed by both residents and non-residents: expressed in numbers per thousand population.
<i>RDEX</i>	Research and development expenditure: expressed as a percentage of gross domestic product.
<i>RRDA</i>	Researchers in research and development activities: expressed in numbers per thousand population.
<i>HTEX</i>	High-technology exports: expressed a percentage of gross domestic product.
<i>STJA</i>	Scientific and technical journal articles: expressed in numbers per thousand population.
<i>TRAD</i>	Trademark applications total filed by both residents and non-residents: expressed in numbers per thousand population.
<i>CIIA</i>	Composite index of innovation activities: a composite index using PAT, RDE, RRD, HTX, STJ, and TRM – derived through principal component analysis (see Appendix C).
ICT INFRASTRUCTURE INDICATORS	
<i>TELL</i>	Telephone landlines: telephone landlines per thousand of population.
<i>MOBP</i>	Mobile phones: mobile phone subscribers per thousand of population.
<i>INTU</i>	Internet users: internet users per thousand of population.
<i>INTS</i>	Internet servers: internet servers per thousand of population.
<i>FIXB</i>	Fixed broadband: Fixed broadband per thousand of population.
<i>CIII</i>	Composite index of ICT infrastructure: a composite index using TEL, MOB, INU, INS, and FIB– derived through principal component analysis (see Appendix C).
ECONOMIC GROWTH INDICATOR	
<i>PCEG</i>	Per capita economic growth: defined as the percentage change in real per capita gross domestic product.

Note 1: ICT is information and communication technologies.

Note 2: Variables above are defined more fully in the *World Development Indicators* of the World Bank.

The study also uses two composite indices, namely, composite index of innovation activities (CIIA³³⁵), and composite index of ICT infrastructure (CIII³³⁶), using principal component analysis (PCA). The advantage of using these indices is that they can harness the richness of information and can capture multiple aspects of the subject at hand. The present study considers seven different samples and six cases on the basis of seven innovation activities and six ICT infrastructure indicators. The seven samples are based on different measures of innovation activities while the six cases are based on different measures ICT infrastructure.³³⁷ All the variables are converted into their natural logarithms for our estimation. Table 3 provides the descriptive statistics and the correlations. The results of the correlation matrix indicate that the individual indicators of innovation and the five individual indicators of ICT infrastructure (i.e., *TELL*, *MOBP*, *INTU*, *INTS*, and *FIXB*) are highly correlated. Hence, the problem of multicollinearity would exist if these variables are used individually at the same time in one’s empirical equation.

Table 3. Descriptive Statistics, Unit Root Statistics, and Correlation Matrix

335 CIIA is the weighted average of six innovation activities, namely, PATE, RDEX, RRDA, HTEX, STJA, and TRAD.

336 CIII is the weighted average of five ICT infrastructure indicators, namely TELL, MOBP, INTU, INTS, and FIXB.

337 The subset of countries and the years covered under each of these set ups and cases are on the basis of data availability for the selected variables. We have an unbalanced panel in this study.

Note 1: PATE is total patents filled by both residents and non-residents, RDEX is research and development expenditure, RRDA is researchers in research and development activities, HTEX is high-technology exports, STJ is scientific and technical articles, TRAD is total trademark applications filled by both residents and non-residents, CIIA is composite index of innovation activities, TELL is telephone land lines, MOBP is mobile phones, INTU is internet users, INTS is internet servers, FIXB is fixed broadband, CIII is composite index of ICT infrastructure, and PCEG is per capita economic growth.

Note 2: Mea is mean, Max is maximum, Min is minimum, Std is standard deviation, Ske is skewness, Kur is Kurtosis, LD is level data, FD is first difference data, and I [1] is integrated of order one.

Note 3: *, **, and + indicate that parameter estimates are significant at the 1%, 5%, and 10% levels, respectively.

4 EMPIRICAL RESULTS AND DISCUSSION

The empirical analysis starts with finding the order of integration and presence of cointegration³³⁸ among ICT infrastructure and innovation activities, and per capita economic growth.

We use three-unit root tests (IPS, ADF and PP) to observe the order of integration of the variables in our panel setting. The test ensures that all the variables are integrated of order one (see Table 2). This finding suggest the likelihood of cointegration among innovation, ICT infrastructure, and economic growth. The Johansen panel cointegration test is subsequently deployed to observe the hypothesis that there is a long-run relationship among these three variables (see Table 4). The results from this test validate the existence of a long-run equilibrium relationship among innovation, ICT infrastructure, and economic growth in the seven samples and six cases of each sample.

Table 4. Empirical Results of Panel Cointegration Tests

³³⁸ Cointegration entails a long-run equilibrium relationship that ties the three-time series variables even though short-term departures from equilibrium may exist.

Note 1: PATE is total patents filled by both residents and non-residents, RDEX is research and development expenditure, RRDA is researchers in research and development activities, HTEX is high-technology exports, STJ is scientific and technical articles, TRAD is total trademark applications filled by both residents and non-residents, CHIA is composite index of innovation activities, TELL is telephone land lines, MOBP is mobile phones, INTU is internet users, INTS is internet servers, FIXB is fixed broadband, CIII is composite index of ICT infrastructure, and PCEG is per capita economic growth.

Note 2: ICTI stands for ICT infrastructure and the inclusion of TELL, MOBP, INTU, INTS, FIXB, or CIII.

Note 3: Tra is trace statistics; Max is maximum Eigenvalue statistics; and NOC is number of cointegrating vector.

Note 4: Statistical significance is checked at the 5% level.

The findings of cointegration supports the positioning of vector error correction model to detect the Granger causal relationship among innovation, ICT infrastructure, and economic growth. The study first observes the long-run Granger causality results, detected by examining the statistical significance of ECT-1 coefficients. We find that when Δ ICTI is the dependent variable, the coefficients for ECT terms are statistically significant at 1 to 5% levels. This implies that ICT infrastructure converges to its long-run equilibrium path in response to changes in both economic growth and innovation activities. This is true for only case 2, where mobile phone is deployed as a proxy to ICT infrastructure (see Table 5).

Note 1: PATE is total patents filled by both residents and non-residents, RDEX is research and development expenditure, RRDA is researchers in research and development activities, HTEX is high-technology exports, STJ is scientific and technical articles, TRAD is total trademark applications filled by both residents and non-residents, CIAA is composite index of innovation activities, TELL is telephone land lines, MOBP is mobile phones, INTU is internet users, INTS is internet servers, FIXB is fixed broadband, CIII is composite index of ICT infrastructure, and PCEG is per capita economic growth.

Note 2: Case 1 is where TELL is ICT infrastructure; Case 2 is where MOBP is ICT infrastructure; Case 3 is where INTU is ICT infrastructure; Case 4 is where INTS is ICT infrastructure; Case 5 is where FIXB is ICT infrastructure; and Case 6 is where CIII is ICT infrastructure.

Note 3: ICTI stands for ICT infrastructure and the inclusion of TELL, MOBP, INTU, INTS, FIXB, or CIII.

Note 4: ECT-1 is the lagged error-correction term.

Note 5: *, **, and *** indicate that the estimates are significant at the 1%, 5%, and 10% levels, respectively.

Subsequently, the deduction is that ICT infrastructure in G-20 countries is significantly influenced by both innovation activities and economic growth. The implication of this finding is that to stimulate long-run ICT infrastructure, it is imperious to facilitate both innovation activities and economic growth in the G-20 countries. However, the short-run results are mostly non-uniform. A brief summary of the non- uniform short-run Granger causality results is provided in Table 6 and reveals that the short-run adjustment dynamics vary across the nine samples and six cases.

Some additional results, though not described in detail, warrant a brief note. Firstly, the deployment of we apply the cross-section dependence (CD) test developed by Pesaran (2004) to check the cross sectional dependency of the data. The CD test results ensure that the variables are not cross-sectionally correlated and hence, justified the use of our first generation panel unit root tests, such as IPS, ADF and PP. The results of these tests are not reported here and can be made available on demand.

Secondly, we performed couple of sensitivity analysis by changing the order of the VECM, deploying separate sample for G-20 countries developed group and developing group separately. There were no significant changes to the earlier results reported in Tables 4 and 5.

Thirdly, we deployed the generalized forecast error variance decomposition method to test the strength of the causal relationship between innovation, ICT infrastructure and economic growth. Variance decomposition shows the expected percentage variation in the dependent variable explained by the expected percentage variations in the independent variables over a forecasting horizon beyond the sample period of our study. The results of this section are not reported here and can be made available on demand. This analysis provides additional sustenance for the argument that there is causality among innovation, ICT infrastructure, and economic growth, as outlined above for seven samples and six cases in each sample of the present study.

4 CONCLUSIONS

This study explores the causal relationships among innovation, ICT infrastructure, and economic growth in the G-20 countries over the period 1961-2016. We find that these variables are cointegrated, depending upon the particular innovation activities and ICT infrastructure indicators that we consider. Most importantly, there is clear evidence that both innovation and economic growth matter in the determination of long-run ICT infrastructure. In some occasions, the effect is bidirectional, while it is unidirectional (either direction) in other occasions, depending upon the types of innovation and ICT infrastructure we incorporate in the estimation process.

The empirical results suggest that in order to stimulate ICT infrastructure in these countries, it is necessary to prioritize both innovation activities and economic growth. The reverse is also true, particularly with reference to short-run results. For instance, economic growth in these countries will generate more pronounced investment opportunities to enhance both innovation activities and ICT infrastructure.

APPENDIX A: FORMULATION OF COMPOSITE INDICES OF INNOVATION ACTIVITIES AND ICT INFRASTRUCTURE, USING PRINCIPAL COMPONENT ANALYSIS

Our paper designs two indices, namely, composite index of innovation activities (CIIA) and composite index of ICT infrastructure (CIII). These two indices are constructed by deploying principal component analysis (PCA) and by the use of innovation activities and ICT infrastructure indicators (see Table 1). The procedure of designing these indices are available in Pradhan et al. (2016a,b; 2017a,b), and hence, these discussions are not available here. Tables A.1 and A.2 present the PCA results for both CIIA and CIII, respectively.

Table A.1: Summary of PCA-related Information for our CIIA

Part A: Eigen Analysis of Correlation Matrix

PCs	Eigen Value	Proportion Variance	Cumulative Percentage
1	2.771	0.396	0.396
2	2.073	0.296	0.692
3	0.918	0.131	0.823
4	0.634	0.091	0.914
5	0.379	0.054	0.968
6	0.118	0.017	0.985

ABSTRACT

This paper, by means of applying hedonic price theory, analyses consumer willingness to pay for the several characteristics attributed to each Spanish wine in the different international markets where the wine is commercialised. The basic methodological idea behind our purpose is that there is asymmetric information between producers and consumers in international markets, and that the degree of asymmetry increases with distance between the country where the wine is produced and the one where it is finally consumed. In order to test the proposed hypothesis we have created a database with more than 30,000 observations corresponding to almost 3,000 Spanish wines sold in 28 different countries. The database has information on the features specific to the appellation of origin, the winery, and the wine, such as the type of wine, vintage, the technical characteristics of the production process... Additionally, we have the prices of the wines in each of these international markets as well as the corresponding markets' structural characteristics. Results show that those objective characteristics and the strongest reputation features, such as main appellation of origin and/or those internationally known, the marks or scores given by international wine advocates, gain relevance when determining the prices for Spanish wines in those farthest markets. In contrast, weakest reputation features such as the characteristics of wineries and smallest appellation of origin with low reputation in international markets, decline with distance.

Key words: Hedonic price theory, Spanish wine, Spatial differences in preferences, reputation and distance.

1 INTRODUCTION

Spain is one of the main world producers of wine. In particular, according to the OIV (2018) it is the first country in vineyard surface area (with near 13% of the world total), the third world producer of wine (almost 15%) and the first exporter of the world in quantity and third in value. Wines with some geographical protection system, such as appellation of origin, hereinafter AO, accounted for more than half of the total value of these exports in 2016 with an increase in the average price over the previous year of more than 2%, while the price of wine without AO it fell almost 8% in that same year (ICEX, 2017). However, wines with AO in 2016 accounted for around 15% of the total volume of wine exported from Spain.

In this market, two phenomena have occurred at the same time: the increase and reinforcement of geographical protection systems for wine, and the increase in the internationally recognized quality of wines produced in Spain.

Geographic protection systems protect both producers and consumers. To the former, because it prevents that other competitors outside the reference zone, or that do not follow certain quality criteria within the area, could use this distinctive denomination in their wines, becoming a barrier to entry. For consumers because it guarantees a certain quality level. Therefore, consumers will be willing to pay an additional amount for the wines included in these protection systems. However, although the effectiveness of appellation of origin as a brand in national markets is tested (Núñez, 2014), it is worth asking to what extent these protection systems act as differentiating elements in international markets.

However, the multitude of appellations of origin, wineries and wines that incorporate differential quality elements generates information asymmetry in this market between consumers and producers. Therefore, mechanisms have been developed to alleviate this problem such as rankings and wine guides with ratings. In this sense, the internationally known Parker list, which evaluates the quality of wines from around the world, included in the 1988-1992 quinquennium around three Spanish wines each year among the top 100 (highest quality), while in the last five years for which this list has been published, 2012-2016, the average number rises to nine, which in some way shows the increase in quality perceived internationally. The importance of these elements of reputation is observed in many articles, showing that these aspects can account for up to 50% of the observed price variations.

However, given that the reputation in this market requires some familiarity and knowledge of the product and that these elements of reputation may disappear with distance, if they are not properly amplified, it is expected that the purchase decision in international markets will be different from the one occurring in the source. In this way, the farther the international market is from the origin, the purchase decision will be based more on objective aspects and on the "stronger" reputation elements that have been promoted in such markets.

The objective of this paper is to investigate the price determinants of the wines produced in Spain in different international markets, using the hedonic approach to price formation. It is possible to assess the changes in preferences in relation to wine, and the role that different reputation elements play in different markets: geographic systems of protection, especially large appellation of origin, as opposed to small ones, as well as the score in the evaluations by experts. Likewise, the role of distance to the market of origin in the changes of these preferences will be verified. For this, the following section summarises the hedonic pricing approach and a brief review of the main papers that have addressed

this issue in the wine market, both nationally and internationally. In the third section we describe the wine database that has been created for this purpose resulting from the fusion of different sources of information. The fourth section presents the results obtained from the estimation of the hedonic function for 28 different markets, as well as the relationship of these coefficients with physical distance. The usual section of conclusions ends the article.

2. LITERATURE REVIEW

One of the most popular procedures used to analyse the prices of different goods is the hedonic pricing approach. This methodology assumes that every product can be broken down into a series of attributes, each of which has a market value. Thus within the product market there is heterogeneity depending on the attributes that are possessed, however, homogeneity is assumed in the attribute markets (that is, all products that have an attribute have it equally). In this way, the price of each product is obtained by accumulation of each one's attributes. An implicit assumption of this model is the competitive equilibrium in the markets of attributes and of the final good. A review on the theoretical and empirical aspects related to this approach can be found in Malpezzi (2002), Chin and Chau (2016) and De la Peña et al. (2016).

There are some contributions that are considered pioneers (Waight, 1929; Court, 1939 and Houthakker, 1952). However, the theoretical support for this theory comes from the work of Lancaster (1966) who developed the New Consumer Theory. This New Consumer Theory analysed consumer behavior in the market of heterogeneous goods, and showed that the utility of the products is derived from their attributes and not the products themselves. Rosen (1974) was the one who finally developed a unified treatment of the underlying market model in the hedonic pricing approach and established the theoretical foundations of hedonic price functions. In his model he considered that there were implicit markets and equilibrium prices for each attribute, so the equilibrium price of the good was the result of the sum of all the prices of present attributes.

In Rosen's (1974) model, a market of a good differentiated by its n characteristics or attributes is considered. In this way, the utility function of the individual depends on the consumption of his basket of the rest of goods and the characteristics provided by the i th unit acquired from the analysed good. Thus, the consumer will maximise his utility subject to the budget constraint and for this he will choose the levels of each attribute that satisfy that the marginal rate of substitution between each of the characteristics of the analysed good and the rest of goods must be equal to the marginal price of such attribute. Therefore, and this is the fundamental result, the implicit marginal price of each characteristic is obtained by taking partial derivatives of the hedonic price function expressed as a function of the characteristics of the good.

The Rosen model has a second stage, usually ignored, in which the supply side is explicit and where the marginal cost of producing an additional unit of each attribute is defined. In equilibrium, the consumer and producer demand and supply functions, respectively, are tangent to the hedonic function in the same point. This point expresses the equality between marginal price and cost, that is to say the equilibrium of the market, so that the quantity of each attribute that will be produced is such that makes the marginal cost of its production equal to the final price that the consumer is willing to pay.

To analyse any market, especially Spanish wine market in different geographical areas, the key assumptions of Rosen's (1974) equilibrium model under perfect competition in the attributes must be validated. These aspects refer to perfect information, the freedom of entry and exit and the non-existence of market power. In this sense, there is a high flow of information available to consumers and producers in the wine market, although information asymmetry is also observed, given that the quality of the product, manifested through some immaterial attributes related to reputation, has a great relevance in the determination of the price. In addition, the transmission of information deteriorates with distance. However, there are corrective mechanisms for this asymmetry. Thus, numerous guides or apps about these specific wine markets are periodically published, accessible to the agents that offer quality evaluations and which allow recovering of some of the lost information. On the other hand, there is a limited freedom of entry and exit in the Spanish wine market with appellation of origin. The entry in the market is limited in the case of geographical protection systems, since vinerias located outside the zones will be automatically excluded and there are entry limitations of the producers within the geographical areas themselves. Nevertheless, the low average size of the firms in the sector seems to point to a low market power of the producers. On the other hand, final consumers are clearly price-acceptors, but channels of distributions (retail distribution and HORECA distribution channel) can operate as a barrier to entry in some markets.

The hedonic pricing approach has made a great contribution to the analysis of the implicit prices of the attributes or characteristics associated to certain goods. There are numerous papers that use this procedure to quantify the willingness to pay for the different attributes manifested by consumers, becoming a tool for analysing revealed preferences. The housing and car markets are where this procedure has been most used.

The paper of Shapiro (1983), for the case of Chilean wines, is considered the first study conducted in the wine market. His aim was to find the effect of the producer's reputation on the price of wine. Ockowski (1993) estimates the function of hedonic prices for Australian premium wine. This author reached the conclusion that quality is a relevant factor in determining the price. He also finds that exclusivity, which he identifies with the vintage and the amount produced of each wine, is also an aspect of great relevance. Another conclusion to be highlighted is the positive influence of innovation. Nerlove (1995) obtains a preference for bottled imported versus bulk wines in the Swedish case. It emphasizes the relevance of the alcoholic content and other identifying quality attributes. Landon and Smith (1998) focus on the impact of wine quality against the reputation of the producer in the case of wines from Bordeaux (France), reaching the conclusion that reputation is more important than quality. Costanigro, McCluskey and Miilhammer (2007) find out, analysing the American market, that the valuations in the attributes are different between white and red wines. They also

encountered hedonic valuation differences when they segmented the sample by category of the wine according to its price. Benfratello (2009), analysing Italian wines, obtains that reputation and more objective characteristics are more influential in the price of wine than sensory characteristics and more subjective attributes, but this author also concludes that the brand is more important than quality.

In the specific case of Spanish wines, the different studies available for small samples and specific regions, show the great importance of reputation aspects and in particular certain appellation of origin, in price determination and especially those of great renown. This result is repeated regardless of the region analysed. Table 1 presents a summary of the papers carried out for the specific case of wines from Spain.

Table 1. Papers that analyse the formation of prices of Spanish wines using the hedonic pricing approach

Authors	Geographical region	Aim	Conclusions
Gil and Sánchez (1997)	Aragón and Navarra	Analysis of consumers preferences and AO in price formation	Important differences in preferences between rural and urban environment. Influence of AO in prices
Angulo et al. (2000)	Spain	Price formation with a large number of attributes	Vintage, quality and AO determine price of wine
Morrilla and Martínez (2002)	Spain	Influence of winery attributes	Quality, vintage and size of winery have an important effect on prices.
Rodríguez and Castillo (2009)	Castilla-La Mancha	Effects of regional AO in Price formation	Very important influence of AO and quality on prices
Núñez (2014)	Spain	Effects of AO in prices. Winery and wine attributes	Very important influence of AO in price formation

3 DATA

The database used in this paper has been developed from merging several sources of information, properly combined to consider the different aspects that can influence the price of wine.

In relation to wines, there is information about the characteristics of the wine: the type of wine (red, white, rosé, sparkling, generous), alcoholic content, aging, sensory characteristics, type of grape used in its production, productive processes used, amount produced and appellation of origin to which it belongs, among other information that correspond to different vintages of each of the different references. This information comes mainly from different editions of the Guide Gourmets of the Wines of Spain. This information is complemented with price data for wines obtained from Wine-Searcher for the 28 markets in which at least 500 different Spanish wines are sold (Spain, Germany, United States, United Kingdom, Belgium, Netherlands, Switzerland, Denmark, Japan, Austria, Australia, Brazil, Canada, Finland, France, Hong Kong, Ireland, Italy, Mexico, Norway, New Zealand, Portugal, Poland, Czech Republic, Russian Federation, Singapore, Sweden and Taiwan). These prices correspond to the average sales' prices (without taxes) in November 2017 in each market. In relation to the appellation of origin, there is a broad set of information on the age, production, climatic characteristics, and indicators of presence in each international market obtained from the two previous sources and the official information from the Ministry of Agriculture.

In relation to wineries, information is also available on characteristics that may influence the price paid for each wine related to its productive capacity and aging, as well as the proportion of sales abroad and the way in which it is present in the different international markets. This information comes mainly from the Guide Gourmets de *Vinos de España*, as well as Wine-Searcher.

There is also firm specific information on features that could influence the final price: their production capacity (size), distribution (belonging to international groups, presence in foreign markets) and promotion (intangible assets, brands and financial capacity). This information has been obtained mainly from the ORBIS database. However, in spite of having this wide database, only some of the variables have finally been used, eliminating others either because they show high collinearity or because they do not affect the price.

Additionally, an indicator on transport costs between Spain and each one of the analysed markets has been calculated using the information provided by the website of UPS transport company. The cost of transport has been constructed by evaluating the cost of transporting a 70 kg package between Madrid and each of the capitals of each market, considering all available transport services. The weighting for each service, among those available for each destination, is the result of ordering the different prices from lowest to highest, giving twice the weight to the cheapest service with respect to the next most expensive one. For the sum to be equal to one, the two most expensive transport services are weighted equally.

The final sample is composed of 32,903 observations, corresponding to 2,910 Spanish wines from 1,048 different wineries, corresponding to 101 appellation of origin and 13 different vintages that are sold in 28 different markets.

4 RESULTS

To estimate the hedonic price function and obtain the coefficients corresponding to the 28 markets, we proceed as follows: First, a single hedonic function is estimated with all data for all countries. Then, we estimate as many hedonic functions as considered attributes, in each of them we choose an attribute which is interacted with a set of representative dummies of each of the markets, eliminating Spain, which is the reference market. In this way we get coefficients for each attribute in each market.

Finally, 81 attributes have been considered. We have included 5 levels of geographical protection (regions with quality wines -*Vinos de calidad*-, regions with local wines -*Vinos de la Tierra*-, appellations of origin, Qualified appellations of origin and Pago wines); 28 specific appellations of origin (only appellations of origin with at least 250 wines in the sample are included). Regarding the wineries, their year of foundation, size, aging capacity, percentage sold abroad and group membership have been considered. In relation to the wines we have included the type (red, white, sparkling and generous), the vintage of the wine, the alcoholic content, the type of official aging (crianza, reserve and great reserve³³⁹), the aging time that takes place specifically in barrels expressed in months, 31 types of grapes (all those found in at least 250 wines), wine production and historical average score of the wine. The transport cost to the market in which the price has been obtained is also included, to control for that direct effect on prices. The results are presented in Table 2.

³³⁹ The official type of aging in Spain for red wines is: **Crianza** (wines that have had a minimum aging period of 24 months of which at least 6 will have remained in barrels. In the case of the appellations of origin of La Rioja and Ribera del Duero, this minimum time in barrels is increased to at least 12 months), **Reserve** (wines with a minimum aging period of 36 months, of which they will have remained at least 12 in barrels. In the case of the appellations of origin of La Rioja and Ribera del Duero, this minimum time in barrels is increased to at least 18 months), and **Great reserve wines** (wines with a minimum aging period of 60 months, of which at least 18 years have remained in barrels. In the case of the appellations of origin of La Rioja and Ribera del Duero, this minimum time in barrels is increased to at least 24 months).

The coefficients and standard deviations obtained for each attribute are presented in the first and second columns. In the third column, we present the estimated increase in the price of wine derived from having the different attributes, in the case of the qualitative variables (increase in prices for owning the attribute versus not possessing it), and the elasticity in % in the case of continuous variables (its interpretation would be the percentage increase in prices if doubling the variable in question). It can be verified that of the 81 variables introduced, 58 have been statistically significant. If we exclude the dummies of different appellation of origin and grapes, 19 of the 23 considered attributes have been statistically significant. However, in the other two groups of variables, as expected, the levels of statistical significance are lower either due to a lack of sufficient number of wines in some appellations or types of grapes or because they do not have a direct effect on the price of wine in the international markets.

The most relevant question for the purpose of this paper is to determine if, as expected, there are systematic differences in the values of the coefficients between markets. Then, we proceed to estimate coefficients particularised by country for each of the attributes, as previously indicated. One issue that should be clarified is that, although a statistically non-significant aggregate result is obtained, this does not imply that it is for all markets, given that the aggregate result is a weighting average of those that could be obtained individually. When the hypothesis of equality of the obtained coefficients for the different attributes between markets is tested, only in 12 attributes this equality hypothesis can not be rejected. For 19 of the remaining attributes where the null hypothesis of equality of coefficients between markets is

rejected, there is not a relationship with physical distance, that is, the differences between markets must be caused by other factors different to distance. On the contrary, in 50 attributes, which represent more than 60% of those initially introduced, this relationship with distance is confirmed.

Consequently, it seems that there is evidence of differences across countries in considered attributes at the time of the formation of wine prices and also in favor of a linear relationship with distance.

In relation to geographic protection levels, it should be noted that correct interpretation of results requires that results presented here must be combined with those obtained by other variables. In particular, since we have included variables for some specific appellation of origin, results should be combined with them in order to obtain adequate interpretation. However, one result that is observed is that in general, at least three of the levels of geographical protection show a greater effect with the distance, being these the ones that larger number of wines and geographical indications comprise. That is to say, the appellation of origin serves as a crucial element to determine the price and, especially for large and/or prestigious ones this importance increases with distance. It is interesting the result obtained in the case of PAGO WINES (wines of the best quality and more exclusive characteristics) whose effect does not differ between international markets. This result may be mainly due to the loss of information with distance and that this type of protection, which usually encompasses a single winery, may not be recognised as a brand in remote markets.

Regarding the attributes of the winery, statistically significant effects are obtained, although of small size, except for the one obtained in the case of the incorporation year (the opposite of the age of the winery). These small impacts reflect that the brand associated with the winery does not survive with distance, opposite to the effect found in relation to the appellation of origin. Age, with a positive sign, probably reflects the ability and experience to penetrate in international markets, as well as the wineries having better competitive positions in the markets, which allows them to increase their prices.

Again, in the case of specific attributes of wine, statistically significant effects are obtained that acquire greater relevance with distance, which would indicate that the objective attributes, although to a lesser extent than those that reflect quality or reputation, serve consumers when deciding their propensities to pay. Special attention must be paid in the case of expert's scores, an attribute of reputation, which has greater relevance in terms of distance and a very high elasticity that reflects the importance that critics have in shaping the price. Regarding this elasticity, it should be noted that by construction scores have a small variance (values can be in the interval 75 to 100). A wine that is at 75 points and that would change to 100 points would increase its score by 33%, which would imply multiplying the price by three. This would be the extreme case. However, the importance of this aspect in shaping the international and also national prices of Spanish wines is notorious, in line with the results found in other papers for wines from different countries.

One of the characteristics that has more impact on the price of wine is aging. The results show a greater propensity to pay for older wines. The elasticity of aging in barrels is applied to a continuous variable, while the one related to the official types of aging are decomposed in three dummy variables. In any case, this objective attribute increases its positive effect on price with distance.

In relation to the different geographical appellation included, such as the appellation of origin, we find somewhat miscellaneous effects. The effect in this Table must be interpreted in relation to all omitted appellations. In the first place, there are more statistically non-significant coefficients than in previous characteristics, although making a country-by-country analysis, some of these disaggregated coefficients become statistically significant. Specifically, in four cases there are no statistically significant differences between country and the aggregate. In nine cases these differences are not related to distance. Finally, in the case of larger or more established appellations (Rioja, Ribera...) their impact is increased with distance. Therefore, only these appellations are relevant in international markets and the rest lose their strength and brand character.

5 CONCLUSIONS

As expected, the estimation of the hedonic functions for Spanish wines in 28 different international markets show that there are different propensities to pay for the different attributes of wine in different markets. In addition, there is evidence that these differences depend on physical distance from Spain, at least for a majority of the wine attributes considered.

The objective elements (for example: type of wine and aging) and reputation (such as criticism made by specialists, or belonging to large and reputable appellations of origin), persist with distance and intensify with it, since they are used as elements to determine the propensity to pay for wines and reduce the existing problem of information asymmetry.

1388 PRODUCTIVITY, ACCESSIBILITY AND FIRM HETEROGENEITY

ABSTRACT

The aim of this paper is to determine if the effect of accessibility on productivity, usually estimated for large sets of firms or sectors of economic activity, differs with firm characteristics. Some reasons may lead to believe that this should be the case. First, the accessibility measures often incorporate an agglomeration component, and the agglomeration of economic activity is more crucial in those activities with larger knowledge spillovers, requiring access to qualified and specific labour markets as well as specific inputs of productions. Detecting this kind of elasticity sensibility to firm heterogeneity could explain the different values provided by the economic literature for the elasticity of accessibility to productivity. For this purpose, we use four different accessibility indicators from the firms’ perspective, (i) accessibility to labour markets, (ii) accessibility to commodities used as intermediate goods,(iii) accessibility to the markets of other firms that use the firm’s production, and (iv) accessibility to final consumers’ markets. The evaluation of these accessibility indicators comes from a previous paper that uses a wide range of microdata datasets that allow the computation of these indicators to firm level, over a sample of nearly 60,000 Spanish manufacturing firms active in 2009 according to SABI database (which belongs to a set of databases including AMADEUS and ORBIS elaborated by Bureau van Dijk). Using the panel data elaborated from SABI we estimate total factor productivity applying non parametric procedures. Applying geographically weighted regression procedures, we obtain an estimate of the elasticity of each of the four accessibility indicators for each firm included in the sample. Resulting elasticities are regressed against several variables of firms’ characteristics to identify the features that may determine observed changes in elasticities and the extent of their exerted influence. Through a polynomial smooth estimation we define the form of derived relationships, without imposing ex ante restrictions on the nature of these encountered relations. Results show that some firm’s features such as the technological content, the relative labour intensity and the type of intermediate inputs requirements, have statistically significant impacts over elasticity values in the expected direction.

1005 MEASURING CAPITALIZED PREMIUMS IN HOME VALUES DUE TO VISUAL ACCESSIBILITY OF SCENIC LANDSCAPES USING GWR BASED SPATIAL HEDONIC MODEL

ABSTRACT

This research uses a hedonic modelling approach to assess the implicit willingness to pay for the visual accessibility of voluntarily protected, privately owned, scenic lands based on single family houses. These lands are perpetually protected to preserve natural, historic, and scenic characteristics. The capitalized house premium was captured using a visual accessibility variable, which was a combined weighted measure of 'view' and 'proximity,' referred to here as the Gravity Inspired Visibility Index. Both global (adjusted R²=0.52, AICc=29,828) and geographically weighted regression models (adjusted R²=0.59, AICc=29,729) estimated the price effect but the geographically weighted regression model outperformed the global model. The results from the geographically weighted regression model indicated an average 3.4% price premium on the mean value of homes in the study area to a high of 34% in few sample locations. The paper offers a useful framework for evaluating the effect of land protection for planning and real estate purposes. It also offers useful insights for conservation agencies, local governments, professional planners, and real estate professionals for prioritizing land sites with scenic views.

SS04.3. Spatial Econometric Interaction Modelling

1555 DEVELOPING A SPATIAL ASSOCIATION MEASURE FOR SYMBOLIC DATA

ABSTRACT

Contemporary spatial data analyses deal with two problems regarding data sets: very detailed or, in contradiction, imprecise description of spatial units. The first one results in data multiplication (e.g. Big Data, interrelated data), while the second one in data generalization (e.g. national average data, average annual data). Both of them are a big challenge for studies of spatial autocorrelation. Symbolic data analysis, introduced by E. Diday in the late eighties, deals with such problems. Its aim is to examine interval, multi-categorical, histogram, and structured data, rather than numerical or categorical data. For such data composition, typical measures of spatial autocorrelation, e.g. Moran's I, join-count statistics, are insufficient. This paper introduces a new spatial autocorrelation index which operates on symbolic multi-categorical data. We apply Allen's set algebra and extend Jaccard index to construct a measure of similarity in space. We examine its properties and limitations, and use real spatial data sets for empirical validation.

1578 THE DYNAMIC IMPACT OF MACROECONOMIC AGGREGATES ON REGIONAL HOUSING PRICES IN THE US: EVIDENCE BASED ON FACTOR-AUGMENTED VECTOR AUTOREGRESSIONS

ABSTRAC

In this study interest centers on regional differences in the response of housing prices to monetary policy shocks in the US. We address this issue by analyzing monthly housing price data for 417 regions using a factor- augmented vector autoregression (FAVAR) model. Bayesian model estimation is based on Gibbs sampling with normal-gamma priors for the autoregressive coefficients and factor loadings, while monetary policy shocks are identified using high frequency surprises around policy announcements as external instruments. The empirical findings indicate the impact of monetary policy shocks on house prices to be relatively small in comparison to the magnitude of real price fluctuations, but with significant differences between regions located in different states, most prominently between those in the Sun Belt and Midwest states. Key words: Regional housing prices, macroeconomic aggregates, factor-augmented VAR, Bayesian estimation, high frequency identification JEL: C11, C32, E52, R31

1682 THE EFFECT OF MONETARY AND POLICY SHOCKS ON REGIONAL DISPARITIES

ABSTRACT

The aim of this paper is to assess the impact of fiscal policy (monetary policy) on regional disparities. From a theoretical point of view, policy changes may affect regions differently due to their heterogeneity in their industry- mix and their financial networks. To test for this hypothesis, we use an unbalanced panel of 26 advanced economies countries from 1990 to 2016, estimating the dynamic response of regional inequalities to policy changes, controlling and interacting for country's structural variables and specific variables associated to regional inequalities. The paper follows the method proposed by Jorda (2005) and Teulings and Zubanov (2014), which consists of estimating Impulse Response Functions (IRFs) based on local projections of the effect of downturns on regional inequalities. In detail, in the first part, to establish the impact of fiscal policy (monetary policy) on regional inequalities, for each future period k we estimate an equation where the change in regional inequality through time is regressed against a measure of unanticipated changes in government spending (policy rates), an autoregressive component to capture persistence and a set of country's controls including: (i) the average regional real per capita income; (ii) the initial level of dispersion in the regional real per capita income; (iii) the number of regions in each country. In the second part of the paper, to take into account the role of macroeconomic and regional conditions in shaping the response of regional disparities to economic downturns, we follow the approach of Auerbach and Gorodnichenko (2013) and Abiad et al. (2015), that allow interaction between policy changes and economic conditions. On the one hand, the set of such variables includes, among others, business cycle conditions, the degree of trade openness, the initial level of inequalities. On the other hand, we take into consideration industry-mix variables to analyse the region's output response to these shocks.

SS05.1. Spatial Analysis: From Neural Computing to Deep Learning

1032 THE MACHINE LEARNING APPROACH TO THE ANALYSIS OF IMAGE-BASED SPATIAL FLOW DATA

ABSTRACT

With the advancement of communication and information technology, we are able to capture real-time or near-real time data on human and vehicle flows in space and time. Such type of data is useful for our understanding of spatial interaction in real time which in turn will shed light on decision analysis and management of pedestrian and vehicle flows. The analysis will also inform and enrich our spatial interaction models which largely target on static data. Real-time modeling of spatial interaction will then be made possible. The analysis of such type of video- based complex data call for new analytical/algorithmic paradigms. Machine learning in general and deep learning in particular appears to be an effective approach to the analysis of people and vehicle flows. This paper introduces novel machine-learning methods for such type of data. The conceptual and theoretical arguments will be substantiated by real-life applications.

1035 SPATIAL STRATIFIED HETEROGENEITY IN REGIONAL SCIENCE: CHALLENGE AND SOLUTION

ABSTRACT

Spatial stratified heterogeneity (SSH), referring to the phenomena that within strata variance is less than between strata variance, such as countries and urban/rural areas, is ubiquitous in regional science. SSH may exist in parameters, covariates or even mechanisms in a spatial dataset, resulting in confounding when a global model was used to the SSH dataset. Therefore, SSH should be tested at the early stage of data analysis. In another aspect, SSH is a window for human to understand the nature from Aristotle time for simplification, and SSH as a pieces of information may imply the determinants of the observed nonrandom pattern. Geographical detector q statistic is a new tool to measure the degree of SSH and to test the statistical significance of SSH. The q-statistic can also be used to explore the determinants of a phenomena, by testing its SSH which is partitioned by a suspected variable, according to a philosophy that two variables may be causally associated if their spatial patterns tend to be consistent. We illustrate the geographical detector q-statistic by two applications: SSH and its determinants of human population distribution in China and urbanization in the country.

1266 MODELING SPATIAL ASSOCIATION AND INTERACTION USING DEEP CONVOLUTIONAL NEURAL NETWORKS (CNNS)

ABSTRACT

Convolutional Neural Networks (CNNS), also known as ConvoNets, are multilayered versatile deep learning machines that are good at image classification/segmentation and object recognition. Even as free-download of pre-trained models of CNNS such as AlexNet, GoogLeNet; LeNet, Unet, etc. make CNNS appear commonplace, they are still largely black boxes. However, there is an active and ongoing research effort to uncover what makes CNNS so successful in many formerly formidable AI/machine learning tasks, and to discover fundamental principles and theoretical underpinnings behind them. Continuing in this vein of research, we propose to explore how we may incorporate spatial interaction into CNN type architecture by using local neighborhood functions, which capture spatial association and interaction at regional and sub-regional level. This is intended to be analogous to how local indicators of spatial association - e.g., Local Moran's I statistic, Getis-Ord statistic, etc. are computed. These types of features capture spatial dependence in a way that the filters that are typically used in CNNS to detect edges (e.g., straight lines, vertical lines, etc.) for image processing do not. For exploring the feasibility and utility of our proposed approach, we will use a set of raster-based images relevant to regional science to conduct a set of empirical experiments. Our paper is intended to explore how ideas from deep learning networks might be useful for characterizing and modeling spatial interaction and association, and to help introduce deep learning to the field of regional science.

SS07.1. Economic Corridors, Development and Regional Cooperation in South Asia and Beyond

1092 THE IMPACT OF TRANS HIMALAYAN TRANSPORT AND INSTITUTIONAL CORRIDORS

ABSTRACT

South Asia forms a quite distinct group of countries in the World, with very low income per capita, strong rural population, high urbanization rates, reduced health care expenditures, high levels of remittances, reduced level of rents from natural resources, young population, reduced amount of trade in services, poor logistics and very reduced level of governmental expenditure. The implementation of Institutional and Transport Corridors across the Himalayas implies potentiates stronger flows of trade, investment and people. Nevertheless the starting point is very low since existing cooperation terms of trade, migration and investment is more connected to countries outside the region than to countries of South Asia. The main research question is to know what are the impediments against a stronger and enriching cooperation between the countries of South Asia that are constraining trade and development in the region? Putting differently will the deployment of transport and communication infrastructure be viable and have impact on trade? To respond to these questions we first formulate a gravity trade model consistent with interantional trade theory and suitable enough to be calibrated with available data on trade flows. Then we collect data on the acessibility patterns of the existing terrestrial and maritime networks and calibrate the trade model. Finally we simulate model for different accessibilities associated to the creation of different links in the Trans Himalayan roads. We conclude that institutional barriers are relevant for trade, maritime networks will continue to play their role and that road networks would have different effects across the regions.

1370 CONCEPTUALISING ECONOMIC CORRIDORS AND ITS SIGNIFICANCE FOR SOUTH ASIA³⁴⁰**Siegfried O. Wolf**Director of Research, South Asia Democratic Forum (SADF), Brussels, Belgium. Email: Siegfried.Wolf@sadf.eu**ABSTRACT**

Economic corridors (ECs) have become the centre of attention of many planned development initiatives worldwide. Yet no source has been able to provide a clear definition. The definition of economic corridors remains challenged largely due to the multitude of factors determining its genesis and nature, and thus no corridor matches exactly the characteristics of another. Most of the conceptual work analysing economic corridors has been conducted in the context of spatial planning and geography, centred around the urban development and potential spill-over effects into peripheral (rural) areas, predominantly linked with ADB initiated projects in Southeast Asia. Although many studies about Beijing's 'Belt and Road Initiative' (BRI), and especially those with regard to the China-Pakistan Economic Corridor (CPEC), have been published in recent years, it remains to be seen, how far these BRI related analysis will contribute to the conceptualisation and commonly accepted theoretical understanding of ECs. In brief, the presented paper understands ECs not only as a sole infrastructural measure for transport but rather as a comprehensive development approach to foster industrial capabilities, services, trade, and investment. It is therefore expected that the establishment of ECs will be accompanied by crucial social and political impacts. To realise its full potential, economic corridors need to determine its economic-, organisational-, institutional-, behavioural-, political-, and planning characteristics. Without these characteristics, any 'corridor' cannot be considered 'economic'. Furthermore, it is argued that these characteristics do not only describe economic corridors as such but also serve as indicators to measure its feasibility, functionality, effectivity, and efficiency. Based on the existing literature and authors' own observations about ECs in Asia (Focus CPEC), the paper offers a new conceptualisation of ECs based on identified characteristics and indicators for a successful planning and implementation of ECs.

GENESIS OF THE ECONOMIC CORRIDOR CONCEPT

As mentioned above, economic corridors (EC) have become the main focus of development projects in various countries and regions.³⁴¹ Nevertheless, there is no clear definition of EC in the literature yet.³⁴² One of the apparent challenges considering the conceptualisation of EC is, that due to the multitude of factors determining their genesis and nature, no corridor 'matches exactly the characteristics of another'.³⁴³ Due to the increasing prominence among political and economic decision-makers and media, ECs moved to the focus of academic research too. Most of the conceptual work regarding ECs were conducted in the context of spatial planning and geography centred around urban development, predominantly linked with Asian Development Bank (ADB) initiated (and funded) projects in Southeast Asia. Also, numerous research projects regarding the geneses of corridor development were conducted by the World Bank. For instance, in the context of spatial development policy frameworks such as the European Spatial Development Perspective (ESDP), the European Union (EU) substantial work are carried out. In order to boost the growth of alternative dynamics 'global economic integration zones' in 'peripheral areas' notions of 'Euro-Corridors' with multimodal infrastructure, 'transnational cross border development corridors', 'infrastructure networks', or 'Trans-European Networks/TENs' are receiving attention and promotion.³⁴⁴ However, it remains to be seen how far the studies on ECs, which are part of the Chinese 'One Belt, One Road' (OBOR) or 'Belt and Road' (BRI) initiative, will contribute to the conceptualisation and commonly accepted theoretical understanding of ECs.

The following statements can be made to encompass the prevalent notions of ECs. Initially, the idea of 'corridor' was developed to address trade and accessibility problems of landlocked countries.³⁴⁵ It is thus expected that corridors should be created along with physical links between regions (besides linking urban nodes) which were not connected before.³⁴⁶ According to more recent consensus, the purpose and function of 'transport corridors' is not just a matter of building

infrastructure, especially not when these corridors should be efficient in reducing trade costs as well as in improving connectivity.³⁴⁷

Furthermore, it is becoming obvious that ‘transport corridors’ are reinforcing the importance of the urban nodes³⁴⁸ but do not create much spill-over effects for the development of peripheries. In other words, ‘transport corridors’ did not aim at the sustainable development and comprehensive modernisation of larger territorial entities. Subsequently, the view on the ‘corridor concept’ just from a transportation perspective must be extended gradually by considering aspects of trade, logistics³⁴⁹, urban development, and supply chains³⁵⁰. As stated by Srivastava³⁵¹, five stages are considered in the evolution of a transport corridor into an EC: Stage 1: transport corridor; Stage 2: transport and trade facilitation corridor; Stage 3: logistic corridor; Stage 4: urban development corridor; Stage 5: economic corridor. Other analysts like De³⁵² having a narrower model of the different phases in the development of an EC and pointing at three stages: (1) transport corridor; (2) logistic corridor; (3) economic corridor. But De is like Srivastava emphasising the significance of trade facilitation, logistics, and services as catalysts in EC development.³⁵³

However, besides the different notion on the development stages of an economic corridor, one can state following: Firstly, an economic corridor can be seen as the most advanced, developed, and complex corridor. Secondly, besides the initial transport corridors, new models appeared like trade, logistics, or supply chain corridors³⁵⁴ which coexist and represent the broad spectrum of different types of development strategies and respective corridors.

The concept of economic corridor was first mentioned and presented as a major goal in the Greater Mekong Subregion (GMS) Development Plan.³⁵⁵ More concretely, the concept of ECs got ‘introduced at the GMS Eighth Ministerial Meeting in 1998 at a time when the GMS-ECP [Economic Cooperation Program] implementation was stalled by the Asian Currency Crisis’³⁵⁶. Against this backdrop, the introduction of ECs in the regional development strategies was supposed to deal with the difficulties and impacts of the financial crisis by stimulating economic endeavours along existing infrastructure for transport.³⁵⁷

It is significant to mention that these innovative types of corridors have exceeded their primary functions by attracting investments and generating economic impulses and actions.³⁵⁸ Through the integration of local economies into international value and supply chains, the newly appeared concept of economic corridors became ‘indispensable in promoting global and regional economic development’.³⁵⁹

CONCEPTUALISATION OF ECONOMIC CORRIDORS

Today, it is widely recognised that EC is a development instrument aiming at the increase of economic growth over a certain period of time and in a specific area.³⁶⁰ Therefore, ECs are linking economic agents along a defined geographical entity and usually provide important connections among major economic nodes centred in urban landscapes.³⁶¹ Consecutively, ECs are seen as ‘driver for inclusive growth’ link production, trade and infrastructure within the identified geographic framework of the centre of economic activities (here described as ‘growth zones’) and extend benefits to their lagging hinterlands (peripheries) as well as more and disadvantaged, remote (rural, mountainous, and arid) areas

348 P. Srivastava, *Regional Corridors Development in Regional Cooperation*, op.cit., p. 2.

349 Ruth Banomyong states: ‘A logistics corridor focuses not only on the physical connection but also on how the flow and storage of freight, people and vehicles is optimised in the corridor with the support of capable service providers and a facilitating institutional environment provided by relevant agencies’. R. Banomyong, *Comparing Corridor Development in the Greater Mekong Subregion and the Indonesia-Malaysia-Thailand Growth Triangle*, op.cit., p. 89.

350 The purpose of such corridors is to reduce costs and time, to reduce the reliability performance, flexibility, and transparency of supply chain networks. As such, supply chain corridors enhance the services associated with the production and movement of goods and other activities that (directly) affect the value of goods.

³⁶¹ H.P.-Brunner, *What is Economic Corridor Development and What Can It Achieve in Asia’s Subregions?*, op.cit.

through transport development and expansion of production activities.³⁶² As such, an EC is designed to create global, regional and domestic value and supply chains through the creation and/or connection of economic centres and produces (ideally) positive multi-sectoral spill-over effects.

In brief, this study understands the concept of EC not only as a sole infrastructural measure for transport of commodities, but rather as a comprehensive development approach to foster industrial and other manufacturing capabilities, services, trade and investment. It is expected that the establishment of ECs will be accompanied by crucial economic as well as social and political impacts within and beyond the chosen areas. Keeping this in mind, an EC requires economic, organisational, institutional, behavioural, political, and planning aspects (interpreted here as characteristics) in order for its full potential to be realised. Without these key characteristics, a 'corridor' cannot be understood as 'economic'. Additionally, it is argued that these characteristics do not only describe an EC but they also serve as indicators measuring the feasibility, functionality, effectivity, and efficiency of an EC. Based on the existing literature as well as on the authors own observations, the following indicators can be identified:

I. Conceptualised geographic framework

As a spatial entity, an EC development is featured by the identification and definition of a geographical framework. According to its conceptualisation, the geographical framework can span different scales³⁶³: from a broad scale which is mostly regional or national to a narrower scale aiming at tackling specific, geographically limited local bottlenecks. As such, a geographical framework for the development of interconnection can take place between entire regions, within a region, across sub-regions (on a national or transnational scale) between states, within a state or subordinated territorial entities of a state (like a province of a state), as well as across regions and sub-regions.³⁶⁴ The chosen space for a corridor can be natural (given) defined area or a specifically planned one.³⁶⁵ In both cases, however, it must possess a minimum of 'geographic cohesiveness' which is not undermined by (extraordinary) unthrifty, unfavourable environmental conditions like vast deserts, restive mountainous areas, or other areas with misanthropic conditions.

Based on Srivastava's³⁶⁶ notion of a development process based on 'sequencing zones' of national corridors and their subsequent transformation into regional corridors, one can state that the geographic framework of EC has been 'fluent' since its establishment. This 'fluency' depends on the extent of regionality and area of influence of an EC. Here, Srivastava identified four zones which are demarcated with inter-zone sequencing: Zone 1: narrow national corridor, with focus on the initial and/or upgrading of existing road infrastructure; Zone 2: broad national corridor, including area development and railroads; Zone 3: narrow regional corridor, including trade facilitation and logistics; and Zone 4: broad regional corridor, including cross-border economic zones (here understood as 'transnational growth zone').³⁶⁷

II. Identified growth zones

The identification of growth zones within the geographical framework is a crucial part of each EC planning process. The growth zones³⁶⁸ are centres of economic activities, which are also described as economic and industrial nodes^{369,370}. These nodes function as a major provider of most of the essential material and human resources³⁷¹ but also as a logistic and communication hubs or gateways within and the outer space of the defined geographical framework of the EC.³⁷² In other words, the growth zones or nodes constitute the backbone of each geographical framework of EC. Basically, there are different types of nodes (growth zones): commercial nodes (linking important places of economic activities in each participating country of an EC), border nodes (containing foremost border hubs like checkpoints and dry ports), gateway nodes (creating access to external markets), or interchange nodes (determining intersects between different routes of a corridor or between different corridors).³⁷³

III. Established special economic zones (SEZ)

In theory and in practice, the establishment of special economic zones (SEZs) is a crucial instrument to develop growth zones. As for economic corridors, there is a multiplicity of names and forms of SEZs with differing functions.³⁷⁴ For example, many SEZs have characteristics of bonded zones (BZs), freeports, export processing zones (EPZs) or free trade zones (FTZs), industrial, science and technology parks, petrochemical zones, and provide special incentives, including tax exemption or reduction to investors, purpose-built production facilities, duty-free imports and simplified customs procedures, and other services.³⁷⁵

There are, however, essential structural features to describe SEZs. Firstly, SEZs can be defined as a geographically demarcated area within a state. Secondly, this formally delimited part of a national territory operates with different — typically more liberal and administrative efficient, regulatory and fiscal regimes (set of laws and/or measures) than to the rest of the state.³⁷⁶ Thirdly, SEZs are usually entrusted with a dedicated governance structure to run the regulatory regime of a SEZ.³⁷⁷ Fourthly, SEZs are usually provided with a physical infrastructure supporting the activities of the firms and other economic agents operating within them.³⁷⁸ In order for SEZ to be fully-fledged, sufficient multimodal infrastructure (road, railway, waterway) connecting the zone to markets, sources of inputs, and major transportation hubs (gateways) such as ports and airports must be provided.³⁷⁹ In addition, there must be an adequate public transportation, real estate for business and housing (e.g. industrial or mixed-up parks), education and health facilities, water supply, and telecommunications networks.³⁸⁰ Plus, SEZs also demand overall security, including energy and food security as well as protection against crime and terrorism.

SEZs commonly serve to numerous objectives: (1) attract foreign direct investment (FDI); (2) create jobs, especially to eradicate local unemployment; (3) improve trade facilitation and promote and diversify exports and imports; (4) modernise economy in general and upgrade industry and manufacturing in particular through technology, knowledge and skill transfers; (5) induce economic reforms and development strategies; and (6) test innovative economic policies while maintaining the status quo for the rest of the country.³⁸¹ SEZs are considered successful if they were able to bring about significant structural change in the economy and long-term dynamic and sustainable economic benefits by achieving above mentioned overall goals.³⁸²

To sum up, SEZs are a development programmes in their own right which determine independent strategies for economic development. However, in the combination with ECs, both the zones and corridors can provide a mutual deepness. In other words, the success of SEZs largely depends on the degree of their integration in domestic economy. The establishment of necessary linkages³⁸³ between SEZs and national economy can be promoted by EC that benefits from the agglomeration effects as well as from other benefits of SEZ. One should mention that EC can help in reducing potential negative side-effects of SEZs, like its tendency to create economic enclaves.³⁸⁴ This is problematic when the enclaves are used by multinational companies and larger domestic investors from export-orientated industries. This could create market distortions and undermine free and fair economic competition since the local entrepreneurship, especially small

and medium enterprises (SMEs), would be hampered in their development by the emergence of SZEs, exclusively towards SMEs. SEZs have been criticised for hosting import-dependent activities that do not add significant value; perpetuating low-skill assembly operations; attracting FDI in low-skill, low technology and footloose industries; suppressing labour rights; allowing poor workplace health and safety conditions; and having weak environmental controls.³⁸⁵ However, 'well-managed' zones can 'play a long-term dynamic role in their country's development process',³⁸⁶ particularly when they embed in an EC development.

IV. Connectivity within the geographical framework (internal connectivity)

Internal connectivity within the geographical framework is a sine qua non condition for EC development. In other words, the growth zones (or nodes) of an EC must be linked through various connectivity projects. Furthermore, the nodes must be integrated into production chains³⁸⁷, trade and logistic networks³⁸⁸ within the given geographical framework. The connectivity between the nodes is essential because without strong functional links, no significant economic movement and interaction can take place along the EC.³⁸⁹ Ideally, there should be a high level of connectivity within a growth zone. For instance, this can be achieved through the existence of an efficient feeder system to improve the overall connectivity and mobility within a zone, such as an integrated train, tram, metro, taxi lines, and bus system that would facilitate pedestrian movement.³⁹⁰ At the same time, the local transport system shall also include effective mechanism for goods traffic. It is essential that the connectivity between the nodes as well as within the growth zones are multimodal, meaning that the various transportation systems, for both the passengers and goods, are complementary, inter-connected and harmonised. The multimodality of infrastructure and transport systems would also help to bridge existing diversity of terrains which is a feature of many chosen area for the EC. Tariq Karim³⁹¹ recommends the adoption an organic to 'configure the corridors and linkages in a manner that best appear to be in consonance with geomorphology of different terrain'. This would contribute to sustainability of implemented infrastructure connectivity. However, in order for the infrastructure to sync with the variety of territorial and environmental conditions, the EC planning should support 'multimodality of transport rather than uniformity'³⁹².

Moreover, the connectivity based on multimodality is crucial to achieve the necessary spill-over effects from grow zones into the remote and/or underdeveloped areas, specifically in order for the peripheral regions to be able to benefit from the growth zones.³⁹³ According to Srivastava³⁹⁴, this 'process is uneven, with the core (the metropolitan/urban areas) benefiting first and the periphery (hinterland/rural areas) becoming integrated only later'.

V. Connectivity beyond the own geographical framework (external connectivity)

To achieve a high level of efficiency of ECs, it is important that measures are conducted to extend the connectivity beyond the borders of the initially defined geographical framework. This is gaining particular significance when the EC connectivity projects involve transnational dimensions. Referring to the above mentioned Srivastava's³⁹⁵ model of sequencing zones of the EC development, this would mean the extension of Zone IV and the creation of a cross-border dimension of economic corridors.

However, the 'external connectivity' of an EC could include initiatives to link different ECs or the linking of growth zones of one EC with nodes outside the own initial geographical framework. In this context, ECs are supposed to serve as promoters of regional cooperation and integration within as well as amongst different regional entities, such as South Asia, South East Asia, Central Asia, Middle East, or South-East Europe. Therefore, ECs must have an inclusive and comprehensive character to function as drivers of economic growth as well as processes of regionalisation. It is not enough that ECs are integral to the economic fabric and the economic actors surrounding it. If this were to be the case, ECs would generate limited economic benefits as they remain isolated—a narrow, exclusive area of operation. For example, they would remain at a narrow national or provincial stage. But in order to achieve the maximum benefit, ECs must pervade into larger economic networks, such as regional and global value chains, production and transport

networks.³⁹⁶ The success of an EC depends not only on a smooth functioning of the inter-coordinated and synchronised multimodal infrastructure, but also on the development or at least on the access to an established gateway node. Ideally, such a gateway node is a port with oversea, blue-water trans-shipment capabilities. The linkage of an EC with one or more airport(s) is, nonetheless, of great importance too.

VI. Articulated common culture and history

Recent and current EC development projects are increasingly featured by an awareness of common culture and history. The complex role of culture and history play a crucial role in the development of an EC initiative.³⁹⁷ The experience of a common cultural and historical ground can contribute to the enforcement of 'people-to-people' contacts but also to the improvement of necessary processes of diplomatic endeavours, negotiations, and communication. Furthermore, the sense of a shared history and cultural belonging can create political and economic loyalties within the geographic framework featured by unequal and competing actors.³⁹⁸ To instrumentals this 'soft power', the awareness, or at least the explicit emphasis, of common culture and history is prevalent in most of the implemented and envisaged EC initiatives, especially in Chinese funded ones.³⁹⁹ But one must be also aware that the extensive use of soft-power instruments can create feelings of cultural deprivation and repression. This is gaining significance when the geographic framework of an EC includes subordinated territorial entities which are already feeling economically exploited and socially, politically side-lined by central authorities. The situation is getting even more complex when these 'restive regions' are inhabited by indigenous population that is feeling increasingly marginalised by the development of ECs. In such a context, there is the imminent challenge that an EC initiative is getting identified as an instrument of exploitation instead of development, and the use of soft-power instruments as cultural suppression instead of building a common ground.

VII. Processes of modernisation and industrialisation

An EC must be endowed with an 'enabling industry, one that is able to meet goals inherent to transport, trade, logistic as well as other pressing national and social objectives'⁴⁰⁰. The development of ECs is not only featured by the stimulation of merely economic growth but also by efforts to push processes of modernisation of economies in general and upgrading of industries in particular. Moreover, a well-planned EC development has the potential not only to create desired industrial agglomeration in urban areas but also industrialisation of the hinterland. It is expected that, especially areas of the hinterland in which economic viability exist, remain under-utilised.⁴⁰¹

Generally speaking, the upgrade of industries is focusing not only on the improvement of existing industrial estates and manufacturing capacities, but also on the creation of new industries and industrial clusters. It is thus hoped that the participating countries and/or regions of a successful EC initiative would achieve a higher position in the global value chain (GVC) production. More concretely, it is expected that the upgrade of industries will help to produce more qualified, technological advanced products. Subsequently, the strengthening of the industrial base due to EC development should not result in an increase in low cost and low technology products. Instead, the EC should promote the improvement of manufacturing innovation and adaption of integrating technology and industry, should foster processes of advanced restructuring of the manufacturing (e.g., by strengthening more service-orientated sectors, introduction of intelligent manufacturing) and internationalisation of industries by fostering own (domestic) brands. Subsequently, the modernisation and upgrade of industry will be most likely accompanied by the build-up of knowledge hubs and respective creation of employment and subsequent reduction of poverty which could lead to positive impacts a social development too.⁴⁰²

VIII. Social and societal development

It is expected that a functional and effective EC is featured by an economic growth which creates a remarkable uplift in the standards of living of people, especially those working and living in functioning and successful growth zones. When these growth zones create sufficient spill-over effects, the whole population of the geographic framework might have the chance to benefit from the EC initiative and its respective projects. For example, the availability and improved access to employment opportunities will not only work towards the betterment of the overall living conditions of the people but increase social integration too.⁴⁰³ More trade and other economic activities between the different areas of an EC and with

neighbouring countries will strengthen people-to-people contacts. The latter one in combination with the rising socio-economic conditions of the people will help to bridge cultural, ethnic and other differences between diverse communities within the geographic framework of an EC and surrounding areas. Furthermore, in numerous cases the overall EC vision is harbouring the hope that the uplift of the people's living standards contains or even reverse unfortunate developments ('social evils') within the societies of the geographical framework (and beyond): like reduction of religious extremism, jihadism, political violence and militancy, terrorism, separatism, ethnic and social cleavages among others. However, one must be also aware that the establishment of an EC, especially when it is not well-planned by centralised decision makers by side-lining local population, numerous societal downsides needs to be factored in, like outbidding of local (especially) disadvantaged communities, social displacements, social conflicts.⁴⁰⁴

IX. Effective and fair regional distribution mechanism

It is in the nature of ECs to create agglomeration effects, which of course are a desired phenomenon in the initial phase, but it could also unfold negative effects on disadvantage areas with low capabilities.⁴⁰⁵ To enhance spill-over effects and to bridge asymmetries, it is significant to establish effective and fair mechanism of financial regulations between the different actors and territorial entities, foremost in centre-region but also in inter- and intraregional relations. This mainly includes distributions between political centres (places of decision-making) and peripheral areas. The establishment of distribution mechanism is gaining significance since in many cases of EC developments, the centres of main political decision making are not identical with the centres of main economic activities and/or revenue creation. In consequence, the establishment of fair allocation mechanisms is necessary due to the fact that territorial sub-entities are often featured by variations in economic conditions and capacities creating 'differentiated abilities' to exploit the benefit on an EC.⁴⁰⁶

Respective mechanism of EC related financial regulations should be established in three priority areas in a transparent and balanced manner:

- (1) Allocation of investments in quantitative (number of envisaged projects) and qualitative ('economic relevance') terms;
- (2) Income and revenue distribution;
- (3) Dispersal of financial costs (e.g., interest rates, maintenance of EC projects, security).

X. Pre-Existence of economic viability

The planning of EC, especially the conceptualisation and definition of the geographic framework in general and the identification of the nodes in particular, usually considers the pre-existence of economic viability.⁴⁰⁷ The area in which a given economic corridor is to be developed has the necessary economic viability when following criteria are addressed⁴⁰⁸:

- (1) The area possesses an 'enabling economic mass' which means that the identified locations ideally encompass a 'large amount of economic resources and actors';
- (2) The area shows a pre-existent strong economic growth;
- (3) The area exhibits a natural propensity and strong effective demand for further mixed-use development;
- (4) The area is free of crucial inhibitors (veto-actors).

To summarise, the criteria ensure that the development of a corridor in a region must make sense in economic terms. A corridor from 'nowhere to nowhere through nowhere' would be futile.⁴⁰⁹ It is also not very meaningful to combine substantive economic hubs when there is 'no potential for growth in between (because of adverse geography such as extremely rugged terrain or desert)'. In other words, if a corridor is not economically feasible and does not offer investors a 'satisfactory cash return' on their investment they will not become a reality, at least not in sustainable, effective and efficient ways.⁴¹⁰

XI. Integrated and comprehensive EC planning

The EC development must be based on an integrated and comprehensive planning. In other words, there needs to be a cooperative and overarching direction to oversee and execute the corridor vision, the respective plan, the planning process, and the implementation of the plan. In order to devise and administer such a centralised approach, all relevant

socioeconomic and socio-political realities have to be taken into account.⁴¹¹ Additionally, governmental actions done by, for instance, sectoral departments responsible for land use policy and management, transportation planning, infrastructure investment and maintenance, and security sector agents, as well as actions by non-governmental actors, are imperative to ensure the realisation of the 'corridor-vision'.⁴¹² Any actions that run counter to the vision will need to be adequately addressed. In practice, the integrated and comprehensive planning of economic corridors require the two below listed elements:

(1) The formulation of an overall EC vision

The overall vision shall manifest the fundamental principles and guidelines for the establishment and functioning of the EC, and a general code of conduct for interaction and cooperation of actors within the chosen geographic framework as well as external relations.

(2) A concrete action plan

The corridor proposal shall also include a concrete action plan with a complementary time-frame. The action plan should outline exactly when key investments (like energy and infrastructure) in the corridor will be made to ensure private sector trust and involvement.⁴¹³

XII. Political will

To implement a mega development project like an EC, all crucial decision-makers need to possess the necessary political will which is constituted by four main criteria: The commitment and constructive mind-set of all major actors, the existence of an encompassing consensus, the accommodation of local concerns and interests, and the existence of driving forces

(1) Commitment and constructive mind-set of all major actors

All actors involved must possess the political will to implement the necessary measures. Decision-makers at all levels of government and sector representatives need to be fully committed to the corridor-project. This requires a cooperative and constructive mind-set among all major actors, because without it, a successful and comprehensive implementation of EC remains unlikely.⁴¹⁴ Most importantly, the constructive mind-set is based on a long-term commitment, making the political will sustainable and not appear as a short-term episode.

(2) Existence of an encompassing consensus

The decision-makers must not only have the political will, but also the know-how and capacities to produce and maintain a consensus on the EC development. The consensus should include the majority of people living within the entire geographical framework of the respective EC. It is not unusual that individual projects or aspects of the concrete action plan faces criticism. Plus, it is not a secret that individual communities and persons are opposing the entire EC initiative. However, on the whole, the core of an overall EC vision should be not challenged fundamentally. A severe questioning of the general benefits of an EC must be interpreted as an indication for maldevelopment in the planning and/or implementation phases. Additionally, it is a pointer that challenges exist towards an unproblematic functioning of the development initiative in the long run.

(3) Accommodation of local concerns and interests

The political will also include the volition and ability to consider the interests and concerns of the local people. Former experiences show that a successful EC demands local ownership of the people. The latter one is calling for the sufficient inclusion of the local people in the decision-making processes of the EC development. This is gaining significance in the context of individual project development in the homelands of the respective local communities, especially in cases leading to compulsory land acquisition and displacements. If the local concerns and interests will not be taken into account adequately, the appearance of veto actors will more likely increase the costs and delay of the EC development.

(4) Existence of driving forces

One of the most significant but also critical factors for building the sufficient political will is the existence of driving forces. These driving forces are usually on the national level governments and/or semi-governmental agencies, business representatives; and on the transnational level, international regimes or organisations. They function especially in the earlier periods of the EC planning and implementation as engine. From a critical perspective, the existence of driving forces fosters the notion that the EC is an exclusive, elite driven project. However, driving forces also ensure the resilience of the necessary political will.

XIII. Enabling institutional structure and mechanism ('hard infrastructure')

411 B. Marrian, Towards a General Theory of Corridor Development in South Africa, op.cit.

412 W. G. Roeseler, D.v. Dosky, Joint development in urban transportation: a practical approach to modern growth management, op.cit., p. 329.

413 W. G. Roeseler, D.v. Dosky, Joint development in urban transportation: a practical approach to modern growth management, op.cit., p. 329; B. Marrian, Towards a General Theory of Corridor Development in South Africa, op.cit.

414 W. G. Roeseler, D.v. Dosky, Joint development in urban transportation: a practical approach to modern growth management, op.cit.; NDoT, Moving South Africa: The Action Agenda, op.cit., p. 30; B. Marrian, Towards a General Theory of Corridor Development in South Africa, op.cit.

It is rather fruitless to prepare corridor plans without enforcing or implementing them, or hamper the realisation of the plans because of unnecessary red tape and lack of functional institutional and skilled human resources.⁴¹⁵ Therefore, to ensure a successful implementation of the EC planning, the following further factors must be addressed:

(1) Institutional capacities

Whereas the integrated and comprehensive planning determine essential preconditions for a successful conceptual and preparatory phases of EC, the consecutive period of the implementation of the overall EC vision, the subsequent action plan and its operationalisation needs to be supported by an institutional structure and mechanism. Hall and Marrian emphasise the significance of the existence of institutions which are able to manage and ensure comprehensive implementation and regulation of the EC.⁴¹⁶ It is crucial that the EC related institutional structure is able to operate independently and is free from the influence of partisan interests of certain driving forces of the EC development.

(2) Abilities to reform

Most likely, the necessary institutional, independent structure for the EC development needs to be newly formed and/or will require an institutional transformation.⁴¹⁷ This requires usually a complex reform measure involving all levels of government and respective administration. In addition to the establishment of effective planning bodies, the EC would also greatly benefit from the reduction of excessive regulations, rigid conformity to formal rules and regulations and, other bureaucratic hindrances imposing on the decision-making- and implementation processes. Moreover, anybody responsible for the planning and the implementation of the corridor and respective projects needs the necessary capacity and mandate to fulfil their tasks.⁴¹⁸

(3) Human resources and management capacities

The pre-existence of skilled human resources in decision-making and administration entrusted with sufficient technical and managerial know-how for the implementation of major development programmes in general and ECs in particular are a prerequisite for any planning and implementation phase of EC.

XIV. Enabling policy framework and mechanisms ('soft infrastructure')

The establishment of ECs requires soft infrastructure, and the relevant rules, regulations, and standards need to be in place.⁴¹⁹ This soft infrastructure is important because there are not only poor transportation related facilities and networks but also non-physical hindrances hampering a smooth functioning of EC. Such hurdles are for example high levels of regulations and trade barriers, red tape, corruption, inadequate enforcement of contracts, poor definition and enforcement of rules of engagement, asymmetry in standards, delays in customs, delays at ports and border crossings, pilferage in transit, corruption, and highly restrictive protocols on movement of cargo, confusing and complex customs clearance procedures (e.g. regarding the numbers of required documents), among other institutional and policy constraints.⁴²⁰ To overcome these challenges, the participating countries in a cross-border EC development need to agree on a harmonised set of rules, regulations, and standards. This calls for the formulation and implementation of well-planned national as well as regional policy frameworks and most likely numerous reform programmes. It would also include steps towards the strengthening of existing or the creation of new regional forums and frameworks like RTAs (regional trade agreement) and FTAs (free trade agreements), and other regional regimes as well as measures against corruption and improvement of transparency. It would be important the respective decision-makers are not only aiming at setting regulatory benchmark for the regional context, meaning the geographical framework of the EC, but attempt to meet international (global) standards. Apparently, such processes require the set-up and strengthening of transnational, effective coordination among the stakeholders and agencies concerned. Without an effective coordination (including respective institutions, 'hard infrastructure'), it is unlikely that an optimal cross-border EC will come into existence. Furthermore, effective coordination will help to maintain and reinforce the political will of the involved actors to participate in the EC development and 'it could also resolve conflicting interests between governments and stakeholders'⁴²¹.

Besides these mainly trade and transport related causalities for the establishment of an enabling policy framework and mechanism, the set-up of financing schemes is of utmost importance for any planning and implementing of an EC vision. The development of an EC demands large investments. This capital needs to be raised, mobilised, and allocated for the individual EC projects. Besides attracting financial resources from multilateral development banks like Asian Development Bank (ADB), World Bank, Asian Infrastructure Investment Bank (AIIB), larger economies such as Japan, China or India could fill financing gaps.⁴²² Concrete financial mechanism could be foreign direct investments (FDI), loans, aid. Furthermore, money could be provided not only from the public but also from the private sector. In this context, the

so called public-private partnership model could serve as a model.⁴²³ Nonetheless, it must be emphasised too, that these financing mechanisms to attract capital must be flanked by national financial, especially regarding taxation, reform measures. The latter ones include the establishment of transparency and accountability programmes and institutions to end the impunity for economic a financial crime and misbehaviour (e.g., lack in payment moral). This is important not only to address sufficiently current and upcoming EC related financial burdens like interest rates or costs of maintaining individual projects.

XV. Enabling and favourable (safe) environment

The success of development projects depends significantly on the geographic stability and zoning security. Stability and security are crucial factors in building a positive image which can be seen as a third precondition for an enabling and favourable environment. Without guarantees to the security and stability—which enhances planning reliability—in the medium to longer term, potential investors will be hesitant to make investments.⁴²⁴ As such, the security concerns must be addressed adequately before countries starting to develop an EC. This includes multidimensional aspects of secure trade like measures to promote transport security, and improvement in customs regimes, port facilities, and logistics management⁴²⁵ as well as new, specific security threats like international terrorism, jihadism, or militant subnational movements. Subsequently, the participating states and regions must develop a collective and coherent concept to ensure the security of the EC development as well as its smooth functioning. This comprises also the delivering of overall good governance by the political decision-makers to create the necessary stability within the chosen geographic framework of the EC. Furthermore, especially potential regional (domestic) and bilateral conflicts have to be taken into account. These conflicts are gaining significance when the chosen geographical framework includes disputed territories and contested claims over local resources leading to an increase of traditional and non-traditional security threats.

One should also note that the success of an EC depends greatly on a positive image and perception among the broader public, the media and potential investors within and beyond the area of an EC.⁴²⁶ A lack of security and stability would harm significantly a positive image and subsequently hamper the creation of a conducive and favourable environment for a flourishing EC.

XVI. Effective diplomacy

ECs are complex development instruments which are not only involving a multitude of different actors (governments, international organisations and regimes, NGOs, individuals among others) but also affecting all spheres of state and society. To avoid conflicts, costs and other hindrances during the EC development, comprehensive people-to-people connectivity and transparent, inclusive policy formulation, decision-making, as well as respective communication are all crucial. Subsequently, for an unobstructed EC implementation, the establishment of effective mechanisms of public diplomacy and negotiations are needed. More concretely, the creation of a set of different negotiation mechanism should include bilateral as well as multilateral formats. Furthermore, mechanism should also incorporate as much as possible different actors involved and/or affected by the EC development. In other words, it is crucial to use not only ‘Track One’ (diplomacy & decision-making is done exclusively on the official governmental level) but also ‘Track Two’ mechanism of negotiations, where civil society and other non-state actors have the opportunity to feedback their insights, opinions, and interests into the EC decision-making processes. Here, it would be of utmost important that local population and civil society representatives are involved in the debates over the distribution over the costs and benefits of the EC initiative.

Besides the achievement of the support of local communities, good public diplomacy and effective negotiation mechanism would help to communicate successfully the overall EC vision on the international level and subsequently to win over more partners. This is gaining significance since there is generally much suspicion towards large-scale development projects regarding concrete incentives, especially when it comes to security and geopolitical orientated consideration.

XII. Sustainability, ecological and environmental awareness

Deteriorating general economics of nature, environmental mismanagement and degradation, environment related social and political conflicts and inefficient use of scarce natural resources have negative impacts on the overall environment within the EC’s geographic framework in general and on certain economic sectors like agricultural production and tourism in particular. Subsequently, a lack of ecological and environmental awareness and protection hampers severely sustainable development which hits not only agrarian communities but also urban areas, especially the growth zones. To achieve sustainable growth, the EC development has to take into account the fact that environmental issues are interwoven with economic and social systems. In other words, the vision of EC needs to consider a so-called triple-bottom line approach,⁴²⁷ focusing on combining environmental, social and economic considerations. But the integrative role of

423 Ibidem, pp. 5-6.

this approach needs to be extended by including built environment, governance and (political, administrative) institutional issues too, which are also essential components of sustainable development.⁴²⁸

The search for sustainability as well as for ecological and environmental awareness emphasise the following determinants: Firstly, any EC development needs to understand the complexity of interactions and relationships which impact the wider environment, economy and social and institutional systems. Secondly, there is a need to move the regions, including local, subordinated territorial entities, in the centre of the EC planning. Here, the incorporation of local based solutions and enhancement of local ownership (e.g., through community participation) are essential elements. Thirdly, to avoid negative impacts of large-scale development projects, the environmental assessment of the participating regions is necessary, since it can support processes of formulating and integrating sustainability objectives into plans and programmes for environmental protection. Subsequently, monitoring and minimising of ecological risks imposed by EC developments in order to achieve sustainable growth, will require new and innovative ways. As such, it is expected that ECs are linked with the promotion of greener technologies and a more efficient use of regional resources, enforcing green manufacturing, as well as consider issues like social justice, needs of disadvantaged local communities, resource sharing among other things.⁴²⁹

FINAL THOUGHTS: THE NEED TO BRIDGE THE CONNECTIVITY GAP IN SOUTH ASIA AND THE POTENTIAL ROLE OF ECONOMIC CORRIDORS

South Asia has reached a pivotal point in time. Comprising the states of Afghanistan, Bangladesh, Bhutan, India, Nepal, Pakistan, Sri Lanka, and the Maldives, and being a home of around one-fourth of the world's population, South Asia has witnessed remarkable up and downs in all spheres of both the state and society. Even a passing view of its current developments shows that the entire subcontinent is in transition and has reached a crossroads. Despite a more or less shared colonial experience of the British Raj (colonial rule), the South Asian states have progressed along widely diverse paths of statehood, nation-building, and different strategies of development. This finds its expression not only in the tremendous variety of regime types ranging from democracies to authoritarian regimes (including monarchical systems and military dictatorships), but also in the subcontinent's emergence as a hub for international terrorism, religious fundamentalism, large sociopolitical movements with separatist and anti-systemic or pro-democratic dispositions. On top of this, several states faced the challenge of boosting their economies to address the worrying manifold socioeconomic difficulties. Having this in mind, it does not come as a surprise that South Asia is a home to persistent encounters between Eastern and Western concepts and notions of institution- and nation-buildings as well as normative foundation of nations to address the manifold tasks. The fact that the region is struggling not only with multi-layered social-economic uncertainties, but also with deeply entrenched national disharmonies and bilateral crisis, makes it a site of some of the world's most intractable intra- as well as inter-state conflicts. This has led critical analysts to identify the region as a part of the global 'Arc of Crisis'.⁴³⁰ In this context, South Asia was unable to fully recover from the traumatic partition that followed the end of the European presence. The latter phenomenon turned into a major source for intraregional diplomatic conflicts and fully fledged wars became rampant and prevailed over the logic of effective and cohesive regional cooperation.

Subsequently, South Asia has not stood out as one of the great success stories when it comes to regional integration and cooperation. This finds its expression in the limited achievements of the South Asian Association of Regional Cooperation (SAARC). Instead of functioning as a vehicle for multilateral collaboration, since its official establishment in 1985, it is hampered by inadequate political will or insufficient capacities to promote sustainable integration and cooperation process.⁴³¹ Fundamental state-building tasks and bilateral issues caught the main attention of the South Asian political leaderships after gaining independence. Regionalism and inter-regional cooperation was therefore a distant concern for these newly founded states.⁴³²

However, one has to understand that regional integration and cooperation is not a linear process; rather, it is an evolutionary path marked by various heights and lows. The appearance of persistent challenges within the EU, which is often portrayed as the world's pioneer of regionalization, can be seen as a proof. Despite having experienced several deep crises, the EU continues to function without undermining its basic normative principles and stresses the resilience of the integration process in Europe. In other words, the traumatic legacies of the past—foremost the experience of two world wars, the destruction of Europe, and the experience of radical ideologies leading to the death of so many millions of

430 'Arc of Crisis' is a term which got introduced into the debate by Zbigniew Brzezinski in 1978. According to Brzezinski, the "arc of crisis," stretches "along the shores of the Indian Ocean, with fragile and social and political structures in a region of vital importance to us threatened with fragmentation. The resulting political chaos could well be filled by elements hostile to our values and sympathetic to our adversaries." Source: I. (accessed on 15 March 2018)

people—and the collective memory of it led to the political determination to change the unfortunate trajectories, creating a path towards European integration which can take multiple ways but does not change its direction.

Today, it seems that South Asia finally reached a turning point which could lead the region towards greater regionalization. Therefore, one should take the current developments in the respective countries into account since it seems that several trends occurred which have the potential dynamic to break with entrenched, unfortunate patterns of the past. Here, besides the steady rise of religious extremism, Jihadism, and cross-border terrorism (including the state-sponsored terrorism) turning bilateral ties sour, there is an awareness among South Asian political decision-makers that the steady process of regional disintegration needs to be reversed. Additionally, suffering from a multitude of socioeconomic inequalities, but at the same time having the opportunity to evaluate one's own situation in a comparative national as well as international perspective, South Asia's growing civil societies are starting to question the harmful logic of fragmented national interests and conflicts. Consequently, the argument that colonialism is the cause of most of the current problems, such as underdevelopment and political instability, is losing credibility. This of course will not force the individual national governments to increase trust and transparency of state behaviour immediately, but it might help to overcome the endemic unwillingness to initiate any cohesive, purposeful action in the direction of ending the traditional political and economic disunity in the region.

Presently, there is a greater perception of the necessity for interstate rapprochement and cooperation to unleash new dynamics in the direction of a more integrated South Asia. This process is undoubtedly enforced through voices from within the region which are increasingly advocating a break with unfortunate historical paths to achieve security, economic development and public welfare, and the complex identity crises of the South Asian states. Along with all the major stakeholders in the region, India is of crucial importance for the success of any kind of regional project. Not only because of the tremendous asymmetries in size and population, which make India the natural centre piece of South Asia, but also because of newly and partly rediscovered interests in the energy resources and trade potential that new routes, allegiances and transport agreements may yield. This is gaining momentum since all South Asian states share a border with India, but practically none of them share a common border, except for the troubled Durand Line between Afghanistan and Pakistan. Furthermore, it is important to note that the smaller states of South Asia too are not spared by the global dynamics and subsequent regional processes of transition. Each of them has discovered their geopolitical leverage within the emerging regional dynamics. Yet they are still constrained by complex internal politics. Needless to say, whichever the outcome of this process may be, it will define the international perception of South Asia as an area of persistent crisis or as a region which still has the potential to develop fruitful cooperation.

But what could the driving forces and appropriate instruments for improved regional cooperation be? It becomes clear that besides some individual success stories (like the growing middle class), South Asian states have to contend with endemic poverty, tremendous inequalities, mega-urbanisation, and extra-ordinary challenges when it comes to infrastructure, environmental issues, food and energy security. Most of these issues can be linked with the lack of connectivity within South Asia and its interconnections with other regions, for example South East Asia or Central Asia. Against this backdrop, the establishment of a South Asia wide EC network would significantly improve trade and transport facilities and ease regional trade. Additionally, it would improve the infrastructure which is still 'abysmally inadequate and of poor quality' compared to the one in other regions.⁴³³ If this challenge is sufficiently addressed, ECs can create more opportunities for the successful establishment of cross-regional linkages. It would also help to link South Asia with global transport and logistic networks and production chains. In this context, ECs are not only able to play a key role in integrating economies⁴³⁴ across a region and functioning as essential building blocks of regional economic integration⁴³⁵, but they can also serve as a confidence building tools in a political non-congenial environment.

However, in order to be able to benefit from these potential positive impacts, the EC planners need to move beyond the economic prism and consider the larger political and social context; because without this the development of an EC can lead to further entrenchment of existing conflicts and cleavages, turning a peaceful regional cooperation, especially in South Asia, into an even more distant dream.

Taken into account the persistent tensions between India and Pakistan as well as New Delhi's unease with Beijing's major development vision—the 'Belt and Road' initiative/BRI (currently the strongest driving force of economic corridor constructions world-wide) and its extensions into South Asia, foremost the China-Pakistan Economic Corridor (CPEC)—it seems unlikely that the political differences can be sufficiently bridged in the near future. The ongoing distrust and subsequent lack of political consensus will continue to severely hamper cross-border connectivity within the region. Therefore, it is imperative to understand the challenges which major, cross-border infrastructure projects in South Asia are facing.

To sum up, by monitoring several economic corridor projects, such as the ongoing implementation of the CPEC and the associated challenges, it becomes obvious that a comprehensive approach to the concept of ECs is needed, not only to guide the formulation and implementation of such a mega development initiative, but also to measure its effectivity, efficiency, and sustainability. An assessment of the performance of EC just on the basis of economic cost-benefit calculations, including the increase in trade volumes, build-up of physical infrastructure, logistics, services, or industrial

and manufacturing areas among other quantitative indicators, is crucial but far too narrow. Assessing the social and political dimensions of the EC implementation should be of utmost importance, especially in the case of South Asian countries faced with a multitude of domestic and bilateral challenges. The case of South Asia clearly underlines the challenges for a smooth implementation and further functioning of EC when overt or clandestine, simmering social, political and economic flashpoints are not taken account sufficiently. The unwillingness and/or inability to create a regional political consensus as well as to bridge the gap in local ownership of the people in remote areas due partisan economic interests of the national decision-makers, the lack in communication and transparency are increasingly provoking additional resistance towards EC initiatives. In tackling this puzzle, the concept of EC shows that numerous aspects have to be factored in to ensure not only a successful implementation but also a smooth functioning offering maximum benefits for the actors involved.

1636 REGIONAL TRADING BLOCS AND GLOBAL WELFARE. THE NEED OF FOCUSING ON HARMONIZATION OF “STANDARDS” WITH REFERENCE TO RTBS

Atreyee Sinha Chakraborty

Assistant Professor, Gokhale Institute of Politics and Economics, Pune

ABSTRACT

Over the last few decades, a large number of trading blocks (RTBS) has been created or proposed in nearly every region of the world. So the study of the welfare implications of trading blocs has become very relevant in the present global trade scenario. While RTBs are believed to increase welfare to countries involved, as it is a movement towards free trade,⁴³⁶ some economists believe that RTBSs can have a negative welfare effect on trade volume and world welfare as the blocks control entry decisions, pricing, marketing etc. which may distort the free flow of trade and the resulting distortion may reduce the welfare. Viner (1950)⁴³⁷ had pointed out Free Trade Agreements can actually worsen the welfare of member countries, and the world wise efficiency by creating trade diversion. Later other economists⁴³⁸ also had come to the judgment that regional liberalization of trade did not necessarily increase the welfare of even the members of the grouping. But all of these studies have discussed the welfare effect from the view pint of “tariff liberalization” and very few studies have focused on the role of RTBs with respect to NON –Tariff barriers to trade and its welfare implications.

With tariff barriers becoming increasingly less important, the regulatory regimes like labour standards and environmental norms as well as product standards and technical regulations are becoming more important determinants of trade. This paper has singled out export standards (termed as Technical Barriers to Trade or TBTs and Sanitary and Phytosanitary measure SPS in the WTO context) as one particular domestic regulatory regime and will analyze its effects on global trade with reference to regional trading blocks. The empirical evidence shows difference in export “standards” i.e. the product standards and conformity assessment procedures across countries can greatly influence trade volumes and patterns. As the governments have the ability to set standards based on domestic firms' product characteristics or technology capacity, it can raise foreign exporters' costs to adjust according to these requirements. Moreover, there often exists a great difference in standards across markets each of which requires an individual compliance cost such as the redesign cost for exporters. Hence, the difference in standards across markets can severely affect a firm’s export capacity and the overall volume of trade. **RTBs** present opportunities for controlling technical barriers to trade (TBTs) by “harmonization” of standards by its in–built advantage as the countries of the same region share similar “geo-climatic and cultural practices” – the preconditions of standard harmonization. Unfortunately export standards are most often not an important issue in some RTAs. The present paper shows harmonization and mutual recognition of standard can be beneficial and can have a significant positive impact on trade within the region and with third countries as well. Harmonization of standards in RTAs can work as a **stimulator for the intra as well as interregional trade.**

1 INTRODUCTION:-

Over the last few decades, the world has witnessed the creation of a large number of Regional trading blocks (RTBs) in almost every region of the world. The North American Free Trade Agreement (NAFTA), the European Union (EU), the Association of south East Asian Nation (ASEAN), the South Asian Association of Regional Cooperation (SARRC) are just a few examples of this trend. Therefore, the study of the welfare implications of trading blocs has become very relevant in the present global trade scenario. In Article 24, the architects of the GATT allowed for free trade areas and custom unions, both being preferential trade agreements (PTAS). The GATT has also overtime permitted developing countries a greater latitude to undertake PTAs that fall short of free trade areas and customs unions: the latter two require a commitment to getting internal tariff barriers down to zero, whereas the former permit permanent discriminations at levels other than zero. (Bhagwati 2002). While RTBs are believed to increase welfare to countries involved, as it is a movement towards free trade,⁴³⁹ some economists believe that RTBSs can have a negative welfare effect on trade volume and world welfare as the blocks control entry decisions, pricing, marketing etc. which may distort the free flow of trade and the resulting distortion may reduce the welfare. But all of these studies have discussed the welfare effect from the view pint of “tariff liberalization” and very few studies have focused on the role of RTBs with respect to NON –Tariff barriers to trade and its welfare implications.

With tariff barriers becoming increasingly less important, the regulatory regimes like labour standards and environmental norms as well as product standards and technical regulations are becoming more important determinants of trade. This paper has singled out export standards (termed as Technical Barriers to Trade or TBTs and Sanitary and Phytosanitary measure SPS in the WTO context) as one particular domestic regulatory regime and will analyze its effects on global trade with reference to regional trading blocks. The empirical evidence shows difference in export “standards” i.e. the product standards and conformity assessment procedures across countries can greatly influence trade volumes and patterns. As the governments have the ability to set standards based on domestic firms' product characteristics or technology capacity, it can raise foreign exporters' costs to adjust according to these requirements. Moreover, there often exists a great difference in standards across markets each of which requires an individual compliance cost such as the

438Johnston (1965), Cooper and Messell (1965), and Berglas (1979).

439Lipsey (1957), Wonnacott(1996). Wei and Frankel (1998), Nitsch (1996)

redesign cost for exporters. Hence, the difference in standards across markets can severely affect a firm's export capacity and the overall volume of trade. **RTBs** resent opportunities for controlling technical barriers to trade (TBTs) by "harmonization" of standards by its in-built advantage as the countries of the same region share similar "geo-climatic and cultural practices"– the preconditions of standard harmonization. Unfortunately, export standards are most often not an important issue in some RTAs. The present paper shows harmonization and mutual recognition of standard can be beneficial and can have a significant positive impact on trade within the region and with third countries as well. Harmonization of standards in RTAs can work as a **stimulator for the intra as well as interregional trade. The second part of the paper has taken into account harmonization and mutual recognition of selected products under ASEAN (as it has done fairly well under standard harmonization for some selected product) and tried to find out how far standard harmonization has affected the volume of trade.**

2 EXISTING LITERATURE:

Though Regional trade blocs were first thought to be formed due to beneficial economic welfare for the countries involved but as early as 1950, this suggestion was questioned. Jacob Viner (1950) pioneered the analysis of the immediate effects (static) of preferential trade agreements (PTAs). He argued that trading blocks may reduce world welfare of member nations if inefficient trade patterns emerge. His argument is that PTAs could act as trade creating or trade diverting entities. While the more obvious trade diversion can impose a cost on the non-member countries, the less obvious welfare costs are endured by consumers of member countries due to low-cost import substitutes coming in from member countries. The first phase of research on RTBs had focussed on the effect of custom unions on production (Viner 1950), trade flows, and consumption (Meade 1955; Lipsey 1957). With the second phase from the 1960s and beyond, economists began to find out the true aims of members of a regional economic integration grouping. By that they came to the opinion regional liberalization of trade did not necessarily increase the welfare of even the members of the grouping. Notable contributions in this phase include those by Johnston (1965), Cooper and Messell (1965), and Berglas (1979).

On the other hand Lipsey (1957) argues that in certain instances trade-diversion in customs unions could be welfare improving for its members. Kemp and Wan (1996) later show that a welfare-improving customs union could be developed leaving the welfare of non-members in their initial state. Bhagwati and Panagariya (1996a, p. 83) have analyzed "... whether the (dynamic time-path) effect of the PTA is to accelerate or decelerate the continued reduction of trade barriers toward the goal of reducing them worldwide." They dismiss Kemp-Wan's (1976) and Krugman's (1991b) static arguments as not meaningful to the context of dynamic path analysis. Bhagwati and Panagariya (1996a, 1996b) also made the point that "free trade areas" and "free trade" is not the same. In contrast to Bhagwati and Panagariya (1996a), Krugman (1991a), and Frankel, Stein, and Wei's (1995) arguments that RTBs may have a negative welfare effect, for members as well as non-members Wonnacott (1996) argues that free trade agreements (FTA) may be better than previously thought. He argues that, even under trade diversion, welfare may increase for both the diverting country and the world due to economies of scale. In a simulation that extends the work of Frankel, Stein, and Wei (1995), Wei and Frankel (1998) examine the effects of forming continental trade blocs on trade volume and overall world welfare. But all of these researches have focussed only on tariff liberalisation but not on trade restrictive impact of technical barriers to trade. Chen and Matoo (2004) had shown theoretically and empirically that regional agreement on standards increases the trade with the participating countries but not necessarily with the rest of the world. Baller (2007) looks at trade effects from TBT liberalization for members of the liberalizing region as well as two separate groups of excluded countries, industrialized and developing respectively. The study finds compelling evidence that Mutual Recognition Agreements for testing procedures have a strong impact on both export probabilities and bilateral trade volumes.

3 THE MODEL:-

3.1 Description of the model:-

Let us suppose there is a Regional Trading Block named R which consists of three countries A, B and C, where country A is exporting to country B and C. The importing country imposes varied standards⁴⁴⁰ and technical requirements on the good that is marketed in its market. The standard is quality related and not negative externality linked. ⁴⁴¹Firstly we assume complying with standards has no effect on consumers' demand for the regulated product. Firm 1 is domiciled in country A, in which it sells Q_{1A} units of output, while it exports Q_{1B} and Q_{1C} respectively to country B and country C. Suppose D_{ij} shows the variable compliance cost for the i th firm to export to j th country market. Initially we assume the production technology shows constant returns to scale. The exporting country has to bear a fixed set up cost F_j to enter into any export market j and the variable cost D_{ij} and we assume F_j and D_{ij} varies across markets. Firm 1 is situated in country A, 2 in country B and 3 in country C. Let us take the total cost of compliance with foreign standard as:- $E_{ij} = D_{ij} + F_j$3.1.1

E_{ij} varies across markets. Initially we assume the production technology shows constant returns to scale.

The Profit of firm 1, (Exporting Firm)

$$\pi_1 = (a - bq_{1A})q_{1A} + \{a - b(q_{1B} + q_{2B})\}q_{1B} + \{a - b(q_{1C} + q_{3C})\}q_{1C} - E_{1B}q_{1B} - E_{1C}q_{1C} \quad (3.1.2)$$

440 By "standard" here we mandatory "standard" which is a part of TBT of WTO

441 or it can be linked with some "imposed" negative externality which has no actual implication for welfare.

The profit of importing country firm:

$$\pi_B = \{a - b(Q_{1B} + Q_{2B})\}Q_{2B} \quad (3.1.3)$$

$$\pi_C = \{a - b(Q_{1C} + Q_{3C})\}Q_{3C} \quad (31.4)$$

The equilibrium exports are:

$$Q_{1B} = \frac{(a - 2E_{1B})}{3b} \quad (3.1.5)$$

$$Q_{1C} = \frac{(a - 2E_{1C})}{3b} \quad (3.1.6)$$

$$\text{Total export:- } Q_{1B} + Q_{1C} = \{2a - (2E_{1B} + 2E_{1C})\}/3b \quad (3.1.7)$$

However assuming production technology shows Increasing Returns to Scale and the cost function showing the cost of exporting to country B & C be: $E_{1B}.q_{1B}^{0.5}$ and $E_{1C}.q_{1C}^{0.5}$ respectively. The equilibrium outputs are:

$$Q_{1B} = \left(a + \sqrt{a^2 - (12b * E_{1B})} \right) / 6b \quad (3.1.8)$$

$$Q_{1C} = \left(a + \sqrt{a^2 - (12b * E_{1C})} \right) / 6b \quad (3.1.9)$$

$$\text{Total export:- } Q_{1B} + Q_{1C} = \left\{ 2a + \sqrt{a^2 - 12b * E_{1B}} + \sqrt{a^2 - 12b * E_{1C}} \right\} / 6b. \quad (3.1.10)$$

3.2 Effect of Harmonization of Standard:

In this section, we examine the impact on both intra-regional trade and trade with excluded countries of regional initiative like harmonization. Instead of straightforward assuming upward or downward harmonization ⁴⁴² we can assume harmonization at the average rate of standard that leads to the compliance cost common to both the markets:

$$E = (E_{1B} + E_{1C})/2 \quad (3.2.11)$$

Assuming initial standard in one of the countries (say country B) is more stringent than another (country C) it is upward harmonization for the later and downward harmonization for the former.

The equilibrium exports under C.R.S,

$$Q_{1B} + Q_{1C} = \{2a - (2E_{1B} + 2E_{1C})\}/3b \quad (3.2.12)$$

The equilibrium exports under IRS,

$$Q_{1B} + Q_{1C} = \left\{ 2a + \sqrt{a^2 - 6b * E} + \sqrt{a^2 - 6b * E} \right\} / 6b \quad (3.2.13)$$

3.2.1 Effect on intra-regional Trade:-

Harmonization of standard will work as a trade booster when the production technology shows I.R.S as the firms can reap the benefits of economies of scale.

Lemma 3.1:-Harmonization to average standard will lead to increase in the import and so as the volume of trade in the region when the production technology shows IRS whereas it will not affect the volume or trade if the production technology shows CRS.

Proof:-Follows from (4.1.7)&(4.2.12);(4.1.10)&(4.2.13) ■

Lemma 3.2:-Import in the harmonizing region increases unambiguously for the country with most stringent initial standard (Country B) as the exporting country can reap the benefits of both the integrated market as well as reduction in compliance cost, whereas for country C the effect on import is ambiguous as the exporting country can get the benefit of only the former.

Nevertheless the import in Country C will increase iff,⁴⁴³

$$E_{1B} < 3E_{1C} \quad (3.2.14)$$

The above result predicts that if the difference between the initial standards is not sufficiently high then the import in the country can increase after harmonization even if it follows upward harmonization.

3.2.2:- Effect on Inter-regional trade:

The interregional trade of the harmonizing region should also increase as the exporting country even if it is not located within the region can target the entire region as the export market and can reap the benefits of scale economies.

Lemma 3.3:- Intraregional trade volume will also increase if the region follows standard harmonization.

3.2.3 Effect on welfare:-

The welfare effect of standard harmonization on exporting country depends on the effect on producer's surplus as the consumer surplus of the exporting country remains unchanged with or without harmonization. The revenue from export

442 Chen and Mattoo(2004)

443 Comparing values of q_{1c} before and after harmonization.

market which has undergone downward adjustment will surely increase unless the demand is highly inelastic⁴⁴⁴.the revenue from the market with upward adjustment will also increase if condition 3. 2.14 is fulfilled and demand is not very inelastic. Though the producer surplus in the importing country will fall due to reduction in domestic production, the consumer surplus will increase due to fall in price surely for country B and for country C as well if condition 3.2.14 is fulfilled. Therefore the welfare of importing countries can also increase due to harmonisation.

4 HARMONIZATION AND MUTUAL RECOGNITION OF STANDARD:-

The exporting country may target more than one export market in a region R. ⁴⁴⁵In that case the standard in different export markets may be different which may lead to difference in both the fixed and variable part of the compliance cost. If production technology shows constant returns to scale then difference in standard **will** lead to the same result as the harmonized standards as long as only harmonization is there.(not Mutual Recognition Agreement). If the production technology shows increasing returns to scale then there will be remarkable difference in the consequences of trade under differentiated standard and harmonized standard both in terms of volume and welfare.

4.1 Effect of Mutual Recognition Agreements (MRAs):-

One of the most powerful measures to boost trade is the mutual recognition of existing Standards, whereby a country grants unrestricted access of its market to products that meet any participating country’s standards. This was the approach taken in principle by the European Union, with the spur of the Cassis de Dijon judgment of the European Court of Justice. Mutual recognition agreements (MRAs) are, however, not likely to be an option if there is a significant divergence in the initial standards of the countries, as became evident in the context of the European Union. In such cases, a certain degree of harmonization is a precondition for countries to allow products of other countries to access their markets.

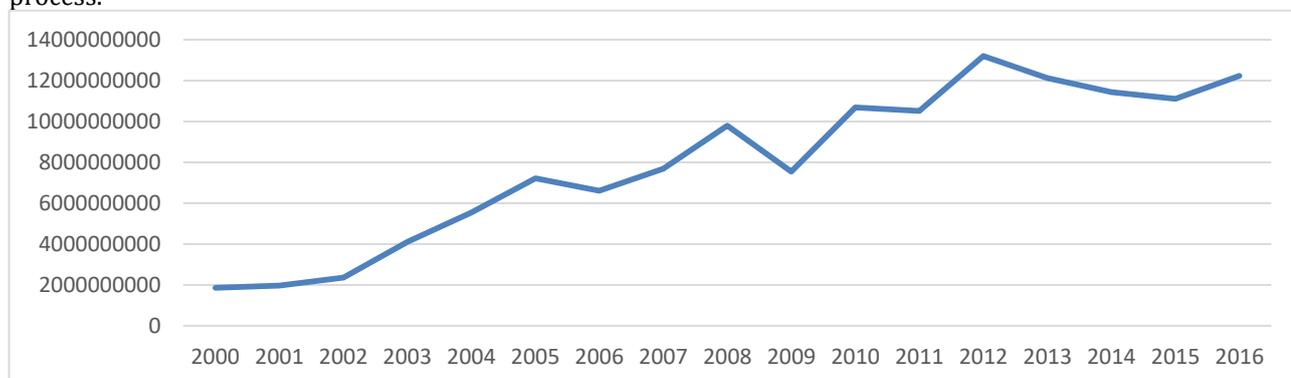

Mutual recognition can be equivalent to downward harmonization⁴⁴⁶,i.e products that comply with a standard set by any participating country can be freely sold in the entire region which will lead to choice of least strict standard. In the present model mutual recognition can be adoption of average standard with the cost of compliance consisting $\min(F_A, F_B)$ instead of $(F_A + F_B)$.

The effect is very obvious. It will lead to a further increase in the volume of trade as it leads to further decrease in the cost of compliance and the exporting firm will reap the benefit of integrated market as well as reduction in cost .

5 EMPIRICAL EVIDENCE: -

Harmonization of Standards is a big issue in negotiating regional trade agreements. In this context we have considered ASEAN which has agreed to align national standards for 11 priority product groups with relevant international standards. These products include some important widely traded product in the region. Working on harmonization Moreover, trade facilitation measures have been undertaken by ASEAN countries to complement efforts in tariff reduction and elimination under African Free Trade agreement. (AFTA). These include the elimination of unnecessary technical barriers to trade, harmonization of standards and conformance measures and simplification of harmonization and customs. The adoption of international standards is equally critical for ASEAN’s external trade as it is for intra-ASEAN trade so that the products could compete at an international level. As international standards define the characteristics that products and services have to meet in export markets, these help developing countries take part fairly and competitively in international trade. The ASEAN framework agreement on mutual recognition which was signed in 1998, provides for a mutual recognition of standards and conformity assessment among ASEAN countries. This arrangement allows products that are certified in one ASEAN country to be sold in other member countries without having to go through the same standards and conformity assessment.

Based on the data on intra ASEAN volume of trade it can be observed that trade volume have improved over time for some selected products like Automotive, foodstuffs, pharmaceuticals which have gone through the harmonization process.

444 As there will be fall in price in the importing country due to increase quantity from exporting country

445 The reason as the same region shares same climatic and socio economic conditions it is comparatively easier for the countries to go for Harmonization of standards.

446 Chen and Mattoo(2004)

Fig 1:-Growth of trade volume of (intra Asian) Automotive products

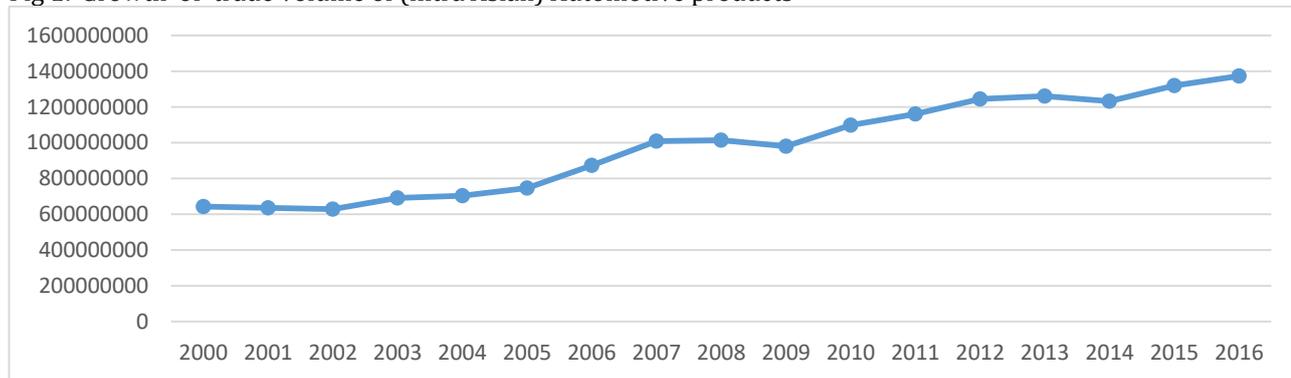

Fig 2:-Growth of trade volume of (intra Asian) pharmaceutical products

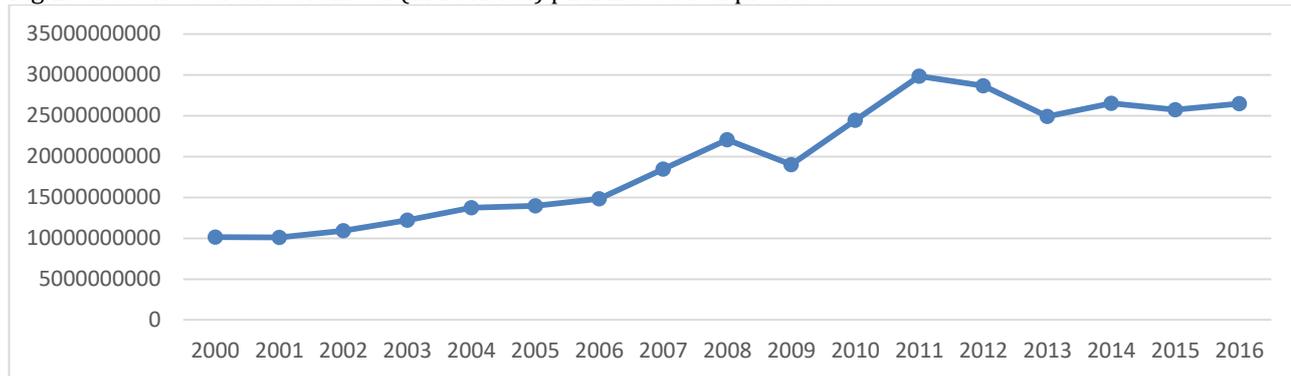

Fig 3:-Growth of trade volume of (intra Asian) food products

The trade volume (at constant prices) has shown an increasing trend for which the possible explanation can be the standard harmonization.

6 CONCLUDING REMARKS:-

Regional trading blocks and regional trading agreements creates opportunity for standard harmonization and mutual recognition as the same region shares various common features and national standards are not sometimes not significantly different. In the present day world trade scenario barriers related to product standards are the main concern of developing country’s export today. Exporters from developing countries are increasingly feeling the pressure to conform to international standards if they are to enter successfully developed country markets. Much has been achieved in various developing countries to construct the requisite quality infrastructure, to enable exporters both to understand the nature and detail of the quality standards to be met and to take the steps to comply with them. The potential to use product standards as hidden trade barriers is immense. Even if a small part of this potential is allowed to be exploited, the implementation of the free trade regime could become dominated by protectionists and those who would welcome trade retaliation and counter retaliation. However, transparency and harmonization of standards could become trade facilitators in addition to providing technical quality and safety parameters. Exporting country has to incur significant cost harmonization of standard meet up the standard specified by their trading partner as the trading partner (importing country) has the advantage to set the “standard” nearer to the domestic standard if its intention is to protect the local producers. As mentioned earlier, this paper specifically deals with the possible welfare effects of regional standard harmonization and shows standard harmonization within the regional trading block can be welfare improving and states the condition under which intra-regional and inter regional volume of trade along with welfare improve after standard harmonization and mutual recognition. It points out if the initial standards are not too different and importing countries are also not too apart (technological improvement etc), which is likely to happen among the members of a regional trading block welfare after harmonization can improve for all the members who has followed harmonization .moreover welfare of non-member exporting country will also improve which is not possible under tariff liberalization within regional trading block.

Agreements on standards raise issues that are both politically and analytically challenging. Unlike tariffs, standards cannot be simply negotiated away because the original reason for their existence is not trade protection but the enhancement of welfare by remedying sale of “low quality products”. If standard harmonization and mutual recognition agreement is feasible, then it will increase the total volume of trade. As mentioned in the introduction many Regional Trading Agreements do not have enough provision for liberalizing TBT by harmonization and Mutual Recognition Agreements though there is enough scope of that.

APPENDIX 1

$$\frac{\partial \pi_1}{\partial Q_{1A}} = a - 2bQ_{1A} = 0$$

$$\frac{\partial \pi_2}{\partial Q_{2A}} = a - bQ_{1A} - 2bQ_{2A} - F_A - D_{2A} = 0$$

$$\frac{\partial \pi_2}{\partial Q_{2B}} = a - 2bQ_{2B} = 0$$

From above equations:-

$$2bQ_{1A} + bQ_{2A} = a$$

$$bQ_{1A} + 2bQ_{2A} = a - F_A - D_{2A}$$

$$2bQ_{2B} = a$$

Solving by Cramer’s rule one can get the quantities.

APPENDIX 2

Country A, Consumer surplus under free trade is: $- 4a^2 / 18b$

The consumer surplus after it imposes standard on imports is: $-(2a - F_A - D_{2A})^2 / 18b$

Producer Surplus for firm 1 i.e firm in Country A under free trade is $a^2 / 9b$ Producer surplus after the country imposes the standard on imports is: $(a + F_A + D_{2A})^2 / 9b$...2.2.15

Country B, Producer Surplus under free trade is $13a^2 / 36b$ Producer surplus after complying with international standard:- $a^2 / 4b + (a - 2 F_A - 2D_{2A})^2 / 9b$ 2.2.1

APPENDIX 3

Firm i situated in importing country j,

Before Harmonization,

$$Q_{ij} = \left(5a - \sqrt{a^2 - (12b * E_{ij})} \right) / 12b$$

$$P_j = \left(5a - \sqrt{a^2 - (12b * E_{ij})} \right) / 12$$

After Harmonization,

$$Q_{ij} = \left(5a - \sqrt{a^2 - (6b * E_{ij})} \right) / 12b$$

$$P_j = \left(5a - \sqrt{a^2 - (6b * E)} \right) / 12$$

1024 LONG CYCLE PLANNING AS A TOOL FOR THE RESILIENCE OF THE TERRITORIES: THE CASE OF EDUCATION SECTOR IN CASCAIS, PORTUGAL

Jorge Gonçalves

IST, Av. Rovisco pais, 1, 1049-001 Lisboa, , Portugal, E-mail: jorgemgoncalves@tecnico.ulisboa.pt

1 INTRODUCTION

It is notorious the persistence of understanding the role of education as a central factor for increasing the quality and intensity of development at different scales - national, regional and local (Saviotti et al., 2016). At the same time, the discussion on how to achieve this importance is practically the same, with a very strong presence of the ideological component, generating instability and fragility to the policies adopted. Knowing that one of the few certainties that are accepted in this area is the requirement of a consistent and steady course of action beyond the ephemeral political cycles, the tension, uncertainty and permanent conflict felt in the educational system ends up inhibiting its role in development.

One of these tensions lies in the management of the education system and, above all, in its ability to connect to the business world (Moberg, 2014.) The greater or less centralization in the bodies of central administration has been discussed at length and even segmented in parts, as the human resources - teachers and non-teachers - facilities, curricula, among other aspects.

This chapter is then born from the municipal ambition to assume extended competences in the educational field motivated by the proximity and adequacy that it may bring to local needs, namely in economic dynamics and social cohesion. This pull factor corresponds to a push factor that is linked to the interest of the ministerial agencies, in a context of structural public debt, to alleviate financial responsibilities.

However, whether by conviction or convenience, this decentralization of powers provided by the Central Administration and in Portugal seems to be generalized (see news), requires clarification of the advantages of the process as well as the forms and costs of its implementation. These are essential challenges to transform the local educational system into a factor of socioeconomic distinction and qualification and create renewed instrument of local development.

The objectives that structure this work and support the validation of the thesis seek to explore the relevance of participation in the redefinition of the local education system; Modalities to foster the relationship between the school and local actors; The importance of strategy as defining a possible future, consensual and desired; Possibilities to design contents that make flexible management of the curriculum possible; Improve school performance.

The methodology is based on the presentation of the case of the municipality of Cascais in the Lisbon Metropolitan Area and its work to create a new educational and training ecosystem, within the scope of the new competences contracted with the State, through the Municipal Educational Strategic Plan, where it is possible to find priorities that sustain a structural change in personal shaping, in the reinforcement of the collective identity and in the articulation with the productive fabric.

Due to the great work of involvement, auscultation and information, due to the concern to guarantee a future of the education system marked by cooperation and co-responsibility, the definition of goals, objectives and actions and also of programs of actions duly scheduled and monitored, it is considered that this is an experience that deserves to be shared and reflected.

2. LITERATURE REVIEW

2.1. Educational policy as a development policy

Education, like health and social protection, is one of the strong pillars of social state, seeking to guarantee equal opportunities for all members of a community and to face trends of inequality and social injustice. With few exceptions, the greater development of these strong pillars corresponds to higher levels of social and economic development. This correspondence can be accessed in many ways, with territorial expression. One of the most popular rankings is the Human Development Index (HDI) (United Nations Development Program, 2017), where education is one of the central aspects contributing to rank the nations of the globe by levels of development. Their acceptance even led to the methodology being applied at regional and local scale, for example in Brazil (Rezende et al., 2005).

But how to transition from education in development and structural change, understood as the pondered reconsideration of basic social principles (McMillan and Rodrik, 2011). It can be discussed in an operational way and in a temporal way. Firstly, it must be recognized that the educational system does not only provide scientific and technical knowledge, directly useful for economic growth and social development, but also provides knowledge that becomes an awareness for the exercise of a more informed, more active, more conscious citizenship.

The shaping of a person has three components: technical, scientific and informative. Sustainable development involves shaping a system of education that promotes structural change by ensuring increasing levels of performance in those three components as well as affirming (Psacharopoulos and Woodhall, 1993), "investment in education is a key element of the development process". Its importance is reflected in the growing recognition, since the early 1960s, that investing in both formal and informal education and training provides and enhances the skills, knowledge, attitudes, and motivation necessary for economic and social development" (p. v).

It is clear that this is a demanding bet on the costs and time it takes to impose. The opportunity costs of investing in the education system make this the best option for the use of financial resources that are thus being diverted from other applications. In other words, “the opportunity cost must be considered in the evaluation of investment projects because, as noted earlier, every investment decision involves a sacrifice of alternative opportunities” (Psacharopoulos and Woodhall, 1993:23). On the other hand, it is a long term bet because the results are not immediate, they are expected to be long-lasting and self-reproducible (Wals, 2012).

2.2. Educational Ecosystem, Local Development and Decentralization

Education as a centralized policy defines contents, objectives and similar goals for all territories regardless of local particularities and interests. It is evident that the autonomy of schools can lighten this “dictatorship”, but their means and energy sometimes fail to promote a curricular offer or educational project as related to the territory as it would be desirable (Veiga, 2003). And so, local identity, resources and dynamics are almost always outside the hard core of educational policies (Brown, 2015; Stromquist and Monkman, 2014). In other words, there is an undeniable qualification of local human resources, which often are fixated in the region itself, but there are also limitations derived from the incipient inclusion of content linked to local and regional specificities.

The opportunity for change arises with the openness to decentralization manifested by central governments that seems to occur both out of conviction and convenience, but which in itself is not a guarantee of quality, as, moreover, underline Winkler (1989), Fiske (1996) and Skeland and Filmer (2007) when they mention the risks associated with the possibility of elite capture, the risks of inequality in access to education and the lack of capacity of local governments and schools to deliver quality education.

The literature also emphasizes “that inconsistent curricular and quality standards, resistance from teachers’ unions, and the reluctance and inability of parents to make technical decisions on education matters may in fact reduce, not increase, the effectiveness of education service delivery” (Qi, 2014).

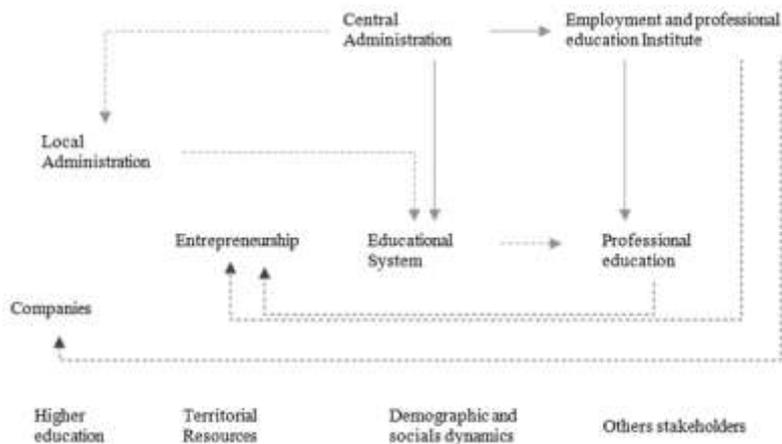

This is why “education decentralization is a multifaceted concept with political and economic aspects. It takes many forms in different countries depending upon how political and fiscal responsibilities are allocated to lower levels of government. Decentralized governance is practiced for different reasons in different places using different instruments” (Jeong et al., 2017).

By controlling these risks, the benefits of decentralization can be enhanced by highlighting local resources (locative, human, territorial, initiative), greater flexibility in curricula and greater participation of local actors in the education system. Parry (1997) stresses that “The benefits of decentralization in broad terms include greater responsiveness to citizens, improved decision making based on more accurate information and better knowledge of local conditions, and improved efficiency in service delivery” (p. 211).

Decentralization can take many forms as Rondinelli and Nellis (1986) e Rondinelli et al. (1989). These authors suggest the possibility of different approaches to understand decentralization: Deconcentration shifts workloads from a ministry’s centrally located offices to staff or offices outside the national capital. Employees are still employees of the central government, however, and generally have little discretion in implementing policies. Delegation is the transfer of authority from the central government bureaucracy to some other public sector authority such as public corporations, regional development agencies, or special function agencies. Devolution is the “true” form of decentralization in which subnational levels of government are given complete authority for specific public services which were previously provided by the central government. Finally, the last approach is privatization which gives responsibility to private organizations such as non-profit or voluntary organizations, trade associations, professional groups, religious organizations, cooperatives, or business firms to carry out functions which were previously performed by the public sector (Parry, 1997:211-212).

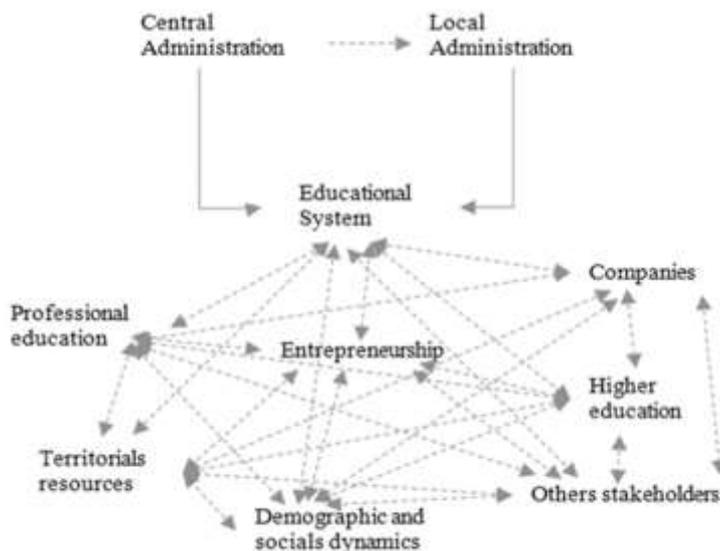

The deepening of this model and its continuity can help to build an educational ecosystem that corresponds to a complex interaction between direct and indirect actors of the educational system and that results in the creation of synergies from its intervention (Figure 1 and 2). As claim by Toutain and Mueller (2015) “Ecosystems are situated in complex contexts. Actors interact in a particular geographical area and their behaviours, responses and actions are influenced by a set of social, political, cultural and economic conditions. This process progressively builds the ecosystem of an organisation or specific domain as educational sector” (p. 8).

3 EDUCATIONAL COMMUNITIES AND TERRITORIES: THE POTENTIAL OF STRATEGIC PLAN FOR LOCAL EDUCATION SYSTEM

Education in Portugal was one of the sectors that most evolved since the second half of the last century and, especially, after the revolution that restored democracy in the country. From an obligatory 4-year schooling that was not respected, "strongly marked by the doctrinal promotion of a citizenship restricted to the logic of the nation-state" (Afonso, 2008:61) and supported in a wide network of local educational equipment, education was understood as a fundamental right inscribed in the Constitution of the Portuguese Republic where Article 73 imposes that "Everyone has the right to education and culture" and schooling has been extended gradually Up to 12 years or until the student is 18 years old.

The concern for a long time was that of quantity, that is, to provide more students and families an opportunity for education and teaching. We therefore agree with Santos et al. (2016) When they stress that "this radical transformation is the result of a profound evolution observed in educational policy and, more specifically, in the planning of educational resources" (p. 19).

Is under way in many European countries a process of decentralization from the central state to local governments of skills in public policy management with the public purpose of more actively involving communities in the fundamental issues of their daily lives. But also as states Cuéllar-Marchelli (2003) "Decentralized services, (...) are expected to improve decision-making, allocate resources more efficiently, and hence report higher quality levels" (p. 146). This is why "one of the most urgent problems is to find ways to involve local society in the development of general education in municipalities" (Laudams, 2014:570).

A less transparent goal may also be to seek to achieve the minimum state by transferring financial responsibilities to local authorities, hoping for greater efficiency and effectiveness. One of the topics that stands out in this general process is education.

In Portugal, this approximation of education systems to local territories formally required the elaboration of a Municipal Educational Strategic Plan with which it would be possible to design a medium / long-term educational system moulded to and by local actors, their needs and their identities. In the case that is intended to illustrate, the future of the Cascais

educational system was actually constructed by the local community through a large participatory process allowing define strategic objectives and concrete lines of action. And the result was the building of a future desired by the community through the educational system.

4. CASCAIS MUNICIPAL STRATEGIC EDUCATIONAL PLAN⁴⁴⁷(CMSEP): AN INSTRUMENT FOR STRUCTURAL CHANGE

The objective of this chapter is to provide a testimonial about the methodological and technical aspects related with each phase and step of elaboration of the educational strategic plan for the municipality of Cascais which is expected to lead over the next five years to important steps in the process of building change in the educational system but in social and economic development, providing the desired structural change.

4.1. Brief notes on the territorial and economic framework of Cascais

In order to understand the territorial context where this educational system is placed it is important to analyse some facts and figures about Cascais municipality. This municipality only has 3,2% of the total area of the Lisbon Metropolitan Area (LMA) and only 7% of all population, counting with an area of 97km² and 206 000 residents in 2011. Though, Cascais has the biggest grow of population, 21%, between 2001 and 2011, one of the best figures in LMA during this period.

Located in the western end of the metropolitan area, shares its borders with Sintra and Oeiras municipalities and has a strong relationship with the country’s capital, Lisbon. The geographical location of Cascais gives it an almost unique specificity at a national level. From the Atlantic coast, to the estuary of the Tagus, to the protected landscapes of Serra de Sintra (Natural Parque of Sintra-Cascais), the municipality has environmental and landscape characteristics with high economic potential for tourism and leisure (Figure 3 and 4).

Figure 3 – Location of Cascais and Lisbon Metropolitan Area at the national level

Source: Author’s elaboration.

Figure 4 – Cascais urban areas and main transportation connections

⁴⁴⁷ Plano Estratégico Educativo Municipal de Cascais

Source: Author's elaboration.

The axis formed between Cascais, Oeiras and Lisbon is densely urbanized but it is still one of the most important areas at a regional level, especially on the potential for tourism and economic development. Therefore, exists here a relationship bigger than simple geography, transportation is in part the base of this strong urban occupation and territorial connection.

In relation to employment and economy, the third sector dominates the local economy with 86% of the employed population working in this sector, the secondary sector only has 13% of employment. These numbers show that local economy is mainly dominated by services, commerce and tourism. Another indicator of the economic condition of this municipality is the percentage of residents working within the municipality, 53%, with one of the best percentages of all LMA. Although business volume still is very low, only 3% of the total for the metropolitan area, nonetheless power of purchase, although being dropping in the last few years is still equal to the metropolitan values but higher compared with the national figures. Unemployment rate has experienced some grow between 2001 and 2011, from 6,5% to 7,4%, but still very similar to the neighbour municipalities and LMA.

On the figures about education, Cascais present levels of schooling superior to those seen in LMA and also at national level. For instance, 21% of Cascais residents have higher education and only 2% are illiterate. In terms of early school leaving, the rate sits on 1,7%, equal to the metropolitan and national rate.

4.2. The motivation for the elaboration of CMSEP

The municipality of Cascais have a long history and experience with the local management of the education, and this experience allowed all the stakeholders to develop good relationships between them. In fact, Cascais was one of the 15 municipalities (from 308 Portuguese municipalities) to sign the Inter-Administrative Agreement of Delegated Competencies. The Portuguese education system has dealt with many changes over the years going from centralization to decentralization, which is the phase we are in nowadays. The decentralization from the Ministry of Education to the local level of power – municipalities – is the result of the application of the principle of subsidiarity to the management of the educational sector. It is also important to retain that in the education sector the municipality of Cascais presents a really particular case in the Portuguese educational scenario, since half of the school population attend to private schools, what brings more challenges and more stakeholders to a already complex and very exceptional territory.

This pilot project has a pedagogic and administrative character and it aims to promote the efficiency in the use of educational resources and built up knowledge and experience in decision making at municipal level in the topic of education.

The evolution from a centralized educational system to a decentralized local and municipal system is materialized and has force of a law with the Inter-administrative agreement. The agreement signed between Cascais municipality and the Ministry of Education⁴⁴⁸, in 2015, transfers the responsibility for a great part of the education sector to the municipality. This is means that the municipality is from now on responsible for all the levels of teaching, from pre-schooling to the secondary level, including the professional education courses and other aspects of the education system. These responsibilities include non-teaching staff (teachers are still under the responsibility of MNE), school social support (such as meals, transport and materials), maintenance and equipping of school facilities (although some school like Secondary Schools are still under the responsibility of MNE), transportation and after school activities.

⁴⁴⁸ Ministério da Educação - MNE

The Municipal Strategic Educational Plan is a completely new instrument of planning in the education and also municipal context, but it is developed along another instrument with more deeper roots in the local context, the “Educational Plan”⁴⁴⁹, a more normative and typical document in the planning environment that can be compared to a master plan for local education.

Planning strategically in education allow us to leave the scale of immediate, the scale of everyday and makes us look the future, using local resources, making use of opportunities and solving the problems of the system, fostering new possibilities for structural change. At the same time, schools have difficulties to link their actions and projects to a strategy design for the local/municipal level, this means education strategic planning design to the municipal level is, until today, hardly incorporated in the school’s action plans and projects.

The introduction of this new strategic document is the result of a new way of managing and arranging the educational system, with the municipalities in the lead of their own system, as part of the new framework of decentralized powers. This gain of more and diverse responsibilities carries the need for more instruments, such as strategic plans and requires the involvement of more and different stakeholders. Stakeholders in this context can take many shapes and forms such as teachers, schools, school districts, technical and elected bodies from the municipality with direct relationship with education, local organizations and groups, among others.

4.3. Path to the Strategy

The strategic educational plan can be divided in three major phases: Diagnosis; Participation and Plan Development. The diagnosis and plan development phases are, as can be further seen, “the most important and also the most time-consuming” (Unesco, 2010 :7).

The Diagnosis phase “is the first step of the strategic planning process. It consists of the critical analysis of the status, functioning and results of the education system, with the view to identifying strengths and weaknesses” (Unesco, 2010 :9). The analysis was not limited to the educational system it was also important to cover the environment in which the systems is operating as so it is important not to limit the analysis to the current situation, past trends are also determinant to understand the current situation (Unesco, 2010). Since this diagnosis took a holistic approach, it can be divided in three different components:

- **the territorial characterization**, with the analysis of local urban dynamics, population, employment, transportation and other indicators;
- **the diagnosis that supports the works of the “Educational Letter/Map”**, with all the indicators related to school population, grades and results, students social support among other subjects;
- **the strategic plan diagnosis** where the legal framework, municipal plans, programs and projects with impact on local education were analysed, as well as recommendations from international and national authorities on the subject of education. Besides this, was made a survey of all stakeholders and resources of this educational system.

The Participation phase was by far the biggest task on this plan, since the goal was to make the plan with and for the educational community (students, families, teacher, schools, city council, etc). Participation is a process very imbued in this community and the municipality has a great experience in this kind of processes. Participation and also consulting took many forms and shapes in this process, from workshops with stakeholders and students, to meetings with elected bodies of the city council and the regular meetings with the team from the municipal education department. Were also sent questionnaires to all entities that could have a saying in the local educational system, and was also organized two rounds of interviews/talks with the directors of school districts.

Workshops were by far the more intense activities of this process and the biggest source of information to the plan. The participation in the workshops was made by invitation to representatives of organizations, which were divided by typology of stakeholders, such as workers from the city council (as test session), representatives from public schools, representatives from private schools, civil society members and the elected deputies of the municipal assembly and other councilman.

Workshop 1 had five sessions that count with 25 to 30 participants each, divided in tables of 5/6 people, accompanied with a Facilitator, usually someone from the technical team, that ensured the development of the workshop exercises smoothly and without incoherencies. As Figure 5 shows each participant had several *post-it’s* where could be written five problems, five opportunities and three resources of Cascais’ educational system. In rounds problems where presented to the table and facilitator would see if there where redundancies or overlapping ideas in the *post-it’s*, finally the table would have a final list of problems that could be voted to find the most important ones. The same procedure was used both for opportunities and resources. By the end of the workshop sessions the top results from each table were presented to the rest of the tables. This methodology was also used in the round of workshops for students from private and public schools, from all ages, with the due adaptations for this group.

Figure 5 Methodology of Workshop 1

⁴⁴⁹ Carta Educativa – CE

Source: Author's elaboration.

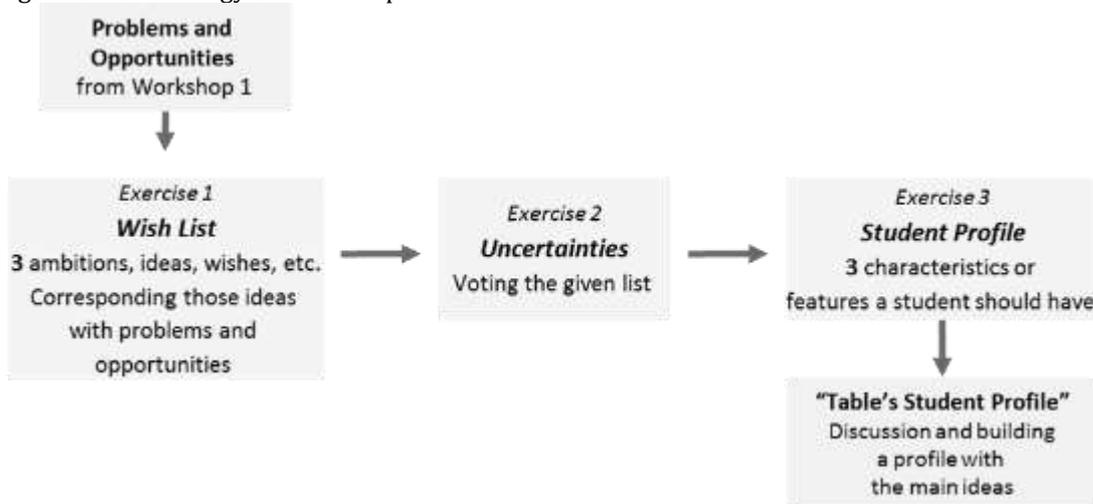

On round 2 of workshops the same organization method was adopted for the sessions, what differs from the first round are the exercises asked to the participants. These sessions had three different exercises: The Wish List, the Critical Uncertainties Framework and the definition of a Student Profile (Figure 6)

On the Wish List exercise the idea was to make the participants suggest three ambitions, ideas, aspirations and wishes to the local education system. With all the *post-its* grouped by themes, the participants were asked to associate these wishes/ambitions/ideas to a list of problems and opportunities (that came from the top problems and opportunities found on the first round of workshops).

On the second exercise the goal was to find out what participants believe to be the biggest challenges in the education sector, and how it's planning is affected by external factors, here named Uncertainties. From a list participants could vote which factors they believe affect more the system, such as policy change, demographics or economic conditions, but could be also added more factors.

The last, and third exercise, was about the Student Profile, or profiles. Here participants could present a few ideas, characteristics or features they believe that students by the end of their academic career should have, or in other words, the product of Cascais' educational system.

Figure 6 Methodology of Workshop 2

Source: Author's elaboration.

At the end of the Participation phase and with the Diagnosis completed the technical team had already much information and data to prepare a final analysis of Cascais' educational system. The SWOT tool was the technique chosen for "identifying internal Strengths and Weaknesses and external Opportunities and Threats" (Unesco, 2010 :15). Since there is no specific tool for moving from diagnosis phase to the identification of objectives and priority programs the procedure was to create strategic objectives that answered the main issues reported about the educational system

Ended the second phase was time to move from Diagnosis and Participation phase to the actual strategy design.

4.4. Designing the Strategy

The participatory process and the diagnosis phase produced, among other results, a set of main principles and values that should be inherent to the strategy to be design. These principles are: capacitation, sharing, opening to the community, co-responsability, participation and social cohesion.

Based on these principles the Strategic Ambition was defined as "Quality education in Cascais is the based on a solid and inclusive individual and collective development capable of capturing, establishing and expanding values, skills, creativity and innovation, promoting an educative territory that fosters participation and sharing of responsibilities."

This Strategic Ambition was divided in three main Strategic Objectives (SO):

- Strategic Goal 1: An Education for Success

Build a successful educational system that guarantees the integral development of each citizen, their knowledge and skills based on equal opportunities that allows the construction of individualized academic or professional paths.

- Strategic Goal 2: An Education for All Life

Ensure an education system that encourages lifelong learning and responds to the training needs of all citizens.

- Strategic Goal 3: Education with and for the Community

The resources of the educational system will provide a wide range of new spaces, values and dynamics that enhance the relationship between the school, the community and the territory.

Each one of this Strategic Objectives has different Action Plans (AP) and inside each AP a set of Actions that have a designated chart (Figure 7). It is worth mentioning only the APs that value the topics of professional education and articulation with economic dynamics. In Strategic Goal 1, AP6 - Valuing Professional Education, where it is considered that the opportunities offered by the system in these areas should be visible, exploited and seductive in order to respond to the needs of those who want to attend and who already attends this type of teaching. In this AP6 we can find the 6 Actions that compose this action plan:

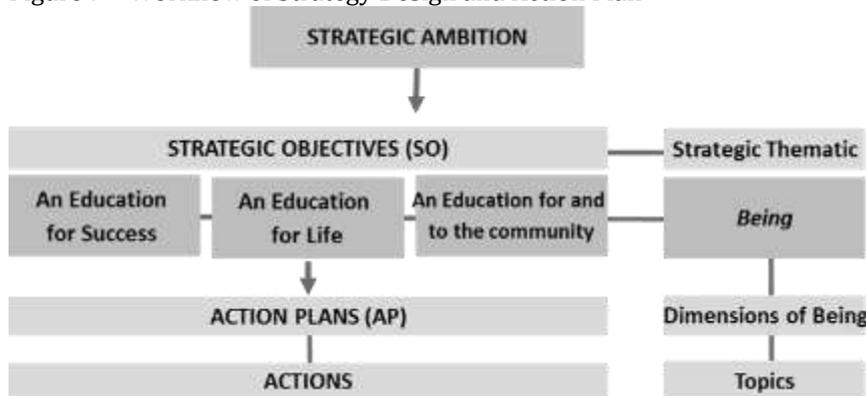

- Observatory of Professions
- Open Day of Professional Education
- Access to Vocational Education Kit
- Demand-offering platform for Professional Internships
- Pivots of Professional Education
- Professional Training Showcase

In Strategic Goal 2, emphasis should be placed on AP9 - Enhancing adult education and training, where it is considered that the school also serves to provide new skills or to deepen knowledge already acquired. Education and training find many ways of achieving this, and one of the most obvious is to consider the professional and personal experience of citizens. The actions that materialize it are:

- Study of the needs of the local labour market
- Exhibition of Professions and Higher Education
- Project "Millennials (Gen Y) and Centennials (Gen Z)"

Every Action chart is composed by the description of the main objective behind the action and how it should be implemented, besides this the chart has identified partners and resources needed, as well as, indicators of performance.

Figure 7 – Workflow of Strategy Design and Action Plan

Source: Author's elaboration.

Side by side with the Strategic Objectives was created a Strategic Thematic (ST), named as "Being". The goal behind this parallel thematic was to create a response for one of the Interadministrative Agreement demands, the flexible curriculum. This means that the 4 subjects included in this strategic thematic can be used as part of a more practical and experimental way of teaching, less formal and more based on exploration and creation outside of the classroom.

Each "Dimension of Being" has a set of "Topics for Implementation" that work as ideas or suggestions for teachers and students to discover and use local resources.

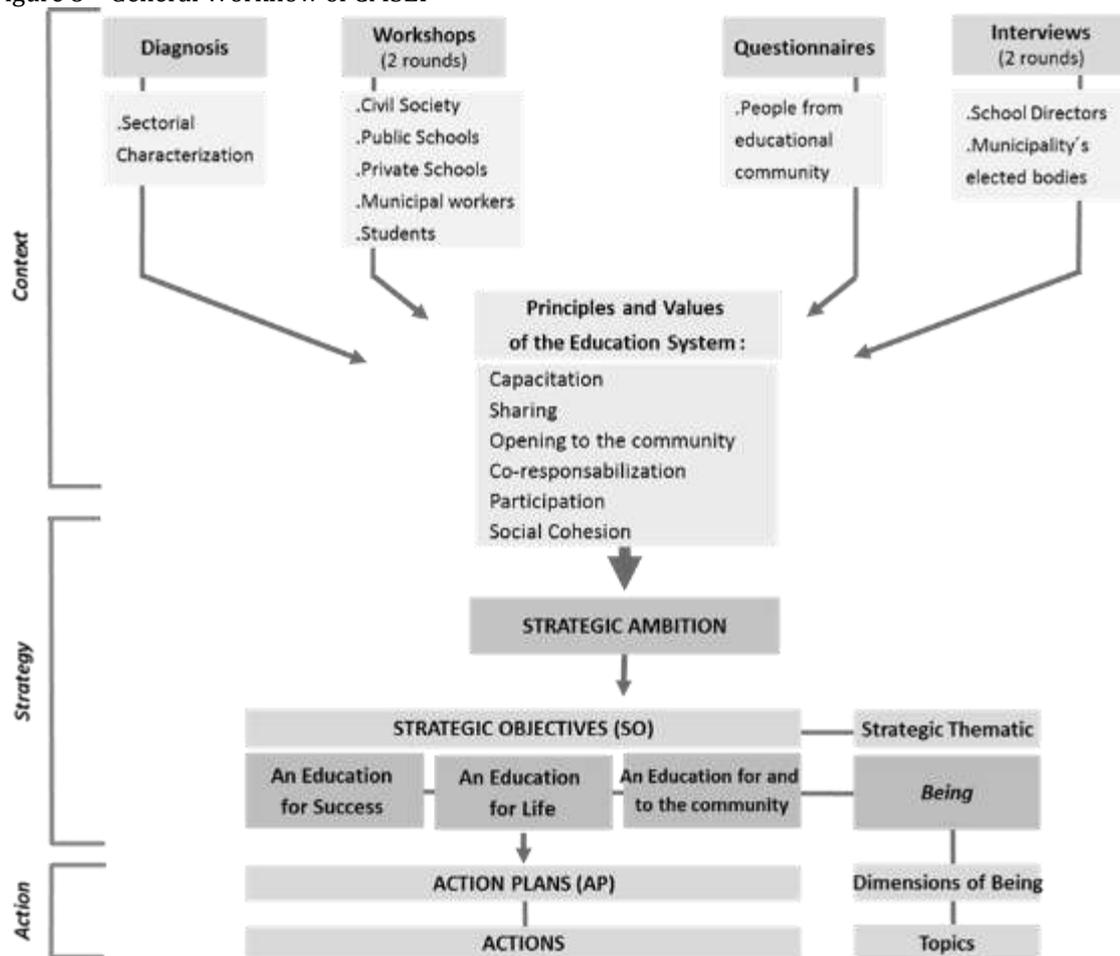

One of the subjects - "Be an entrepreneur" - have as topics the follows

- Entrepreneurship Competition
- Business start-up program for young people
- Creative Cascais / Ideas Contest
- Youth Employment Forums

Since it is non-mandatory schools can choose to explore all the themes or some of them, or just adapt the topics for implementation to their current projects. The freedom allowed in the implementation of this topic explains one of the concerns of this whole project, schools are free to make their own decisions, so the plan should never interfere inside of school decisions and options. The plan was made to provide help to the local municipality at the management of the educational systems and to give support to schools.

The vision of the whole process can be consulted in figure 8, where it is possible to highlight the three fundamental moments: the identification of the measured and perceived reality; the definition of the strategy; and the definition of the action plan.

Figure 8 – General Workflow of CMSEP

Source: Author's elaboration.

Part of the support this Strategic Plan should provide to schools is on the matter of applying strategic thinking to school plans. Each School District has (more or less) a 4-year plan that among other subjects should have the strategy for these group of schools and well as a set of projects that should be implemented in the schools. One of the things noted during the diagnosis phase was that the majority of the plans lacks in strategy because it strategic thinking is something that was never before explored in school management. It also fails on the diagnosis of its own problems, and without proper understanding of their school population and surrounding community it is hard to define a strategy and an ambition. The Interadministrative Agreement also demands that school plans are adapted when the Strategic Plan is approved by the Municipal Education Assembly, so this responsibility was always on the base of the designing of the plan.

Although setting a strategy was the main goal of this plan it was also important to established a Governance framework and a Calendar of implementation. These two tools allow that the plan can be more easily implemented and stakeholders understand better their responsibilities. Setting a Calendar for such a big task is never easy and it is impossible to take on every Action Plan and Action at the same time, so, here the purpose was to define priority groups. In the three priority groups created were distributed the APs, according with the ability of each AP to respond to the main problems identified on the diagnosis. The second and third group of priorities include those AP that are less transversal and with less coverage of the issues previously identified. Since this plan only has 5 years to be implemented the priority programs were distributed in semesters within this time period, has can be seen on the following figure (Figure 9).

Figure 9 – Action Programs Priority Groups Calendar

		Calendar (semesters)										Actions
		1	2	3	4	5	6	7	8	9	10	
Priority 1	AP 1											35
	AP 4											
	AP 6											
	AP 10											
	AP 12											
Priority 2	AP2											24
	AP5											
	AP7											
	AP8											
	AP9											
	AP11											
Priority3	AP 3											12
	AP 13

5. CONCLUSIONS

In Portugal, there is a popular expression that says "there are evils that come for good". And in fact, the recent financial crisis since 2008 that has affected some countries has accelerated the process of "slimming" the state with the goal of reducing costs. This logic of this "Minimum State" had repercussions in several areas, but education was one of the most affected with what is called decentralization of competences at the local level associated with the respective financial transfers.

In this process, "hunger has joined the will to eat" because the municipalities also aspire to a greater role in all areas that can provide an increase in economic and social development, as long as they also see their municipal budget strengthened.

One of the key implications expected from all the changes made in the education system is what we can expect in the field of entrepreneurship and the training of both young people and adults, since local government, in articulation with the interested actors, can more accurately identify trends and needs in regular education and vocational training.

Lastly, the decentralization of education systems has generated the need to find solutions to balance between sensitivity of local diversities and the need to achievement national goals (Burns and Köster, 2016).

The relationship between what was desired by central and local governments identified in the inter-administrative contract and the reality must therefore be mediated by the Municipal Educational Strategic Plan. Where, through a participatory model, the main challenges and ambitions manifested by the Local community were taken into account. Furthermore, a significant part of the plan focused on the articulation of the educational system and the business world, not only in the logic of optimizing the relationship between demand and supply in the local and even metropolitan market of employment, but also accelerating and optimizing the processes of social inclusion by the integration of people in the labour market.

In Portugal, for example, some 175,900 people under the age of 30 have been identified who do not study, work or attend vocational training, and it is therefore urgent to find a strategy for solving the problem, in order to contain social exclusion and others problems derived from it. This grand design has had repercussions on the ambition and strategic objectives, action programs and actions of the **CMSEP**.

The CMSEP, facing the education system as a complex system, relied heavily on fundamental principles for effective governance (Burns and Cerna, 2016):

- Concentration in processes
- Adaptability and flexibility
- Involvement and co-responsibility
- Holistic system approach
- Use evidence and results for policy and technical decision making

Due to its relevance and influence in large domains of local society, and being supported by a more or less formalized diversified governance, its expected the plan will be able to contribute strongly to structural change at the local level.

1371 DEVELOPMENT OF DECISION SUPPORT FOR SPATIAL ENVIRONMENTAL PLANNING OF URBAN COASTAL AREAS**Ravinder Dhiman¹, Pradip Kalbar^{1, 2}, Arun B. Inamdar³**¹Centre for Urban Science and Engineering, Indian Institute of Technology Bombay, Powai, Mumbai, 400076 – India²Interdisciplinary Program in Climate Studies, Indian Institute of Technology Bombay, Powai, Mumbai, 400076 – India³Centre of Studies in Resources Engineering, Indian Institute of Technology Bombay, Powai, Mumbai, 400076 – India**ABSTRACT**

Environmental planning of urban coastal areas is critical for sustainable development of cities. The process of environmental planning involves classification of areas into different categories. Coastal area classification in India is a challenge for decision makers due to uncertainty of current coastal regulations and lack of scientific rational about existing classification methods. In addition to the above challenge, implications of urbanization, pollution and regional vulnerability of coastline highlight the need for developing the methods to protect coastal resources from anthropogenic activities and natural hazards which is possible through suitable planning and policy improvement at national and international scale. This research work aims towards facilitation of synergy between environmental protection and anthropogenic development in coastal cities. In present work, we developed a scientific method by integrating the Multiple Criteria Decision Making methods with spatial science for coastal area classification. A Geographic information system (GIS) based Multi-criteria Decision Making (MCDM) approach is developed in this work to provide scientific rational for classifying coastal areas. Utility functions based on the environmental sensitivity of physical coastal features are used to quantify membership values for coastal features. Furthermore, these quantitative membership values for coastal features are applied in different weighting schemes to derive Coastal Area Index (CAI) which classifies the coastal areas in four distinct categories viz. 1) Extremely Sensitive Zone, 2) Highly Sensitive Zone, 3) Moderately Sensitive Zone and 4) Low Sensitive Zone based on the environmental sensitivity of urban coastal areas. We targeted Mumbai, a coastal megacity in India, as our study area for the purpose of demonstration and validation of developed methodology. Results of CAI showed the distinct classification of coastal areas which can be used a decision support by developmental and planning authorities to prioritize coastal areas for developmental and conservational activities. Most effective coastal management options can be proposed for different classes of coastal areas based on CAI. This decision support will enhance the quality of decision making for coastal planners, managers and researchers during spatial environment planning of urban coastal areas.

Keywords: Coastal Cities; Coastal Resource Management; Urbanization; Spatial Planning, Environmental Sensitivity**1 INTRODUCTION**

Indian coastline is populated with numerous developmental activities and marine resources which supports nationwide economy. Coastal areas along the Indian coastline are under the influence of natural hazards because of vulnerability associated with Arabian Sea and Bay of Bengal in terms of extreme events such as cyclones, extreme rainfall and tsunami etc. (Alcántara-Ayala, 2002; Ramesh et al., 2015). Coastal areas overlapped with huge population such as cities along the coast are having greater exposure to natural and anthropogenic stress. Developmental activities in Indian coastal cities are prominent driver of country's economy which leads to the degradation of marine environment and depletion of coastal resources. In similar way, Indian coastal cities are also subjected to the water and soil pollution due to anthropogenic activities (Datta et al., 2010; Newton et al., 2012; Shirodkar et al., 2009). According to Vaz (2014), urbanization has led the transformation of mangrove area into developed area significantly for different anthropogenic activities in Mumbai city. There is always a need to develop balance between anthropogenic development and conservation of environmental resources to support sustainable development. In similar way, Indian government has made efforts for sustainable utilization and conservation of coastal resources with the help of coastal regulations such as Coastal Regulation Zone (CRZ) notifications (1991, 2011) under Environment (Protection) Act, 1986 (Krishnamurthy et al., 2014). Current CRZ notification is subjective in nature because of unclear definitions and some of other regional challenges at administration level are fragile institutional framework, land encroachment, destruction of coastal biodiversity, ignorance of coastal communities, and violation of regulations in various coastal cities of India (Chouhan et al., 2016; Parthasarathy, 2011). These challenges can be addressed by developing suitable quantitative decision support methods for spatial environmental planning of coastal areas in cities.

This is the high time to develop a scientific quantitative method for suitable planning of coastal areas to synergies the environmental protection and anthropogenic development. In this paper, we developed a quantitative method for decision support using Geographic Information System (GIS) and multicriteria decision making (MCDM) techniques for spatial environmental planning to characterize coastal areas into different classes based on the environmental sensitivity towards anthropogenic development for coastal areas in cities.

Recently, MCDM and GIS techniques are acknowledged as suitable tool for decision making for various applications such as land suitability analysis based on specific criteria (Baud et al., 2015), categorization of animal and plant habitats (Schmoldt et al., 2001), urban planning (Bryan, 1988), agriculture resource management (Ananda & Herath, 2003), natural resource management (Mendoza & Martins, 2006) and storm-water management (Gogate et al., 2017). Some of recent applications of MCDM and GIS in coastal resource management are coastal areas conservation (Pourebrahim et al., 2014), coastal vulnerability assessment (Sudha Rani et al., 2015), coastal reclamation (Feng et al., 2014) and disaster

resilient index (Orencio & Fujii, 2013). Therefore, we found that MCDM and GIS techniques are suitable for development of a quantitative method for spatial environmental planning for coastal areas in Indian cities.

In present study, we developed a classification method for coastal areas for spatial environmental planning which is objective in nature using MCDM and GIS technique. Furthermore, this method can be used as a decision support for integrated coastal zone management by stakeholders in the allied areas.

2 METHODS

This work is based on application of MCDM techniques integrated with GIS tool for unique classification of coastal areas to support spatial environmental planning. A novel quantitative method is developed and applicability of particular method is verified by a case study in coastal area of Mumbai city in India. Results of case study are validated and sensitivity of the same has been tested rigorously. Detailed methodological framework is depicted in figure 1.

Study Area

Coastal areas of Mumbai city in India is selected as a case study for validation of developed method for spatial environmental planning. Study area is surrounded by Arabian Sea on the west and Thane creek on the east. Mumbai city, being the most populous city in India, began with seven islands gradually merged due to land reclamation into one big island city. Some of the major challenges which are being faced by coastal planners in this city are water shortage, coastal soil and water pollution, seasonal coastal flooding, untreated pollution discharge and solid waste dumping in mangroves and adjacent creeks (Pacione, 2006). Severe pollution in coastal areas of Mumbai city is main driver of depletion of coastal ecosystem which required immediate attention for environment management (Murthy et al., 2001).

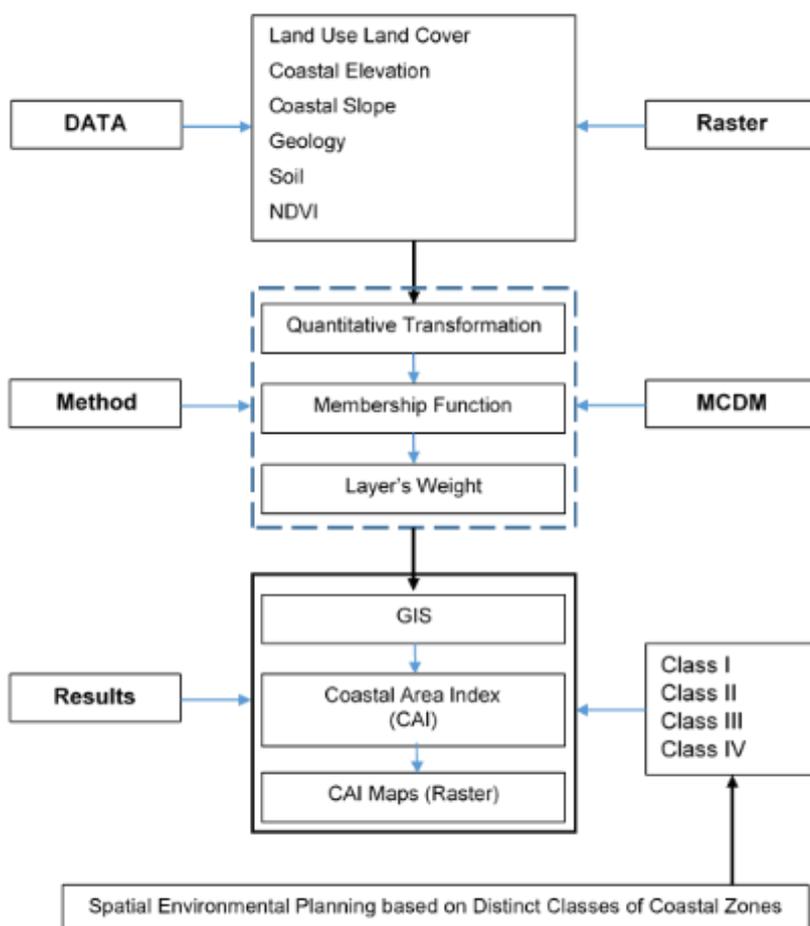

Figure 1 Methodological framework for spatial environmental planning of coastal areas

Data Requirements and Processing

Primary data for this study is used from remote sensing dataset of LANDSAT 8 satellite for different physical coastal features of Mumbai coast and secondary data is used from central agencies of Government of India as referred in table 1. Total 6 variables (LULC, Geology, Soil, NDVI, Slope and DEM) termed as layer for different coastal features, are converted into raster format at pixel level.

Table 1 Detailed description of dataset used for the case study

Coastal Features	Source	Resolution
Marine Geomorphology	Landsat 8	30 m
LULC	Landsat 8	30 m

Coastal elevation and Slope	SRTM	30 m
NDVI	Landsat 8	30 m
Geology and Soil types	Survey of India	Vector dataset

Calculation of Coastal Area Index (CAI)

A novel approach for calculation of CAI in urban coastal areas is developed which can be used for spatial environmental planning of coastal cities. In this approach, we transformed the subclasses of physical coastal features into quantifiable membership functions on a linear scale of 0 to 1 for entire dataset based on the utility of particular coastal feature for coastal ecosystem as described in table 2.

Table 2 Layer weights for coastal features and utility based membership function for subclasses of coastal features

Coastal Features	Layer Weight	Subclasses (Membership Function)
LULC	30	Rocks (0.1), Built-up land (0.2), Fellow land (0.3), Saltpans (0.4), Sandy area (0.5), Vegetation (0.6), Cropland (0.6), Forest (0.8), Marshes (0.8), Mudflats (0.8), Aquatic Veg (0.9), Mangroves (0.9), Water bodies (1)
NDVI	15	Water (0.2), Barren (0.4), Sparse Veg (0.6), Dense Veg (0.8)
Geology	10	Rhyolite (0.1), Trachyte (0.2), Unclassified Flows (0.3), Intertrappean (0.4), Compound Flows (0.5), Alluvium (0.6), AA Flows (0.8), Agglomerates Tuff (0.9), Mud (1)
Soil	10	Backfilled (0.1), Fine (0.4), Clay (0.8), Mud (0.8)
Slope (%)	15	75 - 100 (0.2), 50 - 75 (0.4), 25 - 50 (0.8), < 25 (1)
DEM (m)	20	> 10 (0.2), 5 - 10 (0.6), 1 - 5 (0.8), < 1 (1)

Membership functions are used to assign preferences in numerical format to different variables based on the importance of one variable over other. First of all, membership functions of all subclasses at pixel level are quantified based on the experts' knowledge and author's understanding about study area. After assigning membership function to all pixels of all layers, weights are assigned to different layers according to the preferred importance of the particular layer in context of spatial environmental planning and these weights are assigned by the author based on the regional understanding of the study area. Furthermore, linear weighted summation method is used to calculate the final CAI, where, normalized pixel values are multiplied with respective layer weights and aggregated to generate the CAI.

CAI for the i^{th} pixel can be computed using following equation:

$$CAI_i = \sum_{j=1}^n w_j \cdot x_{ij} \text{ for } i = 1, 2, 3 \dots, m \quad (\text{Eq. 1})$$

Where, i is pixel number in the layer (there are m number of pixel in the one layer)

j is layer number (there are n number of layers)

x_{ij} is the pixel value of the i^{th} pixel in the j^{th} layer

w_j is the weight of the j^{th} layer

The CAI obtained using Eq. 1 is further normalized to express on a scale of 0 to 10. Final CAI map is obtained in GIS and further classified into four distinct categories on a scale of 0 - 10 where each category of CAI represents the environmental sensitivity of natural coastal ecosystem towards developmental activities. In CAI, category 1 is extremely sensitive, category 2 is highly sensitive, category 3 is moderately sensitive and category 4 is low sensitive against the anthropogenic development.

3 RESULTS AND DISCUSSION

In this study, major physical coastal features such as LULC, NDVI, Soil, Geology, Slope and DEM are characterized and further classified in sub-classes at a pixel level of 30m resolution in GIS. This characterization of physical coastal features at pixel level provides the quantitative understanding of spatial distribution of various features along the coastal stretch of Mumbai city.

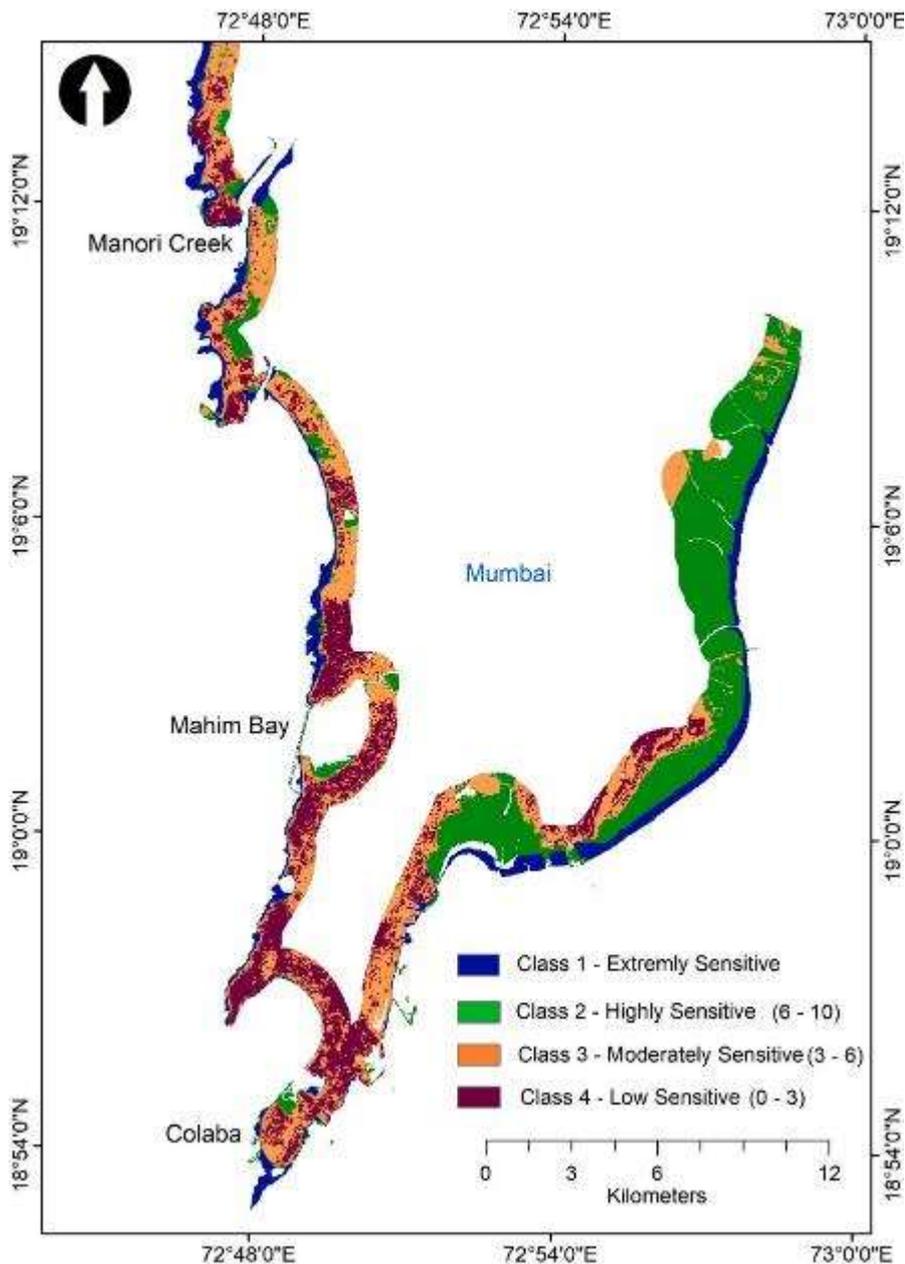

Figure 2 Coastal Areas Index for coastal stretch of Mumbai representing the classification of coastal areas into distinct categories based on the environmental sensitivity.

The CAI as shown in figure 2, is computed based on the GIS coupled MCDM approach for coastal city of Mumbai classifies the coastal area into four major classes within the normalized range of 0 – 10. Coastal stretch of Mumbai is demarcated for prioritization of different categories based on the environmental sensitivity of particular category. Class 1 (Figure 2) is depicted as the intertidal zone of Mumbai city, which is highly dynamic in nature and much important for demarcation of land from sea. Intertidal zones contain high nutrients which supports the productivity of marine life and hence this is considered as no development zone for developmental activities except special cases. Class 2 (Figure 2) is categorized as highly sensitive and CAI index range for this class is 5 – 8 at a scale of 0 – 10, which can be observed majorly distributed along the Thane Creek in Mumbai considering the biodiversity including mangroves, mudflats and other important indicators of primary productivity in the area. Urban coastal area categorized under class 3 (Figure 2) of CAI with in a range of 3 - 5 is showing moderate sensitivity because this area is majorly influenced by open spaces and barren land which can be considered for both conservational and developmental activities according to the desired requirements by coastal planners. Low sensitive area of CAI is categorized as class 4 with an index range of 0 – 3, describing most of the urbanized area in coastal area of Mumbai. Furthermore, these all these classes as shown in CAI, are validated through available latest satellite images combined with field visits. The proposed method for CAI clearly demarcated the boundary lines among these 4 classified areas which is useful for planning process by associated stakeholders such as planning authorities and Urban Local Bodies (ULBs).

Classification of coastal areas for developmental and conservational activities usually carried out by decision makers based on the existing notification of coastal regulations, which is susceptible to subjectivity and bias from different stakeholders. Scientific rationale for coastal area classification in Indian coastal cities with the help of advances in decision science will improve the prevailing decision making process of coastal planning. Outcomes of this work will lead to a scientific tool for coastal planners and decision makers including the benefits for policy makers, coastal managers,

research institutes, coastal communities and other associated stakeholders. The CAI developed in this study is found suitable as a decision support for spatial environmental planning of urban coastal areas and method developed for CAI can be used and applied to other locations with similar settings easily. This study attempt to verify the practicality of developed CAI for better planning of coastal areas satisfying the present research gap in literature. Our CAI method generate the categories of coastal areas where we can propose most effective urban coastal management options. For example, extremely or high sensitive areas require the administrative interventions to improve the inconvenient conditions of natural ecosystem due to anthropogenic pressure.

4 CONCLUSION

Present work highlights and elaborate the challenges of coastal area classification approach in urban coastal areas. In this paper, we proposed a GIS coupled MCDM based CAI approach to classify urban coastal areas for developmental and conservational activities. The developed approach is transparent where physical characteristics of coastal areas are transformed into quantitative measurements. Utility based membership functions are developed and applied to each of the sub class of different coastal features. Application of CAI approach for coastal area of Mumbai City demonstrate the classification of coastal areas according to the usefulness of coastal features and ranking of sensitivity towards effect of developmental activities. Results for Mumbai city will facilitate the efficient management of available coastal resources. Essentially, the method is found useful for highlighting the locations which needs special consideration for sustainable growth of coastal city. This method will enable coastal cities to improve the present decision making regulations and the outcome will lead to the increase in resilience against anthropogenic development.

1073 MULTIPLICITY OF A METROPOLIS: A CASE STUDY OF KOLKATA METROPOLITAN AREA

ABSTRACT

Despite increasing importance of urbanization as a whole and impetus on the small and medium urban units, metropolitan region continues to remain interesting and diverse as ever before. The perception of looking or treating urban is changing, but that does not throw the limelight off the metropolitan region. In fact the region is now seen with renewed interest and in different ways. This study would be based on Kolkata Metropolitan Area (KMA). In this paper I would like to discuss that metropolitan region has grown beyond traditional or conventional functional region or a planning region. It is a space that can challenge any planning initiatives. It is a comprehensive urban comprising of a multitude of hierarchic urban as well as rural units. The range includes core cities, peripheral cities, large, medium and small towns, census and statutory towns and last but not least the villages. So it could be said a metropolis itself presents a full spectrum with diverse issues to understand and multiple challenges to be faced with. Each constituent unit, irrespective of its size and shape contributes to heterogeneity and diversity of the whole; complexities and contestations are thus not problems but inevitable process in the urban discourse. This work is essentially exploratory in nature and would be based on holistic study of a metropolitan area, Kolkata. This is also an intra urban comparative work where different units within a single metropolis would be looked into and their individual identity would be discussed vis-à-vis their role within the entire region. For the purpose, different units within KMA would be studied based on Census of India, their legal statutes as well as planning attributes and governance initiatives. The study aims to explore the position of the city at crossroads of global and post colonial. Though a metropolis is generally named after a single city, as in this case after Kolkata, a number of cities are involved with their identities and intricacies. In the policy initiatives taken up at the central, regional and local level, some gets due attention, some over-attention while others remain in the background. Taking into cognizance of every single unit, though an absolute necessity, often becomes almost impossible and herculean task making governance of the whole metropolitan region rather complex and never-ending process.

1589 PARTICIPATORY BUDGET A TOOL OF URBAN POLICY

ABSTRACT

The issue of sustainable development, brought to the political agenda by the UN, has been developing and settled since the 1970s. With the Declaration of the UN Conference on the Environment, in 1972, the Brundtland Report of 1987 and the Rio Declaration and Agenda 21 in 1992, concern for the development of methodologies that promote the sustainable management of the territory supported by the participation of the population, has become more pronounced. The production of inclusive urban space, integrated with the trend of Inclusive Urbanism, more concerned with the participation of the population in the decisions that affect it, promoted the development of new methodologies in urban planning. In this context, the initiative Participatory Budget emerges, which has its origins in Porto Alegre, Brazil, in 1989. PB can be considered as an informal example of urban management, with the direct participation of the population in determining priorities regarding part of the municipal budget. We can identify a set of PB potentialities as a participatory and territorial management tool: the institutionalization of participation, allowing commitments to citizens in the definition of investment priorities; the balance of power and the creation of a space for direct communication and cooperation between elected representatives and voters; the promotion of an identification of the population with the destinies of its municipality and still contribute to themore sustainable development of the city. In this sense, it can be said that PB is a new form of governance based on the direct participation of citizens. Since the beginning of the first experiences, the PB has been attracting sympathy and recognition from different sectors of society. The OP as a way of giving the population the ability to decide on part of the expense that a parish or municipality does in the territory is one of the methodologies experienced in several countries from the 90's of last century. This is a worldwide phenomenon, with a presence on all continents, with particular emphasis on Latin America, Europe and, more recently, Africa. Although there is no overall statistics on the number of OP experiences, it is estimated that they currently exceed 2,000 worldwide. This research analyzes the results of the PB of the municipality of Lisbon between 2008 and 2016/2017 on various perspectives to characterize the way the projects are organized to vote, which can help to develop citizen movements. The Lisbon PB had its first edition in 2008, distinguishing itself from other similar experiences because it is a truly deliberative process, which gives decision-making power to citizens to present proposals fortheir city or neighbourhoods and to vote on the projects they consider to be priorities. The most voted projects, up to an amount equivalent to 5% of the Investment Budget of the municipality, are integrated with the proposed Budget and Activity Plan of the Municipality of the following year.

1561 UNLOCKING THE PRIVATE-LED HOUSING PROJECTS IN LISBON'S SUBURBIA - A TYPOLOGICAL SURVEY OF EVERYDAY'S RESIDENTIAL LANDSCAPE

ABSTRACT

The paper will explore the conceptual and methodological rationale of a research project based at CIAUD - Faculty of Architecture, University of Lisbon, aimed at surveying and analysing the residential typologies that made a considerable part of Lisbon's metropolitan fabric. The temporal and geographical focus of this research concerns the post-1940's decades and the main suburban corridors west of Lisbon city boundaries. These corridors experienced fast and considerable growth, absorbing not only people who sought Lisbon metropolis away from countryside but also residents who left the city out to the suburbs, especially after the 1960's. In a rather unique pattern, distinct from the American sprawl or European's welfare residential estates, Lisbon metropolis development resorted to considerable areas of medium-to-high rise apartment typologies, even in distant areas from the metropolitan centre. Although single family housing is a major part of the existing fabric, high density suburban areas can be found along and in-between major railroad and motorway axes. Often faced with low quality urban amenities, suffering from critical mobility gaps and strongly shaped by commuting, these urban areas have also evolved during the last decades to a state where some identity and social fabric can be found. Which relationships between architectural, real-estate rationale and everyday life patterns can be found in these landscapes? Which models and references supported their development? How can the private-led development of this de facto social housing offer be assessed, half a century after the first large scale public housing programmes started to be implemented? The research project builds on existing methodological framework already tested for public housing development in various Portuguese cities. New and relevant data are expected to be highlighted when observing, under the same lens, the private-led housing projects. Archive survey at selected municipalities will provide the basis for the database building, with a relevant selection of housing projects. A road map will be developed, helping to decode these parts of the metropolitan landscape, often criticized as unintelligible, piecemeal and fragmentary products of a purely private-led and speculative real-estate market, in which city planning has had limited capacity to control. For each housing project, three levels of information will be analysed and systematized: - The architectural and typological references; - The urban models and spatial patterns that result from this development; - The personal forms of appropriation of the housing space and its cultural and social references. Largely overlooked by architectural and urban research – often targeted at public-led projects usually associated with higher design quality –, these private-led housing neighbourhoods are the home to about half of the metropolitan population. Their acknowledgement as a research corpus is an unavoidable step to inform future policies on architectural, urban and socio-spatial qualification for these territories.

1510 IS HOUSING FOR ALL INDEED FOR 'ALL'? A CRITIQUE OF THE 'HOUSING FOR ALL' POLICY

Namesh Killemsetty

University of Massachusetts Boston

ABSTRACT

The 'Pradhan Mantri Awas Yojana – Housing for All' is the national affordable housing program launched by the Government of India in June 2015 aiming to make affordable housing accessible to every citizen, especially the ones belonging to the Economically Weaker Sections and the Lower Income Groups of the country. 'Housing for All' anticipates bringing massive changes in the affordable housing market with a proposal to provide 20 million housing units in the Indian cities by 2022, 96% of which would be for the urban poor, mostly by incentivizing the private sector to participate in the ongoing redevelopment of slum communities. However, the path may not be that easy for the Government as the policy framework does not reflect the actual needs of the urban poor, and seems to be far away from the reality of the present housing requirement for people living in slums. The paper aims to critically analyze the Housing for All policy guidelines to understand the prospective implications it has on slum dwellers and the urban poor living in Indian cities, and check if the guidelines reflect the current housing situation in Indian cities. Using case studies of two-tier II cities in the states of Odisha and Chhattisgarh, the paper would highlight how the Housing for All guidelines specifically do not address the needs of smaller cities of the country, apparently highlighting the phenomenon of metropolitan bias. Based on the shortcomings, the paper would identify some possible solutions which the Government could think about and undertake for the welfare of the most vulnerable population living in cities – the urban poor.

INTRODUCTION

More than 26-37 million households (33-47% of the total urban household population) in India live in informal dwelling units due to rapid urban population growth and a shortage of planned affordable housing, according to a recent study done by the FSG group in 2016. Approximately 0.1-4% of these households live in informal housing units without any security of tenure, as their place of residence is 'unknown' to the state. People living in these informal housing units are forced to live in poor conditions having poor or no basic services such as sewage, sanitation, etc.; and also face the threat of eviction or demolition due to limited property rights (Jain et al., 2016).

The demographics and its transition from rural to urban are critical in understanding the emergence and persistence of slums in Indian cities. The country's urban population has increased from 62 million in 1951 (17% of total country's population) to 377 million in 2011 (31% of country's total population), living in 7933 urban centers including 53 cities with a population of greater than 1 million (Tiwari and Rao, 2016). India's growth over the last three decades has resulted in a significant influx of human migration coming from the rural to the growing metropolitan areas with a considerable increase in the number of towns and urban agglomerations. This continuous influx of people has oversaturated the existing urban systems in the cities leading to the creation of slums⁴⁵⁰ facing inadequate housing, sanitation, basic services, and security.

Around 65 million out of the 377 million live in inferior housing units in a situation of deteriorated or incomplete infrastructure, termed as slums (Census, 2011a). It was only in the 2011 census survey that details about amenities in informal housing units were measured for the first time. Despite 70 years of planning and policy designing since independence, the 2011 census data highlighted shocking statistics where 53% of the households do not have toilets nor access to drinking water, and 33% of the households do not have access to electricity (Census, 2011b).

With the United Nations' Sustainable Development goals aspiring to halve the population of people living in slums within each country by 2030, the Indian government has a lot of work to do. With this target in mind, the Prime Minister of India Narendra Modi launched the Pradhan Mantri Awas Yojana (Prime Minister's Housing Policy) – popularly known as the 'Housing for All' scheme in June 2015 aiming to provide affordable housing access to every citizen by 2022 (Govt. of India, 2017). The Prime Minister launched the program amidst a lot of fanfare expressing his desire, '*We have a dream for 2022. The poorest of the poor should have a house of his own. And that house must be equipped with electricity, water, and other facilities. There should be hospitals and schools in the neighborhood*' (Khan & Gupta, 2017). Noble sentiments indeed, but could this dream turn to reality with this program?

Therefore, this paper aims to critically analyze the Housing for All policy guidelines to understand the prospective implication it has on its intended target population – the slum dwellers. The study highlights the housing requirements for the urban poor today in Indian cities and goes through the major tenets on why the provisions of the Housing for All policy fall inadequate concerning the current reality in Indian cities. The study goes through all the previous significant programs implemented by the Government of India for the urban poor and looks at the reasons for their failures. Based on the learnings from the past failures, the paper concludes with a series of suggestions and possible solutions the Government should emphasize upon in addition to the proper implementation of the 'Housing for All program' to ensure that affordable housing would be accessible to everyone in the cities.

⁴⁵⁰ Slum is the term used in development regulation codes of Indian cities for a broad range of substandard, informal structures and neighborhoods. UN-Habitat defines a slum household as a group of individuals living under the same roof in an urban area lacking durable permanent housing, sufficient living space, easy access to water, access to adequate sanitation, and security of tenure (UN-Habitat, 2006).

HOUSING REQUIREMENTS FOR THE URBAN POOR

The Government of India estimates the housing shortfall to be around 18.76 million household units in urban areas, with 96% of the deficit for households belonging to Below Poverty Line (BPL), Economically Weaker Section (EWS), and Lower Income groups (LIG)⁴⁵¹ (Govt. of India, 2012). However, Tiwari and Parikh (2012) estimated this shortage to be 21.87 million with the inclusion of non-durable houses in their calculation. They predicted the total housing shortage in India to be approximately 51 million units and an additional 113 million homes nationally if semi-permanent dwellings also are considered. Such kind of large-scale intervention would not be possible by government participation alone. Thus the Housing for All policy was articulated to incentivize the private sector to participate in the redevelopment of the entire slum communities.

Local governments in India are forced to operate with very low tax bases because of the large population involved in the informal sector where most of the transactions are difficult to be recorded for taxes. Because of this phenomenon, the informal areas of the city are the most hit with low service levels (Hindman et al., 2015). Local governments see minimal incentive to spend money on improving the service levels of these areas when the population is mostly informal and are non-compliant in paying taxes. Although the level of access to services in informal housing and slums has increased over the time, there is an apparent drop in access to these services when comparing secure to that of insecure housing⁴⁵² and transitional housing⁴⁵³ (Jain et al., 2016). Most of the insecure housing units come up on the edge of cities or undeveloped land that may not have been zoned out for residential use when the house is built (Ibid, p. 9).

These housing units being not legalized in nature lack access to essential services, and also live under a constant threat of eviction. The occupants of these informal housing units cannot even get formal mortgages as their properties are not legal. The violations imply that the government can legally evict the slum dwellers and/or demolish the housing structure.

The Government of India has tried many approaches since independence in 1947 to improve the living conditions of the informal housing dwellers, but without any significant large-scale impact. It took some time for a change in the government's philosophy from relocating families to improving living conditions *in situ* providing essential services and consequently security of tenure. While many groups have opposed relocation for disconnecting the dwellers from their existing physical and social infrastructure and disrupting their livelihoods (Kapse et al. 2012); redevelopment by the government alone is economically unviable at the scale necessary for large-scale intervention (Jain et al., 2016).

PROGRAMS FOR THE URBAN POOR PRIOR 'HOUSING FOR ALL'

Chronology of Slum Development Projects in India

<p>Pre 1947 No systematic policies- either at local or national level</p> <p>1956 Passing of Slum Areas Improvement & Clearance Act aimed to improve living conditions</p> <p>1958 Launch of Urban Community Development Program emphasizing on community development and self help</p> <p>1972 Environmental Improvement of Urban Slums created to focus on physical development of the area</p>	<p>1970s and 1980s Sites and Services program where slum dwellers use their own resources to build houses in plots allotted by the government.</p> <p>1986 Urban Basic Scheme launched with the financial support from UNICEF for provision of basic social services and physical amenities</p> <p>1989 Nehru Rojgar Yojana launched to cater the economic needs of the urban poor.</p> <p>1996 National Slum Development Program launched with an aim to provide physical amenities</p>	<p>2001 Valmiki Ambedkar Yojana launched to facilitate construction and upgradation of dwelling units in slums</p> <p>2005 Basic Services to Urban Poor launched as part of JNNURM – provided a garland of seven entitlements to slum dwellers</p> <p>2011 Rajiv Awas Yojana implemented with an aim to upgrade and assign title to slum residents, and to plan accommodate the predicted growth</p> <p>2015 Housing for All launched providing affordable housing to all residents</p>
---	--	---

Figure 1 - Chronology of Slum Development Programs in India

No proper study of government policies towards urban slums and squatters in India had appeared for the period before independence as there were no systematic policies, either nationally or at the local level (Basu, 1979). Some slum development programs have been implemented since the country's independence in 1947 by different governments. Tiwari and Rao (2016) mention how these programs could never attain the intended effect for they lacked continuity and

⁴⁵¹ BPL, EWS and LIG are defined by the Govt. of India as having an annual household income of no more than 27,000 Rupees (The Hindu, 2016), 100,000 Rupees and between 100,000 and 200,000 Rupees, respectively (MHUPA 2013, 5)

⁴⁵² Insecure housing has neither de jure nor de facto rights since their existence and/or location is not in any government records. These are typically new settlements and face a high risk of forced eviction. Unidentified slums can be recognized in this category.

⁴⁵³ Transitional housing exists in one or more government records and is progressively gaining de facto rights to use. Identified and recognized slums can be considered as transitional housing.

interconnectedness. In the last six decades, the role of the government has been transitioning from a provider to a facilitator.

India's first set of economic policies focused on rapid development of capital goods industries post its independence in 1947. The industrialization that followed led to migration from rural areas to cities generating a massive housing demand, which, the public sector employers provided to their employees to a certain extent, but mostly ignored the rest. Over time, migration to urban areas continued at an uncontrolled rate, creating deplorable living conditions in cities and leading to the formation of slums. The Government of India passed the **Slum Areas (Improvement and Clearance) Act, 1956** empowering the state to intervene (via notification in the official gazette) with the stated aim of improving living conditions. The Act enabled the state to notify a settlement as a slum and acquire the land under eminent domain, which curtails the landowners' right to retain or sell the land unless the state's acquisition is successfully challenged and defeated in court.

The **Urban Community Development (UCD)** Program was the first formal attempt to experiment with community development approach in cities in partnership with the Ford Foundation in 1958. 20 projects were undertaken in the next ten years emphasizing on community participation and self-help, with 50 percent of the expenditure borne by the Government of India and the rest by state governments and the local bodies (Cousins & Soudiere, 1992). However, the projects could not be replicated to other areas in the cities due to lack of funds and lack of proper training to the communities (Ibid, p.6).

The next major program was the **Environmental Improvement of Urban Slums (EIUS)** introduced in 1972, with an aim to provide an acceptable physical environment in the slum areas. EIUS was created to focus on the physical development of the area but had no component of community participation nor involvement of local NGOs working in the slum areas, which possibly was the primary reason for its negligible success (Mohanty & Mohanty, 2015). The program was also found not having a focus on social services like health, education, community development, etc. Although the scheme was partially successful in improving the physical infrastructure of the slum communities, it did not stop the emergence of new slums arising due to recent migration or natural increase in existing slums.

Sites and Services (S&S) was the most common approach in the 70s and the 80s used all across cities in developing countries. Conceptually, the Sites and Services scheme sought to minimize the public costs and subsidies required by conventional social housing programs by providing only those components individual households could not procure for themselves – land, infrastructure, and services (Wakely & Riley, 2011). The slum dwellers were supposed to build their own resources, labor, and time to develop their houses in serviced plots allotted by the government. The World Bank supported 11 'sites and services' projects across 27 cities in India between 1977 and 1997, providing around 279,000 plots to the slum dwellers (World Bank, 2016). The Sites and Services programs had many problems, including the imposition of standards of design and construction that were unaffordable, high rates of default on loans and rents, and social problems such as unemployment and exclusion (Wakely & Riley, 2011). Most of these problems arose due to the projects being located on cheap land on the urban periphery, far from jobs, transport, and social facilities. Therefore, the Sites and Services scheme was gradually replaced with the Urban Basic Scheme (UBS).

The **Urban Basic Scheme (UBS)** was initiated by UNICEF and the individual state governments in 1986 for the provision of basic social services and physical amenities in urban slums in 200 towns (Cousins & Soudiere, 1992). Central to the UBS program was the neighborhood community, constituted for every 200 families. The committee as a whole would identify the needs of the community, prioritize them keeping given the resources, prepare an action plan, and implement it after the approval of the town management community (Ibid, p.13). However, it was observed that municipalities were not trained to explain the concept and philosophy to the slum communities to enlist their support and participation. Thus, the plans were formulated by the project staff based on their perception of the needs of the community instead of reflecting their actual needs (Prasad, 1993, p.7). Political pressure and interventions was another critical factor for the program's failure. Councilors started feeling that they were overlooked, thus perceiving the committees as a threat to their leadership as well as to their sphere of influence (Ibid, p.8). The UBS scheme was merged with EIUS to form the **Urban Basic Services for the poor (UBSP)**, in 1990.

While the EIUS and 'Sites and Services' was based on an area approach, NRY under the beneficiary approach, and UBSP under the community approach; an integrated approach was still lacking (Ray, 2010, p.5). In an attempt to provide a policy with an integrated approach, the **National Slum Development Programme (NSDP)** was one of the first large-scale slum development schemes launched by the Government of India in 1986. The program was a slum upgradation project started in 1996 with an aim to provide physical amenities like water supply, stormwater drains, community baths, widening and paving of existing lanes, sewers, community latrines, etc. (Govt. Archives, 2008). It was initiated with an aim to upgrade 47,124 slums throughout India, started by identifying a target slum in each city which it planned to develop as a 'model slum.' Beneficiaries were provided loans to make improvements while the government invested in delivering community services. In the implementation of the scheme, NSDP, however, was able to disburse only 70% of its allocated funds with projects lacking proper monitoring and supervision, resulting in time-delays and misused funds (Hindman et al., 2015). The program discontinued in 2005-06 after the launch of Jawaharlal National Urban Renewal Mission (JNNURM), a national urban renewal mission.

At the same, **Valmiki Ambedkar Yojana (VAMBAY)** was another centrally sponsored scheme launched in 2001. The project aimed to facilitate the construction and upgradation of dwelling units of people living below the poverty line, and not having adequate shelter. The program was implemented in partnership with State Governments who had the

responsibility of setting up the implementation machinery, arrange the land where required, and the credit component of the housing program (Govt. of India, 2006). Although the scheme aimed to support the construction of housing for the poor but set 60,000 rupees (\$900) as a limit for the cost of construction of a housing unit to qualify – an amount which was practically impossible to construct a house at that time (Das, 2003). The policy was considered a non-starter in big metropolitan cities where land is a scarce resource, and the government has no vacant areas to consider for distribution for the housing of the poor.

The program was later subsumed into JNNURM where VAMBAY and NSDP were combined to form **Integrated Housing and Slum Development Program (IHSDP)** in 2009 (Govt. of India, 2009). IHSDP attempted to enhance public and private investments in housing and infrastructural development in urban areas, involving private developers for the first time in the slum development process at a national scale.

Basic Services to Urban Poor (BSUP) was the next large-scale slum development program to be implemented in Indian cities after NSDP. BSUP started as a part of JNNURM in 2005. The program aimed to provide essential services to the urban poor in 63 of the largest cities in India by population. It was designed to offer a garland of seven entitlements – ‘security of tenure, affordable housing, water, sanitation, health, education, and social security for poor settlements’ (ESID, 2015). However, it ultimately became a housing construction program subsidized and implemented by the government. Instead of providing incremental improvements to existing housing, many of the projects in the program involved evicting slum dwellers to clear the site and constructing contractor-built small apartments (Patel, 2013)

BSUP failed to address the issue of urban poverty and was considered a policy failure due to its shortcomings in design such as unaffordability, insufficient attention to tenure, and lack of poor urban involvement in the programs (ESID, 2015). Disproportionately low funding was allocated to BSUP compared to larger infrastructure components under JNNURM. Due to non-availability of official statistics on states’ slum populations, there was a lot of large-scale faulty planning, and the financial requirements for JNNURM were underestimated in the absence of an accurate understanding of the extent of the problem due to lack of data on slums (Killemssetty, 2013). There was low satisfaction among beneficiaries due to high costs; inconvenient sites for relocation; poor quality and design for construction; and a lack of provision for operation and maintenance in most of the projects. (Mahadevia et al., 2015).

Rajiv Awas Yojana (RAY) was the last large-scale scheme implemented in 2011 before the announcement of Housing for All after the change of political parties in the National level elections in 2014. RAY was launched in 2011 to support state and city governments to upgrade slums, assign title deeds to the slum residents, and plan to accommodate the predicted growth so that no more slums are formed (Patel, 2013). The program envisioned a ‘Slum Free India’ in five years of its commencement with every citizen having access to basic infrastructure, social amenities, and decent shelter (Govt. of India, n.d., a), something we can now state with certainty that the program failed to meet its intended targets. RAY intended to bring existing slums within the formal system and enable them to avail the basic amenities available for the rest of the city. The Government also approved the scheme of **Affordable Housing in Partnership (AHP)** as a part of RAY to increase affordable housing stock by providing loan subsidies to EWS and LIG.

Most of the schemes in RAY overlapped with other programs in JNNURM such as BSUP and IHSDP. The program failed to take off for over a year after its launch with many states expressing reluctance to comply with mandatory provisions for availing central funds such as providing security of tenure to dwellers and earmarking 25% of the municipal budget for spending in slum colonies (Dasgupta, 2012). RAY also recommended cities to allocate about 25 to 40 percent of their land in their development plans for housing; something municipalities had not been ready to accept (TheHindu, 2013). The most significant challenge that RAY faced was the scarcity of suitable land, with the Planning Commission of India (2012-17) attributing it to suboptimal land-use patterns, lack of long-term planning, and the lack of participatory planning process to determine the most efficient use of parcels of land.

JNNURM overall remained fragmented and project-based with different aspects of the program involving separate ministries at the central level, and being implemented in a very isolated way at the local level (Tiwari and Rao, 2016). Low levels of participation by the slum dwellers led to delays in housing delivery and selection of projects not best suited to the needs of the beneficiaries (Hingorani, 2011). Many scholars reported how JNNURM favored new construction over in-situ development, despite JNNURM priority given to in-situ development (Tiwari and Rao, 2016; Hingorani, 2011).

Most of the slum development programs implemented by the Government of India had good intentions for the welfare of the slum dwellers. However, financial constraints of the government combined with factors such as lack of public participation in the planning and the implementation stages showing lack of sectoral approach played an important role in impeding the aimed developments. At the same time, ad hoc interventions often driven by political and administrative objectives rather than economic considerations and the on-the-ground situations made sure that the slum development programs would not impact the target beneficiaries in the way it was supposed to.

THE PRADHAN MANTRI AWAS YOJANA (PMAY) – HOUSING FOR ALL

The Prime Minister of India, Mr. Narendra Modi in June 2015 announced the subsumption of RAY and other housing schemes in the Pradhan Mantri Awas Yojana scheme to provide affordable housing to all eligible beneficiaries. The PMAY has two components – the PMAY–for the urban poor and the PMAY – Rural for the rural poor. Our focus of research is only towards the guidelines of the urban component of PMAY. The ‘Housing for All’ program has four central provisions–the in-situ redevelopment of slums using private participation, affordable housing through credit linked subsidy,

affordable housing in partnership with the private and public sector, and beneficiary led construction/enhancement of homes (figure 2).

Figure 2: Four central Provisions of Pradhan Mantri Awas Yojana (Govt. of India, 2017)

The first central provision allows in-situ redevelopment of slum households to be carried out by private developers (Govt. of India, 2017, p.4). While the residents would be rehoused in multi-storied structures, the remaining portion of the land would be used to construct commercial/residential buildings by the private developers in the open market. By using the private sector as a financing tool in the Housing for All policy, the government took a departure from the traditional systems focusing on piecemeal upgradation efforts in slums (National Slum Development Program) or using government machinery to build public housing (Basic Services to Urban Poor). The second provision provides an interest rate subsidy as a home loan for up to 600,000 rupees (\$9300) at an interest rate of 6.5% for the weaker section (Ibid, p.6). The third provision mandates 35% of the housing in a particular project to be reserved for the Economically weaker sections (EWS), and each beneficiary would receive a subsidy of 150,000 rupees (\$2300) (Ibid, p.9). And the fourth provision allows an individual to avail a subsidy for beneficiary-led individual housing construction (Ibid, p.10). The four provisions altogether have been framed to rehabilitate slum dwellers and reduce the number of evictions and demolitions, commonly happening before. However, a closer look of these provisions shows the harsh reality on why each of them is grossly inadequate.

The most important criteria for a slum household to be eligible for any developmental activity through the Housing for All policy is by being included in the 'beneficiary list' (Ibid, p.2) prepared by the Government. A beneficiary list is prepared with a defined criterion and only the families on the beneficiary lists are awarded the benefits. The requirements for beneficiary lists could vary from residence in the settlement at the time of cut-off date assigned by the government to income, and so on (Jain et al., 2016). However, the slum dwellers in most of the cases would have very few documents to prove their eligibility, making them ineligible. As families living in a slum for a long time become victims of frequent demolitions, a lot of paperwork required to prove the eligibility often goes missing during the chaos of the evictions. In most of the cases, the land and property records in the country are in such poor records. Many people would continue living in their ancestral home, whose title deeds may be in the name of their deceased forefathers (Deb, 2017). The current occupants, who would arguably be the target beneficiaries of the development program would be unlikely to have title documents.

Occupants would want to get into the lists and thus would leave no stone unturned in gathering the evidence to make them qualify for the beneficiary lists. As transactions and agreements are not recorded in government registers for informal housing, the task becomes all the more arduous. Renters would typically have proof of their identification but not of their address, since rental agreements are mostly informal and unwritten. Thus, many households automatically get excluded from the proposed developmental activities and cannot even apply to claim for one without these documents. The residents end up facing a problem where to prove eligibility for a provision; the resident would have to submit a water/electricity bill. However, to get a water/electricity connection, he would have to prove his residence.

The Deepak Parekh Committee (2008) constituted by the Ministry of Housing and Urban Poverty Alleviation (MHUPA), Govt. of India framed the definition of an affordable house. They defined it to be 'something meaning more than a roof over one's head – having adequate privacy, space, accessibility, security, lighting, heating and ventilation, and basic

infrastructure – all of which to be available at affordable cost (p.7). Later, the Wadhwa Committee (2009), defined that an affordable housing for people living below poverty line (BPL), economically weaker section (EWS) and Lower Income groups (LIG) should be financeable by home loans with estimated monthly installments not exceeding 5% for the BPL 20% for the EWS and 30% for LIG, respectively. Using the definitions provided by the Wadhwa Committee, a person belonging to either BPL, LIG and EWS category would not be able to pay more than 1350 rupees (\$20), 5000 rupees (\$77), and 10000 rupees (\$154) respectively annually as his home loan,

As mentioned before, the 'Housing for All' policy guidelines mention provision of a central assistance of 150,000 rupees (\$2300) or a loan of 600,000 rupees (\$9300) at an interest rate of 6.5% annually for a period of 15 years (Govt. of India, 2017, p.10) for construction of a new house for eligible EWS and LIG individuals. Using basic simple interest calculations, an individual would have to pay approximately 79,000 rupees (\$1200) per year just for repayment of the loan for 15 years, an amount equal to three-fourths of the maximum income an individual from EWS would earn, and one-third of that of LIG. For someone below the poverty line, a person would prefer being in his original situation than be burdened with paying something three times of what he could earn. With income constrained to such an extent that low-income families would find it difficult even to afford for adequate food, it is a huge challenge to fill the gap to pay for a house. It is interesting to observe that the policy favors middle-class families more than the urban poor to acquire new homes. The program incentivizes young middle-class couples to be first-time homebuyers by helping them subsidies for loans up to 1.2 million rupees (Chandran, 2017) – an amount which is half of the loan amount fixed for the EWS and one-fourth for LIG as compared that of the middle-class.

Builders in India today project affordable homes to be costing between 2-4 million rupees (\$29,400 - \$59,400) for a unit of up to 55sq meters (Chandran, 2017), an amount which is 76 times to that of the annual income of a person below the poverty line. Central assistance of 150,000 rupees (\$2300) only takes care of 7.5% of the problems a poor person would have, leaving him with a lifetime of debt for taking care of the remaining amount. Affordable housing finance is estimated to be 6 lakh crore rupees (\$93.12 billion) business opportunity by 2022, a date by when the Government of India seeks to achieve housing for all citizens (Bhunia, 2017). This amount provides enough incentives for the private players to be interested in the housing market.

The entire policy plan of providing loans to EWS and LIG makes very little sense when a majority of the poor lack steady incomes and documents essential to secure bank loans. An estimated 165 million Indians do not have bank accounts, with its unbanked population can stand as the seventh-largest country in the world, by population (Dey & Govindrajana, 2016). Given many migrant workers living in the slums of the cities, the banking process is intimidating, unnecessary, and expensive for them to maintain. The Ministry of Labor and Employment, Govt. of India states that 65-70% of the workers in urban areas work in the informal sector (Hindman et al., 2015). As the workers get paid in real cash, they lack collateral, formal records of identification, thus to be underserved by the Housing Finance Companies. Keeping this in mind, the Government of India launched the Pradhan Mantri Jan-Dhan Yojana (Prime Minister's People Money Scheme) in 2014, a national mission to ensure access to financial services for the poor. The scheme has been able to bring down the number of unbanked people in the country from 557 million in 2011 (Nair, 2015) to 165 million in 2016 (Dey & Govindarajana, 2016) especially in the rural areas. But surely, there is a long way to go in making it more accessible to all for the urban poor.

The policy guidelines conveniently only consider homeowners for any subsidies (Govt. of India, 2017, p.10), leaving aside a large chunk of renters living in the slums. One-third of urban dwellers have been found to be renters, living in poorly equipped homes (Ahmed, 2015). It is difficult to expect a large number of homeowners in a slum community, especially among groups who are struggling to meet their daily expectations. In most of the cases, it would be the slumlords having ownership for most of the household pockets (Gilbert, 2008). Greatly benefiting from these redevelopment schemes, the slumlords evict the renters and get the opportunity to charge the newly redeveloped homes at a higher price than before. Moreover, the guidelines make it clear for states/cities to exclude temporary migrants from taking any advantage of the housing scheme (Govt. of India, 2017, p.12). The guidelines make no effort in defining permanent and temporary migrants leaving it to the state and the local governments to decide. More importantly, a decision to exclude temporary migrants from any of the provisions would mean only half or probably less than half of the urban poor would be able to take advantage of the policy. The census data stands as substantial evidence to highlight the increasing migration of people from rural areas to the cities, most of whom would end up settling in the squatter settlements and non-notified slum pockets looking for better prospects.

Although 'Housing for All' guidelines advocate only for the redevelopment of existing slums without any evictions, it is interesting to observe that only 2.2 percent of the total approved housing under the program has been for in situ development till August 2017 (Bhunia, 2017). Moreover, the policy guidelines do not mention anything on the provision of transit accommodation for dwellers while their slums are being redeveloped, leaving the poor to fend for themselves without any support not knowing anything about the time it would take for redevelopment. Experiences from previous policies should have taught the Government of India by now about the need to have focused primarily on in-situ upgradation which not only would require lower costs for implementation, but would also help build and maintain the social capital of the communities. Having in-situ upgradation becomes a crucial factor considering the scarcity of land as a recurring theme behind the implementation of any new infrastructure project in the Indian cities. Approximately 2 lakh hectares of land would be needed to satisfy the housing shortage of 18 million units as planned by the Government (Ibid, 2017), a prospect challenging to comprehend considering the land scarcity existing in the Indian cities. Keeping this in mind, the Government has made efforts to unlock the land potential by providing Transfer of Development Rights (Govt.

of India, 2017, p.3) to incentivize private developers to undertake affordable housing development programs. While this could be effective in metropolitan cities like Mumbai or New Delhi, the economics won't hold steady in smaller towns where the land values are not that high, and developers would be unable to recover the costs.

Going in line with the previous policies, the 'Housing for All' too does not elaborate a proper framework for incorporating greater community participation in the decision making and the implementation stages. The guidelines mention the approval of detailed project reports by the State Level Sanctioning and Monitoring Committee (Govt. of India, 2017, p.14) but nowhere says if the project reports would be put for public review for submission, or even incorporates citizen inputs in the designing of the project. As mentioned before, lack of community participation was one of the primary reasons why previous slum development policies failed to meet its intended targets.

If the target of providing 18 million houses is to be met by new units alone by 2022, approximately 44,000 homes are to be built every day, which is a tall order to fulfill. Considering the target of creating 18 million new housing units by 2022, the pace of implementation for the Housing for All program has been slow, with only around 380,000 housing units built since 2015 and 4.19 million houses approved as on April 2018 (Govt of India, 2018). Looking at the average time for construction of an affordable home in India being 53 months (JLL, 2012) and the rate in which the houses are currently being built, the Government would surely need to revise its targets of completing the construction of 18 million housing units in 7 years.

CONCLUSION

The pathway to achieving 'Housing for All' is not as simple as the rhetoric given by the Prime Minister and the Government of India. States have still been following their old ways or evicting slum dwellers in the name of effective developmental practices. Many reports show large-scale evictions and demolitions of slums across the country even in 2018 (Khan & Gupta, 2017). While evictions continue being the norm, the government of Maharashtra at the same time decided to cut 14% of its allocation of funds for housing this year, thus showing the indifference of the government towards the massive housing problem that the city faces (Pawar, 2017). Meanwhile, the Government in the State of Odisha passed the Odisha Land Grabbing (Prohibition) Bill 2015, with a provision of seven-year jail term for anyone, including the homeless for encroaching on government land (Govt of Odisha, 2015).

As seen before, targeting to provide affordable homes to EWS and BPL through the Housing for All policy means that around 92% of the cost of the home is borne by the individual even after supposedly making it 'affordable.' The absence of formal financial structures for the poor communities further widens the gap between the purchasing power of the poor neighborhoods to the actual market price. These communities do not have any accumulated or inherited wealth, therefore not having the capability to afford neither the downpayment nor the monthly installments.

There is not only an urgent need to increase the supply of low-income housing as envisaged by Prime Minister Modi while launching the Housing for All policy, but also improve the living conditions for those living in informal housing, especially those in insecure housing and squatter settlements. India urgently needs a law that recognizes housing as a fundamental human right, which would ensure the protection of minimum nature of shelter to the needy for him/her to have a dignified life. Without the security of tenure, the access and quality of services and infrastructure in informal housing would largely depend on the welfare policies of the state and the local politics.

The need of the hour is not just providing cheaper loans, but increased allocations for homeless shelters and social renting housing in urban areas for migrant workers and the poor. Social renting housing as a concept that has slowly started warming up in the policy circles. The National Urban Rental Housing Policy 2017 is currently awaiting the Cabinet's approval (Bhunia, 2017). The most significant advantage of opting for a social renting housing program is that it would absorb floating population of seasonal and temporary migrants, who would not want to invest in a fixed, immovable property in the city – however, subsidized or cheap it is. Conceptually, social rental housing needs a more significant push by the government in the cities, considering the rental housing for commercial purpose is well rooted in the metropolitan cities. Last measured, around 10 million houses lay vacant in the commercial market which has not entered the rental market (Ibid, 2017). A vast majority of these property owners are private citizens who prefer leaving their house vacant, rather than offer it on rent. Property owners often fear that they may lose their property to tenants, leading to under-utilization of their assets. These vacant housing units would take care of half of the estimated housing shortage in the country. In addition to creating new capacity, one needs to study why the owners of the vacant houses do not see any merit in renting out the vacant properties.

However, a major challenge remains defining a standard criterion for allocating property rights to prevent vested interests and/or unintended beneficiaries such as slumlords and high-income families. States would need to simplify the process of updating property records, which would allow citizens help obtain legal documents to entirely be able to access the subsidies offered by the Housing for All program. There is an urgent need to derive a different typology of housing structures that provide variations in sizes of houses, structural quality, infrastructure services, and tenure types to meet the requirement of various income groups and having the essential requirements for a basic home, yet being affordable.

Policies cannot be designed with an overdrive of infrastructure alone, but would also need incorporation of behavioral insights of the intended beneficiaries for them to be successful and achieve its outcomes. Thus, a program like the Housing for All, with all its good intentions can succeed if it can resolve issues of unclear land titles and ensuing claims, build instruments to facilitate affordability of housing by all segments, encourage social rental housing, building adequate

financial resources for affordable housing programs, and overcoming market segmentation. With the incorporation of all of these parameters, someday it would be finally possible for all citizens in a city to live in a home adequate with all the essential services.

WAY FORWARD

The study would like to test the arguments presented in the paper to investigate how does the PMAY respond to the needs of the smaller cities by conducting a comparative case study across four cities along the eastern region of the country. The paper would compare the progress of the PMAY programs in two tier 2 cities – Bilaspur (Chhattisgarh) and Brahmapur (Odisha), and compare it to the progress occurring in two metropolitan cities also located in the eastern part of the country – Kolkata (West Bengal) and Visakhapatnam (Andhra Pradesh). The four cities are selected for the contrast they present not only with respect to the difference in population across the cities but also considering the variation of the political party in power across each state. The research first plans to study the existing deprivation in the slum households for each of the four cities based on the 2011 census data and other secondary sources available. The next phase would involve observing the extent of housing projects covered in each city under PMAY with respect to the deprivation present in each city, and the proportion of the population it is covering. Finally, the study plans to have qualitative interviews with the slum dwellers who would ideally be the intended beneficiaries. Detailed personal interviews with the slum dwellers would give information on their tenure status, number of years of their stay in the slums, annual income and so on. The interviews would provide information on the extent of the eligibility status of the slum dwellers for the Housing for All program. This information would be supplemented with market studies to understand the housing market with respect to information such as the scale of affordable housing in the city, and the average price of a home for the particular city. in each of the four cities. All these details can be used to build a quantitative model to find the correlations between the Housing for all provisions to the actual needs of the slum dwellers in each city, which thus could help us investigate the extent of PMAY coverage concerning both the metropolitan and the smaller cities of the country.

1380 EMPIRICAL STUDY OF THE EFFECT OF FLOOR-AREA-RATIO REGULATION IN JAPAN

ABSTRACT

Local governments in Japan set upper limits on the allowable floor-area-ratio (FAR) with the aim of controlling population growth and externalities. The FAR limit has been treated as a variable in empirical models of real estate prices in Japan. A low-enough value of the maximum acceptable FAR necessitates low building heights, but beyond a certain value it does not have any direct effect on the actual heights of buildings. There are, however, indirect (negative) effects on real estate prices from possible tall buildings in the surroundings. Our hypothesis is that the mechanism by which the FAR control affects real estate prices depends on the relation between the privately determined optimal FAR and the regulatory FAR values. To test this hypothesis, we conduct empirical research using the real estate transaction price datasets from the Ministry of Land, Infrastructure and Transport since 2000. First, each sample is divided into two subsets. In one, the regulation constrains the actual heights. In the other, it does not. The percentage of constrained heights in a municipality reflects the local public policy on population growth. Estimation of spatial econometric models measures strategic interdependence among neighboring municipalities on height regulation. Next, we estimate an optimal FAR function using constrained samples. This estimated function is used to predict the population changes caused by changes in FAR regulation. It also provides a guideline as to whether the FAR limit should be treated as an explanatory factor in models of land price. Finally, we simulate the urban population level without FAR regulations. In other words, we can confirm how much the population concentration in Japanese cities is suppressed by FAR regulation.

1567 FROM THE CITIES TO THE 'NEW CENTRALITIES' IN ANGOLA: INTERCONNECTION BETWEEN URBAN SPACES

ABSTRACT

This article is intended to address the subject of urban space typologies in the “new centralities” of old colonial cities in Angola and their space and time connection. Due to the civil war (1975-2002) informal expansions were created in the borders of cities. They heralded precariousness, the lack of housing and the need of inclusion in the urban tissue. This phenomenon covers the whole Angolan territory and includes 80% of the country’s urban population. Thus, in the beginning of the 21st century, this large urban and demographic transformation and the lack of housing gave way to the present intervention practices (re)designing the national territory. The situation also led the State to create the National Urbanism and Housing Program (PNUH – Programa Nacional de Urbanismo e Habitação) implemented since 2009, under which 1 million dwellings have been built up to 2017. If in the colonial past these planned cities used to integrate pre-existing areas, rendering structure to urban expansion, the present process of the new centralities, distinct in form and content, is distant from the past in terms of time and space, suggesting new ways of living-working connections are now based on very different urban contexts, origins, growth and public spaces. Despite the new interventions, old towns will always remain an inexhaustible source of life, reference and identity: the personal and collective identity of a people, a place and a country. In the wide territory, the memory of the cities and the way in which they have been appropriated in usage and form along the years turn each of them into a space of collective identity. There, each square, each street and avenue, each block and building are urban elements determining different ways of living. And they raise the following question: 40 years after the independence of Angola are these new centralities, far away from the city, the key to new ways of living?

1249 BHISTIS OF KOLKATA-A VANISHING TRIBE

ABSTRACT

Bhists were once a very important part of Kolkata’s water supply is now in apathetic state,they are fast vanishing tribe of Kolkata. The word bhisti probably originated from the Persian word bhisti, meaning paradise. This was probably because of the importance of water and its supplyas there was a serious crisis of water supply. During the British rule they were known for their loyalty and efficiency. Bhists were once the employees of CMC area, butsoon they lost their prime position as suppliers of water after carriages were introduced and plumbing also made things worse. But due to the inefficiency of KMC and poor plumbing experience many houses did not get water and bhists became indispensable. Today a handful bhists operates in a few pockets of Kolkata. The Bow Barracks in Bou Bazar area is the place where only they are found. The bhists of Kolkata will soon be history and the next generation will be unaware of their services and they will only remain as a abstract modern art in front of City Centre 1. This paper will reveal the present condition of the bhists along with their socio-economic, and occupational structure.

ABSTRACT

Livability is an all-inclusive paradigm of human development and community wellbeing based on an expansion of the identical environmental, socio-economic and socio-cultural dimensions of a regional space. At present, livability is an elementary benchmark to evaluate quality of life (QoL) and overall wellbeing of any communities. Today 54% of the world's population is settled in the urban areas and is expected to reach 66% by 2050. The impact of the rising population pressure on the urban environment is a key concern for all the policymakers and researchers from a regional competitiveness point of view. The present paper is trying to ascertain the key aspects of livability and delineate Kolkata Metropolitan Area (KMA) into significant livability clusters to appraise its regional competitiveness.

Keywords: community wellbeing, livability, metropolis, regional competitiveness

1 INTRODUCTION

Livability is an all-inclusive paradigm of human development and community wellbeing based on an expansion of the identical environmental, socio-economic and socio-cultural dimensions of a regional space. Pre-assuming good socio-economic conditions, the capacity to inhabit in a certain regional space is a requirement for livability. At present time livability is an elementary benchmark to appraise the quality of life (QoL) and overall wellbeing of any communities and the essential induced prosperity within any regional space.

The concept of livability reveals its importance for community wellbeing (Tilaki et al. 2014). Livability is a holistic idea (Jomehpour 2015) and a very close aspect of community development and metropolitan management (Wyatt, 2009). It embraces broad human needs ranging from nourishment, shelter and safety to cultural manifestations (Bardhan et al. 2011). Partners for Livable Communities define, livability as the sum of the factors that add up to a community's quality of life, including the built and natural environments, economic opportunities, social equity, educational and health opportunity, and cultural expressions (National Research Council 2002). The dimensions of livability have a direct association with a community's wellbeing and decision making to contrive a region more competitive (Badland et al. 2014). It endeavours to stimulate urban spaces towards an ideal level to improve the overall community's QoL (Tilaki et al. 2014). Numerous researchers have been argued about the concept and dimensions of livability and its association with regional competitiveness (Kennedy & Buys 2009). First, Kevin Lynch augmented five elements of livability, to make a region more livable and competent, namely liveliness, wisdom, fit, access and control (Leach et al. 2017). Secondly, Douglass has initiated labour force, economic opportunities, good governance and quality of environment (Uysal et al. 2012) to understand regional competitiveness. Reham and Elsemary have conducted a research to understand the qualitative conceptions of livability between theory and applications in Egypt based on land use, sense of place, civic amenities and public safety (Momtaz & Elsemary 2015). So most of the cases researchers have used various parameters to understand the association between livability and regional competitiveness based on their own perspectives and propositions pinched from their research setups.

Today, 54% of the world's population is settled in the urban areas and is expected to reach 66% by 2050 (Department of Economic and Social Affairs 2014). The impact of this increasing population pressure on the urban environment is a key concern for all the policymakers and researchers from a regional competitiveness point of view (Cicerchia 2014). From this standpoint, metropolitan livability assessment approach has appeared in regional science to assess a profound and comprehensive relationship between community wellbeing and their urban environment (Tilaki et al. 2014; Paul & Sen 2017). The present paper is trying to identify the key aspects of livability and delineate Kolkata Metropolitan Area (KMA), the largest multicultural metropolis in India into significant livability clusters for appraising its regional competitiveness.

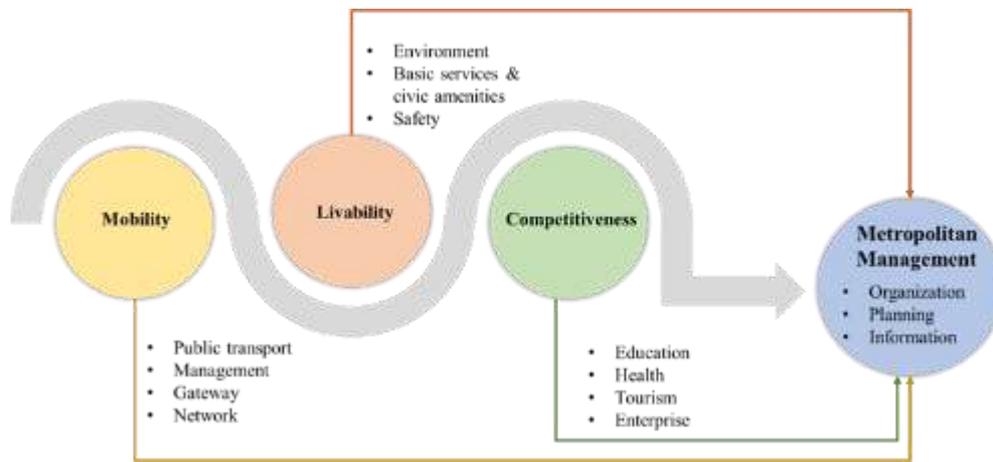

Figure 108 Conception of the Research

2 RESEARCH APPROACH

The research is forwarded in four segments (Figure 2). In the first segment, research background, mainly literature review and need of the research have been assimilated followed by case study selection. After that cluster analysis has been identified for livability cluster development to assess its regional competitiveness. In the final segment the secondary research outcome has been validated based on Residents Reaction survey.

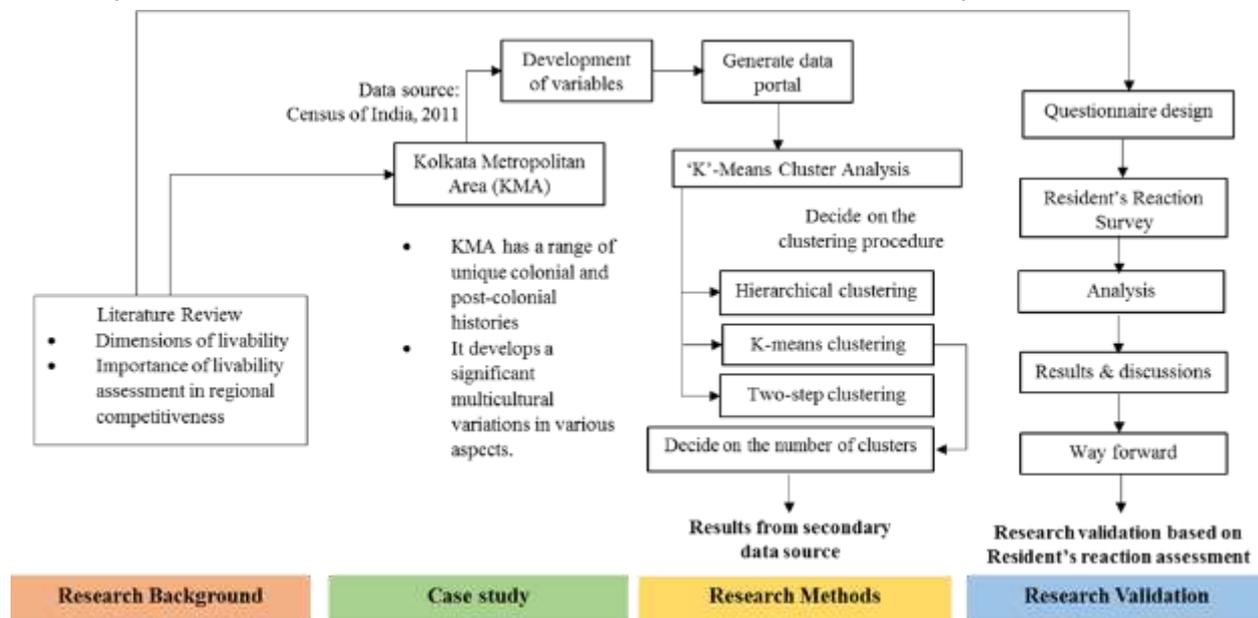

Figure 109 Research Approach

2.1 Development of variables

Data used in this study were obtained from Census of India 2011. To validate the secondary data results, a Residents Reaction survey has been done.

2.2 Selection of case study

KMA is the third largest urban agglomerations in India following Mumbai and Delhi. It extends over 1886.67 Sq.km area and is formally managed by 4 municipal corporations namely, Kolkata, Howrah, Chandannagar and Bidhan Nagar. It also contains, 36 Municipalities, 72 towns and 527 villages across the metropolis (Kolkata Metropolitan Development Authority 2000). The study has only focused on the urban agglomeration of KMA (4 municipal corporations and 36 municipalities). The population density within KMA is quite high (7,480 per km²). But the economic activities and civic amenities are not equally distributed within KMA. Most of these facilities are concentrated within Kolkata and Bidhan Nagar (Bardhan et al. 2011). These features have initiated a sub-regional livability variation based on civic services and facilities within KMA (Paul & Sen 2017). The present paper has adopted a sub-regional clustering approach in analyzing livability variations of KMA.

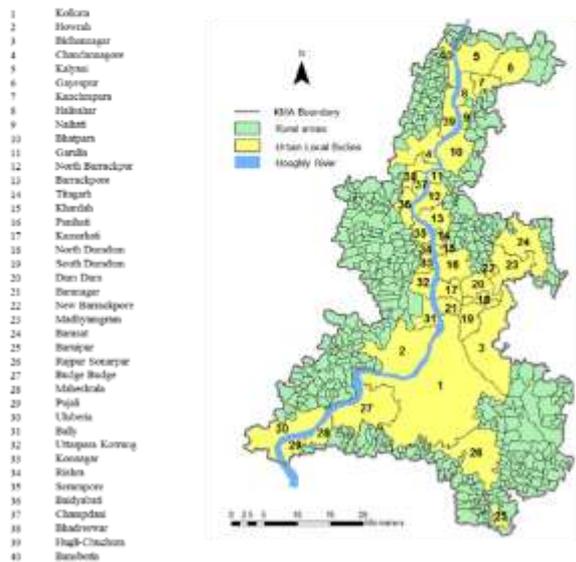

Figure 3 Location of KMA

2.3 'K'-Means Cluster Analysis

This paper has used cluster analysis to delineate KMA into 'N' number of clusters. Cluster analysis is a well-accepted method for statistical classification (Cheong & Lee 2008) of a set of measured variables into defined homogeneous groups (Cornish 2007). In general there are three approaches in cluster analysis namely hierarchical clustering, K-means clustering and two-step clustering, which is largely a combination of the first two methods (Mooi & Sarstedt 2011). To cluster KMA based on its livability variations, the paper has been selected K-means clustering.

3 RESULTS AND DISCUSSIONS

3.1 Clustering urban centers within KMA

Peter J. Rousseeuw (1986) had innovated Silhouette method to determine the actual number of clusters in 'K' means clustering (Kodinariya & Makwana 2013). This method refers the interpretation and validation of consistency within clusters of data. The technique provides a concise graphical representation of how well each object lies within its cluster. The concept of silhouette width involves the difference between the within-cluster tightness and separation from the rest. Specifically, the silhouette width $s(i)$ for entity i is defined as;

$$s(i) = \frac{b(i) - a(i)}{\max(a(i), b(i))}$$

Where $a(i)$ is the average distance between i and all other entities of the cluster to which i belongs and $b(i)$ is the minimum of the average distances between i and all the entities in each other cluster. The silhouette width values lie in the range from -1 to 1. If the silhouette width value for an entity is about zero, it means that, the entity could be assigned to another cluster as well. If the silhouette width value is close to 1, it means that the entity is misclassified. If all the silhouette width values are close to 1, it means that the set I is well clustered (Kodinariya & Makwana 2013). This paper has been identified (Figure 4) that at cluster 5 the quality of clusters are very close to the highest value, when it assume the cluster number is 6, the level of cluster quality has been decreased. So from this technique if the cluster number would be 5 then the Silhouette measure of cohesion and separation value comes very close to 1, which signifies the cluster quality is good. The present paper has delineated KMA into five clusters to understand the inherent livability variations.

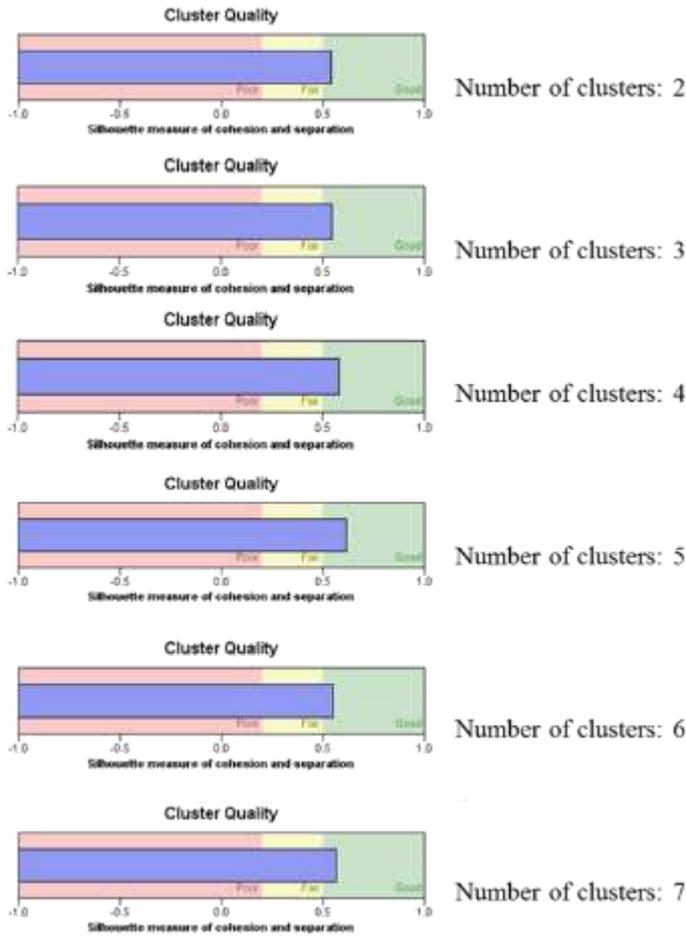

Figure 110 Silhouette measure of cohesion and separation based on quality of clusters

Table 47 Schedule of Agglomeration

Stage	Cluster Combined		Coefficients	Stage Cluster First Appears		Next Stage
	Cluster 1	Cluster 2		Cluster 1	Cluster 2

39	1	18	.644	37	38	0

Table 48. Initial Cluster Centers

	Cluster	Mean Square	df	Mean Square	df	Error
Population Density	8.297	4	0.166	35	49.959	
Housing Density	8.398	4	0.154	35	54.366	
Employment Rate	6.839	4	0.333	35	20.559	

In Initial Cluster Centers (Table 2) denotes the Euclidean distances between the cluster centers. Larger distances indicate more differences within the algorithm. In this case, the groups are shaped intentionally in accordance with the distances between them.

Table 2 shows that the selected variables have an impact in cluster development and employment rate has the minimum impact in it. The F-test used for graphic purposes, to maximise the differences among cases in different clusters. It indicates the probable standards of each variables within predefined groups vary from one another. In Table 2 the positive and large F values of the variables signify the higher contribution of variables to the categorizing the clusters.

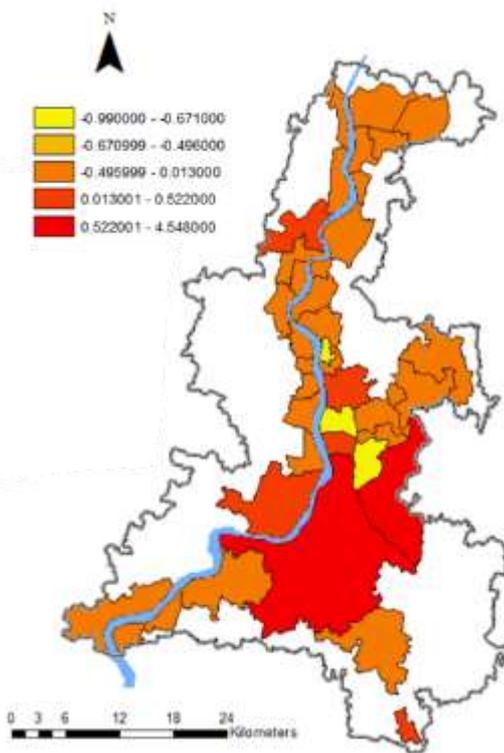

Figure 5 Livability clusters within KMA

From the cluster analysis results, five cluster explanations were used to demarcate KMA. Figure. 5 shows the characteristics of the five clusters. On a standardized scale, cluster 1 has higher and positive values of population and housing density and Employment rate than the other clusters. Cluster 2 has higher positive values of population and housing density and higher negative value on the Employment rate. Cluster 3 has negative population and housing density. Cluster 4 has the positive population and housing density but negative value for the Employment rate. Cluster 5 contains lower positive values of the selected variables.

3.2 Existing and desired livability variations

To understand the association between livability variations within KMA and its regional competitiveness, the paper has carried out a resident’s reaction survey within the selected five clusters within KMA. Kolkata (Cluster 1), Kamarhati (Cluster 2), Chandannagore (Cluster 3), Rishra (Cluster 4) and Howrah (Cluster 5) have been selected for the assessment based on their urban settings and good connectivity with the primate city. Kolkata, and Kamarhati located along the east bank of the Hooghly River. The urban local body of Kolkata develops as the primate core having highest concentration of good physical and social infrastructure compared to others. Whereas, Chandannagore, Rishra and Howrah are located

along the west bank, where comparatively native settlement pattern and their associated colonial heritages have been observed.

A total of 67 residents have been interviewed based on simple random sampling. Residents reaction has acquired based on five-point likert rank approach. Respondents were 51.3% male and 48.7% female. High literacy rate has been observed in cluster 1, 3 and 5. 40.1% residents were engaged in full-time employment while 16.4% respondents were devoted into various business oriented activities. It was also evident that, 16.4% of the respondents within KMA moved to the present community due marriage, 23.9% moved to succeed a desired livable setting for family, within Kolkata and Howrah. Along the east bank, 70.7% respondents are from older communities' residing there for last 50 years. On the whole, it is evident that core Kolkata still provides good to better quality of physical and social infrastructure in comparison to other urban centers to improve the regional competitiveness. Most of the cases rest of the other urban centers are dependent on Kolkata for better and reliable health options, educational facilities and economic opportunities.

Variables	Level of satisfaction	Cluster 1	Cluster 2	Cluster 3	Cluster 4	Cluster 5
Economic possibilities and job opportunities	Very Satisfied	13.3	0.0	15.4	0.0	5.9
	Satisfied	26.7	60.0	23.1	33.3	41.2
	Neither satisfied nor dissatisfied	40.0	40.0	7.7	8.3	17.6
	Dissatisfied	13.3	0.0	15.4	16.7	17.6
	Very Dissatisfied	6.7	0.0	38.5	41.7	17.6
Level of social infrastructure (Health & educational facilities)	Very Satisfied	20.0	0.0	15.4	16.7	17.6
	Satisfied	13.3	90.0	30.8	25.0	35.3
	Neither satisfied nor dissatisfied	40.0	0.0	30.8	33.3	29.4
	Dissatisfied	26.7	0.0	23.1	16.7	5.9
	Very Dissatisfied	0.0	10.0	0.0	8.3	11.8
Affordable public transportation options	Very Satisfied	20.0	10.0	7.7	0.0	5.9
	Satisfied	0.0	90.0	30.8	8.3	41.2
	Neither satisfied nor dissatisfied	6.7	0.0	15.4	41.7	23.5
	Dissatisfied	40.0	0.0	30.8	16.7	5.9
	Very Dissatisfied	33.3	0.0	15.4	33.3	23.5
Level of safety & security	Very Satisfied	13.3	0.0	0.0	0.0	5.9
	Satisfied	26.7	30.0	15.4	8.3	29.4
	Neither satisfied nor dissatisfied	20.0	20.0	23.1	58.3	47.1
	Dissatisfied	26.7	50.0	38.5	25.0	17.6
	Very Dissatisfied	13.3	0.0	23.1	8.3	0.0

To comprehend the existing living standard, comfort and economic opportunities available within KMA, the paper has finally assessed the resident's contentment. Within KMA, most of the respondents prefer to stay in Kolkata and Howrah for availability of best civic amenities and facilities. 43.7% respondents have shifted to Kolkata and its surrounding areas for jobs and diverse employment opportunities. So the demand for rental housing is much higher in core Kolkata and Howrah. 37.3% respondents prefer to live in apartments (mostly in 1 BHK and 2 BHK) in Kolkata. But the situation is much different in Chandannagore, Panihati and Rishra, where 60% of the respondents seek to have their individual house in a relatively less dense and economically affordable livable settings.

4 CONCLUSIONS

The present paper has identified two research outcomes to perceive the effective way to evaluate livability variations within KMA. The first outcome has attempted to identify the variables to determine livability variations within KMA by clustering approach. Application of Silhouette method to determine the number of clusters in the clustering algorithm. The present paper accordingly has delineated KMA to understand the existing livability variations.

The second outcome was to establish the significance of livability variations within KMA. In this segment, a residents' reaction survey has been accompanied to observe the existing metropolitan livability variations and its impact on the regional competitiveness. From the result, cluster 1 (Kolkata) and 5 (Howrah) have pledge much livable than the others based on the existing civic amenities and facilities.

The present paper has mainly focused on clustering KMA and evaluating the metropolitan livability variations. Therefore the research endorses further subsequent investigations to examine the dynamics of livability potential within these clusters and also understand the good livability flow assessment between these clusters to ensure the overall community wellbeing and metropolitan decision making of the metropolitan indwellers.

1465 ASSESSING U.S. STATE EFFORTS TO INTEGRATE TRANSPORTATION, LAND USE AND CLIMATE CHANGE

ABSTRACT

Climate change is increasingly recognized as a threat to life on earth. “Continued emission of greenhouse gases will cause further warming and long-lasting changes in all components of the climate system, increasing the likelihood of severe, pervasive and irreversible impacts for people and ecosystems. Limiting climate change would require substantial and sustained reductions in greenhouse gas emissions” (International Panel on Climate Change 2014, 8). The transportation sector accounts for almost one-third of all greenhouse gas emissions (GHG) in the United States. Reducing GHG from transportation rests on the “three-legged stool” of improving vehicle efficiency, reducing the carbon content of fuels, and reducing vehicle miles traveled (VMT). But “technological improvements in vehicles and fuels are likely to be offset by continuing, robust growth in VMT” (Ewing et al. 2007, 2). Thus, a crucial strategy in curbing GHG from transportation relies on reducing total VMT by promoting alternative modes of transportation hand-in-hand with promoting development patterns that support the use of such modes, possibly along with attaching a price to GHG. In developing climate action plans, states have begun to acknowledge the connection between transportation and development patterns. This paper examines state level approaches to mitigate greenhouse gas emissions from transportation, focusing on the integration of land use and transportation in California, Maryland, Oregon and Washington. Though greenhouse gas emissions extend beyond state boundaries, the political boundaries are well-suited to addressing greenhouse gas emissions from transportation. This paper highlights the analytical approaches for identifying strategies to reduce GHG and describes the models used at the state level. Then, this paper moves beyond the models to identify political barriers to implementing various strategies to reduce GHG from transportation.

1467 PLANNING FOR EXTREME HEAT: A VULNERABILITY-ORIENTED APPROACH

ABSTRACT

This paper presents an approach for mapping and addressing the negative impacts of extreme heat events on vulnerable populations. The authors assess distribution of surface temperatures in the Chicago metropolitan area using Daymet dataset [maintained by the Oak Ridge National Laboratory and hosted by the NASA-supported Distributed Active Archive Center]. Separately, they identify locations of populations most vulnerable to extreme heat events using Census data and maximum likelihood factor analysis to derive an index that captures where residents exhibit greater sensitivity and/or lower adaptive capacity to extreme heat. Using overlays and scenario analysis, the authors identify areas with the greatest need for emergency response in case of future extreme heat events, and well as areas that need long term adaptation and mitigation in the long term. Finally, the authors illustrate a web-based tool developed to assist organizations like Chicago's Office of Emergency Management. Please note: This abstract is submitted towards the special session Analytical Approaches to Climate Change at Multiple Scales, organized by Professor Gerrit-Jan Knaap.

1468 AUTONOMOUS VEHICLES, ENERGY PRICES, AND DEMOGRAPHIC CHANGE IN THE BALTIMORE-WASHINGTON REGION: SCENARIO ANALYSIS WITH LOOSELY COUPLED MODELS

ABSTRACT

Demographic Change, autonomous vehicle technology, energy price volatility and the regulatory environment could have dramatic but uncertain impacts on development patterns, travel behavior, and environmental quality in metropolitan areas of the United States over the next several decades. In the context of this uncertainty, exploratory scenario analysis has become an increasingly common practice in metropolitan and regional planning. Unlike normative scenario analysis, exploratory scenario analysis does not take development patterns as choices, but instead takes development patterns as the outcome of exogenous driving forces and policy choices. Policy choices are thus better informed when driving forces and their impacts on development patterns are well understood. In this paper, we report the latest results of a multi-year exploratory scenario exercise for the Baltimore-Washington region. To develop four scenarios, we formed a Scenario Advisory Group and asked them to identify driving forces that could have important but uncertain impacts on the Baltimore-Washington region in the near future. From these driving forces, we constructed four exploratory scenarios that vary in assumptions regarding economic growth, the uptake of transportation technologies, energy prices, and more. The assumptions behind these scenarios were then conveyed as input values to a suite of integrated models. This suite of models-- that includes economic, transportation, land use, air and water emissions, and health impact models--is then used to derive for each scenario parameter values for development patterns, travel behavior, GHG emissions and water quality, human morbidity, mortality, and more. The results suggest that plausible differences in critical driving forces could have important ramifications for the sustainability of the region. Rapid growth, autonomous cars and low fuel prices, for example, could escalate urban sprawl, vehicle miles traveled, greenhouse gas emissions and water quality degradation. The rapid adoption of electric vehicles, however, in a high growth and high fuel price environment, could encourage more compact growth, transit ridership, reductions in GHGs and improved water quality. Alternative assumptions, reflected in the other two scenarios yield different results. We then conducted policy experiments in each of the four scenarios to identify robust strategies that yield more sustainable outcomes under a range of driving forces. We also identify key flags to monitor in the trends in key indicators in real time. We also set targets for some of the indicators that reflect the desired set of robust actions.

1236 EVALUATING HEAT STRESS IN URBAN INFORMAL HOUSING THROUGH SPATIAL ANALYSIS: A CASE OF MUMBAI

¹Surabhi Mehrotra, ¹Ronita Bardhan, ²Krithi Ramamritham

¹Centre for Urban Science and Engineering (C-USE), Indian Institute of Technology Bombay, India

²Department of Computer Science and Engineering (CSE), Indian Institute of Technology Bombay, India

ABSTRACT

This paper proposes indicator based approach to investigate urban heat island in urban areas to mitigate its adverse impacts on human wellbeing like heat stress. UHI investigation becomes exigent in rapidly urbanising and fast –growing cities like Mumbai, that has high density of population with varied built forms. The uncontrolled growth of informal housing in Mumbai has emerged as a prominent built form that has transformed the built environment of the city. The current study examines impact of informal housing on the thermal conditions of the city through indicators of thermal profile. The Informal housing areas are examined at two levels of atmosphere using thermal profile indicators that are defined as 1) surface heat island intensity, estimated using land surface temperature (LST) and, 2) Screen level heat stress (at 2m height) which is measured using air temperature profile. The spatial pattern of both indicators is then computed to identify hot spot areas of heat stress through geo-spatial statistical analysis. Results of spatial patterns of heat stress indicates high vulnerability of informal housing compared to formalised housing in the city.

Keywords: urban heat island; Informal housing; land surface temperature; spatial analysis; heat stress vulnerability

1 INTRODUCTION

Mumbai, once known as the India’s most premier city because of its high economic growth, has fallen prey to its own development policies. Past urban development policies in a certain way have led to the growth of informal housing - which is concentration of low income population in the city (Bardhan, Sarkar, Jana, & Velaga, 2015; Nolan, 2015).The growth of informal housing has become inevitable consequence of rapid urbanisation pattern in similar rapidly developing megacities of the world (Ooi & Phua, 2007). Informal built typology has distinct structure which can be characterised as typically low rise compact built form, that currently houses about half of its population in 9% of total land. The ‘informal’ housing could be categorised majorly as ‘slum’ or ‘chawls’ in Mumbai. One of the major character of informal housing is the way it is interwoven in the landscape of urban built areas and spread as a large mass of impervious built-up land. As per the Census of India (2011), the city has 12.5 lakh slum households comprising 41.5 per cent of its population — that is over 60 lakh people residing in informal housing. Figure 1 gives account of slum population in each ward of Mumbai.

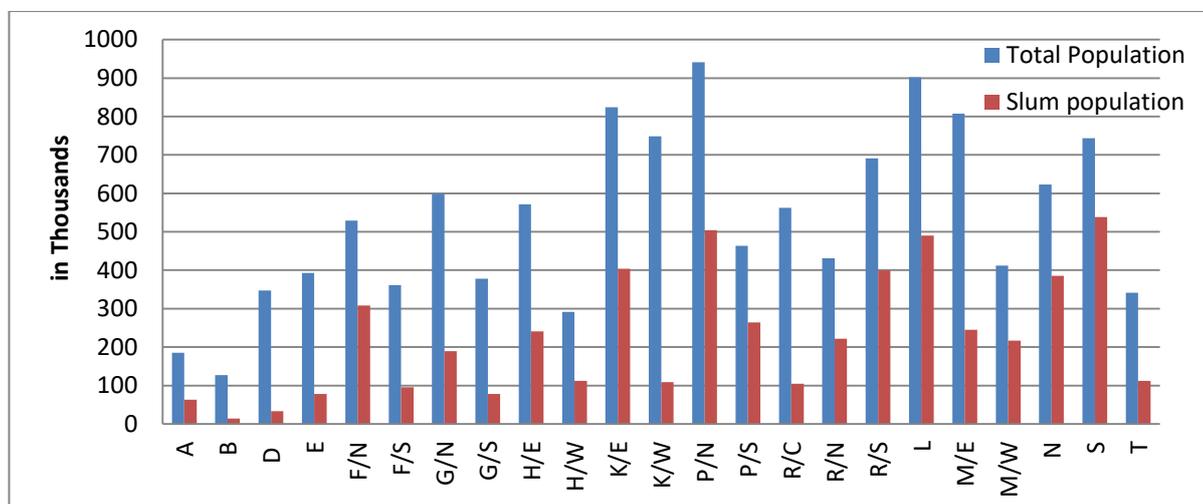

Figure 111:Ward wise total population and slum population (source: 2011 census)

Some wards have more than 50% of population as slums (P/N, N, S wards). Dharavi in ward G/N, is known to be biggest slum having 79 slum clusters that house about 6 lakh population in 1 lakh hutments. Andheri east (K/E) has 281 slum clusters housing about 8 lakh population (see Figure 2). The sudden proliferation of slum clusters in the landscape of Mumbai is large enough to have high ecological impact on the surroundings. Due to its density and typical built characteristics, informal housing has emerged as a prominent urban built form typology in Mumbai and therefore needs detail investigation of its vulnerability to heat stress as well as its thermal impact on environment.

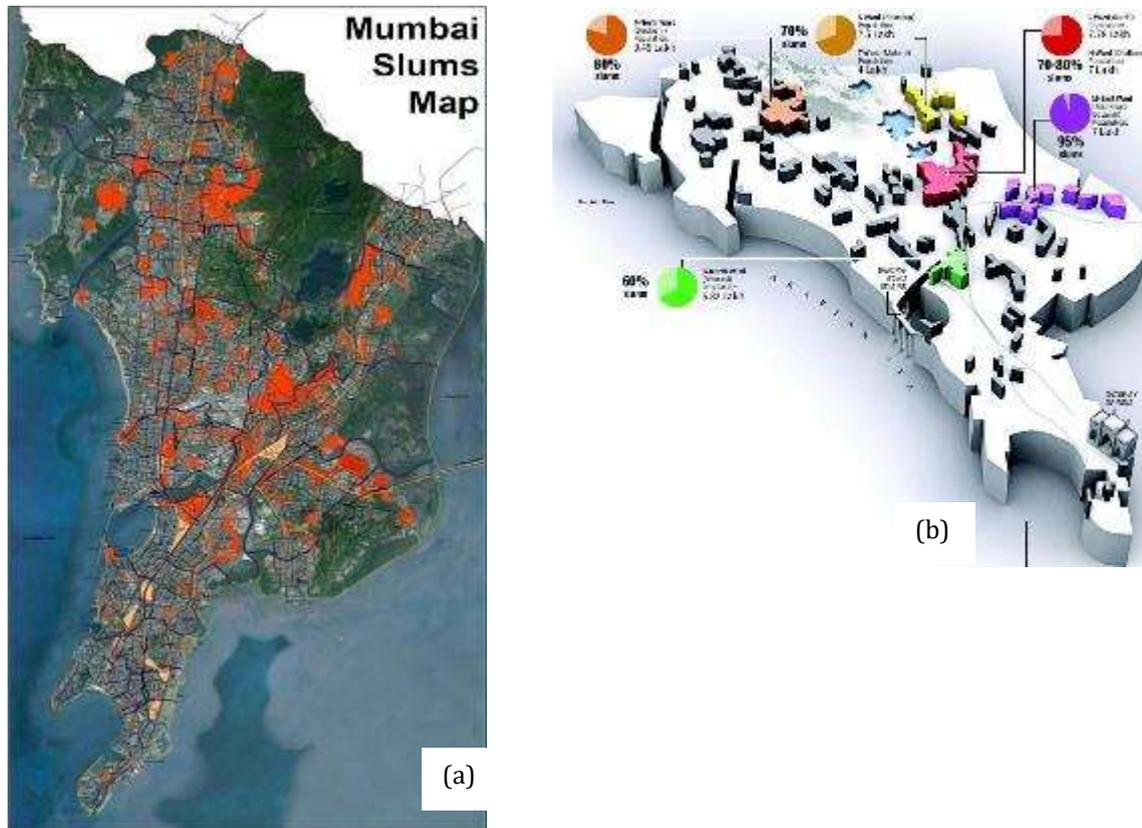

Figure 112: (a) Mumbai slum map and (b) schematic Representation of new slums areas in Mumbai city map (Lewis, 2011)

1.2 Past literature and Gaps

In last decade, there have been extensive study on urban built form characterisation and thermal profile. Urban climate studies have showed that the geometrical and structural parameters of urban form have direct significant impact on UHI (L. Chen & Ng, 2012; J Unger, 2004; Janos Unger, 2006). However, informal areas are not considered for evaluation in most of the urban built studies. The study holds importance due to its unique structural form that creates extensive horizontal spread in urban landscape. Apart from physical transformation, these urban forms also impact environmental, social and economic structure of the urban area.

Investigation of urban surface have been widely carried out using land surface temperature (LST) derived from satellite images that provide thermal images of urban area. It provides synoptic view of thermal characteristics of urban surface for urban heat island studies (Y. C. Chen, Chiu, Su, Wu, & Cheng, 2017; Javed Mallick & B.D.Bharath, 2008; Mehrotra, Ronita, & Krithi, 2016; Song, Du, Feng, & Guo, 2014). However, the heterogeneity of urban forms at local level and atmospheric noise between urban surface and satellite, pose limitation of LST for urban form thermal analysis. This substantiates the need of local level thermal monitoring methods to investigate heat stress differences between informal and formal built forms with empirical evidence. For local level monitoring of thermal profile, air temperature is widely used variable in urban climate studies (Eliasson, Geography, & Sciences, 2003; Fenner, Meier, Bechtel, Otto, & Scherer, 2017; Nazarian, Fan, Sin, Norford, & Kleissl, 2017; Stewart, Oke, & Krayenhoff, 2014). Thus, by recognising the variability of thermal processes at different level of urban atmosphere, we have used two indicators for heat stress investigations. LST is an important indicator of urban surface thermal variations which is used an UHI indicator and secondly, we have used air temperature variations as an indicator of UHI at local level (Jérémy, Marjorie, Isabelle, Erwan, & Pascal, 2015; Schwarz, Schlink, Franck, & Großmann, 2012). Both the indicators are used to identify thermal hotspots using spatial analysis. Due to stochastic nature of microclimatic variables, spatial analysis has been used for identifying hotspots of heat at local urban level. The heat stress profile at local level is then correlated to locations of heat stress identified using LST.

With this conjecture that informal areas have distinct thermal profile, different from formal areas, this study aims to investigate thermal profile in informal housing clusters of Mumbai and derive empirical evidence of its thermal variability compared to planned housing areas.

This study is structured in two parts: - In the first part, we have identified distinct areas informal housing in the landscape of Mumbai. In the second part, we have modelled spatial pattern of land surface temperature which was further investigated for its location of hotspots. Next part deals with local thermal profile using field measurements and correlating it with LST hot spots identified by spatial statistics. The study is an attempt to determine the how informal housing – an emerging and wide spread typology in megacities like Mumbai contributes to heat stress in an urban area.

2 STUDY AREA

Mumbai has high density and heterogeneity of residential typologies. Among this heterogeneity of built typologies, there exist high percentage of informal housing in all areas of Mumbai. As evident from Figure 2, the slum clusters- a major type of informal housing⁴⁵⁴ has extended in almost every ward. More over some wards have about more than 50% of population residing in slum clusters. The slum clusters have basic facilities like electricity and water but lack acceptable housing conditions due to scarcity of space.

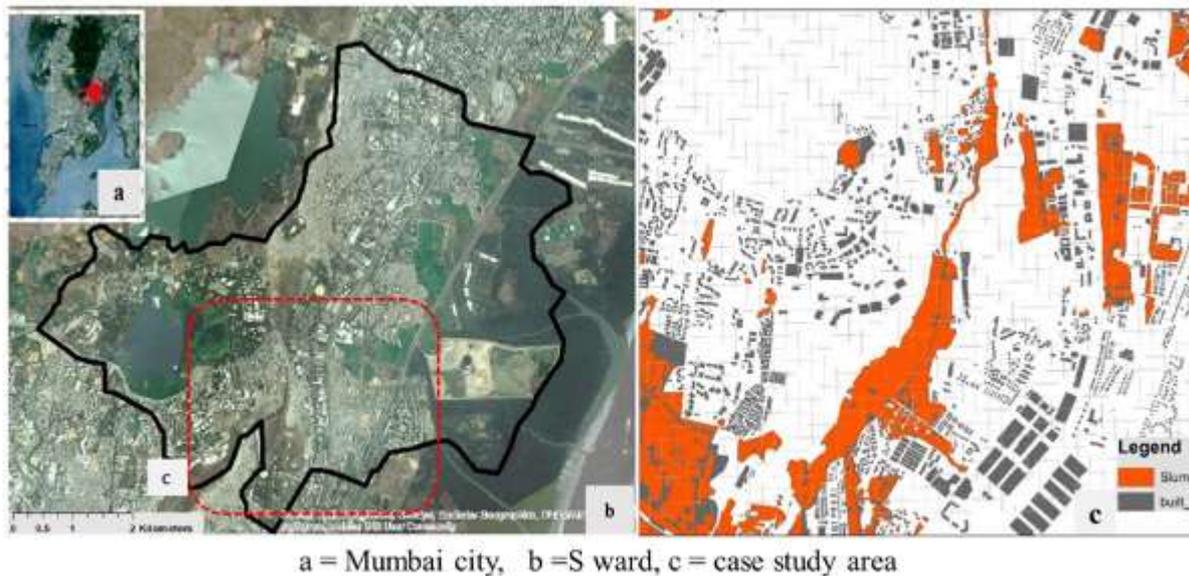

Figure 113: a, b and c showing case study area with slum and planned housing areas

Mumbai is chosen as a backdrop of the study and for detail investigations at local level a central part of Mumbai – ‘S’ ward is chosen. The study area houses a large percentage of informal housing along with a variety of built typologies. The ‘S’ ward has about 5,37,900 of slum population as per the Census (2011) which accounts to about 70% of the total population.

3 DATA AND METHODS

Thermal profiles in both formal and Informal built typologies were analysed at two different level of atmosphere, i.e. at above the surface of urban area and secondly at screen level using indicators in a stepwise manner. The methodological steps are explained below:

Step 1. Land use map of Mumbai is procured from MCGM and converted to GIS layers using ArcGIS 10.1. The residential areas were converted into slum areas and planned residential areas.

Step 2. Thermal satellite image- Landsat 8 OLI/TIRS is used to capture surface urban heat island (SUHI) on the surface of urban areas using land surface temperature (LST). Based on SUHI, hotspots of surface temperature forming heat islands are identified.

Step 3. Investigation of thermal characteristics at local level was carried out using sensor-based field measurements at multiple locations during both day and night time. Near ground air temperature was measured using environmental sensors, that measures micro-meteorological variables like ambient air temperature (Ta) and relative humidity (Rh) to out to identify heat -stressed areas in the urban areas.

Step 4. Spatial analysis is carried using ArcGIS 10.2 geo statistical tools. Inverse weighted distance (IDW) interpolation of Ta gave a continuous surface showing spatial and temporal variation of Ta. The association between the two housing typologies and LST were. Heat stress Index, an index of heat stress conditions was used to compare thermal comfort conditions at local level.

The flowchart of methodology is given below as Figure 4:

⁴⁵⁴ Informal housing includes identified, notified and illegal slum as per the census definition

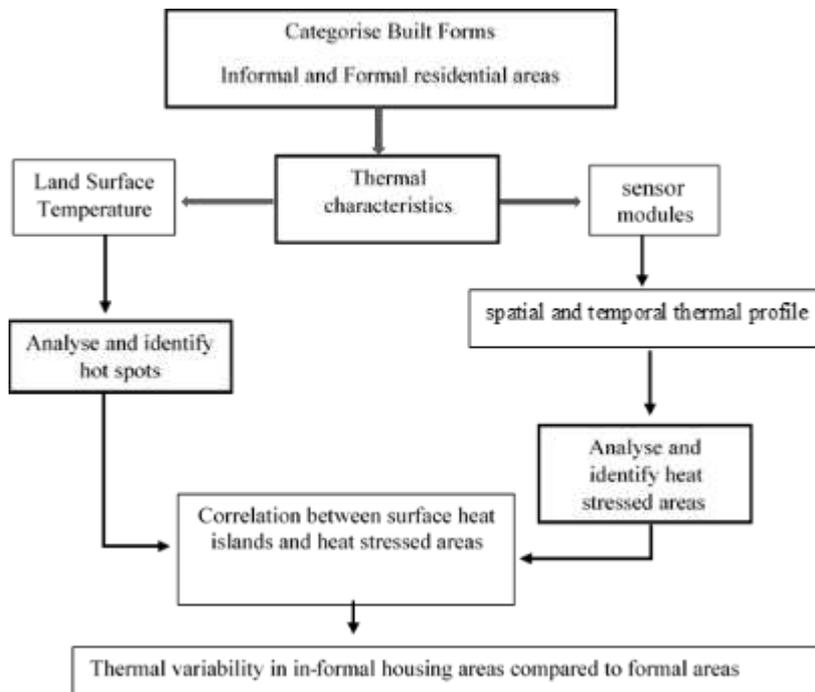

Figure 114: Methodological frame work

3.1 Preparation of LST

As shown in Figure 6, the heat stress profile is measured. The land surface temperature is computed using Landsat imagery of 2016 October for the city of Mumbai (Mehrotra et al., 2016). The emissivity-based radiative transfer methods are used to derive Land surface temperature using single channel (TIRS band) of the Landsat image. The brightness temperature is derived using radiative transfer equations, that measures top of the atmosphere (TOA) radiances from which blackbody temperatures are derived using Planck’s law (Li et al., 2013). Figure 7 shows LST of S ward captured at 30 m resolution and resampled into 100m grids for spatial analysis. Later to see spatial clustering of high LST, local Getis-ord spatial statistic is employed for the study.

3.2 Slum Area Demarcation

Urban residential areas both planned and informal areas – predominantly slum clusters are converted into vector format in GIS using Mumbai development plan 2034 (Municipal Corporation of Greater Mumbai, 2014). The Mumbai data was converted into grids of 100m x 100m for spatial analysis and analysed for s ward of Mumbai (see Figure 5).

3.3 Air temperature

To determine local level heat stress areas, environmental sensing instruments LSI heat stress meter and sensor modules that measures Ta and relative humidity (Rh) were placed at about 12 locations in built-up areas, both in formally planned areas having high-rise, mid-rise open, mid-rise compact housing as well as at two types of informal housing - slum and SRA, as shown in Figure 6 for the case study.

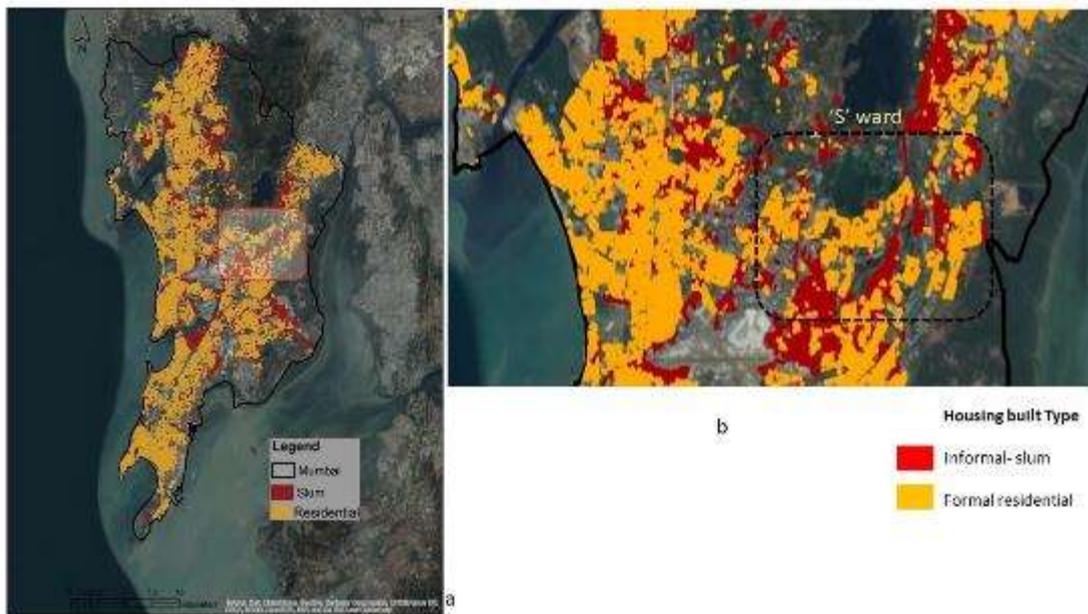

Figure 5: Mumbai residential and slum areas. Source: Municipal Corporation of Greater Mumbai (MCGM), 2014.

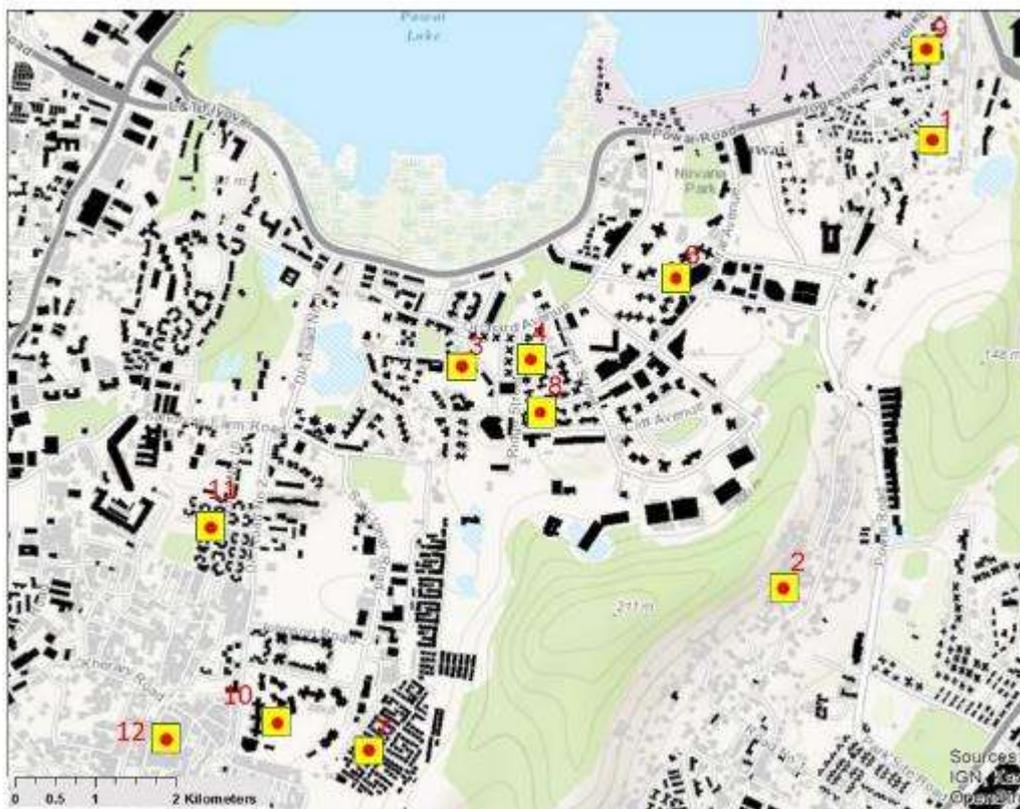

Figure 6: Placement of sensor modules in the study area.

Sensor instruments used in the study for monitoring air temperature were made by readily available off the shelf modules. For ease of handling, a low-powered, low-cost sensor unit for measuring temperature and humidity was made. The stand-alone prototype sensor module was prepared using a microcontroller (Arduino Nano v3.0 board) attached to two units of DHT22 humidity/temperature sensor operating at 3.3-5.5V DC with an accuracy of $\pm 2\%$ and $\pm 0.2^\circ\text{C}$. A Real Time Clock (RTC) (DS3231) for real time stamping attached to the microcontroller. DHT22 sensors are calibrated, digital sensors that give high precision data. Two sensors were placed in one module to improve accuracy. The sensor units are powered by a battery (3.7v 5000mAh Li-on battery) had the capability to log sensed data at the 10 minute frequency for about 30 days.

Deployment of the sensor at right location was carefully done such that effect of building parameters like height and distance between the buildings is accurately sensed and captured by sensor modules (Figure 6). To assess pedestrian level thermal comfort, the sensors were placed at a 2-meter height above ground as per the standards adopted in outdoor monitoring studies (Johansson, Thorsson, Emmanuel, & Krüger, 2014; Oke, 2004). The sensors modules are could be

easily mounted on poles or trees trunks and were shielded from the direct sunlight. Sensors were placed inside an inverted insulated material covering that allows free airflow across the sensors but shields from the direct sun. The data was collected from 12 number of sensors at 10 min frequency continuously for a week time and then analysed in ArcGIS for spatial variance.

3.4 Spatial analysis methods

Spatial analysis tools of ArcGIS 10.1 S/W is used to spatially identify the clustering of high surface temperature locations, signifying the heat hotspot areas using land surface temperature (LST) as indicator 1. Secondly, the air temperature data from the sensor data is used create spatial temporal hotspots in the study area using geostatistical tools in ArcGIS 10.2 ESRI software. Spatial variability of the air temperature was assessed for four-time periods of the day using Inverse distance weighted interpolation method (IDW) predicts values of non-measured locations assuming spatial autocorrelation. These time period indicate peak heating, peak cooling and transition time of the day. We have mapped the air temperature data obtained from 12 sensors at formal and informal areas (shown in Figure 6). The variance in two groups of housing is then analysed using above indicators.

4 RESULTS

4.1 Spatial clustering of High Land surface temperature (LST) - Indicator 1

To find clusters of high LST, Getis-ord G_i^* tool of spatial statistics tool (ArcGIS 10.1) is used. The Figure 7 below provides results of hotspot analysis showing z-scores, computed on LST data. Spatial map of z-scores and p-value tells where high or low clustering of features in space exist. This analysis indicates locations where high LST is surrounded by neighbours of high values of LST, just creating hotspot areas. For creating weights, inverse distance squared function is used. Local Getis-ord G_i^* is calculated as given in Equation 1 and S is given by Equation (2) and

$$G_i^* = \frac{\sum_{j=1}^n w_{i,j} x_j - \bar{X} \sum_{j=1}^n w_{i,j}}{S \sqrt{\frac{n \sum_{j=1}^n w_{i,j}^2 - \left(\sum_{j=1}^n w_{i,j}\right)^2}{n-1}}} \quad 1$$

$$S = \sqrt{\frac{\sum_{j=1}^n x_j^2}{n} - (\bar{X})^2} \quad 2$$

where, w_i is weight of attribute at j , \bar{X} is mean of X_j and w_{ij} is spatial weights between features i and neighbour j . G_i^* is the z-score.

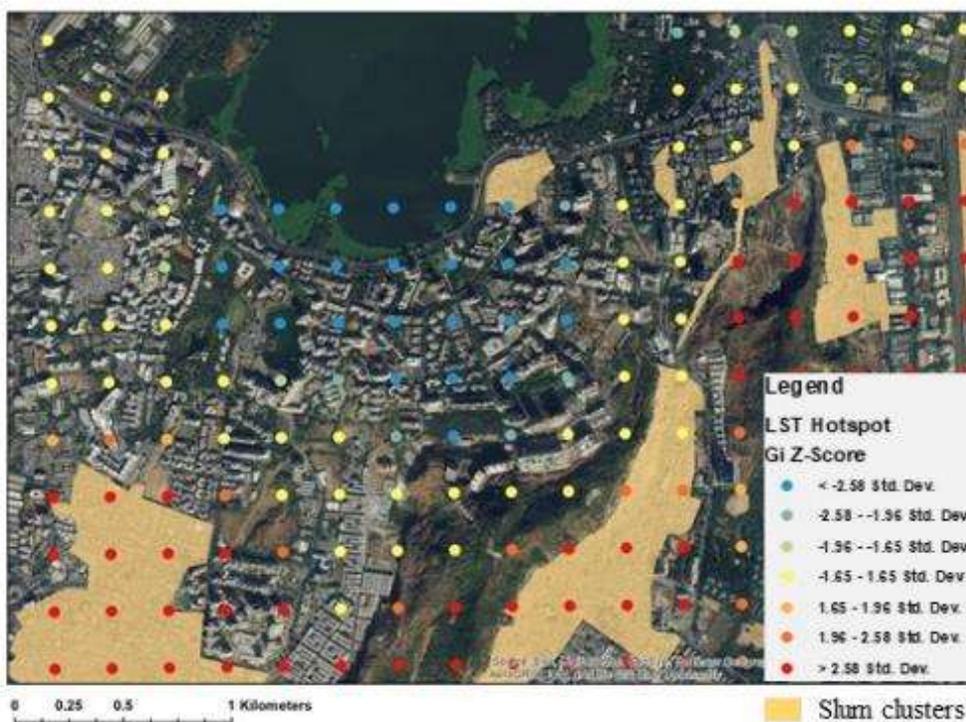

Figure 7: The clustering of high LST given by Gi Z score and slum clusters

The positive z-score with high values and low p-value indicate that there exist spatially statistically significant clustering or dispersion of LST. As observed from the analysis high Z- score were largely concentrated at slum housing areas (see figure 7). It clearly depicts that slum areas were correlated with the hotspot areas of LST.

4.2 Spatio- temporal variation of air temperature (Ta)

The IDW interpolation of Ta data, show spatial and temporal variation in Ta calculated for 12 am, 6pm, 6am and 12 pm hours. Ta undergoes diurnal variations, but for current study we have considered the heat stressed areas during a single time period for comparison with LST that captures image at 11:00 hours. The spatial data of Ta was converted to grids of 100 m resolution for correlation analysis. Morning hour Ta was considered to correlate with LST data. Figure 8 shows spatial patterns of two indicators of heat stress. The correlation between LST and Ta is depicted by scatter plot with shows a relationship of $R^2 = 0.65$ (Figure 9)

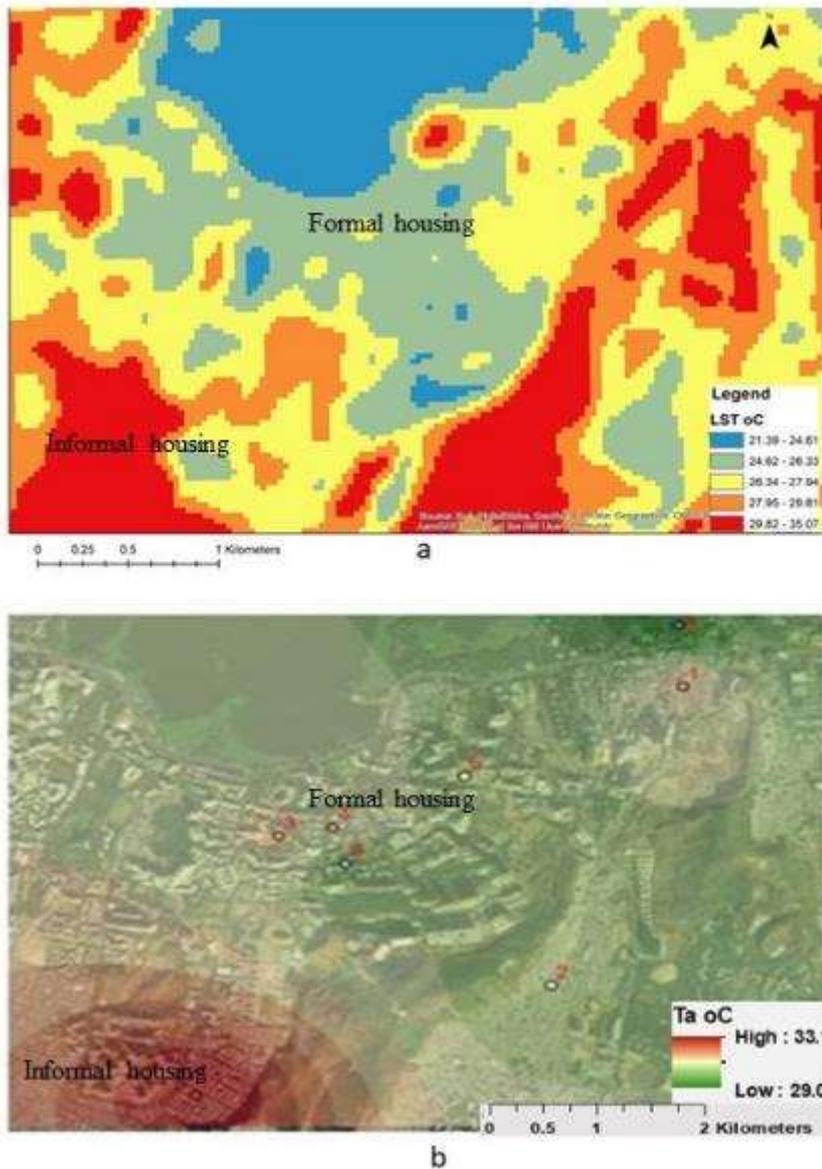

Figure 8: Hotspot areas of (a) LST and (b) ambient air temperatures (Ta) in the study area.

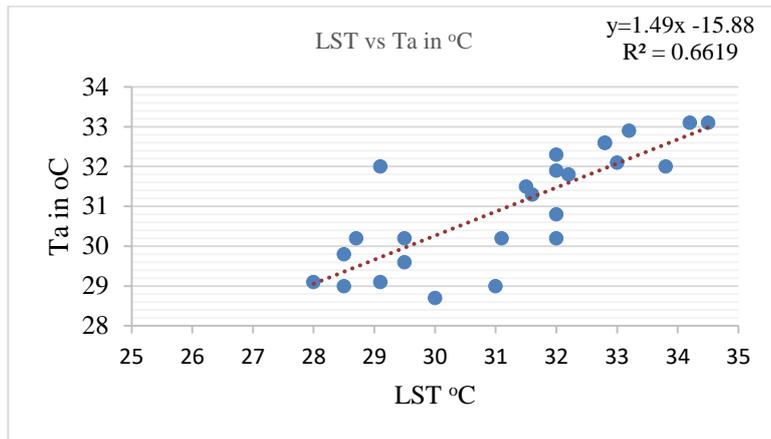

Figure 115: Scatterplot between LST (°C) and Ta (°C) at screen height (1.5 m)

4.3 Results and Discussions

The study presents results of spatial analysis of two thermal indicators: Land surface temperature (LST) and ambient air temperature (Ta), both representing different levels of urban heat stress areas. First indicator LST reveals a statistically significant spatial clustering of LST using Getis-ord z-score in Informal housing area. The figure 8 shows that grids of high LST clusters with high z-score coincides with the slum areas location.

Figure 9 shows LST values ranging from 21°C to 35°C. We found higher variation in LST compared to ambient air temperatures in the study area. The high LST range was found to be ranging from 29.3 °C to 35°C which could be attributed to variable forms of built area. LST was substantially high in Slum areas, which was assessed at 11:00 am, during the time of pass of satellite image.

Second indicator Ta revealed variable thermal profile in two housing groups at various time periods. Ta profile interpolated over the study area for day and night hours (12:00 hrs, 18:00 hours, 24:00 hours and 6:00 hours) show that hotspot of Ta varied in day and night hours. After 12:00 pm the formal areas were higher in Ta but after sunset Informal areas showed hotspots of Ta. From Figure 9, it could be inferred that hotspots of LST and high Ta is spatially concentrated in informal areas. Also, there exist LST difference between the formal and informal housing typologies which could be because of high variation in structure of two housing patterns. Ta profile also show hotspot over informal clusters that correlated with LST thermal profile.

Temporal variations in build typologies are extremely sensitive to environmental parameters. Sensor modules were able to capture the hourly variation for each typology. Slum areas were having high temperature during night time and early hours of the day due to trapped heat in the built form. The formal areas show high temperature during the day after 13:00 hours but cool down by night. And the hotspot moves from formal areas to informal areas during the night and early morning hours. Thus finding from this study is that through spatial analytical tools like hotspot analysis and spatial interpolation we can identification of distinct time-based hotspot areas and their spatial variance.

The form and type of built structure in informal housing is different from the formal housing. They have large impervious roof structures that have high heat retention capacity. This necessitates the need of appropriate policy interventions for improving the quality of economically backward class by providing affordable housing which is climate adaptive and resilient. In depth study regarding form of informal areas will be carried out as future extension of this work.

5. CONCLUSIONS

Results from the case study show that by using indicators of thermal profile at two different levels - LST and ambient air temperature, we could analyze the spatial thermal patterns of thermal heat stress. Also, the hot spots of LST and air temperatures obtained by spatial analysis emphasise on vulnerability of informal areas compared to formal areas. However, at local level we found high diurnal variability in air temperatures in built areas. The thermal variability was found to be low in slum areas, depicting long exposure to heat stress specially during the late hours of the day extending to early morning hours. The spatial non-stationary and scale-dependent relationships between built environment and thermal profile was accurately analyzed through spatial analytics. Although for better accuracy, no of sensors and locations should be increased for continuous monitoring of thermal environment. The correlation between LST and Ta was significant with $R^2 = 0.6$. However, a detail analysis would be required to build and validate the relationship between informal housing and LST. The study brings under our knowledge the thermal variations in informal areas compared to other areas of urban built up areas and how it would help to aid suitable policies for affordable housing, that adapts to climate change.

1423 MODELING THE RELATIONSHIP BETWEEN LANDSCAPE STRUCTURE AND LAND SURFACE TEMPERATURE - A CASE STUDY ON BARASAT MUNICIPALITY, WEST BENGAL, INDIA

ABSTRACT

Rapid urbanisation has hastened the conversion of vegetation and agricultural land to impervious surface, and engenders urban heat island (UHI) effect. UHI refers to the relative atmospheric warmth of a city in contrast to its countryside. At present UHI is considered to be a conspicuous problem of human civilisation. In the regions of humid climate like India, the development of heat island increases discomfort and potentially raises the threat of heat stress and mortality. It also has an impact on rising cost of air conditioning and the demand for energy. Land Surface Temperature (LST) is widely used to measure UHI effect. For sustainable urbanisation, evaluation of the complex interaction between the spatial structure of the landscape and LST deserves more research. This paper proposes an integrated approach to investigate and identify distribution-pattern characteristics of heat landscape by gradient analysis, landscape matrix and correspondence analysis. Landscape matrix and gradient analysis of thermal landscape were employed along the urban-rural transect. The influence of landscape structure on elevated LST has been recognised through correspondence analysis. In this paper, Barasat Municipality is taken as the study area. The area has experienced unprecedented urbanisation and consequent rapid environmental degradation during last few decades. For this work the land surface temperature at the pixel size of 30m×30m was derived from Landsat image. Landscape metrics and gradient analysis of heat pattern of the study area were computed by using GIS and remote sensing platform, FRAGSTATS, SPSS. We have selected few key landscape matrices which are effectively used to characterise the landscape spatial structure of the study area, including: patch density (PD), edge density (ED), mean nearest neighbour distance (MNN) and area weighted mean shape index (AWMSI). Correlation between landscape metrics and LST is analysed for both the class and landscape levels. As a major finding it has been observed that connected urban patches are positively correlated with higher LST neighbourhood values in the study area. Different landscapes along the transect exhibit diverse heat characteristics. From correspondence analysis it has been observed that high temperature type is associated with dense built-up and bare land. Medium temperature and low temperature types are allied with the rural land use categories. Heat pattern in the fringe area exhibits a complex relationship resulted from the existence of mixed land use.

1462 DOES ISTANBUL ENVIRONMENTAL PLAN CONTRIBUTE TO URBAN RESILIENCE?

ABSTRACT

Metropolitan areas and cities are threatened by external shocks such as; economic crisis, natural disasters, climate change, terrorism, etc. Those uncertain externalities are the main challenges of cities. The impacts of threats and risk should be reduced to sustain a safe environment for citizens and viability of the city system. Therefore, cities and metropolitan areas should be evolved into more resilient structure and prepared for the threats. Increasing resilience of cities is important to avoid being under continuous threat and vulnerable to any external shocks. The critical part is defining the strategic roadmap to more resilient structure. Istanbul is the biggest metropolitan city of Turkey with more than 15 million citizens. It has a critical role for the country in terms of cultural, historical, social and economic aspects. Therefore, the resilience of Istanbul is an important issue that should be considered comprehensively. This paper discusses the context and decisions of Istanbul Environmental Plan in terms of whether it contributes to more resilient urban structure. In this context, the resilient city framework that suggested by Jabareen (2013) have been conducted. Jabareen tries to answer the question of “what cities and their urban communities should do in order to move towards a more resilient state in the future” and defines the conceptual framework for resilient city and resilient community by his study. That conceptual framework has been the basis for this study. Istanbul Environmental Plan has been examined within 4 concepts as defined by Jabareen; “Urban vulnerability matrix analysis, Uncertainty oriented planning, Urban governance and Prevention”. This study investigates whether the plan includes the resilient city key measurements defined under those 4 concepts and how the plan decisions have considered resilient development. This paper has addressed the question whether Istanbul environmental plan context and decisions contribute to urban resilience. Through considering the resilient city framework, expected results of this study are to distinguish missing parts of plan regarding urban resilience and to determine issues to be more emphasized. It is critical to evaluate the environmental plan considering the resilient city framework in order to make more accurate and effective decisions for future plans at national and local scale.

SS09.3. Analytical Approaches to Climate Change at Multiple Scales

1608 THE ECONOMIC IMPACTS OF CLIMATE CHANGE ON AGRICULTURE IN TURKEY

ABSTRACT

Many regions are under various forms of climate related stress (e.g., drought, floods, rainfall variability, etc.) that coupled with low adaptive capacity, make them highly vulnerable to climate change. The Mediterranean Basin is one of the most vulnerable regions in the world to the impacts of global warming. The sectorial and regional analyses show that the impacts of climate change spread across all sectors and all regions, nevertheless the largest negative consequences are found in the health and agriculture sectors and coastal zones. Being located on the Mediterranean Basin, Turkey is one of the most affected countries from the climate change. The estimated impacts of climate change in Turkey are: (i) an increase in temperatures – 2oC increase in the next 50 years according to the best scenario –, (ii) a decrease in precipitation – an approximately 20% decrease – and therefore; (iii) an inevitable drought. The changes in temperature and precipitation are expected to have severe impacts especially on the agriculture sector which is one of the most important economic sectors in Turkey. This paper analyses the economic impacts of climate change in Turkey with a particular focus on agriculture sector. In order to assess the economic impacts of climate change, Computable General Equilibrium (CGE) Model is employed. By this model; different socio-economic structures and different exposures of climate change effects at regional level are compared and the projected economic impacts are visualized for the future development alternatives. Finally, strategies and policy choices for climate change adaptation and mitigation are discussed and the challenges are highlighted. The study reveals the inevitable economic impacts of climate change on the agricultural economy, fills the gap of scientific researches on climate change in Turkey and enlightens the strategic path towards a more resilient future by addressing adaptation and mitigation policies.

1633 MAPPING REGIONAL DICHOTOMY OF GREEN GROWTH: 175 GW RENEWABLE CAPACITY & INDIAN STATES (E3-INDIA SESSION)

ABSTRACT

The paper evaluates dynamics of change across regional boundaries as India adds 175 GW of grid connected renewables by 2022. The decision to transform energy mix also brings with it concerns of distributional impacts across Indian states given the geographic availability of conventional resources (i.e. coal is available mostly in five eastern states while renewables more prevalent in the western and southern states). The analysis compares and contrasts sustainability impacts of meeting designated state-level targets for renewable capacity additions in three (Gujarat, Madhya Pradesh & Jharkhand) distinctly positioned states i.e. i) High renewable energy generation (RET) capacity state ii) Coal Bearing State with high RE capacities iii) Coal bearing state with low RE capacities using E3- India model. The model provides an integrated evaluation of economic, energy and environmental linkages dynamically using a macro-econometric framework at the state level for India. This not only allows estimation of crucial energy and environmental indicators but also bring in state specific economic structures within the assessment framework. The assessment mapped economic and social indicators like GDP, investments, employment and real personal income along with environmental benefits of renewable capacity addition in terms of reduction in emissions (CO_x, NO_x, SO_x) at the state level. Preliminary results reveal that under Business as Usual scenario the existing RET targets will have strikingly different manifestations for the three different categories of states. Fulfilling the existing renewable energy technology (RET) deployment targets can induce GDP growth of over 6.01 % in coal bearing high RET capacity states like Madhya Pradesh, it may also lead to decrease in GDP for a coal bearing state like Jharkhand due to reduction in coal use. While in high RET state like Gujarat indicates moderate GDP increase. Similarly, investments, employment generation and personal incomes due to RE capacity addition are higher in Madhya Pradesh and Gujarat as compared to Jharkhand where RET capacity installation is low and backlash of idled capacities is significant due to overall reduction in coal consumption nationally (30%) with 175 GW of new renewable addition. The results of the study highlight the existing dichotomy in the Indian green growth agenda from a spatial and sustainability perspective. The work also demonstrates relevance of an integrated quantitative assessment framework like E3-India to analyse distributional impacts of an existing policy target at regional level thereby enabling and informing various stakeholders for suitable policy interventions. 1714 CLIMATE CHANGE DISPLACEMENT: SPATIAL-DYNAMIC MODELING OF OCCURRENCE, EFFECTS, AND ADAPTATION

ABSTRACT

In the coming decades, climate change displacement of residents of coastal communities in the United States and other countries is likely to affect large portions of national populations. Estimates of sea-level rise are constantly being revised upwards and it is not clear that strategies proposed to make coastal areas more resilient to coastal flooding—including sea walls of various design—will be effective. Clearly, both short-run and long-run response strategies are needed. (See Donaghy, 2017.) Not only physical attributes of communities but also social, political, and economic institutions of communities must be relocated to higher ground. A major concern is that in making current assets more robust to the effects of climate change and in relocating communities a form of ‘climate gentrification’ may be effected and existing inequalities of access to public amenities and safety from extreme weather events may be reproduced or exacerbated. Given the failure of climate change mitigation strategies (for a large number of reasons, many of which are political) the challenges to the regional science community include 1) developing reliable projections of sea-level rise, coastal flooding, and extreme-weather event incidence; 2) working out social, economic, and environmental impacts of climate-change-related effects, 3) exploring response strategies that are effective in the short run but which put communities on the ‘right paths’ in the long run. In this paper I review existing sea-level-rise response programs for several large east-coast U.S. municipal areas, review adaptive response plans for extreme-weather events, sketch a spatial-dynamic integrated assessment model for supporting adaptive response planning over the short- to long-run planning horizons, and demonstrate the appropriateness of the model with proof-of-concept simulations and assess its performance properties. Donaghy, K.P., 2017, “Making an Integrated Assessment of the Boston Harbor Barrier Proposal,” presentation made to the School for the Environment, University of Massachusetts at Boston, April 14th.

SS10.1. Rural Transformation

1006 HOUSEHOLD DIETARY DIVERSITY SCORE AS FOOD SECURITY MEASUREMENT: THE CASE OF MAIZE FARMERS PARTICIPATING IN BUFFER STOCK OPERATIONS IN GHANA

ABSTRACT

Food security is not only a development issue but in recent years it has become a human right issue as well. The right to an adequate standard of living and well-being implies that every individual has the right to freedom from hunger and adequate food. Food security is an essential measure of welfare, especially for low-income families in developing countries. Policy makers are aware of the harm food insecurity has on vulnerable households (Magan- Lemus and Lara-Alvarez, 2015). As a multi-dimensional concept, several indicators and approaches to measuring food security has evolved over the years. The implementation of agricultural output price support through the National Buffer Stock Program in Ghana is not only to stabilize food prices but to also to improve the food security status of the farmer’s household. This paper employs the household dietary diversity score (HDDS) as a proxy for measuring household food security status of the rural farmer in Ghana. We use cross-sectional data from 305 rural households from maize growing communities both from the policy on and policy off areas of the country by way of multinomial logistic regression and the Blinder- Oaxaca Decomposition technique to analyze the determinants of HDDS and the effect of the program on household’s food security. We find that marital status, sex of the household head, household size, access to fertilizer and irrigation facilities, and engagement in off farm activities are the determinants of HDD. We also conclude that buffer stock operations have had positive impacts on the rural household’s dietary diversity score. The findings suggest that investment in rural infrastructure such as warehouses for capacity improvement of the buffer stock operations can effectively enhance the food security of rural farmers. Policies that are targeted to addressing food security should not only focus only on agricultural activities but also on non-farm economic activities that have the potential to increase the income of the rural household. Therefore, programs that target food security could be implemented as an integrated program to include both agricultural and off-farm livelihood activities in a bid to transform rural Ghana.

1076 PEASANTS' INCOME DIVERSIFICATION AND COPING STATUS: A CASE OF NORTHWESTERN BANGLADESH**Md Shafikuzzaman Joarder**

University of Rajshahi, BANGLADESH

ABSTRACT

Considering the agricultural 'optimistic' and 'skeptical' views, peasants' income diversification is an autonomous and reactive process as some of them are drawn to it while others are forced. The peasants of Bangladesh, to whom agriculture acts more as a source of food and labor than that of growth, are facing substantial challenges to secure their livelihood from a single source of income. From a skeptical point of view, evidence shows that the sole reliance on farming sometimes makes the peasants' livelihood fragile if production fails or they face a deficit in returns from production due to climate variability, volatile market, lack of access to services, unfair tenancy arrangements and so on. Consequently, they are likely to give immense efforts to earn more from different off-farm sectors to avoid chronically insufficient farm income and to cope with challenges. Some of them also apply different cropping strategy to ameliorate their capability for future investment. To investigate further of the association between incomes and coping, the study purposively selected two villages from a drought-prone northwestern Bangladesh. All the households occupying 0.2 ha to 0.40 ha of farmland (56 and 47 from Babupur and Haripur villages respectively; 103 in total) were interviewed by a questionnaire survey. Qualitative tools were also applied to get insight into the socio-historical context of the peasants' livelihood. Findings show that drought and climate variability reduced crop production of 69 percent of the respondents. About 70 percent of the respondents stated that they experienced seasonal unemployment of two to three months each year while 88 percent of them reported that their input costs for cultivating crop stepped up significantly in comparison to the return. Responding to these different constraints, peasants diversified their income sources in many informal sectors including changing of cropping pattern. According to the study, the off-farm sectors contributed more than half of the respondents' total household incomes. Animal husbandry was the most preferable activities under this sector followed by wage employment and fishery. Transformation of paddy field into mango orchards also got high preference among some of the peasants having limited irrigation facility. Some of them found this transformation process as an opportunity in the agriculture sector to step up their income. Despite taking various strategies, 88 percent of peasants earned less than US\$ 2 per capita income. It indicates a high rate of poverty among peasants. As a result they descended far behind to cope with different constraints while 34 percent of peasant households coped partially. Coping moderately was claimed by 16 percent of the respondents. Only 10 percent of households acclaimed successful coping. Avoidance coping strategies i.e., reducing food intake, taking loans or selling household assets and labor in advance undermined the further coping ability of many peasants. Livestock rearing and transforming crop-field into mango-orchard, however, showed a positive association with successful coping. The mango cultivation, however, has an investment cost as it usually takes 3 to 5 years to give return. Many resource poor peasants cannot afford the cost of this transitional period. Overall, the study shows that multiple sources of income may enhance resilience of the peasants to different shocks at some extents. But, they are not strongly tied up with the investment capacity of the peasants for their future welfare.

Key words: Peasants, livelihood, income diversity, coping.

INTRODUCTION

The nature, social bases and socioeconomic consequences of peasantry were among the most longstanding foci in rural sociological research that received a substantially increased attention and exhibited considerable theoretical reformation in the 1970s and 1980s in many countries (Buttel *et al.* 1990). However, 'peasant as a concept' is still complicated because it's contentious history. In many parts of the world the word 'peasant' used to imply criminality, villain, rustic, devil, robber, brigand or looter (Edelman 2013). In general, it is often referred to poor and landless farmers and agricultural laborers who have low social status (Webster 1926). These derogatory meanings indicate both of peasants' extreme subordination and of a ubiquitous elite practice of blaming peasants for a variety of economic and social ills. From a social point of view, peasants are always treated as a subjugated community in most part of the world (Freedman 1999) because of their lower strata and position in the social, political and economic hierarchy (Singharoy 2004, Shanin 1971, Wolf 1966). In Bangladesh, the peasants have paradoxical social identities over times. Beteille (1974) defines peasants of Indian subcontinent from three major perspectives, such as (a) they are attached to land either as owner, tenant, or sharecropper (b) they occupy a lower economic and political position in the society, and (c) oppression and exploitation of the peasants have a political dimension. Many scholars indentify them as rural cultivators, for whom subsistence agriculture is the most important means of livelihood (Sivakumar and Hansen 2007, Schüren 2003, Bernstein *et al.* 2003).

Historically, the peasants accomplish a major share of their entire livelihood from agriculture which is highly sensitive to weather, climate variability and availability of water (Wreford *et al.* 2010, Salinger *et al.* 2005). Bangladesh as being one of the most vulnerable countries in the world (Ericksen *et al.* 1997) suffers more in this regard as the pace of technology generation, innovation and adoption do not allow her to counteract effectively to the adverse effects of varying environmental conditions. A well-functioning market, however, can shape livelihood of the farming community through many avenues, including generating their incomes (Rapsomanikis 2015). But, seasonal price fluctuation of major food grains is a serious concern for Bangladesh economy (Chowdhury and Haggblade 2000, Dorosh 2000 and Chowdhury 1992). The farmers experience seasonal variation in prices — lower prices during the immediate post-harvest months and higher prices during the pre-harvest or off-season months each year (Salam *et al.* 2012, Dorosh and Shahabuddin

2002). The peasants usually sell out major share of their production immediately after harvesting as they run out of money whereas they have to buy rice during off-peak season in high price. 'Distress-sale' is another important aspect that represents the vulnerable situation of the peasants in which they are forced to sell their product or labor in advance or at a very low price if they face income shortage. More to the point, land-tenure system also has a major impact on agricultural productivity of the peasants. About forty percent of farmland in Bangladesh is cultivated under different kind of tenancy arrangements (Taslim 1995). A significant number of the tenants are peasants. These tenants hardly have any say in the arrangement of contracts because of their lower position in the society and their fear of eviction from farmland.

Overall, they face prodigious challenges to get access to service and resources, and are more vulnerable to the market and vagaries of weather since a long. They get limited assistance from development agencies to cope with this kind of constraints as their problems and voices can easily be ignored. Besides, a number of changes have taken place in recent economic and agricultural sectors of Bangladesh, so are in the peasants' livelihood. Evidence shows that the share of agriculture to gross domestic product (GDP) of Bangladesh had fallen sharply from 55 percent in 1970 to 16 percent in 2015. In contrast, the total population of the country shot up from 71 million to 160 million (nearly 2.5 times higher) during the same period. Consequently arable land per person had decreased from 0.128 hectares (ha) in 1975 to 0.049 ha in 2013. However, the country had made its gross national income (GNI) doubled from US\$ 540 in 2005 to US\$ 1212 in 2015 (World Bank 2015). A precipitous fall in contribution of agriculture to GDP does not necessarily depict that the importance of agriculture is also declining. Recent data depicts that the largest proportion (45.1 percent) of the employed population of Bangladesh is engaged in agriculture sector. If we count the informal sector employment, then agriculture counts nearly 90 percent of rural employment generation (BBS 2015). For the majority of people living in rural Bangladesh agriculture is not all about growth, but its importance is embedded in employment generation, food production as well as in a total livelihood system of the society. Agriculture and agriculture centered economy have always been the dominant and an integral part of rural and national economy. The country has made significant progress in different sectors including agriculture, but a crucial concern arises here, whether this development has empowered the farmers or peasants similarly or not. In reality, the benefits of the development hardly have percolated to the peasant community over the last few decades. They suffer from low level of resources that can be used for the productive sectors further. Fundamentally, as Madalgi (1969) stated many years ago, the emergence and growth of small farmers or peasants are still mainly the result of population pressure and lack of employment opportunities outside farming. Hence, the recent trends of changes in economic structure, employment sector and living standard of the country show that the agriculture sector alone is unable to provide a secured income to maintain a sustainable livelihood especially of the people who depend on agriculture at subsistence level and for whom poverty is defined by their economic and political marginalization. Thus, the peasants, to whom agriculture acts more as a source of food and labor than that of growth, face an increasing need of looking for alternative income sources to supplement their small scale agricultural activities (Yizengaw *et al.* 2015, Khatun and Roy 2012, FAO 2001) and to hedge against social, climatic and other market risks. As an immediate response they employ a diverse set of activities to explore their income opportunities at various levels outside crop cultivation. Most of the cases, they engage them in wage employment and animal husbandry if they face income constraints due to seasonality, or face a deficit in return from agricultural production. Some of them also change their cropping patterns. As Ellis (2000) indicated, the peasants diversify their income sources to construct an increasingly diverse portfolio of activities and assets in order to survive and to improve their standard of living. Ellis also noted that there were two opposing theories regarding the actual driving force that causes the emergence of rural livelihood diversification — the 'agriculture optimistic' and 'agriculture skeptic' theories. Agriculture optimist stance is related to the emergence of diversification as a result of success in agriculture while the agriculture skeptic view sees diversification as responding to the failure of agriculture to generate secure livelihoods for those in rural areas. Both the views are basically derived from success and failure of agriculture. Reardon *et al.* (1992), however, found diversification process as a self-insurance by which individuals mitigate their risk exposures eventually. But, the major difficulty to analyze peasant economy is the inseparability of economic functions within a peasant household (Hayami *et al.* 1978). There are many reasons inducing income diversification out of farming. Sometimes diversification is born of desperation, sometimes of opportunity. Some diversifications are related to low-return from labor or land due to market failure, unfavorable tenancy arrangement and climate change. Still, some are attributed to frictions for mobility or to entry into high-return niches. Besides, diversification of income does not necessarily ensure better income and successful coping. Coping refers to the specific efforts that people employ to master, tolerate, reduce, or minimize stressful events, and it requires continuing awareness, resources and good management, both in normal times as well as during crises or adverse conditions (UNIDR 2009). In general, there are two types of coping strategies such as (i) active coping strategies and (ii) avoidant coping strategies. Active coping strategies are thought to be better ways to deal with stressful events, whereas avoidant coping strategies appear as adverse responses to stressful life events (Holahan

& Moos 1987). With limited resources in hand, the peasants are always in harsh position to cope with constraints. Dercon (2009) stated that lack of human capital, limited access to infrastructure, market and technologies sometimes put smallholder farmers to pursue more subsistence-oriented activities that ultimately causes smallholders' poverty to persist.

Hence, the study intends to understand the peasant livelihood from a sociological point of view, and to investigate the pattern of income and coping strategies among the smallholders, and in what extent(s) they are associated.

METHODOLOGY

The study is exploratory in nature and was conducted in August, 2016. Primarily Sapahar upazila of Naogaon district was selected purposively after carefully reviewing the poverty and drought maps of Bangladesh as developed by the World Bank⁴⁵⁵ and Bangladesh Agriculture Research Council (BARC)⁴⁵⁶ respectively. At the second stage, two adjacent villages namely Babupur and Haripur from Tilna union of Sapahar were selected based on the secondary data collected from the department of agriculture extension office and consultation with the agriculture extension workers of Sapahar upazila. The study also considered the fact that the majority of households of the villages would be engaged in farming or crop cultivation. Household was the unit of analysis, and household heads were interviewed as respondents. Peasant household is considered as the marginal or small farmer whose primary occupation is farming, and depends on agriculture at subsistence level. The study used BBS's classification in identifying marginal and small farmers based on their ownership of farmland. According to BBS 1986 marginal and small farmers occupy 0.2 ha to 0.40 ha of farmland respectively (quoted in Orr *et al.* 1995). Hence, all the marginal and small farmers from two villages (56 and 47 from Babupur and Haripur villages respectively; 103 in total) were interviewed by making personal visits to the selected peasant households with the help of structured questionnaire. To identify all the marginal and small farmers, the study collected a baseline survey report of 2014 and secondary data from a local NGO (Dabi Moulik Unnayan Sangstha of Naogaon, Bangladesh) working in the villages, and from upazila offices respectively. The questionnaire is mostly closed ended for taking the advantage of analyzing data with ease, and to collect data in a shorter period of time. It was divided into three sections. The first section dealt with the basic demographic information of the respondents while section two was for collecting data on different income sources at household level. Income in this paper is defined as the cash or cash-equivalent yield from a peasant household's assets. It is typically classified into three groups by its sources, such as (i) income from crop cultivation, (ii) off-farm income and (iii) income from current transfer from non-government organizations or/and government organization. The categorization of income sources is adapted from income diversity as classified by the International Labor Organization (ILO 2004, Quoted in Canberra Group Handbook 2011⁴⁵⁷). The sum of income from the farm and household production of services for own consumption is referred to as income from crop cultivation. The terms 'off-farm', 'non-farm', and 'nonagricultural' appear routinely and in seemingly synonymous ways. However, there are some differences in opinion regarding the issues 'off-farm' and 'non-farm' income. One controversial point is whether non-farm means only non-agricultural activities or whether it should refer to all non crop activities (Bakht 1993). Makita (2007) stated that if the non-farm is regarded as the same as the non-agricultural, the non-farm sector does not include homestead-base agricultural production (e.g., raising vegetables and fruits) and other non-crop agricultural production such as raising livestock and poultry, fish cultivation, sericulture, apiculture and silviculture. However, some argue that wage employment in the agricultural sector can be considered in agricultural income. But, according to Haggblade (2002) off-farm income includes agricultural wage employment in other's farm along with all other activities outside agriculture. In classifying income of rural households, Ellis (2000) also includes labor as off-farm income. Thence, the study includes wage employment (either in agricultural sector or other sector), petty business, handicrafts, rickshaw-van pulling, construction works etc. under the off-farm income activities. Transformation of agriculture to mango orchard is a unique characteristic of the study area. Plantation, harvesting, management and marketing strategies of mango farming are somehow different from that of traditional agricultural practices. So, it is also taken under the off-farm income. Precisely, off-farm income is meant in this study as the income from all other activities outside crop cultivation and current transfer received. Current transfers are receipts that the peasants get from government organizations (GO) and/or nongovernment organization (NGO) under safety-net programs at regular intervals, and for which they don't give anything to the donor in direct return for the receipts. 'Total income' is the sum of the income from production, off-farm income and transfer income.

The third section focused on major exposure to risks of the peasants and their strategies for coping. The term 'coping' refers to the strategies that are medium-term ex-post strategies in response to unanticipated failure in major resources necessary to make ends meet (Zoomers 1999). Since there is a little data on strategies taken by the peasant community of rural Bangladesh to counteract different vulnerabilities and that can be classified as adaptation strategy, the study uses 'coping' as strategies taken by the peasants to overcome constraints for shorter to relatively longer period. Both erosive and non-erosive coping strategies are considered at different stages to classify the status of coping of the peasant community. Overall, the capacity to cope is the capacity to respond to, and to recover from stressful events. By coping, the study refers to actions that peasant households take to deal with income constraints resulting from drought/climate variability, volatile/erratic market, unfavorable tenancy arrangements and seasonality. Respondent's perception regarding his position of coping was categorized in five scales, i.e., (i) failed to cope – the condition of the household is deteriorating as they are cutting of food intake substantially, loaning shark and locking into debt, selling both productive and non-productive household assets, and depending on aid; (ii) neither failing nor succeeding – socioeconomic status did not change much; (iii) coping partially – households that minimize risk and loss at small scale, compromise with food intake at minimum level, sale stack rarely; (iv) coping moderately – enhanced income or asset base of the household at such a point that is potential for further development of the household, but had to compromise with some aspects; and (v) coping successfully – households gain potentials for adaptation.

Besides, a total of four group discussions and key informant interviews with different stakeholders were conducted to collect information on income diversity, socioeconomic constraints and coping strategy. Both quantitative and qualitative

techniques were applied to analyze the field data. At first data were processed with SPSS software by using simple statistical techniques. Then, the quantitative data were analyzed through frequency distribution tables and chi-square tests. Different descriptive statistics such as frequency analysis, cross tabulation, graphical presentations and Pearson chi-square test were applied to analyze data. Qualitative data collected through group discussions and key informant interviews by using ‘qualitative analysis’ technique in which data are examined and interpreted non-numerically (Babbie 2013) through a narrative approach (Lichtman 2014) and analytic description (Warren and Karner 2015).

RESULTS AND DISCUSSIONS

Pattern of total household income and its sources

Considering sector-wise contribution to the total household income, it is observed from table 1 and figure 1 that all 103 peasant households produce crop for market and get about 33 percent of their total income on an average. The income ranges from 50 thousand taka (US\$ 625 @ 1 US\$ = 80 taka) to 237 thousand taka (US\$ 2962.5). All the respondents but four produce for their own consumption also. The market value of the household consumables contributes nearly 13 percent to their total income. In total, crop cultivation generates 46 percent of total household income.

Off-farm income sector contributes substantially to the total income of the peasant households. It constitutes more than half of total household income (52.38 percent). Findings show that households with little farmland depend heavily on off-farm employment for their livelihoods. Especially the marginal farmers seek employment in the rural off-farm sectors to add to their chronically insufficient farm income. Off-farm employment typically includes animal husbandry, fruit gardening, fishing, tailoring, engaging in petty business etc. Animal husbandry is the most preferable activities under the sector. It not only provides food and animal protein – meat, milk and eggs for sale or home consumption – but also yields manure for use as fertilizer. Oxen are used for tillage as well. In addition, livestock are assets that can be sold in emergencies to provide essential cash. Peasants in the study area are more likely to keep poultry, sheep, goats and cattle. A total of 96 (93 percent) respondents are engaged in livestock and poultry rearing. In calculating income from animal husbandry, the study has considered the consumption of meat and milk at household level, as well as the earnings from selling of livestock and poultry. The average income from livestock or poultry rearing is about 23 thousand taka that ranges from 5 thousand to 83 thousand taka. It depicts that small-scale livestock husbandry is very common among the peasant households. On the other hand, 55 percent respondents have changed their farmland into mango orchards and get nearly 48 thousand taka on an average. There are 44 households (43 percent) who earn their significant share of income from wage employment. The income ranges from 9 thousand to 90 thousand taka. Fishery is also preferable among 30 households (29 percent) followed by petty-business (11.7 percent) and van-rickshaw pulling (10.7 percent). Only 8 households get salaried income. The peasants get nearly 1.6 percent of their income under different safety-net programs implemented by the government and non-government agencies. Overall, the analysis reveals that peasant households are getting their income from a diverse set of activities. However, crop production as a single source still contributes majority of the total household incomes.

Table 1: Total household income and their sources of the peasant households

#	Income components	N	Minimum	Maximum	Percentage	Mean (in BDT)
1	Income from Crop Production					
1a	Return from crop production (production for market)	103	50000	237000	33.40	55310

(Source: field study 2016)

Table 2 compares the different types of income group in two villages. Annual household income is categorized into five groups. The table shows that nearly 53 percent of the total households earn less than 150 thousand taka yearly. A total of 17 households (16.5 percent) earn in between 150 thousand to 200 thousand taka, while 9 households earn 200

thousand to 250 thousand taka. A total of 22 households are earning over 250 thousand taka. On the other hand, annual household income less than 100 thousand taka comprises more in Babupur (15 out of 23).

Table 3.3: The distribution of income groups in the study villages

Annual Income Classification (in thousand taka)	Village Name		Total
	Babupur	Haripur	
50 to < 100	15 (26.8%)	8 (17.0%)	23 (22.3%)
100 to < 150	16 (28.6%)	16 (34.0%)	32 (31.1%)
150 to < 200	8 (14.3%)	9 (19.1%)	17 (16.5%)
200 to < 250	5 (8.9%)	4 (8.5%)	9 (8.7%)
More than 250	12 (21.4%)	10 (21.3%)	22 (21.4%)
Total	56 (100.0%)	47 (100.0%)	103 (100.0%)

(Source: field study 2016)

Table 3 depicts that about 41 percent of the households are having per capita income of less than 80 taka (US\$ 1.0). These households are certainly living under the poverty line. Per capita income from 80 to less than 120 taka accounts for about 27 percent households. In both cases, most of the households are from Babupur. In contrast, the percent of earning more than 120 taka per person per day cuts high in Haripur. A total of nine households have per capita per day income of 160 to less than 240 taka. Seven out of these nine households are from Haripur. The numbers of peasant households having more than 240 taka per capita income are shared among two villages. Overall, nearly 88 percent of the peasant households have less than US\$2 per capita income, that in turn indicates a high rate of poverty among peasant households.

Table 3: Per capita income of the peasant households

Per capita income (per person per day)	Village Name		Total	Cumulative figure
	Babupur	Haripur		
less than 80 taka (Less than US\$ 1.0)	27 (48.2%)	15 (31.9%)	42 (40.8%)	42 (40.8%)
80 to 120 taka (US\$ 1.0 to less than US\$ 1.5)	16 (28.6%)	12 (25.5%)	28 (27.2%)	70 (68.0%)
120 less than 160 taka (US\$ 1.5 to less than US\$ 2.0)	9 (16.1%)	11 (23.4%)	20 (19.4%)	90 (87.4%)
160 to less than 240 taka (US\$ 2.0 to less than US\$ 3.0)	2 (3.6%)	7 (14.9%)	9 (8.7%)	99 (96.1%)
More than 240 taka (More than US\$ 3.0)	2 (3.6%)	2 (4.3%)	4 (3.9%)	103 (100.0%)
Total	56 (100.0%)	47 (100.0%)	103 (100.0%)	-

Pattern of secondary occupation of the respondents

In many parts of rural Bangladesh, full employment is achieved through the introduction of high yielding variety (HYV) or *boro* cultivation and by expansion of irrigation and technological facility. But the study area is prone to drought and has partial irrigation coverage. The farming community, especially of Haripur village usually depends on the rain-fed *aman* crop. Considering a whole year employment it is revealed from the group discussions that the peasants face a slack or lean period of 2 to 3 months each year. It ultimately generates seasonality in livelihoods of the peasants, eventually uneven income flows disrupts continuous household consumption needs. Findings show that the most serious problem facing peasant households remains how to cope with agricultural slack seasons. The off-farm income sources, however, play an important role in livelihood management during this slack period. The major concern is whether peasant communities can overcome seasonal fluctuations by involving them in a number of non-crop production sectors.

With little productive capital, marginal and small farmers depend on off-farm unskilled agricultural labor far more than their larger counterparts. The smaller the farm is, the higher the share of wage employment in household income. Figure 3.4 shows that nearly 30 percent of the total respondents do not have any secondary occupation, and most them are living in Babupur. Wage employment is the most dominant secondary occupation (29 percent) followed by petty business (17.50 percent) and van/rickshaw pulling (13.60 percent).

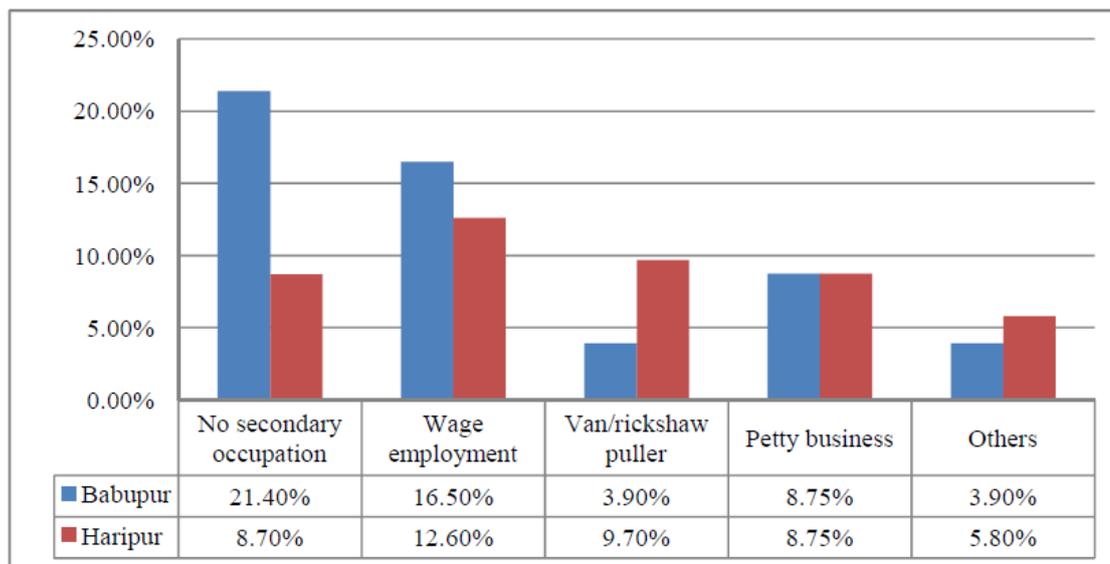

Figure 1: Pattern of secondary occupation among the respondents (Source: field survey 2016)

Total household income and secondary occupation

The table 4 represents that most of the respondents whose total household incomes are more than 250 thousand taka per year, are less inclined in having secondary occupations. In contrast, 20 out of 30 households with less than 150 thousand taka earnings per annum are earning from wage employment. Interestingly, three households despite having more than 250 thousand taka per year are engaged in wage employment. On the other hand, most of the respondents having an income more than 150 thousand taka are willing to invest in different kinds of petty business. Hence, it can be said that the total household income of the respondents has a positive relationship with their secondary occupation. It also has an impact on what kind of job the peasants will involve in.

Table 4: Respondents' secondary occupation and status of households' total income

HH head secondary occupation	Annual Income Classification (in thousand taka)					Total
	50 to <100	100 to <150	150 to <200	200 to <250	More than 250	
No secondary occupation	4 (12.9%)	7 (22.6%)	4 (12.9%)	5 (16.1%)	11 (35.5%)	31 (100.0%)
Wage employment	9 (30.0%)	11 (36.7%)	4 (13.3%)	3 (10.0%)	3 (10.0%)	30 (100.0%)
Van/ rickshaw puller	5 (35.7%)	3 (21.5%)	3 (21.5%)	1 (7.1%)	2 (14.2%)	14 (100.0%)
Petty business	3 (16.7%)	4 (22.2%)	5 (27.8%)	0 (.0%)	6 (33.3%)	18 (100.0%)
Others	2 (20.0%)	7 (70.0%)	1 (10.0%)	0 (.0%)	0 (.0%)	10 (100.0%)
Total	23 (22.3%)	32 (31.1%)	17 (16.5%)	9 (8.7%)	22 (21.4%)	103 (100.0%)

(Source: field study 2016)

Nature of major challenges peasants face in the study area

The peasants usually depend on agriculture both for food security and for household income. Apart from having limited size of farmland and drought, peasants face a considerable period of slack season each year. There are four major causes were identified through group discussions and key informant interviews that reduce income and induce production losses of the peasants. Data in the table shows that the majority of farmers (88.35 percent) reported that their input costs (seeds, fertilizers, pesticides, etc.) for cultivating crop increased significantly in terms of the return they got from market after selling their product. The percent of claiming this was almost similar in two villages. About 71 percent of peasants indicated that they experienced seasonal unemployment of two to three months almost every year. The percent is quite high among the peasants living in Haripur than Babupur. The former village has a very limited irrigation facility, and single crop cultivation (rain-fed *aman*) is the only option resulting in higher seasonal unemployment. A similar pattern is also observed regarding impact of drought on crop cultivation. Drought and climate variability reduced crop production about 69 percent of the respondents. But, this rate is two times higher in Haripur than that of Babupur. In contrast, a majority of peasants (64 percent) from Babupur claimed that a grave share of their profit from crop cultivation went to the pockets of the landlords due to an unfavorable tenancy arrangement. The percent (26 percent) is quite low in Haripur. Lack of irrigation facility is another important factor that does not allow the landlords of Haripur to impose a large discriminating arrangement onto the tenants. Overall, marginal and smallholder farmers are at great risk from the impacts of different kind of social and environmental constraints.

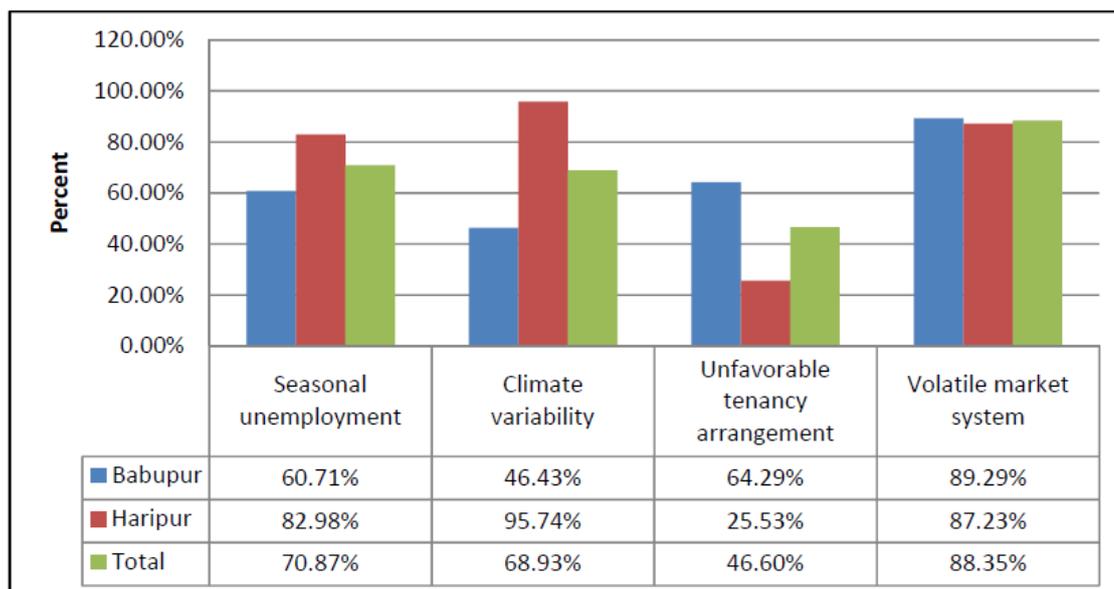

Figure 2: Major causes of deficit in income and loss of production (Source: field study 2016)

Nature and pattern of coping strategies

There is a little information available on how peasants prepare and cope with drought and other socioeconomic problems in this region. The study finds a number autonomous response among the local people. The strategy differs considerably if access to asset and service varies. The study mainly considers the coping strategy of the peasants due to unemployment, income deficiency, and losses of production. Peasants have to invest their financial resources for different inputs of the production like seeds, fertilizer, and labor-cost and they receive the return after the harvest. So, most of the peasant households, especially marginal farmers face challenges to ensure sufficient food and other basic needs for their families during this period. Since these groups live from hand to mouth round the year, and they often have to spend their surplus to pay back loans, they hardly can save some resources to cover their basic needs during lean seasons. As a result, they are facing great challenges to prevent their families from food and income insecurities. The table 5.1 and figure 5.2 depicts different kinds of coping strategies adopted by villagers. Among them, engaging in wage employment is the first choice of the peasant households (60 percent) followed by transformation of paddy field into mango orchards (about 54 percent). The transformation of agriculture rate is higher in Haripur than that of Babupur. In contrast, the percent of behavioral or avoidance coping strategies like reducing food intake, getting aid (mostly food) from neighbors, and selling household asset are high in Babupur. A considerable percent of peasant households (37 percent) took loans from different sources to cope with constraints. However, result from group discussions indicated that taking loan created further vulnerability to the peasants as the interest rate is very high. Selling labor in advance is another very common coping strategy found among the peasants which counts about 40 percent of the total respondents.

Table 5: Type of coping strategies in two villages

#	Type of coping strategies	Village Name		Total (N=103)
		Babupur (n=56)	Haripur (n=47)	
1	Engaging in wage employment	57.1%	63.8%	60.2%
2	Taking loan	41.1%	31.9%	36.9%
3	Engaging in petty business	14.5%	20.5%	17.5%
4	Transforming paddy field into mango orchard	48.2%	60.7%	53.4%
5	Changing time of crop cultivation	8.9%	12.8%	10.7%
6	Selling labor in advance by accepting low wage	37.5%	42.6%	39.8%
7	Getting aid from neighbors	45.7%	22.3%	34.0%
8	Reducing food intake	48.2%	23.4%	36.9%
9	Selling household assets (productive and non- productive)	26.8%	10.6%	19.4%
10	Others (fishing, handicrafts, rickshaw pulling, etc.)	19.6%	31.8%	25.2%

(Source: field study 2016)

Status of coping

Considering the above discussion, the study asked the respondents to posit themselves in overall coping status of the household. A five-scale statement was used in this regard. A significant number of peasants (23 HHs) claimed that they were falling far behind to cope with different constraints. The number is almost two times higher in Babupur than that of Haripur. About 23 percent of the peasants (24 HHs) reported that their position had not been changed so much comparing to near past. A total of 30 peasant households (29.10 percent) had been coping partially. Coping moderately was claimed by 16 percent. Only ten households (9.70 percent) acclaimed successful coping (figure 5.3). The figure also states that there are some differences regarding coping status between two villages except 'neither failed nor succeeded'. Haripur has a greater number of respondents who are coping partially (34 percent) and coping successfully (12.8 percent) in comparison to that of Babupur.

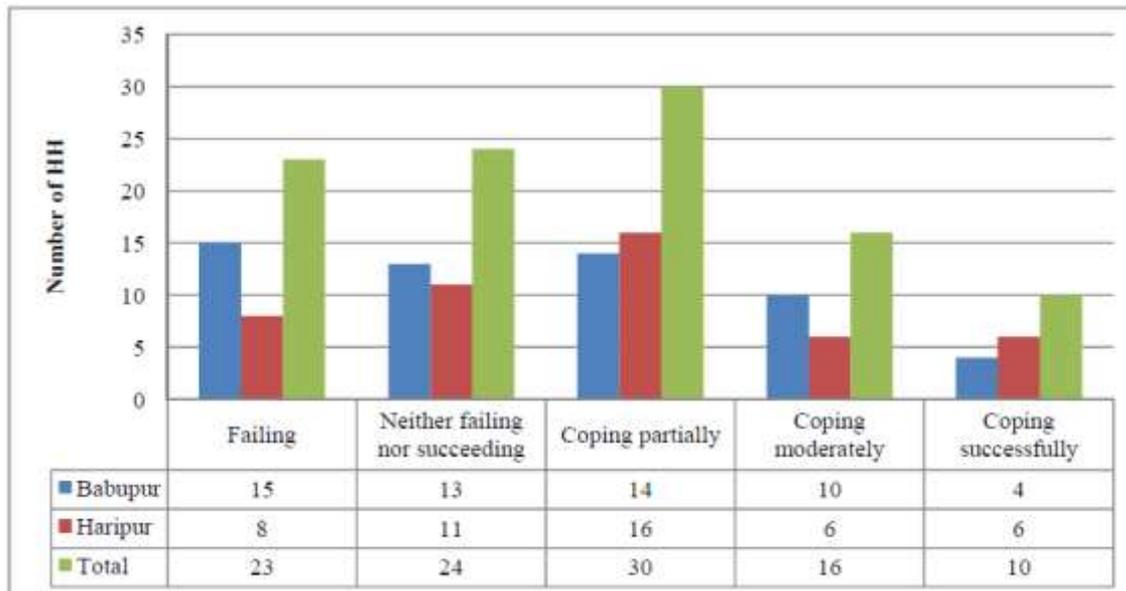

Figure 3: The percent of overall coping status of the peasant households (Source: field study 2016)

ASSOCIATION BETWEEN INCOME DIVERSIFICATION AND COPING

Coping strategies and total household income

Peasant households just do not undergo the consequences of various idiosyncratic shocks, rather they apply different strategies to cope with the challenges. Most of the cases income determines the nature and pattern of coping strategy. As discussed earlier, majority of the peasants face persistent poverty which in turn causes entry barrier for choosing a sustainable coping strategy. Hence, peasants apply informal risk-managements such as selling labor in advance, taking loan with high interest, selling household assets and/or engaging them in informal wage-sectors. These kinds of strategies are only able to provide limited protection, and leaving many peasant households exposed to further vulnerability.

The table 6 depicts that peasants engaging themselves in wage-employment are mostly having income less than 150 thousand taka. The percent of taking loans stand high in the same group. Households going for petty business are mainly having an income over 100 thousand taka. About 90 percent of the households selling assets as well as reducing food-intake are earning less than 150 thousand taka per year. Getting assistance from neighbors during shock periods is almost evenly distributed among the income groups. The percent of selling labor cuts very in the income group of 100 thousand to less than 150 thousand taka. In contrast, the percent of peasants who transformed their traditional cropland into mango orchards are distributed in all income groups. However, the percent of such transformation rate is higher among the households having income over 100 thousand taka. Despite taking different kind of coping strategies, however, poverty- driven risks remain high.

Table 6: Association between coping strategies and total household income

Type of coping strategies	Category of total household income (in thousand taka)					Total (N= 103)	Pearson Chi-Square test (P- value)
	50 to <100	100 to <150	150 to <200	200 to <250	More than 250		
Engaging in wage employment	17 (27.42%)	19 (30.65%)	9 (14.52%)	7 (11.29%)	10 (16.13%)	62 (60.20%)	.254
Taking loan	15 (39.47%)	11 (28.95%)	8 (21.05%)	2 (5.26%)	2 (5.26%)	38 (36.90%)	.002
Depending on earning from petty business	1 (7.14%)	7 (50.00%)	3 (21.43%)	0 (0.00%)	7 (50.00%)	14 (17.50%)	.268
Transferring paddy field into mango orchard	6 (10.71%)	18 (32.14%)	8 (14.29%)	8 (14.29%)	16 (28.57%)	56 (54.40%)	.004
Changing time of crop cultivation	3 (27.27%)	3 (27.27%)	5 (45.45%)	0 (0.00%)	0 (0.00%)	11 (10.70%)	.038
Selling labor in advance by accepting low wage	8 (19.52%)	20 (48.78%)	7 (17.07%)	5 (12.19%)	1 (2.44%)	41 (39.80%)	.794
Getting aid from neighbors	6 (17.14%)	11 (31.43%)	4 (11.43%)	3 (8.57%)	11 (31.43%)	35 (34.00%)	.408
Reducing food intake	21 (55.26%)	14 (36.84%)	2 (5.26%)	0 (0.00%)	1 (2.63%)	38 (36.90%)	.000

Others (fishing, handicrafts, rickshaw pulling, etc.)	6 (23.08%)	6 (23.08%)	6 (23.08%)	0 (0.00%)	8 (30.77%)	26 (25.20%)	.191

(Source: field study 2016)

Coping status and total household income

Poverty and economic stress remain realities of daily life for a substantial proportion of the peasants in the study area. It is observed from the table 5.4 that almost all the households falling behind of coping belong to the less than 150 thousand taka of annual income groups. A total of 18 out of 23 households having incomes less than 100 thousand taka have all failed to cope with different constraints. Only 4 households of the same income group are coping partially. There are 32 households in the income group of 100 thousand to less than 150 thousand taka. Among them, 20 households have been coping partially followed by 8 who are in a neutral position. Most of the households coping moderately have an income over 150 thousand taka annually. Only 10 households (9.70 percent) are coping successfully who belong to the income group of over 250 thousand taka earnings per year. Hence it can be said that there is a very significant relationship between household income and status of overall coping of the peasants.

Table 7: Coping and total household income

Overall coping status at household level	Category of total household income (in thousand taka)					Total
	50 to < 100	100 to < 150	150 to < 200	200 to < 250	More than 250	
Failing	18 (78.3%)	4 (17.4%)	1 (4.3%)	0 (.0%)	0 (.0%)	23 (100.0%)
Coping partially	4 (13.3%)	20 (66.7%)	6 (20.0%)	0 (.0%)	0 (.0%)	30 (100.0%)
Neither failing nor succeeding	1 (4.2%)	8 (33.3%)	6 (25.0%)	5 (20.8%)	4 (16.7%)	24 (100.0%)
Coping moderately	0 (.0%)	0 (.0%)	4 (25.0%)	4 (25.0%)	8 (50.0%)	16 (100.0%)
Coping successfully	0 (.0%)	0 (.0%)	0 (.0%)	0 (.0%)	10 (100.0%)	10 (100.0%)
Total	23 (22.3%)	32 (31.1%)	17 (16.5%)	9 (8.7%)	22 (21.4%)	103 (100.0%)

2 Pearson Chi-square test value (df = 16; χ^2 value = 131.113; p-value = .000)

(Source: field study 2016)

Relationship between coping strategy and coping status

On the other hand, findings show that the peasants of the study villages take different coping strategies ambiguously. The table 5.3 illustrates that some of the coping strategies such as reducing food intake, selling productive and non productive household assets, selling labor in advance and taking loans are undermining their coping capacity significantly. In contrast, transforming crop-field into mango-orchard shows a positive correlation with coping status. All other strategies are not significantly tied up with the status of coping (see chi-square result in the table).

Table 8: Relationship between coping status and coping strategy

Coping strategy		Status of coping					Total	Pearson Chi-square P-value
		Failing	Neither failing nor succeeding	Coping partially	Coping moderate ly	Coping successful ly		
Engaging in wage employment	Yes	15	13	19	11	4	62	.571
	No	8	11	11	5	6	41

Total number of coping strategies and coping status

The total number of coping strategies taken by each household is also not significantly linked with the status of coping (see table 9). However, it does not depict any significant connection between successful coping and diversity of income or occupation.

Table 9: Overall coping status and total number of strategies taken by each household

Overall coping status at household level	Total number coping taken by each household						Total
	One	Two	Three	Four	Five	Six	
Failing	1 (4.3%)	6 (26.1%)	5 (21.7%)	7 (30.4%)	3 (13.0%)	1 (4.3%)	23 (100.0%)
Neither failing nor succeeding	0 (.0%)	2 (8.3%)	8 (33.3%)	10 (41.7%)	4 (16.7%)	0 (.0%)	24 (100.0%)

Coping partially	0 (.0%)	5 (16.7%)	10 (33.3%)	10 (33.3%)	4 (13.3%)	1 (3.3%)	30 (100.0%)
Coping moderately	0 (.0%)	1 (6.3%)	6 (37.5%)	7 (43.8%)	1 (6.3%)	1 (6.3%)	16 (100.0%)
Coping successfully	0 (.0%)	2 (20.0%)	4 (40.0%)	3 (30.0%)	0 (.0%)	1 (10.0%)	10 (100.0%)
Total	1 (1.0%)	16 (15.5%)	33 (32.0%)	37 (35.9%)	12 (11.7%)	4 (3.9%)	103 (100.0%)

CONCLUSION

The participation in diversified income generating activities by peasant community is not new but the dimensions of activities are taking new shapes. The study depicts that the peasants are increasingly earning their major share of household income from off-farm sectors. Return from income diversification also varies across time or among individuals within households or community as asset-bases and intra-household skills are heterogeneous. Since the returns to on-farm labor are high during wet period, peasant households in the study area allocate their labor to on-farm activities during this time. On the other hand, they reallocate their labors to non-farm activities during the dry season or during the period when crops fail. Usually small landholders exhibit greater demand for diversification for the purpose of ex-ante risk mitigation. There is a very significant relationship between household income and status of overall coping status. But, it is observed from the study that almost all the households indicated falling behind of coping are all belong to having less than 150 thousand taka of annual income. Only 10 households coping successfully have been earning more than BDT 250 thousand annually. The study reveals a very strong association between income and successful coping as an increase of household income is likely to have a positive impact on coping. However, it does not depict any significant connection between successful coping and diversity of income, occupation or coping strategies. Besides, total number of coping strategies taken by each household is also not significantly linked with the status of coping. It is quite evident that a large share of peasants' income constraints as well as vulnerability is typically a result of many factors. Apart from climate variability or drought impact, they also face a number of social and economic challenges in their everyday life. Some coping strategies such as selling labor in advance, reducing food intake and selling out of household assets (both productive and non-productive) create further vulnerability of the peasant households in many regards. On the other hand, multiple sources of income, transformation of agriculture to more profitable crop, having secondary jobs etc. enhance resilience of the peasants to different shocks. The analysis suggests that that income constraint and limited farm ownership of the peasants are hindering their ability to cope with shocks as well as to invest for their future welfare. On a whole, evidence shows that income and occupational diversification contributes in lessening vulnerability by ameliorating risk and reducing the adverse consumption effects of seasonality in some extents. But, the off-farm income opportunities are poorly distributed in the study area. The peasants face entry barriers to many productive sectors due to lack of investment capabilities that ultimately limiting their capacity for effective ex-post coping. Some of their risk management efforts are also limiting their ability to build up an asset base that may take them out of poverty.

Given the complex nature of rural development, income diversification should be part of a broader integrated policy goal to protect peasant livelihood. Multi-sectors developmental strategy or approach is needed to assist the peasant community as well. Since peasants or smallholder farmers are the major food producers of the country, there is an urgent need for government and donor agencies to come up with strategies that can help farmers to build up their capital. It will ultimately help peasants to invest in their farms while not exposing them to horrendous financial risks.

1095 REDESIGNING RURAL DEVELOPMENT STRATEGIES: INNOVATION DYNAMICS RECONSIDERED

ABSTRACT

There is now a considerable set of theoretical approaches concerning the need rural world faces in the global knowledge economy. In particular, there is a rich academic production of territorial innovation models from which we can learn, extending the concept of regional learning to the field of developing predominantly rural areas. The first part of this article examines the challenges rural territories are facing against the background of modern theories of innovation and regional policies. It is argued that the role of localized learning is of strategic importance in the promotion of endogenous rural and regional development. Then, departing either from the handicaps either from the assets of rural areas, this paper argues that development in rural regions is made up of a complex set of interactions between different actors and processes. We question whether current rural policies are adequate to guarantee the competitiveness and sustainability of rural territories. Studying and intervening on the rural dynamics requires a shift from focusing on forms of knowledge and innovation outputs towards focusing on learning and innovation dynamics, exploring the diverse dimensions of knowledge building and promoting social capital.

ABSTRACT

The main purpose of the study is to clarify the relationship between Rural and Agricultural Development and Human Resource Development in Russian Federation since 2000s. In order to achieve our purpose, we set two hypotheses for verification by using the methodologies of Data Envelopment Analysis (DEA) and Structural Equation Modeling (SEM).

Analytical results from the research clarified that there have been a positive relationship between agriculture and human resource development in Russia since 2010, which has given impact on rural development as well (Hypothesis 1). It also clarified that structural changes in agricultural sector have impacts not only on agriculture but also on rural development (Hypothesis 2). Although agricultural enterprises (AEs) remain important role in the agriculture performance among three agricultural producers, its importance is changing along with the country's social-economic situation and is uneven across region. Additionally, among the agriculture enterprises, the role of agricultural holdings in the country's agricultural performance is extremely important but its development is uneven across regions and even within some regions such as in the Siberian FD.

Policy implications drawn from the research for both central and regional government indicated that agriculture development in Russia should pay more attention to human resource development and rural development when considering food security in a long-term perspective, especially the impacts of structural changes in agriculture sector on the human resource development in rural areas needs careful analysis.

JEL Classification: O10, O11

Keywords: Rural and Agricultural Development, Human Resource Development, Russian Federation

1. INTRODUCTION⁴⁵⁸

The government of Russian Federation has implemented various kinds of policy to improve the productivity in agriculture, such as the current agricultural policy of 'State program for the development of agriculture and relation of markets for agricultural products, raw materials and food during 2013-2020'. However, the survey on the 'Current Status and Trends in Russian Agribusiness' undertaken by Deloitte in 2015, clarified that the key constraints on the Russian agricultural industry are the shortcomings of government regulation, insufficient government support and financing, and lack of skilled personnel etc.

On the other hand, Russia's agricultural revival has been leading by the South district, where producers appear to have exploited climatic, infrastructural, and institutional comparative advantages over other districts. Modern agricultural practices (e.g., hybrid corn combined with specially tailored fertilizer application) and new processes (e.g., vertically integrated poultry operations) have also likely contributed to boosting output in the region. Despite the South's early rebound, the rest of the country has lagged. As for Siberian Federal District (SFD), although the higher share of the district in Russia's agricultural production in comparison with its ratio in the population size owing to its better land endowment, the productivity of agriculture is declining in the period of 2001-2005 and 2011-2015.

Therefore, the main purpose of the study is to clarify the relationship between Rural and Agricultural Development and Human Resource Development in Russian Federation since 2000s. The remaining parts of the paper are designated as follows. In Section 2, we will make a brief literature review on the rural and agricultural development and human resource developments, some related issues in Russia will be referred. In Section 3, we will present our analytical framework, hypotheses and methodologies for the research. In Section 4, we will verify our hypotheses by describing the changes in rural and agricultural development and clarifying the relationships between agricultural development, human resource development and rural development at regional level in Russian Federation since 2001-2015. Finally, in Section 5, policy implications draw from the analytical results will be suggested for the government to set their strategies for rural and agricultural development.

2. REVIEW OF LITERATURES

2.1 Rural and Agricultural development

According to Kiminami and Kiminami [9], rural and agricultural development concerns both the issues of development within a geographical region of an "agricultural community", and the issues of developing "agriculture" as an industry. First of all, there is the dimension of "quantity and quality" in economic development, in which the quantitative aspect includes the increase in wealth, income level, and availability of assets or services, and the qualitative aspect includes the realization of social welfare, creation of employment opportunities, sustainable development, and improvement in

⁴⁵⁸ The earlier version of this paper was presented at the 54th Annual Meeting of the Japan Section of the RSAI (6-8 Oct. 2017, Ritsumeikan University, Kyoto, JAPAN)

quality of life (QOL). Furthermore, in terms of rural and agriculture development today, geographical spatial links are strengthening as well as widening in the issues covered.

However, despite convincing successes, agriculture has not been used to its full potential in many countries because of anti-agriculture policy biases and underinvestment, often compounded by misinvestment and donor neglect, with high costs in human suffering. New opportunities for realizing this potential are present today, but also coming are new challenges, particularly in pursuing a smallholder-driven approach to agricultural growth that reconciles the economic, social, and environmental functions of agriculture (World Bank [22]).

During the transformation of Russia's economy in the 1990s, agriculture became one of the most unattractive areas for investments because of its longer capital turnover, low return, outdated infrastructure and specific natural conditions of production. That, in turn, decreased the level of income of rural people, created unemployment and forced migration to urban centers. Consequently, rural regions of Russia lacked not only capital, but also labour, leading to the degradation of agricultural production and rural infrastructure, and giving rise to social tensions.

Recently, the Russian Government has begun to pay special attention to ensuring sustainable rural development. General programs and concepts accepted at the federal level ⁴⁵⁹ defined the main state approaches to rural issues, but concrete rural areas need real and effective mechanisms of social and economic revival (Erokhin et al., [5]).

According to Kurtsev [10], in the Siberian economy, agricultural production plays more significant role than the average for Russia. The agrarian aspect of the social and economic development of Siberia in its concrete expression due to the multifunctionality of agriculture encompasses a number of directions. Quantitative and qualitative characteristics of nutrition are the most important criteria for the level of social development of the territory, since it is about satisfying the most important everyday life needs of people. The creation of a food base that meets the quantitative and qualitative parameters of a full-value nutrition of people at prices for food products that are acceptable in terms of incomes of the population is one of the prerequisites for the further development of the Siberian region.

In the long term, the main functions of the rural sector should not be limited to agricultural production, which is, of course, important for the country's food security, but include other production activities. For instance, the reanimation of the social and production infrastructure of rural areas, the development of agricultural product processing, the revival of vernacular arts, the involvement of various recreational resources into the rural economy, and the development of industrial production sites based on the use of local natural resources and raw materials etc. In other words, the idea is to diversify the rural economy.

2.2 Human Resource Development

Human development is a process of enlarging people's choices. Human development is also the objective, so it is both a process and an outcome. Human development implies that people must influence the processes that shape their lives. In all this, economic growth is an important means to human development, but not the end. Human development is the development of the people through building human capabilities, by the people through active participation in the processes that shape their lives and for the people by improving their lives (UNDP[17]).

The composite of Human Development Index (HDI) integrates three basic dimensions of human development. Life expectancy at birth reflects the ability to lead a long and healthy life. Mean years of schooling and expected years of schooling reflect the ability to acquire knowledge, and gross national income per capita reflects the ability to achieve a decent standard of living.

According to the calculation of UNDP [17], HDI of the Russian Federation in 2015 ranked No.49 among 188 countries with a very high level of index (0.804) for Human Development⁴⁶⁰, key indicators of life expectancy, particularly child and maternal mortality had improved, and rates of major infectious diseases had stabilized. Nevertheless, some studies showed that huge inequalities in human resource development such as three distinct dimensions of inequality affect access to health care: household-level, regional-level and rural-urban differences within region exist in Russia (Cook [4]).

In general, development of human resources such as educational investment and health improvement in rural areas contribute to the promotion of modernization of agriculture (Mellor [12]). However, empirical researches on the relationship between the development of the agricultural sector and human resource development in Russian since the 2000s are insufficient so far.

On the other hand, human capital, a key for the development of human resources is the main engine and the foundation of the industrial economy (Schultz [16]). Since public policy prioritizes food production in Russia's agricultural sector, there are insufficient resources allocated to support human capital in the sector. As a result, the serious problems of human capital such as a shortage of qualified specialists and an outflow of rural residents continue to deteriorate, and it will damage the aspirations of Russia's leadership and competitiveness in the world food market (Wegren [20][21]).

2.3 Economic transition in Russia

The sharp decline in Russia's agricultural output and use of inputs (land, labor, materials, and capital) as the sector transitioned to a market economy affected all Russian districts rather equally. A higher level of specialization in output across districts has been a common feature of Russia's subsequent agricultural recovery. Since 2000, the South district

459 For example, Agricultural Development Program of Russian Federation for 2013-2020

460 See also UNDP Russia [18] for the regional difference in the country.

has increased production of wheat, corn, and sunflower seed while decreasing production of potatoes and eggs. The Central district has traditionally been the country’s biggest producer of sugar beets and is now the largest meat producer. A high level of specialization for some districts are not by increasing output of particular commodities but rather by decreasing production (Rada et al. [15]). However, the extreme specialization on a specific type of activity may carry high risks in some regions with the possibility of economic instability.

There have been three major kinds of agricultural producers in Russia since the collapse of the Soviet Union: former state and collective farms (called as agricultural enterprises by the Russian statistical authorities), household plots and private family farms. Agricultural enterprises have been the dominant producer in the post-Soviet period, at least in terms of institutional structure and influence. In the early 1990s, the former state and collective farms reorganized from the Soviet period. Households working on agricultural enterprises have retained the Soviet-era practice of maintaining small plots, with the right to consume or sell their products. The total amount of agricultural land used by these plots increased from 3 percent in 1990 to 16-20 percent by 2013. The third type of agricultural producer in Russia is the private family farm. In the Soviet planned economy, farms did not have decision making power over their input use and output mix; rather, farms received from central planners a specific allocation of inputs tied to mandated output targets. Farms faced no competitive market pressure to be efficient, reduce waste, and economize on inputs. In Russia’s market economy, however, farms not only have the potential to earn profit but also to be largely self-financing. They have the freedom of decision making, including the choice of output and input mix, and stronger managerial control to improve labor incentives (Rada et al., [15]).

3. RESEARCH FRAMEWORK, HYPOTHESES AND METHODS

Based on the review of the existing literatures and achieve our purpose to clarify the relationships between rural and agricultural development and human resource development in Russian Federation, we set the following conceptual framework as shown by Figure 1 and two hypotheses to explain the relationships. Furthermore, Table 1 showed the methodologies and variables for verifying each hypothesis in the research.

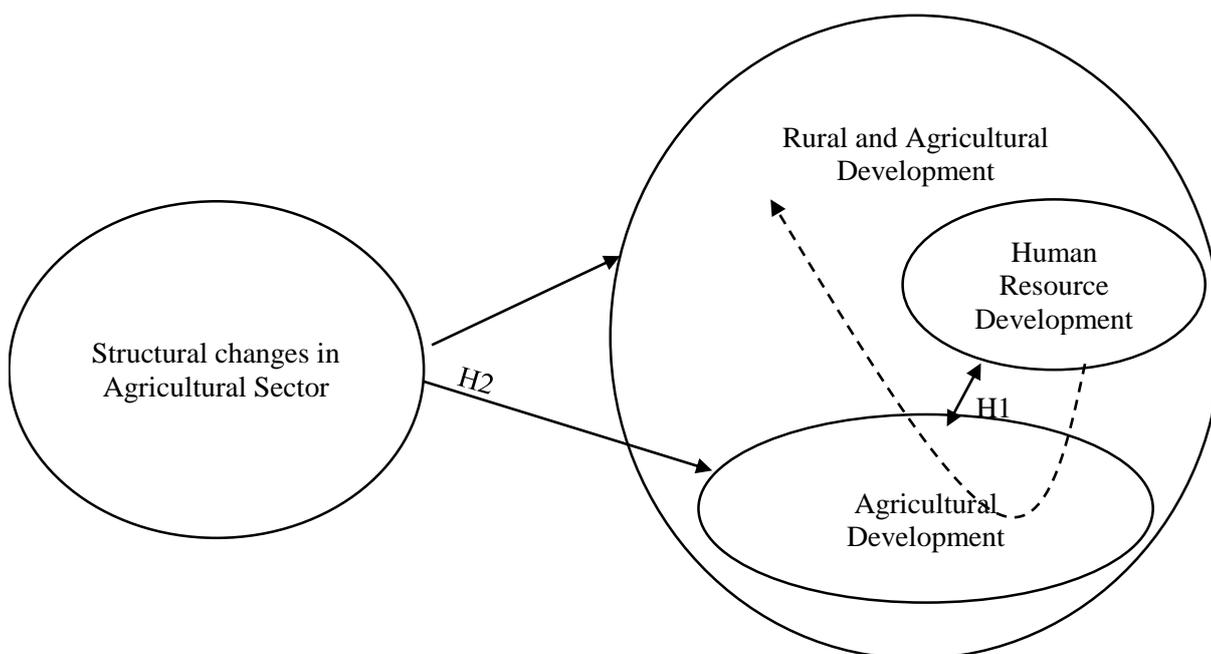

Figure 1 Conceptual framework

Hypotheses

H1: There is strong relationship between agricultural development and human resource development in Russia since 2000s.

H2: Structural changes in Agricultural Sector have impacts on the Rural and Agricultural Development in Russian Federation since 2000s

Table 1 Analytical methods and variables

Hypotheses	Main Methods
H1: There is strong relationship between agricultural development and human resource development in Russia since 2000s.	-Data Envelopment Analysis(DEA) -Structural Equation Modeling(SEM)
H2: Structural changes in Agricultural Sector have impacts on the Rural and Agricultural Development and Human Resource Development in Russian Federation since 2000s	

4. ANALYTICAL RESULTS

4.1 Human Resource Development and Rural and Agricultural Development in Russia

4.1.1 Human Resource Development in the Regions of Russian Federation

Table 2, Table 3 and Table 4 showed the situation of human resource development in the regions of Russian Federation during the period of 2001-2015. As for the life expectancy in Russian Federation, it has expanded 6.1 years from 65.29 years in 2001 to 71.39 in 2015. However, uneven improvement of life expectancy across regions, such as a big gap between Central, North-West, Southern and Siberian, Far East FD. Although, the average income in Russian Federation has been increased more than 10 times in 2015 comparing to that in 2001, there is a big gap between the highest region (Central FD with 38,776 rubles) and the lowest region (Siberian FD with 23,584 rubles). Furtherly, the level of education especially in the number of graduates of university has increased in all regions of Russian Federation during the period but its distribution is still extremely uneven across regions. Although Russian government has implemented reforms to improve the quality of high education since 2011, the reason for the decrease in the number of graduates of university from 2010-2015 might be explained as due to the sharp decline in the fertility rate in the first several years of 1990s because of the economic stagnation (Filatova et al. [7]).

Table 2 Life expectancy in the Federal Districts of Russian Federation

	Life Expectancy (years)				Rate Changes 2001-15(%)
	2001	2005	2011	2015

4.1.2 Agricultural Development in the Federal Districts of Russian Federation

In this section, we will firstly analyze the performance of Russian agricultural sector at regional level since 2000s in order to understand the situation of utilizing human resource. The productivity of labor, land and capital of 7 federal districts are calculated from the statistical database (*Regions of Russia*) in order to analyze the performance of Russian agricultural sector at regional level (See Table 5). They showed the differences across districts by average. For Siberian FD, labor productivity and capital productivity were higher than the average in Period 1, but the growth rates of them were lower than that of the average in period 2.

Table 5. Agricultural Productivity of Federal Districts in Russian Federation

	Productivity					
	Period1 (2001-2005)			Period 2 (2011-2015)		
	Labor	Land	Capital	Labor	Land	Capital
Central FD (17)	98.0	5.3	0.9	184.7	7.4	1.3
North-West FD (9)	91.1	11.8	0.8	109.9	9.8	0.9

Southern FD (12)	85.9	5.8	1.0	131.8	7.1	1.8

Ural FD (4)	99.1	3.8	1.0	169.2	4.1	1.4
Siberian FD (12)	98.5	2.5	1.0	139.3	2.4	1.4
Far East FD (9)	99.0	10.1	0.9	110.4	6.7	1.5
Average	94.5	6.0	0.9	142.7	6.1	1.4

Notes: The value in parentheses is the number of regions in simple average. The units of productivity are as follows: Labor Productivity (1,000 rubles/person); Land Productivity (1,000/ha); Capital productivity (rubles/rubles). Data of the agricultural outputs and capital (Fixed Asset) deflated by using the agricultural producer price index and agricultural price index respectively.

In order to understand the efficiency of agricultural sector in each region, we use Data Envelopment Analysis (Charnes et al. [3]; Bankers et al. [1]) to calculate the efficiency of 77 regions in Russian Federation from 2001-2005 to 2011-2015 as shown in Table 6 (See Appendix). It is clear that the efficiency of agriculture in Far East FD is the highest and the main reason for this is due to a high technical efficiency, but the efficiency of agriculture in the Siberian FD is moderate in period 1. However, in period 2, the ranking of Far East FD as the highest efficiency replaced by Central Federal District and dropped to 6th place. Efficiency in the Siberian FD declined from number 3 to number 5 in period 2.

Table 6. Results of DEA (Output-oriented, VRS model) analysis (Federal District)

	Efficiency					
	Period1 (2001-2005)			Period 2 (2011-2015)		
	CRSTE	VRSTE	SCALE	CRSTE	VRSTE	SCALE
Central FD	0.687(7)	0.729(6)	0.946(5)	0.678(1)	0.697(3)	0.975(2)
North-West FD	0.695(6)	0.708(7)	0.982(1)	0.523(7)	0.527(7)	0.991(1)
Southern FD	0.699(5)	0.767(5)	0.919(7)	0.639(3)	0.785(1)	0.825 (7)
Volga FD	0.722(4)	0.788(2)	0.920(6)	0.603(4)	0.706(2)	0.865(6)
Ural FD	0.745(2)	0.772(4)	0.963(3)	0.671(2)	0.691(4)	0.972(3)
Siberian FD	0.744(3)	0.772(3)	0.964(2)	0.595(5)	0.641(6)	0.926(4)
Far East FD	0.773(1)	0.813(1)	0.952(4)	0.585(6)	0.673(5)	0.894(5)
Average	0.718	0.762	0.946	0.616	0.681	0.916

Notes: The rank of the score of each district indicated in the form of parentheses. Simple average scores calculated in each federal district used the results of regions (77 regions in total). The input variables of data for the analysis are agricultural labor, agricultural land and agricultural capital. The output variable of data is agricultural output.

4.1.3 Share of output by type of agricultural producers

Table 7 shows the share of output by type of agricultural producers in federal districts. The ratio of Agricultural Enterprises (hereafter, AEs) and Family farms (hereafter, FFs) rises while the ratio of Household Plots (hereafter HPs) declines from the period 1 to the period 2. With regard to HPs, although the share of output is highest in all areas except Northwest FD in the period 1, it has declined in all federal districts, and the ratio of AEs in the Central FD and Volga FD have become highest in the periods 2.

However, the ratio of AEs in Siberian FD is second lowest in the period 1 and period 2, and the ratio has not changed during these periods. This means that the importance of AEs for Russian agriculture has increased from the period 1 to period 2 as a whole. Furthermore, around year 2000, a different type of AEs so called “new operators” (a particular class of these new operators is the very large agroholdings) emerged (Rada et al. [15]), and it has given great impact on the agricultural sector.

Table 7 Share of output by type of agricultural producers (%)

	Period1 (2001-2005)			Period 2 (2011-2015)		
	Agricultural Enterprises (AEs)	Household Plots (HPs)	Family Farms (FFs)	Agricultural Enterprises (AEs)	Household Plots (HPs)	Family Farms (FFs)
Central FD	45.7	51.7	2.6	56.6	37.7	5.7
North-West FD	50.5	46.8	2.6	59.9	36.3	3.8
Southern FD	30.8	59.1	10.1	30.1	49.2	20.7
Volga FD	43.0	53.5	3.5	46.5	46.0	7.5
Ural FD	42.9	53.4	3.7	46.2	46.6	7.2
Siberian FD	33.3	61.8	4.9	33.8	56.8	9.3
Far East FD	35.6	56.1	8.4	36.4	48.5	15.1
Average	40.2	54.8	5.0	44.6	45.5	9.9

Source: Calculated from the EMISS (<https://www.fedstat.ru/>)

Figure 2 shows that AEs are concentrated in the Southern FD, the Ural FD, and some regions of Central FD. The regions (500 or more companies) with the largest number of AHs (500 and more firms) is located in three regions (Krasnodar, Rostov and Stravropol) within the Southern FD and one region (Moscow) in the Central FD. The regions with the second

large number of AEs (260 to 499 firms) located in the eight regions (Chuvash, Kirov, Nizhny Novgorod, Orenburg, Samara, Saratov, Tatarstan and Udmurt).

Note: Red color (less than 20), Pink color (21-49 firms), Orange color (50-139 firms), Yellow color (140-259 firms), Light green color (260-499 firms), Green color (500 and more firms)

Source: Russian Agriculture Census, 2016

Figure 2 The Number of Agricultural Enterprises (including Agroholdings) in the Russian Federation (2016)

4.2 Role of Agroholdings (AHs) in the country agricultural performance

There are three major types of agricultural organizations (agricultural enterprises, households plots, family farms)⁴⁶¹ in Russian agricultural production. According to Russian Agriculture Census (2016), the category of “**agricultural enterprises**” includes economic partnerships, societies, limited liability companies, state and non-state, joint-stock companies, production cooperatives, unitary enterprises, subsidiary farms of non-agricultural organizations and institutions. Among the agricultural enterprises, a new type of organization called agricultural holdings have emerged dramatically since 2000s. **Agroholding** is a group of legally independent farming, processing and service organizations, reference (highest) statutory capital packets which belong to the same person (the parent company, the owner), the manager (organized by the Office) Group (Uzun [19]).

As regarding to the differences in the location of agricultural holdings (AHs), Table 8 showed the concentrated location of AHs in Federal Districts of Russia. Furthermore, Table 9 summarizes the profitability and productivity by the types of agricultural enterprises. First, non-state agricultural holdings have higher profitability and productivity than that of state. However, among the state agricultural holdings, the profitability of each type is in the order of Federal >Regional>Municipal; the productivity of labor is in the order of Non-State>Regional>Federal>Municipal; and the productivity of land is in the order of Non State>Regional>Federal>Municipal. This means that non-state agricultural holdings generally have higher profitability and productivity than state holdings, while federal holdings have lower productivity but a higher profitability than regional holdings. The reason that municipal holdings have the lowest productivity and profitability among state agricultural holdings due to its inefficient management.

Table 8 Number of Agroholdings in Russian Federation

	State AHs		Non-State AHs		Club Agro-300 ⁴⁶²	
	Regional State	Municipal State	Number	(%)	Number	(%)
	Number	(%)				
Central FD	1	7	32	(33.7)	56	(22.0)
North-west FD	1	1	9	(9.5)	17	(6.7)
Southern FD	6	4	18	(18.9)	96	(37.8)
Volga FD	6	8	20	(21.1)	39	(15.4)
Ural FD	1	0	4	(4.2)	17	(6.7)

461 The other two types of agricultural production are household plots and family farms. Household plots include personal subsidiary and other individual farms of citizens in rural and urban settlements, as well as farms of citizens who have land plots in horticultural, gardening and dacha non-profit associations. Personal subsidiary plots are a form of non-entrepreneurial activity for the production and processing of agricultural products carried out by the individual labor of a citizen and members of his family in order to meet personal needs on the land plot granted or acquired for the maintenance of a personal subsidiary farm. Land use of farms can consist of personal and field sites. The Family farms is an association of citizens related to relatives and (or) property having common property and jointly carrying out production and other economic activities (production, processing, storage, transportation and sale of agricultural products) on the basis of their personal participation. An individual entrepreneur for agricultural activities is a citizen (an individual) engaged in entrepreneurial activity without the formation of a legal entity from the moment of its state registration.

462 The Agro-300 club has farms from 56 regions of the Russian Federation. Regions with the most favorable conditions for agriculture are represented in the Club by the largest number of agricultural organizations

Siberian FD	3	(15.0)	8	(28.6)	12	(12.6)	29	(11.4)
Far East FD	2	(10.0)	0	(0.0)	0	(0.0)	0	(0.0)
Total	20	(100.0)	28	(100.0)	95	(100.0)	254	(100.0)

Note: Agricultural enterprises that agricultural land is 0(zero) are excluded from the calculation.

Table 9 Agricultural Production and Profitability by Type of the Agricultural Holdings (2004-06)

		Agricultural Holdings (AHs)				Non-State AHs
		State AHs				
		Federal AHs	State	Regional State AHs	Municipal State AHs	
Profitability	(%: profit/sales)	4.1		-5.2	-15.4	18.0
Labor Productivity	(1,000 rubles/person)	192.8		244.3	63.5	391.1
Land Productivity	(thousand rubles/ha)	6.1		22.0	3.0	38.3

Note: Agricultural enterprises that agricultural land is 0 (zero) are excluded from the calculation.

Source: Calculation based on Nikonova [13]

Furthermore, looking at the profitability of agricultural holdings at regional level as shown by Table 10, non-state holdings have a higher profitability and a higher productivity than state agricultural holdings almost in all regions. On the other hand, profitability of municipal holdings in all regions have a minus number, especially the situation is bad in Siberian FD.

Table 10 Regional Difference of Profitability by Type of the Agricultural Holdings (2004-06)

	State AHs		Non-State AHs
	Regional State AHs	Municipal State AHs	
Central FD	18.4	-12.5	17.0
North-west FD	10.4	-4.0	20.8
Southern FD	-17.8	-4.5	24.7
Volga FD	11.5	-2.6	14.0
Ural FD	16.9	-	19.4
Siberian FD	2.1	-37.6	15.3
Far Eastern FD	-58.8	-	-
Average of FDs	-2.5	-12.2	18.5

Note: Agricultural enterprises that agricultural land is 0 (zero) are excluded from the calculation.

Source: Calculation based on Nikonova [13]

The agroholdings acquire existing corporate farms and vertically integrate them, combining primary production, processing, distribution, and sometimes retail which have some similarity as the dragon-head agro-food enterprises in China (Kiminami and Kiminami [8]). However, the lack of empirical evidence from nationally representative farm-level or farm-type data raise the question whether agroholdings represent the best production practice in Russian agriculture.

4.3 Hypotheses verification: Structural Equation Model (SEM)

After having examined the situation about rural and agriculture development and human resource development in Russian Federation since 2000s, we introduce the Structural Equation Model (SEM) to verify our two hypotheses. Figure 3 shows the analytical framework for the verification and the method of Maximum likelihood is applied. The number of sample is 77 (regions).

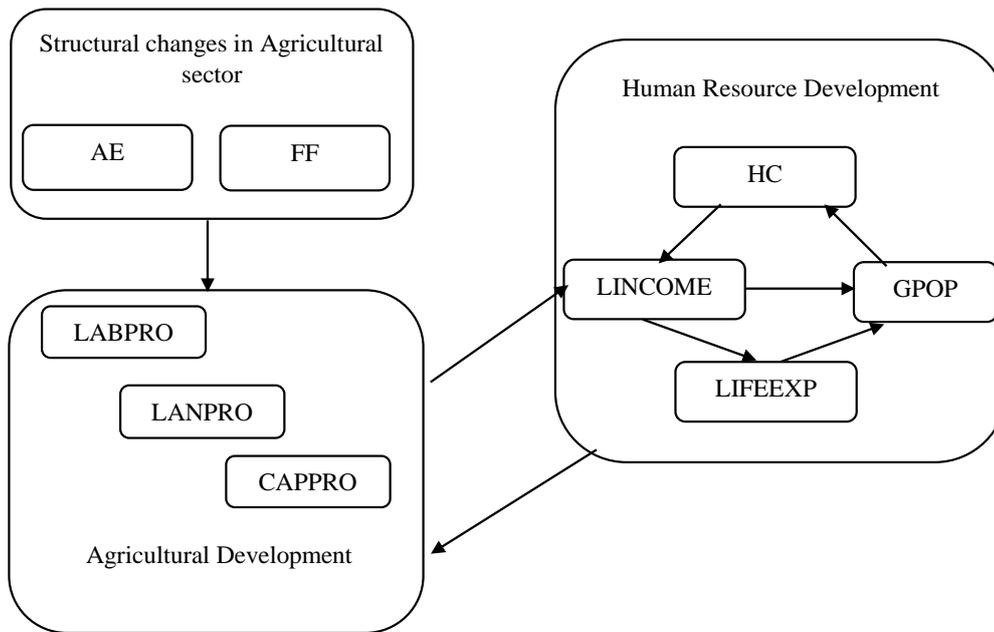

Figure 3. Analytical framework for hypothesis verification

We use the indicators for Agricultural Productivity (labor, land, capital) in each region calculated in the section 4.1. As for the structure of agriculture, we will use the ratio of production value by agricultural enterprise (AE) and family farms (FF). Therefore, the benchmark of path coefficient about AE and FF is the ratio of household plots. Finally, as for the variables of human resource development, we use the number of graduation specialists in higher education divided by number of population (HC), life expectancy (years), and natural logarithm of average income (LINCOME). In addition, we use annual growth rate of population (GPOP) as one of the indicators for sustainability. Table 11 showed the explanation of variables used for the SEM analysis.

Table 11 Explanation of Variables

Variables		Explanation	Period 1		Period 2	
			Mean	S.D.	Mean	S.D.
Agricultural Development (Productivity)	LABPRO	Labor productivity	94.539	24.432	142.725	61.170
	LANPRO	Land productivity	6.022	5.490	6.128	5.625
	CAPPRO	Capital productivity	0.936	0.264	1.401	0.624
Structure of Agriculture	AE	Ratio of production value by agricultural enterprises (%)	40.182	14.706	44.568	18.400
	FF	Ratio of production value by family farms (%)	5.036	4.395	9.898	8.501
Human Resource Development	HC	Graduation specialists in higher education divided by number of population	0.502	0.161	0.795	0.234
	LIFEXP	Life expectancy (years)	64.594	2.790	69.602	2.388
	LINCOME	Natural logarithm of average income (rubles)	8.307	0.360	9.930	0.266
GPOP		Annual growth rate of population (%)	-0.011	0.017	-0.001	0.005

Table 12 summarized the path coefficient among these indicators from SEM analysis both for the period 1 and period 2, although the sample size (77 regions) is relatively small (RMSEA >0.150, CFI <0.750). Figure 4 and Figure 5 are the path diagram obtained from the results of each period.

First, land productivity (LANPRO) had a positive impact on income (LINCOME) in both periods and started to have a positive impact on life expectancy (LIFEXP) in the period 2010-2015. However, graduation specialists in higher education divided by number of population (HC) had a negative relationship with land productivity in the two periods but a weak positive impact on capital productivity in period 1.

Secondly, as for the relationships among the indicators of human resource development, no relationships could be found between human capital (HC) and other indicators such as income (LINCOME), life expectancy (LIFEEXP) and number of population (GPOP), however life expectancy (LIFEEXP) had been positive to the number of population (GPOP) in the two periods.

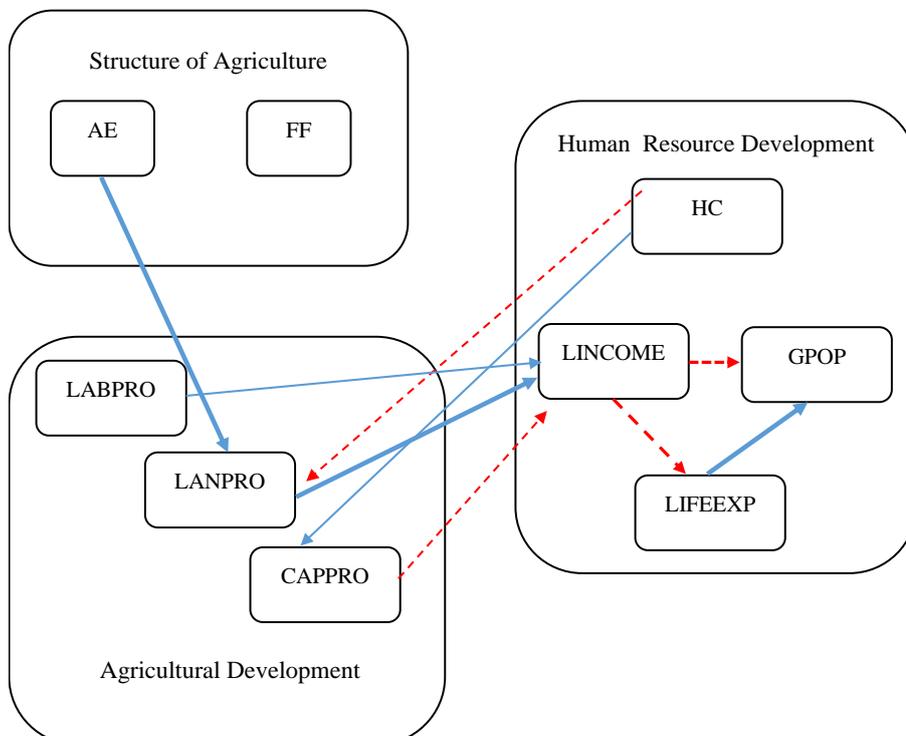

On the other hand, income had negative impact not only on life expectancy in periods 1 and 2, but also on population in period 1. Therefore, our hypothesis H1 is limitedly verified that “There is strong relationship between agricultural development and human resource development in Russia since 2000s” because the lack of skilled personnel in agricultural sector and a high level of alcoholism in rural areas had negative impacts not only on agricultural development but also on rural development.

Thirdly, there was a strong positive relationship between agriculture enterprises (AE) and land productivity (LANPRO) in both periods. AE had positive impact on land productivity that contributed to the increase in income in period 1 and started to have positive impact on labor productivity in period 2 as well. Furthermore, a positive relationship between family farm (FF) and capital productivity (CAPPRO) was found in the period 2010-2015. This means that agricultural development in Russia since 2010 has been contributed not only by agriculture enterprises through the improvements both in land and labor productivity but also by family farm through the improvement in capital productivity under the structural changes in agricultural sector. Therefore, we verified our hypothesis (H2) as “Structural changes in agricultural sector have impacts on agricultural development”.

Table 12 Results of SEM Analysis

			Hypothesis (predicted sign)	Period 1(2001-2005)		Period 2 (2010/11 – 2015)

5. CONCLUSIONS

Based on the above-mentioned analytical results, we obtained the following conclusions:

First, agricultural development in Russia has made a significant progress since 2000s, it has not only improved the nation's food security but also improved rural development, especially since 2010, a positive relationship between agricultural development and human resource development has increased which have positive impact on rural development as well (Hypothesis 1). However, rural and agricultural development in Russia has been uneven across regions; some regions such as Siberian FD has left behind dynamic changes.

Secondly, structural changes in agricultural sector have impacts not only on the agricultural development but also on rural development (Hypothesis 2). Agricultural Enterprises (AEs) remain important role in the country's agriculture performance among three agricultural producers but is changing along with the country's social-economic situation and is uneven across region. For instance, the ratio of AEs in Siberian Federal District is second lowest in the period 2001-2005 and period 2011-2015, and the ratio has not changed during these periods. Additionally, among the agriculture enterprises, the role of agricultural holdings in the country's agricultural performance is extremely important but its development is uneven across regions and even within some regions such as in the Siberian FD. Furthermore, non-state holdings are more profitable and more productive than state holdings and municipal holdings are least profitable and unproductive among agroholdings.

Policy implications drawn from the research for both central and regional government indicated human resource development should be paid more attention in Russia when considering food security in a long-term perspective, especially the impacts of structural changes in agriculture sector on the human resource development and rural development needs careful analysis. This will be our next research agenda.

APPENDIX. EXPLANATION OF DATA FOR DEA ANALYSIS

The data used for the DEA analysis is collected from the official statistics "Regions of Russia" (each year version). Coverage years for the analysis is from 2001 to 2005 and 2011 to 2015. If there is a change in the regional classification due to merger etc. during these period, Data of the past year are also revised according to the regional classification after the merger. In addition, we analyzed 77 regions where all variables are available excluding regions with missing data.

Production activity of Russian agriculture fluctuates year by year, and the production level can change greatly due to factors such as weather conditions every year. In this analysis, in order to grasp structural differences and changes in the relative efficiency of the agricultural sector at the regional level, the five-year average from 2001 to 2005, and from 2011 to 2015 will be used.

Labor, land and capital were used for input factors of the agricultural sector. In order to eliminate the influence of price fluctuation, the fixed asset value is deflated using the agricultural input price index as a proxy variable of the capital of the input factor. Also, the agricultural output value is also deflated using the agricultural producer price index.

Output-oriented model with VRS (Various Return to Scale) was applied to the analysis. The relationship of three efficiency can be expressed as follows: $CRSTE = VRSTE \times SCALE$ where CRSTE indicates the overall technical efficiency, VRSTE indicates pure-technical efficiency and SCALE indicates scale efficiency (Banker et al. [1]). Here, the value of each efficiency takes 0 to 1.

Efficiency calculated here should be utilized for the analysis with reservation hence technical efficiency depends on the production structures of agriculture.

Labor: The definition of labor is the annual average number of employee in agriculture, forestry and fishery industries (1,000 people).

Land: The definition of agricultural land here is "Agricultural land - land that is systematically used to produce agricultural products." These include arable land, fallow land, perennial plantations, hayfields and pastures. (Regions of Russia, 2016, p. 567)". Data of four years from 2006 to 2009 are not reported in the statistics.

Capital: The definitions of fixed assets (million rubles) owned by profit organization in agriculture, hunting and forestry, here refer to production assets that are used repeatedly or permanently over a period of one year or more and are assets for leasing to other organizations. It includes buildings, structures, agricultural machinery, transport machines, livestock, perennial plantations and others (Region of Russia, 2016, p. 567). It is calculated by full accounting value.

Output: For output factors, we will use agricultural output (million rubles). Agricultural output is the total value of crop and livestock by all types of agricultural producers (Region of Russia, 2016, p. 802).

<Descriptive Statistics>

Table A1 summarizes descriptive statistics of the data. As the overall mean average, Inputs of Capital and Land, and Output increase from the period 1 to period 2. Looking at the coefficient of variation (average / standard deviation), the variation in the size of the Land between the regions decreased in the same period, while the variation in Output, and Input of Labor and Capital has become large.

Table A1. Descriptive Statistics

Units: Million Rubles, 1,000 people, 1,000ha

	Period1 (2001-2005)				Period2 (2011-2015)			
	Output	Labor	Land	Capital	Output	Labor	Land	Capital

SS10.2. Rural Transformation

1231 DYNAMICS OF INDIAN RURAL TRANSFORMATION – A CASE OF WEST BENGAL

Ashfaque Alam

Assistant Professor, Department of Planning, School of Planning and Architecture, Bhopal, Madhya Pradesh, India. ashfaquealam@spahhopal.ac.in

1 INTRODUCTION

India had 5.94 lakh inhabited rural areas (villages) in 2001 and it was supposed to be figured out to 6.02 lakh in 2011, out of these a number of 2,691 rural inhabited villages were transformed to urban areas in 2011 which had a population of 30.84 million. In 2001 only 145 villages were upgraded or merged with statutory towns. National level only 3.57 percent of rural population has been transformed to urban, however, state and union territory level it varies too much. State level West Bengal stands first with 498 new census towns have been added in 2011. For the first time since Independence of India an absolute increase of 10 million people in urban areas than rural areas has been seen in the year 2011 (Census of India, 2011).

The evidence of India's rural transformation was based largely on the official data on employment released by the National Sample Survey Office (NSSO). The employment survey conducted by the NSSO showed that between 2004-05 and 2011-12, a huge section of India's workforce, 33.3 million to be precise, left farm jobs to take up non-farm occupations, primarily in the construction sector (Bhattacharya, 2016). In India several profound transformations in the nature of social relations in rural areas took place in the post-Independence period, especially in those regions that underwent the Green Revolution. These included an increase in the use of agricultural labour as cultivation became more demanding; a shift from payment in kind (grain) to payment in cash; a loosening of traditional bonds or hereditary relationships between farmers or landowners and agricultural workers (known as bonded labour); and the rise of a class of free wage laborers took place (Majumdar, 2016).

Rural India is going through or passing through a widespread transformation or change. The transformation ranges or the extent of the transformation varies from the growth rate of population (1.7% during 1991-2001 to 1.2% during 2001-2011), agrarian distress and huge number of farmers' suicide, increasing rural to urban migration, declining growth rate of agricultural out-put, social insecurity and many more as the negative indicators of transformation (Majumdar, 2016).

A brief study national level rural transformation has been carried out with the factors of percentage of rural population transformed, share of non-farm sector in GDP (Gross Domestic Product) and growth of agriculture sector state level. The analysis draws three observations that the proximity of large cities, good accessibility or location along highways and low production of agriculture have positive impact on the transformation of rural areas. The issue therefore ultimately converges towards finding the transformational path of a rural settlement and examines how far the above impetus has been responsible for this transformation. The present study is an endeavour to investigate the extent of such transformation in India and particularly in two districts of the state of West Bengal.

2 RESEARCH QUESTIONS

The study has been attempted to find out the answers of the following research questions: - a) which factors are responsible for changes in occupational structure and economic diversification, which in turn led to rural transformation in India?, and b) whether proximity of large city has an impact on the socio-economic transformation of the rural settlements?

3. CONCEPT

3.1 Rural Transformation

Rural transformation (RT) involves rising agricultural productivity, increasing commercialization and marketable surpluses, and diversification of production patterns and livelihoods. It also involves expanded decent off-farm employment and entrepreneurial opportunities, better rural coverage and access to services and infrastructure (IFAD, 2016).

Rural transformation is a process of comprehensive societal change whereby rural societies diversify their economies and reduce their reliance on agriculture and become dependent on distant places to trade and acquire goods, services, and ideas and become culturally more similar to large urban agglomerations. Rural transformation is the reorganization of society in a given space, rather than about a space that empties as people and economic activity move away. It is embedded within a wider process of structural change that involves the whole of a country and that sees a decline in the relative weight of agriculture in the overall economy, a corresponding increase in industry and services, migration of rural people to nearby urban areas. While regional and global forces drive this transformation, they are mediated by localized social structures and institutional frameworks. However, rural transformation has different outcomes in terms of economic growth, social inclusion, and environmental sustainability both at inter country and intra country level (Berdegue et al., 2013).

Kumar et al. (2014) find that there are multiple dimensions of rural transformation. The diversity of production and economic activities of the people results into income flows from diverse sources. The agrarian economy could not satisfy

their aspirations for social and cultural mobility. The surplus they generated from agriculture thus goes into education, urban trade and other non-agricultural activities.

Majumdar (2016) described rural transformation as a proactive, positive as well as dynamic process of changes and development among the rural areas in the context of national social and economic changes. The rural transformation involves the introduction of urban facilities in rural areas, which generates a favorable environment that have a significant proper affect over standard of living condition in terms of qualitative and quantitative characteristic of rural. Rural transformation is usually characterised by changes in civic amenities, female literacy, gender ratio, employment structure, agricultural intensity, crop selection pattern, farm income, labour productivity and major improvements in housing, economy and social conditions resulting from industrialisation and urbanization (Ohlan, 2016).

The Rural Development Report of International Federation of Agriculture Development (2016) aims to shed light on the transformation of rural areas and the wider economy, yielding the following main messages:

- 1) Rural transformation does not happen in isolation, but as part of a broader process of structural transformation shaped by the interlinkages between agriculture, the rural non-farm economy, manufacturing and services.
- 2) While rural transformation may generate both positive and negative effects for rural people, inclusive rural transformation must be made to happen; it will not happen automatically.
- 3) Rapid rural or structural transformation, while necessary, does not automatically lead to a minimization of rural poverty level.
- 4) Rural development strategies for rural transformation are context-specific, but have a similar direction, with high-priority policy reforms, institutional innovations and investments dependent on the speed and inclusiveness of the transformation.

World Bank (2007) categorized the developing countries in three categories i) agriculture based, ii) transforming, and iii) urbanized in the context of contemporary issues such as rural, rural transformation and rural development. It has been found in the World Development Report, 2008 that amongst the developing countries fourteen percent of rural population are dependent on agriculture, seventy seven percent are in the stage of transforming countries including India and nine percent are in urbanized developing countries stage.

3.2 New Towns

In this study 'New Towns' refer to the urban centres which are emerged first time in 2011 census due to transformation of rural areas (villages). These new towns also termed as 'census towns' by Census of India which came into existence as they have fulfilled the census criteria, such as population at least 5,000; density of population 400 per square kilometre and at least 75 percent of male workers engaged in non-agriculture activities.

4. FACTORS RESPONSIBLE FOR CHANGES IN OCCUPATIONAL STRUCTURE AND ECONOMIC DIVERSIFICATION

Berdegue et al. (2013) identified three factors behind rural transformation as - i) diversification of rural economies, ii) progressive globalization of agri-food systems, and iii) urbanization of rural regions. Nathan et al. (2010) list the drivers of rural transformation - as i) infrastructure: roads, electricity, irrigation; ii) technology: green revolution; iii) government policy: support to cereal production; iv) entrepreneurial farmers, v) mobilization for social and gender equality: influencing government allocations through electoral system, vi) migration: commuting, circular, permanent and vii) telecommunications. Gupta (2013) listed 30 indicators under the sub categories of i) demography, ii) social, iii) economic, iv) spatial, v) infrastructure: physical, social, vi) connectivity with town, vii) banking, viii) household assets, ix) administrative/governance.

Mazumdar (2016) observed that the extent of rural transformation can be portrayed in its 'technology', 'economy', 'social institution', 'ideology', 'art' and 'religion' even it may result from one kind of rural society into another depending on the extent of change. He also argued that there are two principle factors behind the rural transformation that are: i) 'Natural factors' like earthquake, floods, famines; and ii) 'Technological factors' like the scientific inventions, new means of communications and transportation, governmental measures, etc.

Based on literature review the following indicators have been used in the present study: a) Contribution of non-farm activities in district gross domestic product (GDP); b) Demographic: literacy rate, sex ratio, household size; c) Economy: change in percentage of non-farm workers; d) Infrastructural: percentage of house electrified, percentage of households with LPG as fuel for cooking, percentage of households having latrine facilities, percentage of households having two wheelers; and e) Behavioural: mobile phone.

5. MATERIALS AND METHODS

This study is based on secondary data collected from Census of India, National Sample Survey Office (NSSO), Agriculture Survey Reports, etc. Two levels of data analysis have been done, firstly state level of India to see the spatial concentration and distribution of rural transformation and secondly, district level of the state of West Bengal.

The evidence of India's rural transformation was based largely on the official data on employment released by the (NSSO). The employment survey conducted by the NSSO showed that between 2004-05 and 2011-12, a huge section of India's

workforce, 33.3 million to be precise, left farm jobs to take up non-farm occupations, primarily in the construction sector (Bhattacharya, 2016).

To understand the dynamics of Indian rural transformation, the following data have been considered: a) Workers employed in farm and non-farm sectors in India; b) Percentage of rural population transformed; c) Share of non-farm sectors in GDP (State/UT level); d) Percentage of rural workers in non-farm activities; and e) Share and growth of agriculture and allied sector in the state GSDP. To find out the rural transformation in case study area of West Bengal, and further detail study of its two districts, the following data have been used: a) Share of non-farm sectors in GDP (district level); b) Change in occupation pattern; c) Demographic data; and d) Household assets

6. ANALYSIS AND FINDINGS

Data from NSSO and Census of India (Table 1) reveal that the share of workers employed in farm sector declined during 2000 - 2011 and it has been increased in non-farm sector, though this change in maximum in NSSO data. This is one of the evidences that change of occupancy has taken place from farm to non-farm sectors. On the other hand the share of rural population to total population has declined from 72.19 percent to 68.84 percent during 2001-2011 (Figure 1).

Table 1: Workers employed in Farm and Non-Farm sectors, India

Categories	NSSO (%)		Census (%)	
	1999-2000	2011-2012	2001	2011
Employed in farm sector	60.30	47.58	58.25	54.60
Employed in non-farm sector	39.70	52.42	41.75	45.40

Source: Estimates based on NSSO (2001 & 2014) and Census of India (2001 & 2011).

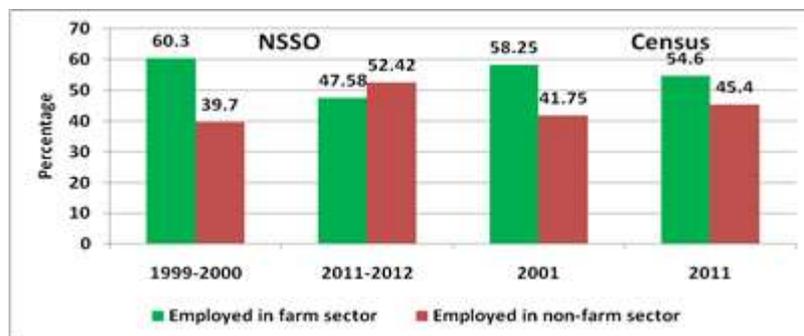

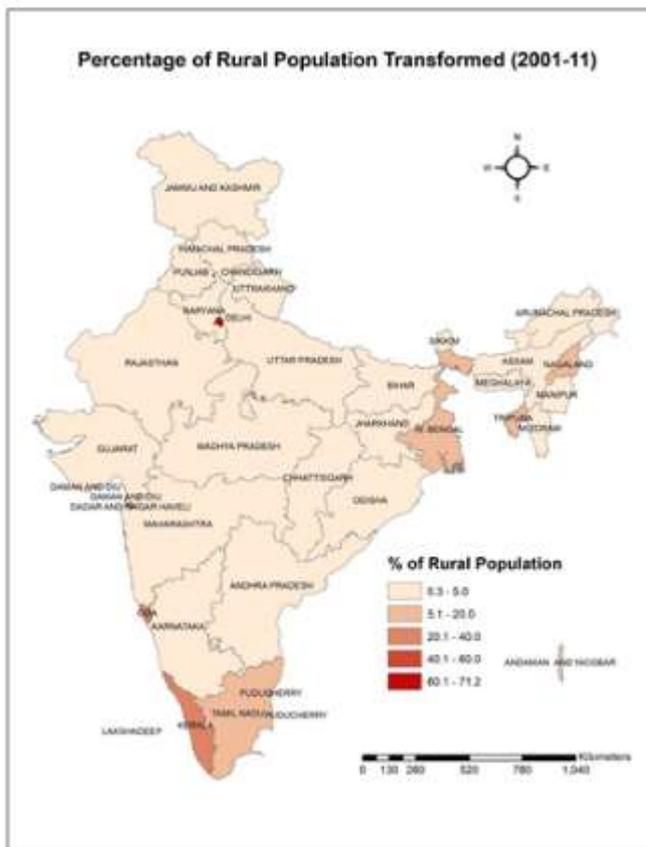

Figure 1: Workers employed in Farm and Non-Farm Sectors (NSSO and Census data)

In rural areas there are two sources of income, namely farm and non-farm activities for the households. Income of the household from non-farm activities may be one of the pull factors that are responsible for shift in occupation from farm to non-farm sector. The developmental factors like modernization of agriculture and its commercialization, increased demand for non-agricultural goods and services, growing literacy, urbanisation, have tried to pull the labour force away from farm sector to well-paid non-farm sector. At the same time, distress factors like poverty; unemployment, underemployment and natural calamities like drought have tried to push the rural workforce away from the farm sector to various nonfarm activities to supplement their income (Sinha, 2007).

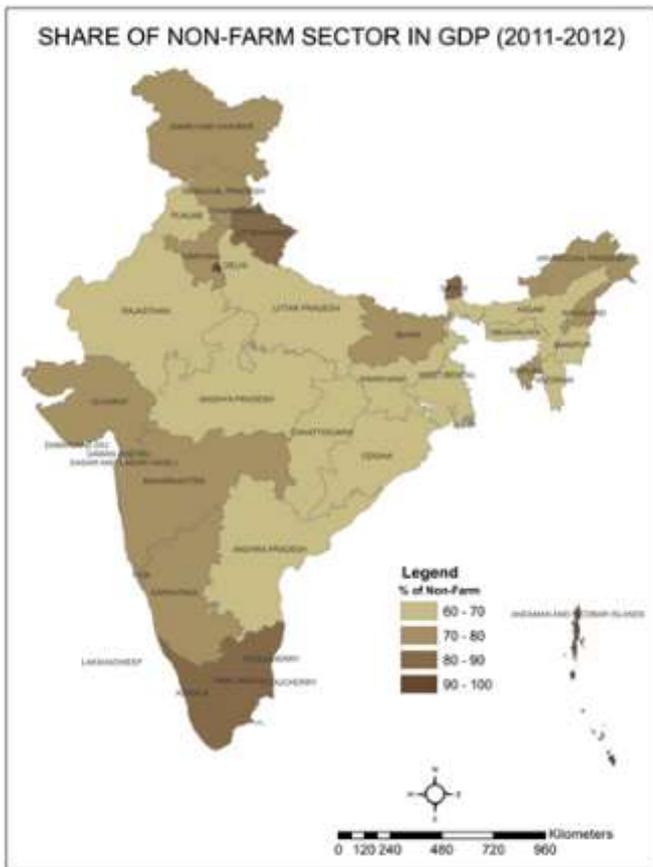

Map 1: Percentage of Rural Population Transformed during 2001-11 (state level)

6.1 Rural Transformation

An attempt has been made to find out State/UT level the percentage of rural population transformed to urban. National level 3.57 percent of rural population has been transformed to urban in character during 2001-2011. State/UT level data analysis has shown that this transformation was a maximum in case of NCT of Delhi (71.17%), Chandigarh (65.83%), Daman and Diu (65.48%), Lakshadweep (59.78%), Kerala (28.09%), Dadra and Nagar Haveli (25.39%) and Goa (22.77%). In 2011 a number of 2,691 new towns have been added in Indian urban system due to rural transformation. Amongst these 498 new towns (18.51% of 2,691) were added in West Bengal, followed by 320 in Kerala, 247 in Tamil Nadu, 214 in Uttar Pradesh, 157 in Maharashtra, 121 in Andhra Pradesh, and 104 in Gujarat (Annex I). A graphical presentation of these data has been presented in Map 1.

6.2 Non-farm Sector in GDP

The share of non-farm (secondary and tertiary sector) sectors in GDP of 2011-12 was a maximum in case of Chandigarh and NCT of Delhi 99 percent each, followed by Puducherry (93%), Andaman and Nicobar Islands (90.50%), Sikkim (85%), Uttarakhand (82.30%), Kerala (82.29%), Tamil Nadu (81.28%), Himachal Pradesh (77.08%), Maharashtra (76.75%), Nagaland (76.63%), Bihar (76.17%), Haryana (75.21%), Jammu and Kashmir (73.93%), Goa (73.50%), West Bengal (68.61%), Uttar Pradesh (67.86%) and Andhra Pradesh (66.96%) (Annex - II and Map 2).

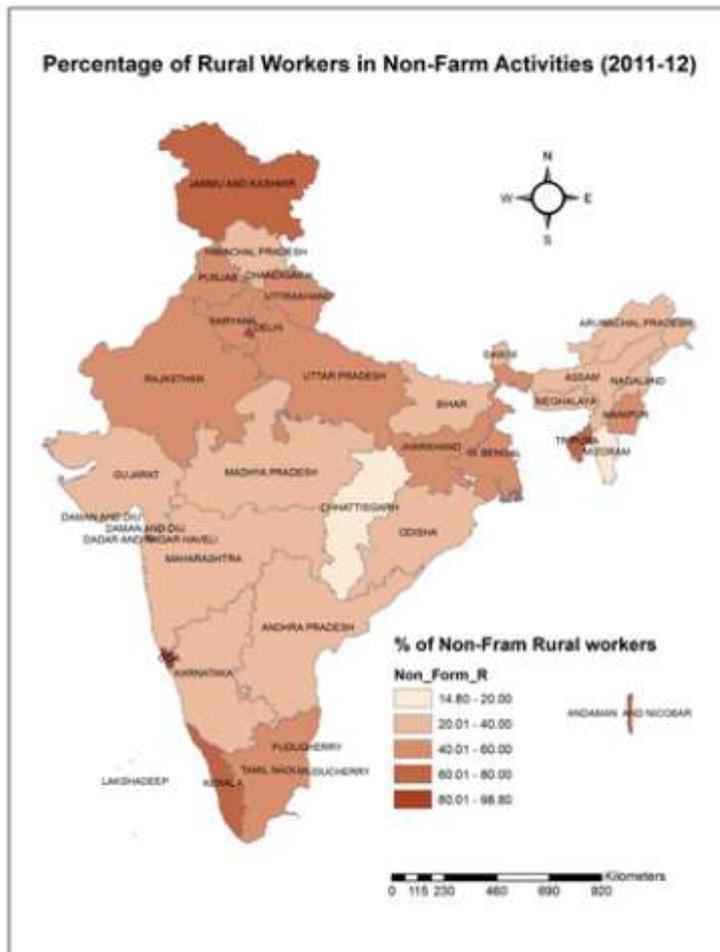

Map 2: Share of Non-Farm Sectors in GDP (2011-12)

There is a positive correlation between the state level number/percentage of rural transformation and the share of non-farm sectors in state GDP (Gross Domestic Product) as well as with percentage of rural non-farm workers.

6.3 Rural Workers in Non-farm Activities

National level the percentage of rural workers in non-farm activities was increased from 25.10 percent to 37.20 percent from 1999-2000 to 2011-2012. The percentage of rural workers engaged in non-farm activities was found maximum in the year 2011-2012 in Chandigarh (98.80%), NCT of Delhi (98%), Goa (95.40%), Lakshwadeep (90.90%), Daman and Diu (90.80%), Kerala (72.10%), Puducherry (69.60%), Dadra and Nagar Haveli (65.40%), Tamil Nadu (46.40%), West Bengal (44.80%), and Uttar Pradesh (40.80%) (Annex – III and Map 3).

Map 3: Percentage of Rural Workers in Non-Farm Activities (2011-12)

6.4 Agriculture in state GSDP

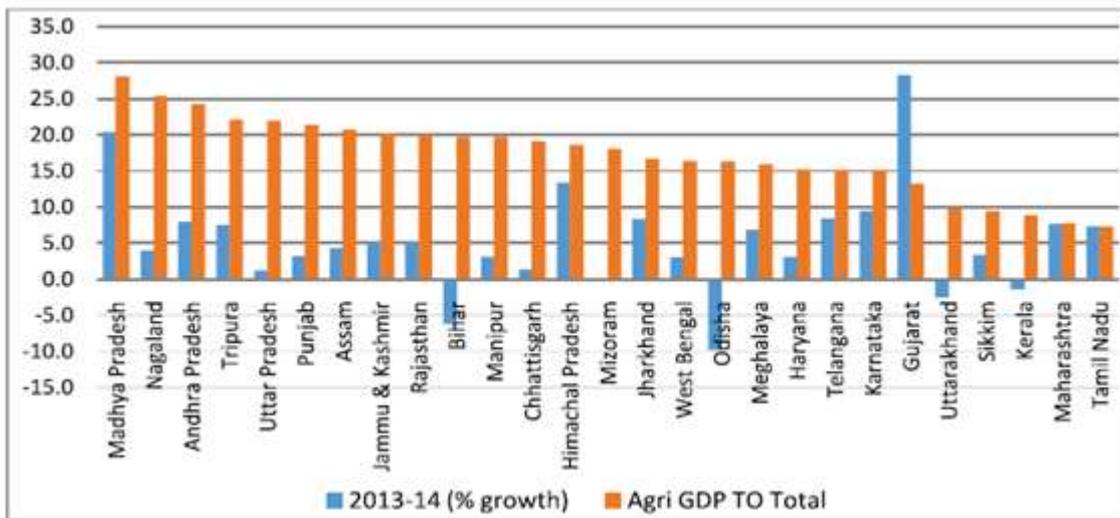

The share and growth of the agriculture and allied sector at the state level presents a very different picture from that at the national level. While at the national level, the agriculture and allied sectors contributed about 14 per cent to the GDP in 2013-14 (at constant 2004-05 prices), a number of states showed a much larger share of agriculture in GSDP. As shown in Table 2, about 13 states earn over 20 percent of their GSDP from agriculture, and only 7 states earn less than 15 per cent of their GSDP ((GoI, 2016).

Inter-state and inter-temporal variability in agricultural growth rate has also been observed. The share of agriculture in GDP was high in case of the state of Madhya Pradesh, Nagaland, Andhra Pradesh, Tripura, Punjab, Assam, Jammu and Kashmir, Rajasthan, Bihar, Manipur, Chhattisgarh and Himachal Pradesh (Figure 2). On the other hand it was low in case of the state of West Bengal, Kerala and Tamil Nadu where the share of non-farm workers was more in GDP during 2011-12 (GoI, 2016). Further it has been observed from Figure 2 that the states where the percentage of growth of agriculture during 2013-14 was more has less transformation of rural population to urban.

Table 2: Share of Agriculture and Allied Activities in State GSDP at constant 2004-05 prices

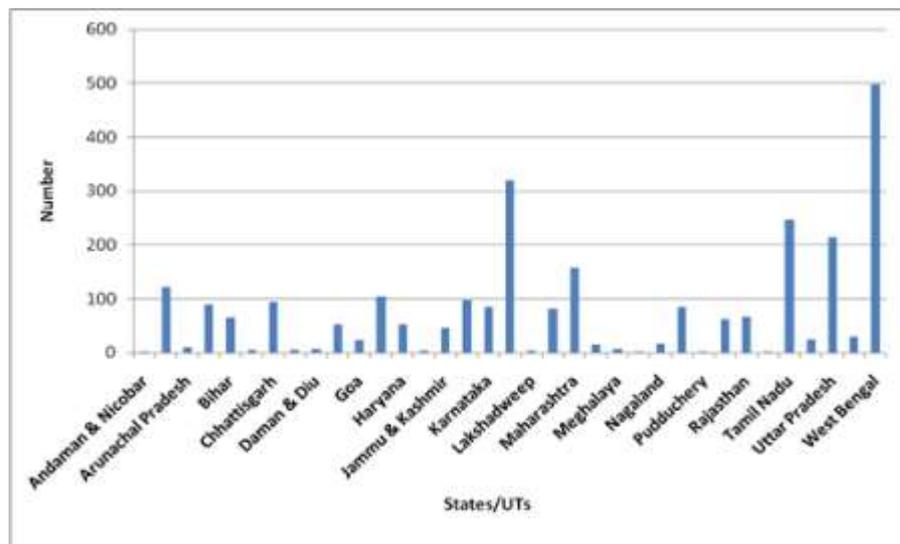

Share of agriculture and allied sector in GSDP	States
30% and above	Arunachal Pradesh
20 - 29 %	Andhra Pradesh, Assam, Bihar, Chhattisgarh, Jammu and Kashmir, Madhya Pradesh, Manipur, Nagaland, Punjab, Rajasthan, Tripura, Uttar Pradesh
15-19%	Haryana, Himachal Pradesh, Jharkhand, Karnataka, Meghalaya, Mizoram, Odisha, Telangana, West Bengal
Less than 15%	Goa, Gujarat, Kerala, Maharashtra, Sikkim, Uttarakhand, Tamil Nadu

Source: Central Statistical Office

Source: Government of India (2016): State of Indian Agriculture 2015-16, Ministry of Agriculture & Farmers Welfare, Department of Agriculture, Cooperation & Farmers Welfare, Directorate of Economics & Statistics, Delhi
 Figure 2: State-wise Growth and Share in Agriculture-GDP (2013-14)

From the above discussion based on percentage of rural population transformation, share of GDP of non-farm sector, percentage of rural workers in non-farm activities, share of agriculture in state GSDP and decline of average growth rate of agriculture reveal that the states where rural transformation is more, the share of agriculture and allied sector is less and vice-versa relationship with tertiary sector and increase in non-farm activities. The analysis also reflects that the proximity of mega or metropolitan city playing a significant role in rural transformation. Beside this the dominance of secondary and tertiary sector and decrease in primary sector workers has also an important role in this transformation. The concentration of newly emerged towns have been seen particularly around, Delhi, Chandigarh, Kolkata, Chennai and Hyderabad.

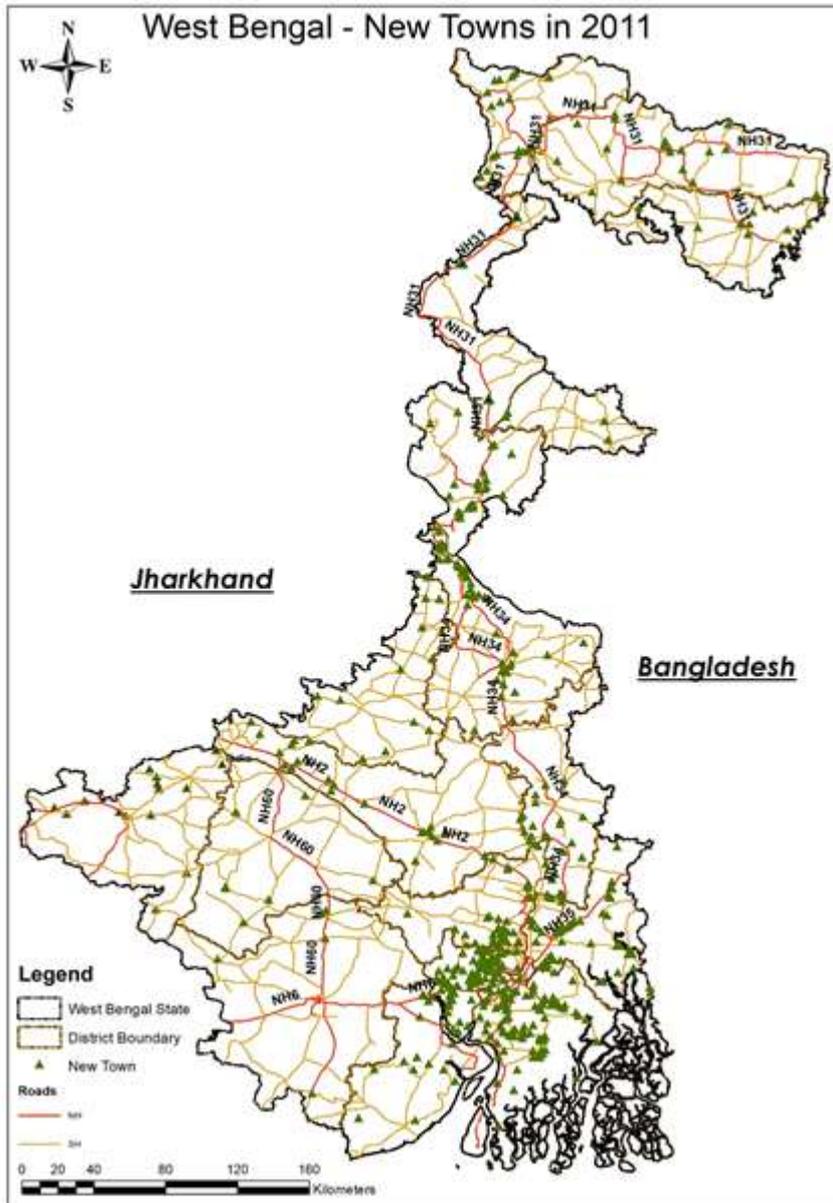

Source: www.censusindia.gov.in/2011census/population_enumeration.html accessed on 8 December, 2017
 Figure 3: Newly added Towns in 2011 (State/UT level)

It has been observed from the Figure 3 that West Bengal state has the maximum number of towns added in 2011 Census year. The detail study on rural transformation has been taken care for the state of West Bengal since it has the highest number of new towns emerged in 2011 census.

7. RURAL TRANSFORMATION IN WEST BENGAL

In 2011 a number of 498 (out of 2,691) rural areas have been transformed to urban areas. This number was the highest amongst the States/UTs of India. All these 498 new towns were rural (village) in character in 2001 (Map 4) (Table 3). This study is mainly focusing on the determinants and characters of newly emerged towns from villages.

Map 4: Location of New Towns added in 2011 in West Bengal

Table 3 reveals that a total 261 rural areas in the surrounding four districts of the megacity Kolkata, namely Hoara, Hugli, North and South Twenty Four Parganas, counts to 52.41 percent of total of the state. The proximity of megacity and increase share of rural workers in non-farm activities have resulted this transformation. Beside these a significant number of rural areas transformed in the districts of Murshidabad (42), Nadia (34), Bardhaman (29), Maldah (22) and Jalpaiguri (22).

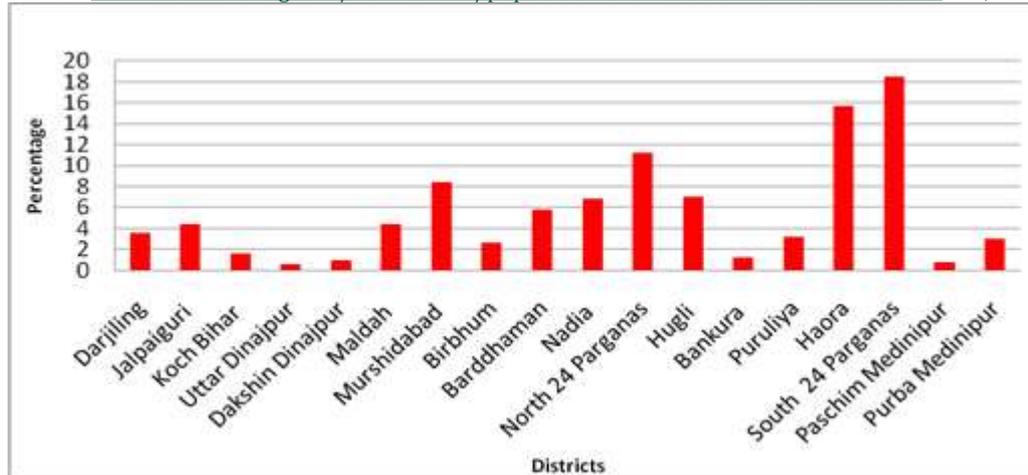

Table 3: New Towns added in West Bengal (district level) - 2011

SL. No.	Districts	Newly emerged towns in 2011	% of new towns to total of 498
1	Darjiling	18	3.61
2	Jalpaiguri	22	4.42
3	Koch Bihar	8	1.61
4	Uttar Dinajpur	3	0.60
5	Dakshin Dinajpur	5	1.00
6	Maldah	22	4.42
7	Murshidabad	42	8.43
8	Birbhum	13	2.61
9	Barddhaman	29	5.82
10	Nadia	34	6.83
11	North 24 Parganas	56	11.24
12	Hugli	35	7.03
13	Bankura	6	1.20
14	Puruliya	16	3.21
15	Haora	78	15.66
16	South 24 Parganas	92	18.47
17	Paschim Medinipur	4	0.80

18	Purba Medinipur	15	3.01
Total		498	100.00

Note: In the surrounding four districts of Kolkata 52.41 percent of new towns added in 2011

Source: www.censusindia.gov.in/2011census/population_enumeration.html accessed on 8 Dec, 2017

Source: www.censusindia.gov.in/2011census/population_enumeration.html accessed on 8 Dec, 2017

Figure 4: District level Percentage of New Towns in West Bengal (2011)

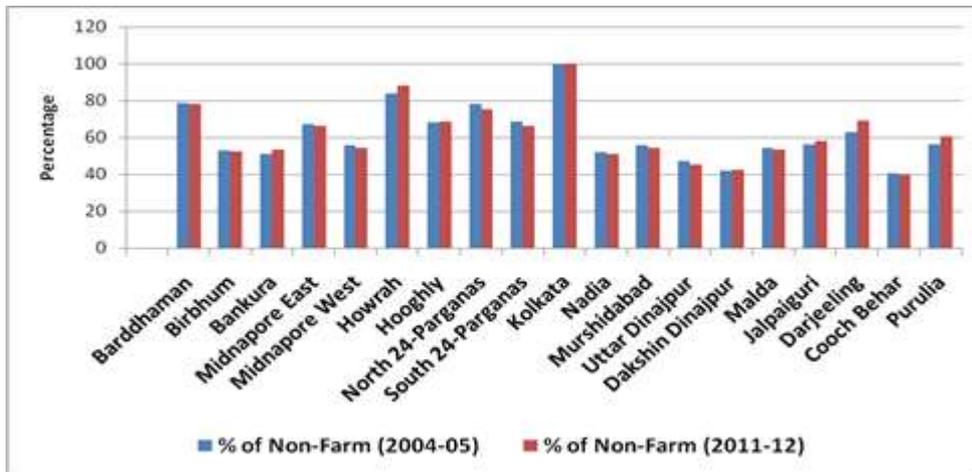

It has been seen that the districts far from Kolkata megacity have also a good number of new towns added in 2011. This is due to high growth rate of urban population during the decade 2001 – 2011. The urban growth rate (2001-11) was 85.52 percent in the districts of Maldah followed by South Twenty Four Parganas 62.62 percent, Murshidabad 57.89 percent, Jalpaiguri 53.48 percent, and Nadia 30.89 percent.

Table 4: Contribution of different Districts in GSDP, West Bengal

Sl. No.	District	2004-05			2011-12		
		Agriculture & Allied	Industry	Service	Agriculture & Allied	Industry	Service
1	Barddhaman	7.53	18.41	9.05	7.57	16.96	9.87
2	Birbhum	4.15	2.07	2.57	4.27	2.15	2.52
3	Bankura	4.80	2.14	2.87	4.88	2.66	2.92
4	Midnapore East	8.29	9.99	7.11	8.02	8.59	7.03
5	Midnapore West	7.12	4.08	4.84	7.23	4.13	4.55
6	Howrah	2.51	6.77	6.43	2.02	8.40	6.63
7	Hooghly	6.31	6.90	6.47	6.16	6.71	6.63
8	North 24-Parganas	6.83	11.70	12.96	8.63	12.40	14.04
9	South 24-Parganas	7.86	9.31	7.71	8.15	7.97	7.88
10	Kolkata	0.08	5.51	15.15	0.01	5.24	13.28
11	Nadia	7.67	3.80	4.48	7.82	3.81	4.29
12	Murshidabad	8.67	6.41	4.50	9.25	6.77	4.26
13	Uttar Dinajpur	3.06	1.07	1.65	3.43	1.19	1.63
14	Dakshin Dinajpur	2.67	0.69	1.23	2.64	0.75	1.21
15	Malda	5.05	3.28	2.78	5.18	3.38	2.61
16	Jalpaiguri	5.15	3.12	3.50	4.97	3.50	3.47
17	Darjeeling	2.51	1.67	2.60	2.32	1.94	3.24
18	Cooch Behar	4.62	1.23	1.94	4.58	1.24	1.77
19	Purulia	3.10	1.85	2.16	2.87	2.21	2.17

Source: Govt. of West Bengal (2015): State Domestic Product and District Domestic Product of West Bengal, 2013-14

The district level contribution in state gross domestic product is showing that the district around Kolkata megacity has maximum share from industry and service sectors which reflect more non-farm activities in these districts. Ultimately it has transformed the scenario of rural areas in these districts. District level the contribution of agriculture and allied sector in the state GSDP, Murshidabad, Midnapur East, North and South 24 Parganas, Midnapur West, are important. However, it is difficult to draw a conclusion that the districts which have low share in agriculture and allied sector are more urbanized. For example, in Howrah this share was 2.02 percent in 2011-12, but this district has a maximum of 78 newly added towns due to rural transformation. Detail study of two districts have been carried out, one based on highest number of new towns added in 2011 and another based on the highest percentage of rural population transformed to urban. In this method one district near mega city (South 24 Parganas) and another far from megacity (Murshidabad) are taken to capture the rural transformation process across these two districts over inter censal periods.

Source: State Domestic Product and District Domestic Product of West Bengal, 2013-14
 Figure 5: West Bengal: Contribution of Non-Farm in GSDP in 2004-05 and 2011-12

Analysis reveals that increasing contribution of non-farm activities have led to the transformation of rural areas in West Bengal

7.1 Selection Criteria of Case Study Districts of West Bengal

To find out two districts from nineteen districts of the state of West Bengal the following two criteria have been identified based the these two criteria – a) Maximum number of New Towns added in 2011 due to rural transformation, and b) One district near mega city Kolkata and the other far from mega city along national highways (NH). Therefore, based on above criteria the following two districts has been selected for detail study – i) South 24 Parganas (92 New Towns added in 2011), and ii) Murshidabad (far from mega city Kolkata and having located along NH)

7.2 Rural Transformation of Two Districts of West Bengal

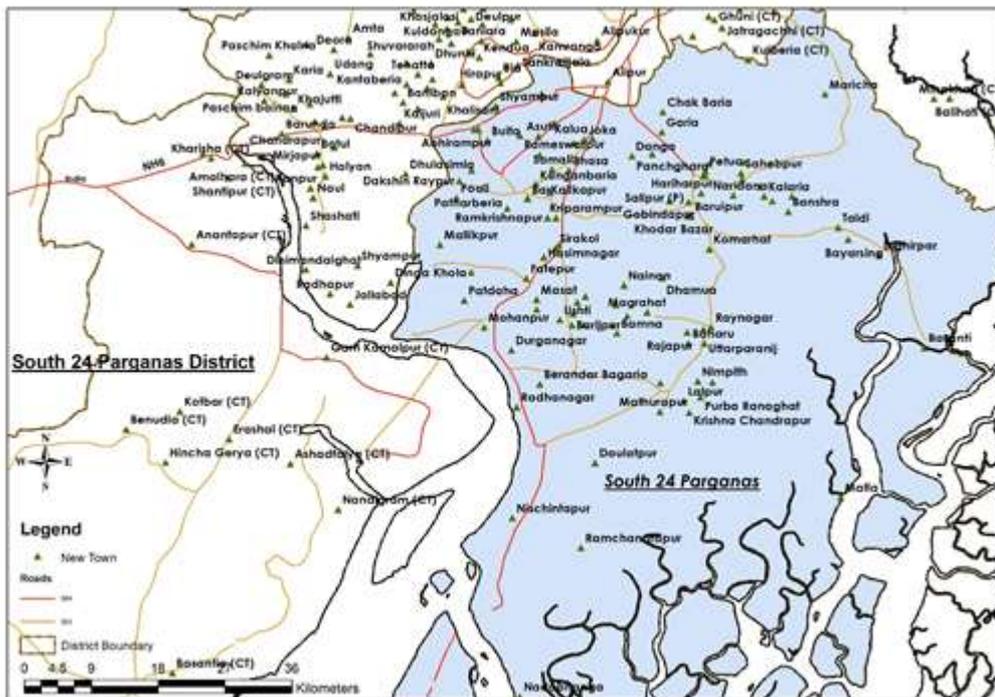

An attempt has been made to capture the rural transformation process across the newly added towns of two districts of West Bengal namely South Twenty Four Parganas with 92 new towns (Map 5) and Murshidabad with 46 new towns and located along NH 34 (Map 6) (Tables 5 and 6). The newly transformed urban centres have observed a positive change in demographic characters. The household size of the newly added towns of South Twenty Four Parganas has decreased from 5.10 to 4.46 and the sex ratio has increased from 943 to 964, these are the positive sign of urbanization. In case of the new towns of Murshidabad the household size has decreased and sex ratio has increased (Table 5) due to rural transformation.

Table 5: Demographic change in Case study New Towns of two Districts, 2001 and 2011

Sl. No.	District	Household Size		Sex Ratio		Literate		Non-Farm workers	
		2001 (Rural)	2011 (New Town)	2001 (Rural)	2011 (New Town)	2001 (Rural)	2011 (New Town)	2001 (Rural)	2011 (New Town)
1.	South 24 Parganas	5.10	4.46	943	964	75.68	78.29	70.59	87.93
2.	Murshidabad	5.54	5.05	976	970	58.43	65.03	73.23	88.31

Source: Census of India 2001 and 2011

The literacy rate of the new towns of both the districts has increased during the period of transformation. The literacy rate of the new towns has increased in South Twenty Four Parganas district but it is less than the urban average of 82.67 percent as of 2011. However, the literacy rate of the newly added towns of Murshidabad district is also less than the district urban average of 71.85 percent (Census 2011).

Map 5: Location of New Towns in South 24 Parganas District

Table 5 reveals that the percentage of non-farm workers has been increased in case of the newly added towns in 2011 for both the districts. However, the overall percentage of urban areas of South Twenty Four Parganas was 94.55 percent in 2011 as compared to 87.93 percent. However, in case of the new towns of Murshidabad district the percentage of non-farm workers is much more than district urban average of 40.59 percent (Census, 2011). This district is very well connected by national highways. This shows a positive impact of national highways on rural transformation.

Map 6: Location of New Towns in Murshidabad District

An attempt has been made to observe the impact of change of occupation pattern and provision of amenities, mainly percentage of households having - electricity, LPG (liquid petroleum gas) as fuel for cooking, latrine facilities, two wheelers and mobile phone. It has been observed from Table 6 that the above mentioned household assets are still less than the district urban average in the newly transformed settlements of both the districts (Table 6).

Tables 5 and 6 also address that there is a role of large city in the socio-economic transformation of the rural areas of South Twenty Four Parganas as compared to Murshidabad. The purpose behind the rank correlation is to establish the verity that improvement in one aspect of life and livelihood positively impacts other aspects and thus a cascading effect generates whereby each aspect mutually impacts one another. The Spearman rank correlation coefficient has been found to be 0.95 at 5 percent level of significance. It validates the argument that the demographic, economic and infrastructural

factors in case of the new towns of South Twenty Four Parganas have not only vastly transformed positively, each one of the factors (and sub factors) have impacted the others and in turn got impacted by other factors.

Table 6: New Towns having Household Assets, 2011

Sl. No.	District	Percentage of Households having				
		Electricity	LPG as fuel for cooking	Latrine facilities	Two Wheelers	Mobile Phone
1.	South 24 Parganas	59.37	15.66	63.19	6.03	50.05
2.	South 24 Parganas (District's urban average 2011)	90.30	37.20	83.10	8.90	61.10
3.	Murshidabad	47.61	11.73	48.06	7.06	37.69

Spearman rank correlation coefficient, $\rho = 1 - 6\sum d^2 / n(n^2 - 1)$ where d is the difference between the pair of ranks for each pair of observations and n is the number of paired observations.

8. CONCLUSION

The rural transformation has been much more in the state of West Bengal in India as compared to other states and union territories. It has been observed that the states and union territories where agriculture and allied sector is declining the agricultural labourer forced to change their occupation. There is a fact that mega/metro cities and alignment of national highways also played a significant role in this massive transformation during 2001-2011. A detail study of West Bengal reveals that the socio-economic transformation of rural South 24 Parganas ostensibly due to its proximity to mega city, Kolkata. Demographic, economic and infrastructural factors in case of South 24 Parganas have not only vastly transformed positively, but each factor has impacted the others and in turn got impacted by other factors. On the other hand in Murshidabad, well connectivity with National Highways 34 (NH) and proximity of large city Malda has impacted the transformation. The occupational pattern of the newly added urban settlements largely non-farm (secondary and tertiary) since 2001, the transforming is also a fulfilment of census criteria. While doing analysis it has been observed that few villages are of above two case study districts are not fulfilling one of the criteria of census that 75 percent of male workers will be engaged in non-agricultural activities. A question arise here whether all these newly added towns in 2011 census are census towns or some of them are statutory towns also. This needs further research.

1400 CHANGING NATURE OF TRADITIONAL TRIBAL WEAVING IN TRIPURA, INDIA: A STUDY ON CHAKMA COMMUNITY

ABSTRACT

Tripura, a small state in the North-Eastern region of India is the homeland to 19 tribal communities with an area of 10,486 km². The communities have their own fine cultural and proud heritage. The Chakma is one such rich cultured tribe among them. According to the Census of India, 2011 the total population Chakma population in Tripura is about 79,813 which is the fourth largest tribal community of the State after Tripuri, Reang and Jamatia. They are mainly concentrated in Belonia and Sabroom sub-divisions of South Tripura District, Kanchanpur sub-division of North Tripura and Amarpur sub-division of Gomati District respectively. Weaving is the primitive self sustainable economic activity as well as cultural symbol of this tribal community. Now a day, the Chakma men have given up their traditional clothes for western-style shirts and trousers but the Chakma women maintain the traditional style of dresses. Globalised market, impact of westernisation, mechanised product and others socio-economic factors cumulatively make a negative impact on traditional handloom weaving among the Chakma Community of the state. This research work attempted to understand the changing nature of traditional tribal weaving in Tripura. About 200 samples have been collected from Chakma concentrated clusters of Tripura through Stratified Random Sampling technique by Systematic Schedule Survey. Secondary data also has been collected from the Census of India and Rural Development Blocks, Gram Panchayat Offices of different districts of Tripura. The finding reveals that the traditional handloom weaving culture is annihilate from the state due to social upliftment of Chakma Community both in terms of educational as well as economical. 1419 RUBBER PLANTATION PLAYING A MAJOR ROLE AS THE ECONOMIC BACKBONE AMONG THE TRIBAL GROUPS TOWARDS THEIR SOCIO-ECONOMIC DEVELOPMENT: A STUDY ON THE WEST GOALPARA DISTRICT, ASSAM

Kasmita Das

MPhil Research Scholar, Department of Geography, Gauhati University

ABSTRACT:

Goalpara District is one of the leading producers of Rubber in the entire state of Assam, and also in North-East India. The major production of Rubber came from the West Goalpara District. However, since 1980s, small growers have been switching to rubber with some help from the Rubber Board. Out of the total rubber plantations in Assam, Goalpara alone has 8460ha under Rubber Plantation. The district is having 47 RPS (Rubber Producer's Societies) covering more than 2068 rubber growers. In Goalpara District, the indigenous tribes have realized the benefits of rubber cultivation and are shifting their occupation towards the prospective venture. Over 7,000 families are dependent on rubber cultivation for their livelihood. Rubber cultivation provides them a golden opportunity to become self-employed. The analysis has been done with the help of Extensive field survey with suitable sampling technique and addition with some secondary data collected from Rubber Board Regional Office, Census data and NGO. This paper focuses on the role of natural rubber (*Hevea brasiliensis*) cultivation as a source of income for rural tribal communities. The cultivation and establishment of rubber plantations have a very positive socio-economic impact in the study area.

Keywords: Rubber Plantation, Tribal, Socio-Economy, Livelihood

INTRODUCTION

Rubber Cultivation is undertaken as a plantation crop mostly in the hills and plains of tribal dominated areas of the entire North Eastern region. This region comprising of eight states has tremendous potential for production of Rubber Cultivation. Nine percent of the country's rubber production comes from the North-East India and Tripura is considered as the "Second rubber capital of India" by the rubber broad. There are six rubber nurseries in the North Eastern Region: Three in Assam (Cachar, Goalpara and Karbi Anglong District), Two in Meghalaya (East Garo Hills and West Garo Hills) and one in West Tripura.

Goalpara district exhibits a remarkable diversity as the hills of Meghalaya forms its southern boundary and major part of the district is constituted by the plains of the Brahmaputra. The landform of the district, especially in the entire western part and southern part, along the foothills of Meghalaya has much upland. These uplands along with the favorable climatic condition have supported rubber plantation in many parts of the district. Replacement of natural vegetation with various plantation crops is a global phenomenon. Rubber was introduced in Goalpara as one of the plantation crops in 1980s. Attracted by the economic benefits and incentives to convert traditional farming areas into high value commercial crops many farmers switched to rubber cultivation in the District. Government policy and incentives have also given a shift towards rubber plantation. The ability to store and transport rubber easily as well as overall return on investment make rubber superior to other cash crops. Assam, where Rubber Plantation was launched even before in Tripura, has a potential for about two lakh hectares, where only 42,097.01(Statistical Handbook of Assam 2015) hectares have been brought for rubber cultivation. The rubber Board has identified Assam as a "Potential State" for rubber cultivation. Rubber is cultivated in almost all the districts of Assam.

Farmers of the district are taking up the highly lucrative rubber cultivation on a large scale and as future prospects of the rubber industry grow brighter, the Government has come up with various schemes for the entire region. The first plantations, mostly confined to large estates, trial plantations were taken up by the forest and soil conservation department. However, since 1980s, small growers have been switching to rubber with some help from the Rubber Board. In fact, Goalpara district of Assam has been one of the Rubber Board's success stories. The Rubber Board had in fact implemented a project called Accelerated Development of Rubber Plantation in the Northeastern region during the six-year period, from 1984-90. While the target under the project was to bring 24,000 hectares under rubber plantation, around 23,155 hectares was achieved.

STUDY AREA

Goalpara district of Assam is located between 25°33' and 26°12' North latitude and 90°07' and 91° 15' east longitude. The district covers an area of 1,832 sq.km. It is bounded by West and East Garo Hill districts of Meghalaya on the South, Kamrup district on the East, Dhubri district on the west and the river Brahmaputra on the North. The district is in the south-western part of the state bordering national boundary between Assam and Meghalaya and adjacent to international boundary between India and Bangladesh in the west.

The district is situated entirely on the south bank of the river Brahmaputra. The district has 5 Revenue Circles. These are 1) Lakhipur Revenue Circle 2) Balijana Revenue Circle 3) Dudhnoi Revenue Circle 4) Matia Revenue Circle and 5) Rangjuli Revenue Circle. There are 81 Gaon Panchayats and 837 revenue villages in the district.

LOCATION MAP

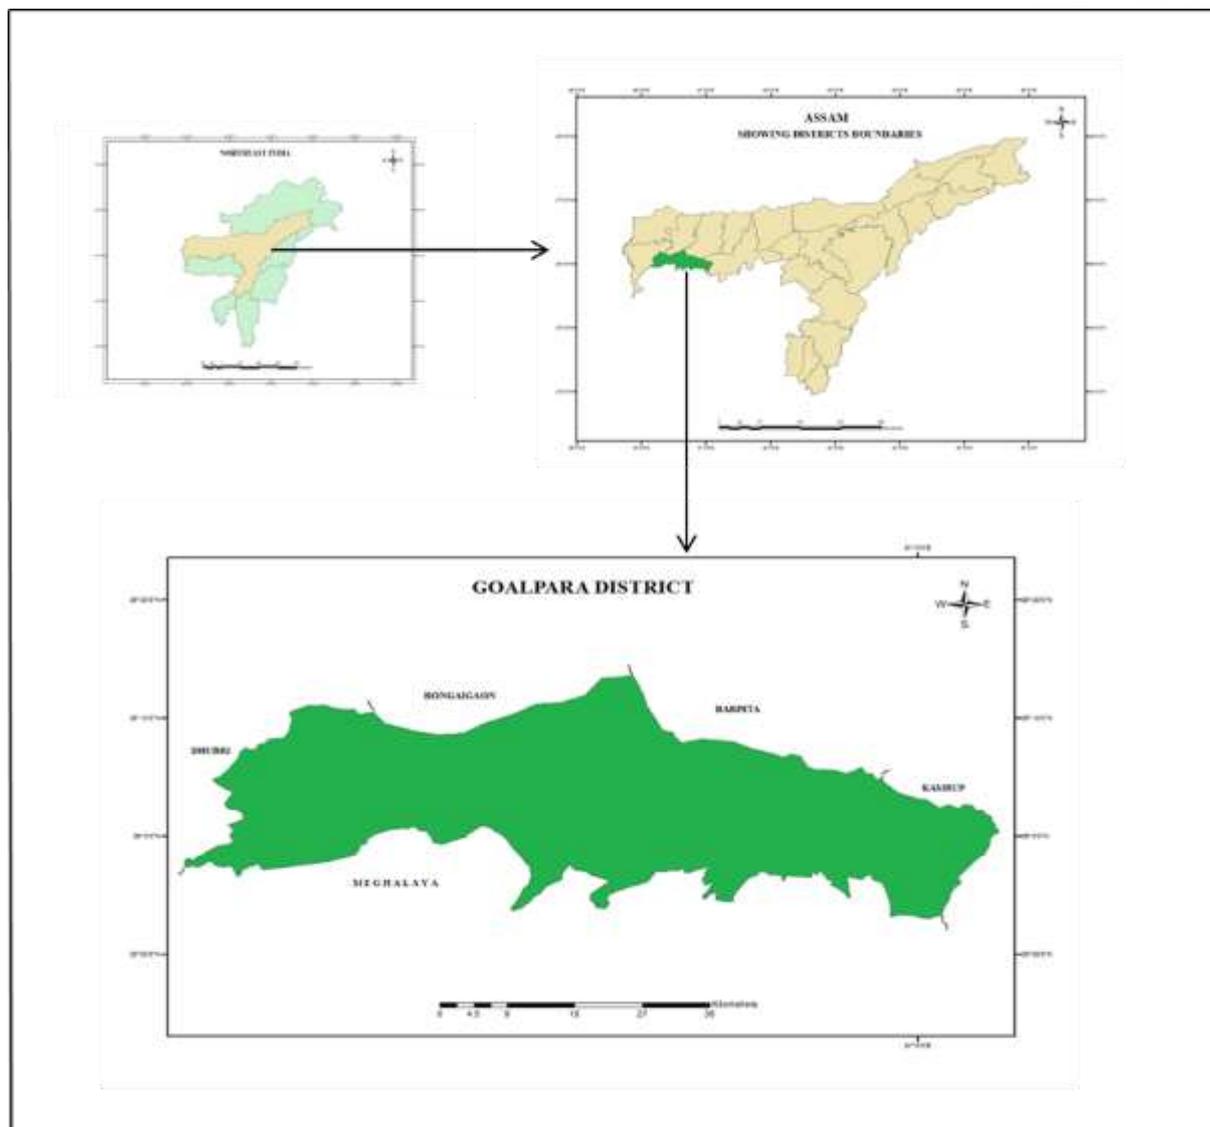

Fig-1) Map of the study area

OBJECTIVES

The main objectives of the study are:

- i) to analyse the trend of development of rubber plantation;
- ii) to study the social characteristics of the people associated with rubber plantation, and to examine the economic change among the rubber growers; and
- iii) to discuss the positive aspects of rubber plantation in relation to the society.

DATABASE AND METHODOLOGY

The study has been carried out with the help of primary and secondary data. The relevant secondary data has been collected from the sources like-(i) Directorate of Economics and Statistics (ii) Rubber Board Regional Office (iii) Office of the Circle Officer (iv) Satellite imageries of the study area.

Firstly, by using some GIS techniques, the relief has been represented (using DEM), and the satellite imageries of three different years i.e. 1990, 2004 and 2017 were used to show the development of rubber plantation and also the land use change in the areas.

Secondly, the primary data has been collected based on the objectives with the help of a well-designed survey schedule. The survey was conducted using suitable sampling technique. As the area is a larger one, the Stratified Random Sampling was followed for collecting primary data.

RESULTS AND DISCUSSION

Rubber is one of the important cash crops among the rural tribal in Goalpara. It was introduced in 1985-1986. The first plantations were started in two villages i.e., Ghengamari and Pandoba in the Western part of the district by the indigenous tribes. The district is the leading producer of rubber and the indigenous have realized the benefits of rubber cultivation and are shifting their occupation towards the prospective venture. The fact that small and marginal landholders, especially from tribal communities (Rabha, Garo, Bodo, and Hajong), are the majority participants in the rubber

plantation in the district implies that this new form of economic activity has contributed significantly to economic empowerment at the grassroots.

AREA UNDER RUBBER PLANTATION

Out of the total area of the district, i.e., 182400 hectares, the area under rubber plantation seems to be increasing year after year. Over 7,000 families are dependent directly or indirectly on rubber plantation for their livelihood. As per the data of 2017-2018, the total matured area under this plantation is 4812 hectares; immature area is 3783 hectares (Rubber Board Data). **Table 1** shows the area and the production of Rubber in the district. **Table 2** shows the employment generation in rubber plantation activities in Goalpara District from 2003-2004 to 2015-2016.

Table 1: Year wise extension in the area of rubber plantation

Year	Area (in hectare)	Production (in metric tons)
2012-2013	8045.6	1745
2013-2014	7640.14	2625.8
2014-2015	8595.72	6937.2
2015-2016	9595.75	6699.65

2011-2012	241368
2013-2014	21441
2014-2015	20268
2015-2016	30515
Total	1562592

Source: Statistical Handbook of Assam 2010, 2011, 2012, 2015 and 2016

Rubber has already started influencing the socioeconomic profile of rural tribes. The Rubber Grower's Association was formed in 1994-1995 which supported the indigenous towards the rubber plantation and the rubber nursery came up in the area in 1998 and it has helped the farmers in saving their time and money from purchasing the rubber saplings from Kerala. From the beginning the Rubber Board has been giving great importance to rubber and implementing a variety of programmes for the development of tribal people through rubber plantation along with subsidy of 30,000 per hectare to the farmers. The government agencies and NGO's like *Ajagar Social Circle*, *NABARD*, *Pradhan Mantri Kaushal Vikas Yojana (PMKVY)* have contributed significantly for the development of rubber plantation in the rural areas by giving loans, Tapping Skill Training and some awareness programmes.

AREAS CONTRIBUTING MAXIMUM PRODUCTION

The major areas of the district which are contributing towards the growth of rubber plantation are mostly from the villages of Balijana, Dudhnoi and Lakhipur Revenue Circle. The villages engaged in Rubber Plantation are, *Ghengamari, Tilapara, Rangapara, Bardamal, Rampur, Bairang, Chotadamal, Bamungdanga, Hadlapara, Salpara, Maladhara, Lemakona, Pandoba, Mojaipara, Lengpara, Darani, Kuruwabasha, Goroimari, Dariduri, Bhalukdubi, Majpara, Gendra, Baida, Borjhora, Rangasai, Satabari, Borjuli, Balasari, Thakurbila, Derek*, and some parts of *Darangiri*. These villages have adopted rubber plantation and are developing it at a large scale, where some trees are at the growing stage and most of them are yielding latex at good amount. The plantations are mostly of individual type, and some are cooperative. Rubber production has steadily emerged as an important economic activity among the people in the study area, especially among the youths. The people in the study area are shifting themselves from multiple cropping to monocropping. Earlier there was large number of people engaged in paddy, banana, arecanut and such other type of cultivations. But after knowing about the profit and income from rubber, most of them have shifted or adopted the plantation of rubber, and empowered themselves. Sensing the pulse of the rising demand for rubber products in markets across the country, farmers in the Goalpara district of Assam are taking up rubber cultivation on a grand scale.

FIELD SURVEY

The household survey was conducted via face-to-face interviews using a well-designed questionnaire. Information was collected in the interview about the changes in the livelihoods of people in the villages before and after the establishment of rubber plantations. The information gathered includes the income generated from natural forests and rubber, the contribution of rubber plantations in improving livelihoods, the direct and indirect values of rubber plantations and reasons why local people decided to plant rubber. The information collected included the history of rubber development,

costs of establishment and maintenance of rubber plantations, expected income from production of latex and timber over a production cycle, location of rubber plantations in relation to preferred soil type, or originality of land use type (e.g., forest or barren land).

The people engaged in this plantation are earning income through various ways, like as:

IMMATURE PLANTATION:

Intercropping:

During the initial years of a plantation when the interspaces receive plenty of sunlight, a variety of intercrops (i.e. banana, medical plant, pineapple, ginger, turmeric etc.) can be cultivated.

Casual worker:

In immature plantation casual workers are needed for cutting the unnecessary small plants, forming the boundary of garden and also looking the drainage facilities. In many cases watchman were also employed by authority for providing the security of the garden.

MATURE PLANTATION:

Tapping:

It is method of collecting latex from rubber plants and the workers who involve in this work are known as rubber tapper. This work is generally done in the early morning.

Rubber agency:

Some private garden owners produce large amount of latex/sheet and when they are unable to sell those directly in the rubber factory, the rubber agencies collect those and this way the unemployed youths can engage themselves in those agencies or can also start new agency.

Rubber honey:

Rubber tree is a rich source of nectar. About 15 hives can be placed in a hectare of rubber. About 10 kg of honey is obtained from one hive.

Casual worker:

In rubber processing centre additional workers are needed for various activities i.e. accounting, security, water collection etc.

LIVELIHOOD BEFORE AND AFTER THE INTRODUCTION OF PLANTATION

Before the growth of rubber plantations, surveyed households depended mainly on forest products collection, paddy, banana, arecanut and such other type of cultivations. Nearly 33% of respondents put wet season rice production as the main source of income. The percentage of respondents and their main source of income are shown in the Figure 3 below. They were engaged in hunting, vegetable farming, collected fuel woods, wild fruits and veggies and sell their domesticated animals for their subsistence. Some people were dependent on small business, livestock and wage earner at daily basis.

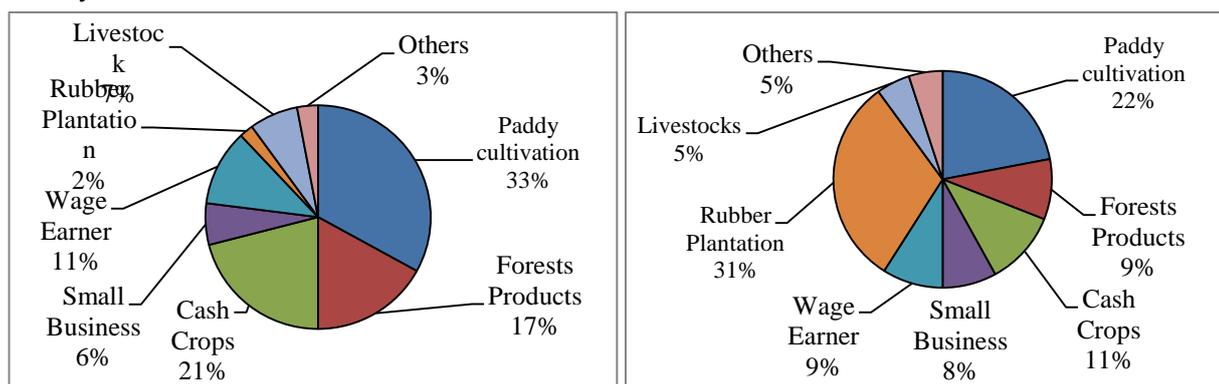

Figure 3: Sources of income before (left) and after (right) Rubber Plantation

After the establishment of rubber plantations, people’s livelihoods in the area have changed rapidly. As the forest area has been converted into rubber plantations only 9% of respondents relied on forest products as the main source of income compared to 17% before. Only 22% relied on paddy cultivation, and 31% have shifted to rubber plantation. The economy of the people grew more after adopting the plantation. Now the people can send their children to schools and colleges for further studies, they are also connected to the world after buying television. After introducing the plantation the rural tribal villages have been developed, and it is clearly reflected in their houses, education, dressing sense, food habits etc. As stated by the farmers, the youths in those backward areas started to join the terrorists groups before the adoption of rubber plantation, because they couldn’t do anything due of poverty. But after the plantations the youths realized its benefits and started to work on it either individually or collectively.

At the initial stage, the growers need to spend a sum of 20000/25000 per hectare for the plantation and its maintenance. As rubber starts to give latex from the 7th year of its plantation, so till that period it is very crucial time for the growers to take care of the trees and to protect it from animals, natural calamities etc. Once the latex is extracted, it has to go through many processes to form the rubber sheets, and the sheets need to smoke before selling. Thus a smoke house is required near the plantation area. The farmers having large plantation areas have smoke house in their compound, while the small growers have to go to other place for the same. The modern smoke house made of iron and steel having the capacity of nearly 100 rubber sheets cost around 80,000 to 1 lakh including the construction of the house.

The farmers got 20,000 to 25,000 per quintal of rubber during 2000-2010, but the price has decreased later and presently the growers are getting 11000-12000 per quintal.

DEVELOPMENT OF RUBBER PLANTATION

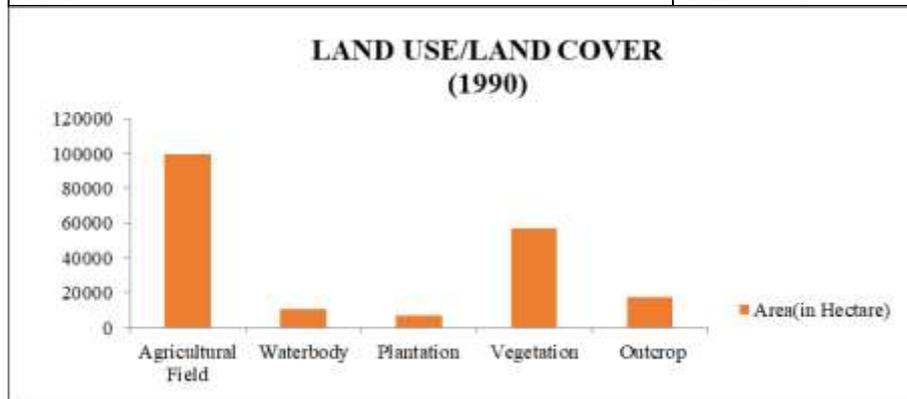

The first plantations were started in 1980s but there was much struggle in the area to make the indigenous understood about the production and benefits of rubber. During 1994-1995 the Rubber Growers Association was formed and started the plantation programs in some areas, preferably the slopes. Later the Rubber nursery was also came up in the district which helped in manifold. One NGO *Ajagar Social Circle* and the *Rubber Board Regional Office* supported the farmers for their growth and development by giving different skill development training related to plantation for better quality of latex extraction and productivity, and also helped financially. The land use/land cover maps (Figure 4, 5 & 6) of three different years i.e. 1990, 2004 and 2017 of the months between October to December shows the growth of plantation in the district along with the related tables (3, 4 & 5) and graphs. It has been found that the area under plantation has been increasing rapidly.

DIGITAL ELEVATION MODEL

CONCLUSION

The landform pattern of an area plays a vital role on the type of agriculture practiced in that area. Goalpara district exhibits a remarkable diversity as the hills of Meghalaya forms its southern boundary and major part of the district is constituted by the plains of the Brahmaputra. The landform of the district, especially in the southern part, along the foothills of Meghalaya has much upland. These uplands along with the favorable climatic condition have supported rubber plantation in many parts of the district. But looking at the economic benefit of rubber, the farmers are doing the plantation near or in the agricultural land which is not much favorable for rubber plantation.

It is a more popular plantation crop in the district. Contribution of rubber production is higher mostly from the western part of the district. The district has many government and private agencies (*i.e.* , Rubber Board, NABARD, Ajagar Social Circle, Rubber Growers Association etc.) which are working for the expansion of rubber plantation in hilly areas where maximum peoples are tribal. In Goalpara (entire western part) large numbers of rural tribal live below the poverty line and rate of unemployment is also very high. This poverty and unemployment are the major reasons for violence, clashes, robbery, terrorism etc. Extension of rubber plantation in rural areas has solved all those kinds of problems to a great extent and it also helping the tribes to overcome poverty and unemployment.

Rural people can earn income from rubber plantation in various ways. In immature plantation people can earn income through intercropping in rubber plantation and also as casual worker. Mature plantation is the main source of income because of latex collection. Therefore, rubber plantation benefits the rural tribal people in many ways.

SS10.3. Rural Transformation

1422 SUSTAINABILITY OF RURBAN SETTLEMENTS IN AN URBANIZING MILIEU: A PROBE INTO SELECTED PARTS OF HAORA DISTRICT, WEST BENGAL

ABSTRACT

Rurban settlements are basically hybrid settlements symbolizing a blend of rural and urban characteristics. Between the dualism of two dichotomous but interactive components of human settlement, viz. urban and rural, a concept pertaining to their hybridization has been emerging significantly. The present study focuses on the issues of sustainability of rurban settlements in selected parts (Domjur and Panchla Blocks) of Haora — the smallest but the most urbanized district (excluding Kolkata) in West Bengal, India. The urban landscape of the district is dominated by a large number of census towns and only three statutory towns with 63.38% urban population as against 36.62 % rural population. The prime objectives of this research are: i) to observe the process of rurbanisation in Haora District, ii) to identify the rurban centres (ii) to analyse the potentials of these identified settlements in terms of their infrastructure and (iii) to suggest the necessities to be introduced in these settlements. The methodology applied here includes rurban index, gravity model, and functional classification of rurban centres, correlation and regression analysis and cartographic representation of data collected through primary and secondary sources. It has been observed that the block of Panchla has witnessed larger areas to be designated as rurban settlements than that in Domjur block where settlements are more urban rather than rurban. The Shyama Prasad Mukherji Rurban Mission (SPMRM) has declared two rurban clusters in these two blocks with an ambitious bid to transform these clusters in near future. This area with its traditional site for jewellery and zari work has a huge growth potentials supported by its transport network (made under the scheme of Golden Triangle) and other infrastructure. Among a number of problems identified by the people of the surveyed areas, a major one is the problem of governance of these rurban or quasi-urban settlements. The scattered picture of urbanization emerged from these types of hybrid settlements could boost the pace and quality of urbanization if statutory status is accorded to these towns. The sustainability of these quasi-urban settlements depends largely on strengthening the intrinsic services which simultaneously de burden the urban areas; it may ultimately lead to balanced regional development.

1475 RURAL LAND TRANSFORMATION AROUND A PLANNED CITY: SOME ISSUES AND POLICY CONCERNS (A CASE STUDY OF CHANDIGARH PERIPHERY)

ABSTRACT

In the last two decades, urban fringes have witnessed a massive rural land transformation and Chandigarh periphery is no exception. This period, in fact, coincides with radical changes effected in India’s macroeconomic policies to promote the role of private sector and attract foreign capital. Under the privatization policy, super specialization in medical, educational, banking and other professional services recorded a mushrooming growth around urban centres especially in cities like Chandigarh. Under the liberalization policy, private investment both foreign and Indian, found an added attraction in cities like Chandigarh where availability as well as quality of services was par excellent. Chandigarh thus became a great attraction for investors, service providers, job seekers and professionals. Consequently urban land prices shot up in the city. This led to the emergence of a number of residential colonies which sprung up in the villages and towns in Chandigarh periphery in the wake of exorbitant land/real estate prices in the city. Similarly, many private institutions for technical and professional education have come up in the surrounding villages. A number of malls, restaurants, resorts, marriage palaces can be seen all along the major roads. All this has come up on prime fertile agricultural land. The villages which earlier supplied vegetables, milk and grains to the city are dotted with residential complexes and institutional buildings. The villagers have sold out their land to the private land developers and are weaning away from agriculture with no alternate livelihood options. This paper in similar vein tries to capture these land use changes in rural areas through remotely sensed satellite data and primary data collected during field work. Further, an attempt has also been made to bring forth the socio-spatial implications and policy concerns for Chandigarh city as well as its periphery.

1480 AN EXPERT SYSTEM FRAMEWORK FOR HOLISTIC DEVELOPMENT OF RURBAN CLUSTERS IN INDIA: CASE OF TRIBAL ORISSA**Ahana Sarkar, Ronita Bardhan**

Centre for Urban Science and Engineering, IIT Bombay

ABSTRACT

In this study, a novel step wise conceptual framework for rural development in an Indian Rurban cluster was developed, to make it a self-sustaining growth centre. This methodology encompasses a people participatory model with a blend of sustainability into it. This study critically appraises the newly formed Indian rural development scheme (SPMRM) and intends to bridge the gap in rural development policies in relation to social interaction models and bottom up approaches. The need of the villagers and deficiency of the rural cluster was assessed through household surveys and resource mapping of the village. A mixed mode research method was adopted through participatory rural appraisal activities for involving local people and their requirements in designing the framework model. While the rural urban disparity analysis (RUDA) estimated the gap between the village cluster and urban areas, problem identification and infrastructure prioritization that was performed through personal and collective interviews of the villagers formed the core basis for sustainability assessment. This step helped in personalizing the individualistic linkages for sustainable rurban development. The efficiency of the proposed methodology over existing strategy was validated through employment of social benefit analysis and rurban ecosystem health assessment (REHA). Results show that current methodology could improve the ecosystem condition of the rural cluster to 71.6% within ten years period (FY 2017-FY 2027) while the improved methodology could improve it to 87% within the same time frame.

1. INTRODUCTION

Although rapid urbanization has led to deep transformation in urban quality of life in India, rural communities are benefitting on a *trickle down* basis[1]. According to Planning Commission 2017, India has recorded an annual growth rate of 6.8% in 2016. However, rural poverty still remains a significant policy concern[2]. Rural development has seldom attracted the awareness of planners and has turned to be a rarely intervened field from planning perspective. Rural areas in India lack essential services like clean water supply, education and health centers, all weather roads, clean energy and sanitation provisions. The search for an improved quality of life has exaggerated the influx of rural urban migration, creating resource constrained stress on urban areas like lack of affordable housing and employment opportunities[3]. This phenomenon has led to the development of slums in the cities, which are portrayed by UN Habitat as 'dwellings unfit for human habitation'[4]. This widespread poverty and deprivation of rural population amidst the shining metropolitan cities has captured the planners' attention by indicating an urgent need for bottom-up approach for rural communities to curb large scale migration.

There is a critical shortage of empirical studies about the effectiveness of rural development policies and this study seeks to make an initial exploratory step in this direction. Rural sector development has been identified as one of the major drivers in accomplishing the UN Habitat Sustainable Development Goal (SDG) of inclusive development[5]. World Bank defines rural development in terms of improvement of quality of life of low-income group of people residing in rural areas and making the process of this development self-sustaining. India has witnessed policies regarding rural development since pre-independence era where rural policies were described majorly as experiments of various individuals. The post independence era however linked rural development with five year plans (FYP) thereby incorporating strategies like rural reconstruction through enactment of three tier Panchayati raj administrative system, rural poverty alleviation by increasing employment in agricultural systems etc. The major flagship programmes in India for rural development, some of which have been revamped envisaging wider outreach and acceptability, include Indira Awas Yojana (IAY), Mahatma Gandhi National Rural Employment Guarantee Act (MNREGA), Pradhan Mantri Gram Sadak Yojana (PMGSY) and Provision of Urban Amenities to Rural Areas (PURA). Despite prolonged attempt by the Government of India (GoI) to improve the policy strategies, the rural development schemes have failed to achieve the desired goals. Most of these schemes were found incompetent in accomplishing the structured objectives mainly due to the loopholes in implementation such as lack of a proper institutional structure or dedicated professional support, and lack of awareness among people[6]. In a recent initiative by GoI to bridge the gap between the urban and rural circumstances, the government metamorphosed PURA 2.0 into Shyama Prasad Mukharjee Rurban Mission (SPMRM) in 2015[7]. The SPMRM mission acts as an impetus to stimulate local economic development, enhance basic services, and create well-planned Rurban clusters. Ministry of Rural development (MoRD), GoI elucidated Rurban clusters as large parts of rural areas often in close proximity to each other which typically illustrate potential for growth, have economic drivers and derive locational and competitive advantages. This mission aimed to create 300 'Rurban Clusters' within next five years, across the country with about 100 Rurban clusters approved every year[7].

However, the SPMRM policy like other foregoing schemes does not take into consideration the bottom-up strategies like peoples' participation and contextual factors into the planning process. This study applies a dissection strategy to assess the substructure followed by the existing Rurban policy and has intended to propose a revised conceptual framework for sustainable Rurban development taking Rurban mission identified tribal cluster of Mayurbhanj, Orissa as the case scenario[8].

The objective of this study is to provide a holistic methodology for enacting rural development scheme in India through consolidation of social, technical, economic and environmental factors. This study enables in deciphering major socio-

technical and context-based parameters which when incorporated in existing rural development policies will promote holistic Rurban clusters leading to enrichment of quality of life of rural population. The novelty of this study lies in the development of transverse approach for efficient and sustainable Rurban development and rural policy efficiency in Indian context. It intends to fill the blind spot in methodological intervention in the field of existing rural development policies by applying mixed mode approach and adding a scientific value to it. This study can pave a path towards the direction of enhancement of rural development policies that is comprehensible with the current social issues.

2. STUDY AREA

The Rurban mission identified tribal cluster, located in the Mayurbhanj district of Orissa (state of India), comprises of three adjacent gram panchayats namely Digdhar, Thakurmunda and Bharandia (see Figure 1). The cluster includes twenty eight villages and covers an area of 9838 hectares with 31% area covered with dense sal forests. Apart from spatial inequality, the lack of basic infrastructure was observed to be the main reason behind the poverty and seclusion of the study area. Out of 4430 households, only 557 households are exposed to individual level water supply connection with a distribution capacity of only 27 lpcd (much below than ICAP prescribed required level i.e. 70 lpcd). 87.73% households lack individual household level sanitation facilities. The cluster is also devoid of basic amenities like drainage system, street lighting, and inter village connectivity. Thirty-nine community dustbins covering 1330 households is the main solid waste management alternative present in the rural cluster. 25% of households are exposed to LPG as cooking fuel while rest of the villagers used unclean fuels like kerosene and other solid fuel to serve their cooking needs.

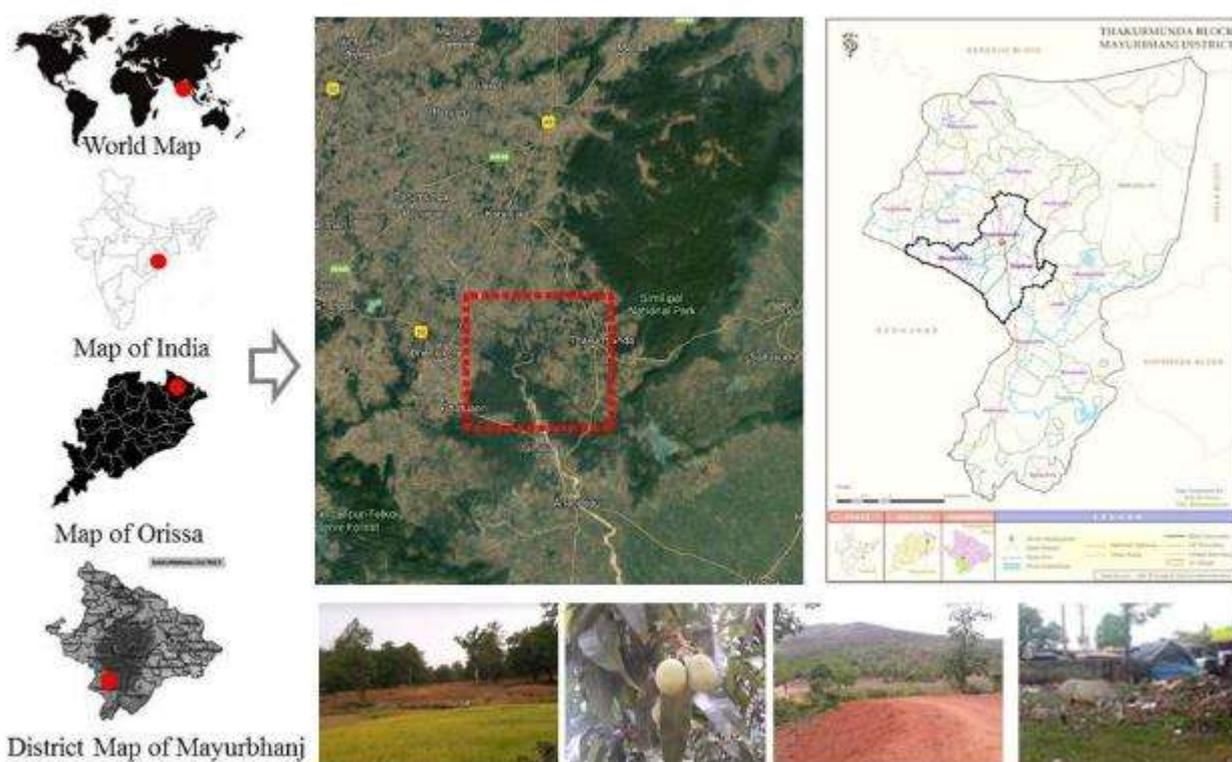

Figure 116 Thakurmunda Rurban Cluster (source: ICAP, SPMRM)

The total population of the cluster as per the 2011 records is 19757 with a decadal growth rate of 12.61%. The female population is dominating with a sex ratio of 0.93:1. During the survey tenure, the total number of households was accounted to be 4430. Table 1 presents the population statistics of the three gram panchayats which collectively constitute the rurban cluster.

Table 49 Population statistics of the cluster

Details		Thakurmunda	Digdhar	Bharandia	Total
Existing					
1	Total Population (As per census 2011)	8793	8544	2420	19757
2	Decadal Growth in Rural Population (%) (2001-2011)	12.34	13.16	11.67	12.61
3	Total Household	1928	1954	548	4430
4	Sex Ratio (M/F)	0.88	0.98	0.93	0.93

3 METHODOLOGY FOR RURAL PLANNING

The policy framework under current RURBAN mission follows the conventional top down approach, regardless of the fact that the proposals approved by the schemes may be found inconsistent with the sustainable needs of the specific

rural area. This study proposes a methodology (see Figure 2) that tries to eliminate the pitfalls of current planning methodology followed by Rurban mission (SPMRM). The broader level methodology followed in this work is presented in Figure 1.

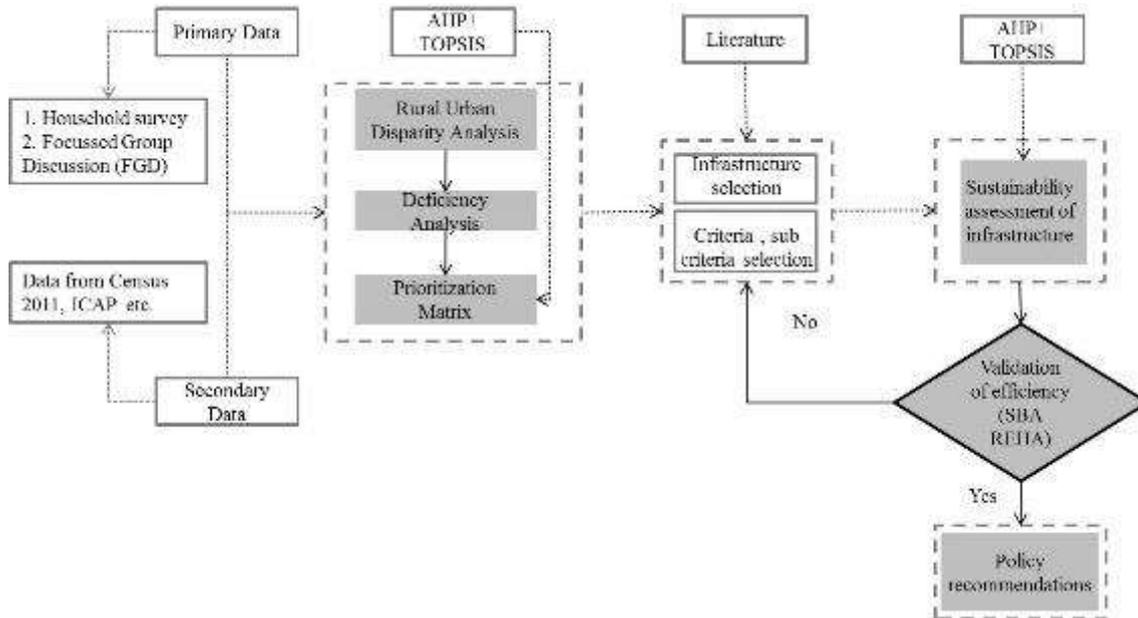

Figure 117 Proposed methodology for Rurban planning

In this study, the mixed mode research method was employed to investigate the planning strategies for holistic development of the Rurban cluster. First, field surveys were conducted in the month of September 2016, which included quantitative as well as qualitative data collections through participatory rural appraisal (PRA) methods that include household surveys, personal interviews and Focus Group Discussions (FGDs). Sixty household surveys were performed to apprehend the existing deficiency level of the village, the conditions and need of the villagers thus intensifying the bottom up approach. The data collection method included cognitive mapping of the cluster through reconnaissance survey, deficiency ranking of infrastructure levels from the villagers’ response, and accumulating local resource knowledge base from the Block Development Officers (BDOs). The framework model initiated with rural urban disparity analysis, deficiency analysis, and prioritization of infrastructure followed by sustainability assessment of infrastructure for the cluster. The efficiency of the proposed methodology over the existing one was validated using two distinct methods of Cost Benefit Analysis (CBA) and Rurban Ecosystem Health Assessment (REHA).

Rural Urban Disparity Analysis

The concept of Rurban mission (SPMRM) envisages in strengthening the rural and urban linkages in a developing nation. The Rural Urban Disparity Analysis (RUDA) approach [9] was employed to recognize the level of discrepancy between rural and urban areas. The selected Rurban cluster was compared with urban areas of Banpur (Non tribal cluster), Baripada (District town), Cuttack (Tier II city) and Bhubaneswar (Tier I city) in the same state of Orissa to highlight the gaps in terms of employment opportunities and infrastructure provision. A Rural Urban Disparity Index was derived to understand the current status of the rural development. A step wise methodology was applied to compute the RUDI which is elaborated in Eqs 1, 2 and 3. The major elements for comparison analysis not only included literacy rate, employment rate and life expectancy but the disparity level was also investigated in terms of accessibility to basic infrastructure like sanitation, clean water, electricity, cooking fuel, health and education facilities.

Step 1: Calculation of each component

Each of the criteria was measured using the following formula:

$$I_{ij} = \frac{\text{Actual } X_{ij} \text{ value} - \text{minimum } X_{ij} \text{ value}}{\text{Maximum } X_{ij} \text{ value} - \text{minimum } X_{ij} \text{ value}} \tag{Eq 1}$$

Step 2: Calculation of Urban and Rural Composite Index (RCI)

The weighted components were calculated by multiplying I_{ij} with weightages (W_n). Rural Composite index (RCI) and Urban Composite index (UCI) were calculated by averaging the aggregated components.

$$\text{Rural/urban Composite Index} = \frac{\sum_{n=1}^n w \cdot I_{ij}(\text{rural/urban})}{N} \tag{Eq 2}$$

Where N is the total number of components considered for measuring the disparity level.

Step 3: Calculation of Rural Urban Disparity Index (RUDI)

Lastly, Rural Urban Disparity Index (RUDI) was evaluated using the following formula.

$$RUDI = 1 - \frac{RCI}{UCI} \tag{Eq 3}$$

The value of RUDI in the above equation ranges from 0 to 1, where greater value indicates higher level of disparity between rural and urban areas.

Deficiency analysis

The major components considered for deficiency analysis included water supply, sanitation, solid and liquid waste management, street lights, drainage system, health facility and education levels. The number of households with access to the infrastructure was evaluated against the total number of households in the Rurban cluster. The existing condition of the cluster for each of the infrastructures was weighed against the desired ICAP prescribed levels and deficit level was calculated in percentage taking 100 as the maximum deficit. Deficiency analysis was performed using the following step.

$$Deficiency = 100 - \left(\frac{\text{Number of HHs with access to infrastructure}}{\text{Totl number of HHs in the cluster}} * 100 \right) \tag{Eq 4}$$

Prioritization Matrix

The deficit level values obtained from the deficiency analysis were used as a criterion for executing prioritization matrix. Higher deficit value indicated more criticality of the component and hence was given higher score. The respondents ranking presented in Likert scale (1 to 10) and capital expenditure spent by SPMRM on that particular infrastructure were added as two major criteria. This step was calculated using MCDM[10] [13] approach of Analytical hierarchy process (AHP) coupled with Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) [14]–[20].

Sustainability assessment of infrastructure

This section adopted multi criteria decision making (MCDM)[10][11][12][13]approach to select the most feasible infrastructure from a finite number of alternatives. The major sustainability criteria i.e. technical, environmental, economic and social factors and their respective key assessing indicators were chosen based on widespread literature studies. The household surveys mainly contributed to the social ranking in each case. An expert choice system i.e. Analytical Hierarchy Process (AHP) was employed to provide weight to the criteria and their respective sub criteria. (TOPSIS)[11], [14]–[20]was then applied for ranking the alternatives based on the different indicator scores. The best solution derived from MCDM could be considered as the ultimate proposal best suitable for the cluster. The major components of infrastructure used in this study are explained below in Table 2.

Table 50 Infrastructure alternatives and their key assessing indicators for sustainability assessment

Components	Alternatives	Technical Criteria	Economic Criteria	Environmental Criteria	Social Criteria
Street Lighting	Grid Electricity	Technical feasibility, Life expected	Installation cost, Operation and Maintenance Cost	CO ₂ emission, SO ₂ emission	Social acceptance
	Diesel Generator Set				
	Onsite Solar PV				
	Off-site solar PV				
Domestic Electrification	DG set (10 HH)	Coefficient of efficiency, Availability of primary energy supply, Reliability of technology	Installation cost, Operation and maintenance cost	CO ₂ emission, SO ₂ emission, NO _x emission	Creation of jobs, Citizen participation, Acceptance of power
	Biogas plant individual house				
	Solar panels individual house

PNG					

4. RESULTS

Rural Urban Disparity Analysis

The calculated values of Rural Urban Disparity Index (RUDI) showed existence of deep incongruity between the Thakurmunda rural cluster and Bhubaneswar with a RUDI value of 0.47, followed by a medium level of disparity with Cuttack (0.30) and Banpur (0.39). However, a very low RUDI value was observed when Thakurmunda was compared with district town of Baripada. These results identify that enormous intervention is essential to bridge the gap between Thakurmunda and other nearby urban areas in Orissa and transform it into a ‘Rurban Cluster’ in real terms.

Deficiency Analysis

The RUDA step was followed by Deficiency Analysis. Out of the thirteen components for which deficiency level was evaluated, maximum gap was observed in case of provision of village street lighting with a deficit level of 100, and digital literacy (100), followed by water supply (88.83), sanitation (87.73), cooking gas connection (75) and solid waste management. The findings identified that the village lacked basic facilities, primarily because of negligence caused due to remoteness from state capital (Bhubaneswar city).

Prioritization matrix

Social respondents ranking was given utmost importance in this step followed by deficiency level and cap-ex while developing prioritization matrix. In case of existing methodology, where deficiency level was taken as the sole criteria, street lights received the maximum priority followed by drainage system, skill development, digital literacy, sanitation and water supply. However, by taking the aggregated value of three above-mentioned criteria, sanitation received maximum preference with a TOPSIS ranked value of 0.841; followed by village street lights (0.806), water supply (0.769), and domestic electrification (0.641). The results of prioritization matrix proved that attaching villagers’ ranking to the prioritization process would transform the overall policy framework and aid in investment phasing in later stages of rural development.

Most sustainable infrastructure alternative

The most feasible infrastructure alternative derived from MCDM (i.e. AHP coupled with TOPSIS) approach is elucidated in Table 2. As observed from the table, the multi criteria evaluation differentiated the behaviour of the alternatives under different viewpoints of comparison. The Consistency ratio (CRs) obtained across the process demonstrated the reliability of the method as the values of CR ranged from 0.01 to 0.20 with the final CR as 0.016 for domestic electricity and 0.19 for street electricity. For street lighting, off-site solar powered LED ranked highest with a value of 0.867 followed by onsite solar power (0.80), diesel generator (0.61) and grid electricity (0.17). On comparing the technical and economic criteria for domestic electrification, grid electricity came up as the most preferred one with value of 0.908 and 1 respectively. However, with the importance of social and environmental criteria being considered, the preference shifted to solar PV. On aggregation of the four criteria in the second tier, off-site solar power with micro grid came up to be the highest ranked with TOPSIS value of 0.633 followed by grid electricity (0.473) and compact biogas plant (0.471).

Table 51 Results of sustainability assessment of infrastructure

Proposed alternatives	Technical	Economic	Environmental	Social	Aggregated Ranking
Street Lighting	-	-	-	-	Onsite solar power (0.80)
Domestic Electricity	Grid electricity (0.90)	Grid electricity (1)	SPV batteries, micro grid (1)	SPV batteries, micro grid (1)	SPV batteries, micro grid (0.63)
Solid Waste	Landfill (0.75)	Vermin compost (group of 5 HH) (1)	Vermin compost (group of 5 HH) (0.61)	Vermin compost (group of 5 HH) (0.54)	Vermin compost (group of 5 HH) (0.83)
Sanitation	Compost Pit (0.87)	Overhung+fish pond (0.97)	Bio digester (1)	Pit latrine (1)	Compost pit (0.88)
Water supply pumping system	DG set (1)	Solar PV (0.97)	Solar PV (0.98)	Solar PV (1)	Solar PV (0.82)
Cooking fuel	Biogas IHHL (0.72)	Natural Draft ICs (0.90)	PNG (0.60)	Natural draft ICs (0.93)	Natural draft ICs (0.93)

In the case of solid waste management, landfill ranked highest when technical criteria was solely considered. When social, economic and environmental criteria were taken into consideration, vermin compost became the most sustainable alternative. Similarly, for the case of sanitation, water supply pumping system and cooking fuel cases, the compost pit latrine, solar PV supported pumping system and improved cook-stoves were evaluated as the most sustainable alternatives respectively.

5 EFFICIENCY OF THE PROPOSED METHODOLOGY

The efficiency of the proposed methodology was validated through social benefit incurred and health level of the ecosystem.

Social benefit calculation

Cost benefit analysis (CBA) was performed for both existing and proposed methodology to understand whether the social benefit of a project was worth its cost. The benefits incurred from both the methodologies reflected a major difference when it included social ranking in the process. This score, derived from respondents survey was employed to evaluate the annual social benefit gained by the cluster. Table 4 represents the overall social benefit gained from the proposed methodology.

Table 52 Social benefit from the proposed methodology

Components	No of units benefited more from proposed methodology	Total benefit incurred from proposed methodology (INR)	Social score (from HH survey)	Social benefit (INR)
Domestic electricity	375 HH	405000	0.641	259605
Street lighting	144 no.	1147500	0.806	924885
Solid waste management	1511 HH	5439600	0.625	3399750
Cooking fuel	4674 HH	26641	0.851	22672
Total				4606912 INR

Rurban Ecosystem Health Assessment (REHA)

The method of Set Pair Analysis (SPA) [21]–[26] was introduced to assess the Rurban ecosystem health. The approximate degree of Rurban ecosystem health was compared with the optimal set to describe the level of the rural ecosystem by combining multiple health indices. Set Pair analysis proposed by Zhao in 1989 is a modified uncertainty theory considering both certainties and uncertainties as an integrated certain uncertain system and depicting the certainty uncertainty systematically from three aspects as identity, discrepancy and contrary. A health assessment scale was generated to understand the condition of rural ecosystem across a given time period. The evaluation of the ecosystem health scale followed a step wise approach which is demonstrated in Eqs 5 to 9.

The identity degree and contrary degree of the set pair can be defined as Eqs 5 and 6:

$$a_{kr} = \frac{h_{kr}}{u_r + v_r} \tag{Eq 5}$$

$$c_{kr} = \frac{h_{kr}^{-1}}{u_r^{-1} + v_r^{-1}} = \frac{u_r v_r}{(u_r + v_r) h_{kr}} \tag{Eq 6}$$

Where a_{kr} is termed as identity degree that means approximate degree between h_{kr} and u_r while c_{kr} contrary degree that represents approximate degree between h_{kr} and v_r . Here u_r and v_r represents the upper and lower threshold values of the components.

AHP was used to assign weights to the components. Taking the weight of each matrix into account, the average identity degree and contrary degree can be counted through Eqs 7 and 8 in the comparative interval of $s_k [U, V]$:

$$a_k = \sum_{r=1}^n w_r a_{kr} \tag{Eq 7}$$

$$c_k = \sum_{r=1}^n w_r c_{kr} \tag{Eq 8}$$

Where a_k stands for the average identity degree representing the close extent between s_k and U, while c_k describes the average contrary degree expressing the close extent between s_k and V. Then, the approximate degree between s_k and U can be expressed as the following:

$$r_k = \frac{a_k}{a_k + c_k} \tag{Eq 9}$$

With larger value of r_k the situation of s_k is better.

The matrix contained three layers, including object layer O, i.e. urban ecosystem health, criteria layer F, i.e. F1 to F5, and index layer, i.e. I1 to I12 as listed in Table 5. Analytic hierarchy process (AHP) was employed to determine the weightages of each indicator.

Table 53 Judgement matrix for Set Pair Analysis

Assessing factors (F)		Assessing indicators (I)		2017	2022	2027
Vigor	F1	Annual Per capita income	I1	50,000	86000	86,000
Structure	F2	Farm/ Total workforce	I2	42%	50%	50%
		Population density	I3	290/sq.km	326.4/sq.km	390/sq.km
Resilience	F3	% of utilization of solid waste	I4	0	60%	60%
				0	9.3%	9.3%
				Existing Rurban policy		
Ecosystem service function	F4	% HH using renewable energy	I5	0	76.4%	100%
				0	38.2%	50%
				Existing Rurban policy		
		Employment rate	I6	46.6%	52.4%	62.2%
		Productivity hours per capita per day	I7	12	18	18
				12	16	16
Existing Rurban policy						
Population health	F5	Number of sub centres/ 20000 population	I8	2	7	12
				% of access to electricity	I9	43.9%
		43.9%	53.95%			82%
		Existing Rurban policy				
		% of access to cooking energy	I10	29.1%	88.79%	100%
				29.1%	29.1%	29.1%
Existing Rurban policy						
% of access to safe drinking water	I11	11.17%	88.79%	100%		
% of access to sanitation	I12	13.81%	97.7%	100%		

The identity and contrary degree was calculated for each indicator with respect to upper and lower threshold values. Weightages were assigned to the values and their aggregation lead to the formulation of the ecosystem health levels. The range of the scale for evaluating health level varies from 0 to 1 where higher values indicate better health condition of the ecosystem.

Ecosystem health assessment was performed for both existing and proposed methodologies. Figure 3 highlights the differences in the Rurban ecosystem health assessment for the two methods. The final results showed that the present value of rural ecosystem health is only 0.33 which can be increased up to 84.3% in 2022 to a value of 0.61 and 0.63 in 2027 in case of proposed methodology. The same procedure was carried out for Rurban prescribed existing methodology where the value increased by only 66.2% i.e. 0.55 in 2022 and 0.57 in 2027.

Rurban Ecosystem Health Assessment

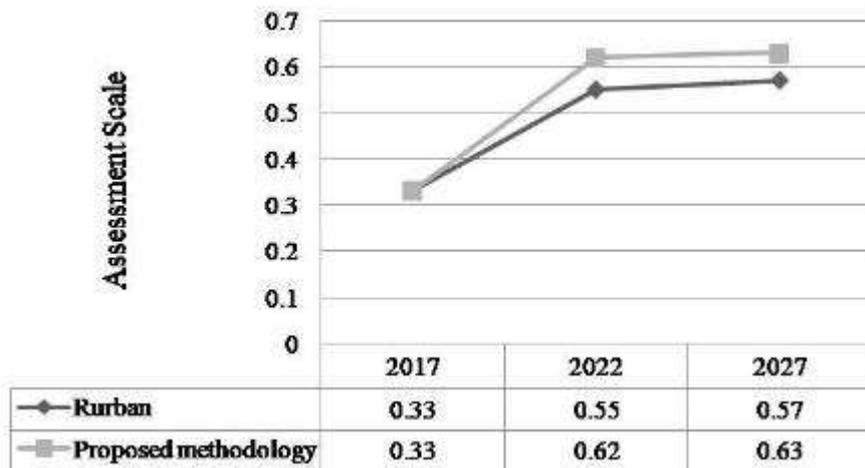

Figure 118 Rurban Ecosystem Health Assessment (REHA) results for both methodologies

6 DISCUSSION AND CONCLUSION

This paper has critically analyzed the limitations of strategies employed by current Rurban mission. A novel strategy was applied in this paper to assess the existing framework model followed by the current Rurban mission (SPMRM). The major steps in existing policy include the deficiency analysis and prioritization of infrastructure elements directly followed by implementation strategies like scheme convergence and investment phasing. The major loopholes in this planning process encompass the lack of social coherence factor and sustainability aspect. Hence, this study made an attempt to develop a holistic methodological framework which tried to overcome the faults of existing case. The proposed structure introduced additional socio-technical approaches like Rural Urban Disparity Analysis (RUDA) which describes the incongruity of rural cluster with respect to nearby urban areas. This evaluation-based step was necessary as Rurban mission aims to bridge the gap between rural and urban areas. Hence, the selected Rurban cluster was compared with tier I, II cities and district towns of the same state to comprehend the intricacy of operations required for its development.

This was followed by deficiency analysis which is in sync with the existing methodology. The infrastructure components were prioritized based not only on deficit analysis but also on respondents ranking and cap-ex of infrastructure projects. FGD and household surveys emphasizing the need of the local people formed the core basis of the whole method. This step enhanced the concept of bottom up approach in prioritizing the components of a rural cluster. The aftermath of investment in infrastructure projects in rural areas often present economic benefits but do have negative impacts, particularly for social and environmental assessments. Thus there lies an ambiguity on the effectiveness and adequacy of the assessment of infrastructure investment. Assessment in this case was improved by incorporating attributes embodied in sustainable development principle which is widely described as a triple bottom line (economic, environmental, social and technical). In sustainability assessment of infrastructure, social criterion was given more importance for highlighting the idea of bottom up path. This study introduced a set of key assessment indicators (KAIs) for assessing the sustainability of the infrastructure which can be used in future for planning other rural clusters in India. The most sustainable infrastructure alternative was selected by applying MCDM method i.e. AHP and TOPSIS. The authors further validated the efficiency of the proposed methodology by comparing the proposed with the existing Rural Mission methodology. Social benefit was computed to show that the existing method led to a total social loss of Rs. 46 lakhs (INR) as shown in Table 4. Rural Ecosystem Health Assessment (REHA) also proved the proposed methodology to be more efficient than the existing one. The SPA generated ecosystem health levels show that the current methodology could improve the ecosystem condition of rural cluster to only 71.6% within ten years period (FY 2017- 2022-2027) while the transformed methodology could improve it to 87% within the same time frame.

Although Rural Mission (SPMRM) launched by Indian government (GoI) has set up proposals for rural areas, it can be noticed from this study that there are certain discrepancies in selection of the best fit alternative. The whole scenario changes when social choice and the concept of peoples participation is taken into consideration. Future work can include rural infrastructure benchmarking to identify any differences found between analyzed standard and ICAP prescribed benchmarks. In this study, coupled method of AHP-TOPSIS was applied for sustainability analysis which has drawbacks.

Cumulatively, the proposed methodology qualifies as a suitable and holistic methodology adopted for Rural development in India that can fill the gap in the existing Indian rural development policies. This methodology with an iota of social coherence and sustainability aspect enhances the notion of rural development from a purely top down to bottom up approach. This methodological intervention can carry forward towards the direction of growth of rural development policies that is comprehensible with the current social issues.

1569 GEOGRAPHY AND CRAFTS: GEOGRAPHICAL INDICATIONS FROM SOUTH INDIA***Soumya Vinayan, N. Lalitha***

Soumya Vinayan is an Assistant Professor at the Council for Social Development, Hyderabad and N. Lalitha is Professor at Gujarat Institute of Development Research, Ahmedabad.

1. CONTEXT

Regional products often produced by small producers use geography as an important marker of quality in the realm of trade. The land based qualification conveys to the consumer that the location of the activity is in fact based in the region and is inextricably linked to the characteristics of the product. Geographical Indications (GIs) is such a form of origin labelling used by producers to capture market. Economic assets of the region form core of production and larger the share of such assets, stronger the multiplier effect on the regional economy. India has a sui generis law on GIs (since 1999) which recognises the link between the region (both the natural and human factors) and products; assumes added significance since every region of India has a unique product whether agricultural, foodstuff, textiles or handicrafts. In this paper, based on primary data, the authors focus on three crafts which are registered GIs: Swamimalai Bronze Idols (SBI), Aranmula Mirror (AM) and Pochampalli Ikat (PI).

The most commonly used form of IPR by industrial production which was organised on small scale since the times of trade guilds as early as the 13th century has been the use of marks indicating geographical origins of goods. These indicated that products from a certain region were superior in relation to goods from other regions because of their better quality. The superior quality of the goods were attributed to the natural factors such as climate or geological conditions such as the quality of the soil (Burgundy wine) or to human factors such as skills (Dacca silk), food processing techniques (Frankfurter sausages). In the present day, Geographical Indications (GI) has become a catchword not only among academicians, lawyers and policy makers but also among the general public ever since its inclusion under TRIPS Agreement. GIs have been heralded by the developing countries given its potential to boost rural development, ensure economic returns to stakeholders in the value chain and protect traditional knowledge.

2. THEORETICAL FRAMEWORK

There are several features of GIs which makes it more amenable to be a community right. Unlike other intellectual property rights which are owned by an individual or a single company, GIs are held by a group of producers who maintain the required quality and characteristics of the product within a specific geographic region which is well defined. Moreover, the right cannot be transferred and thus remains within the community of producers as long as the geography-quality link is maintained. The GI products also hold the characteristics of being excludable (if specificities of the products are not adhered to by the produced within the geographic region defined) and that of being non-rivalrous (enjoyment of GI by one does not diminish the enjoyment by the other). Thus, one can clearly discern that 'geography', 'local use of resources' are at the centre of use of GI. These coincide with the objectives of rural development. Rural development approach is a holistic agenda encompassing not only economic progress of the area but also focuses on the socio-cultural cohesiveness of the region. The growing importance of the 'rural' (Warren 1993), the 'terroir' (the French concept) (Barham 2003) and the 'local' (Bowen 2010), in promoting market access of products which are region specific has been widely recognized. In addition, in the era of mass production of commodities across the globe, there is a rising recognition to "protect, preserve, maintain and exploit culture" through legal claims (Coombe 2005). A GI certified product with the strong emphasis on the use of 'quality and local' resources in the making of the product, can reach a specific and sustainable market, which rewards with a premium price and recognition. Thus, the objectives of GI and rural development merge in realising the market potential of local resources through sustainable use. Moreover, the major concern of policy makers across the world is to mitigate out-migration from rural to urban areas especially distress migration and production and marketing of 'rural cultural distinction' has become a catchword in local development strategies (Coombe 2005).

Nonetheless, the registration of GI does not automatically guarantee rural development. The potential benefits are considerable if the following are met: "strong organizational and institutional structures to maintain, market, and monitor the GI; equitable participation among the producers and enterprises in a GI region; strong market partners committed to promote and commercialize over the long term; effective legal protection including a strong domestic GI system" (Giovannucci, D n.d.). She further opines that most often the negative effects arise out of inadequate planning and governance mechanisms. An institutional mechanism which fosters network of relationships (Giovannucci and Claudia 2008) and the level of cohesion in the collective organizing body (Bowen 2010) determine the sustainability of GIs, along with institutional and political context of GI supply chains has been well-established. Tregear et al (2007) also raises the pertinent questions as to (1) who are the actors who get involved in product qualifications and what are their motivations and (2) terms of reference of qualification (code of practice) and its evolution (consultative process, who and what determines exclusion of stakeholders).

This is also reflected in the Indian context. Studies point out that the clusters (agricultural and non-agricultural) engaged in producing regional products has the potential to become IP clusters to show case heritage and traditional knowledge and thus have tremendous scope for rural development through sustainable livelihoods (Das 2009). However, the involvement of middlemen who act as a bridge between communities and market also has the potential to exploit the artisans who may not reap the economic advantage of the GI status as is evident in the case of Pochampalli prints (Das

2009, Vinayan 2013) and the difference in the price paid to the artisans and the final market value of the product disappoints the artisans and discourages the younger generation in pursuing the craft (Gopalakrishnan et al 2007).

In other words, a certification mark like GI, can boost the livelihoods of people associated with its entire value chain, if the different stake holders of the entire value chain is appropriately identified, sensitized and are subject to rules laid out by the producer associations to realize the economic benefits out of the certification mark. Thus, the legal recognition of geographical indications is only an institutional tool through which to address these problems and consequently provide rural communities with the opportunity to valorize their local production and extract rents based on local *savoir faire* (Cerkia 2013). It is on this premise that GIs are considered as a potential tool for promoting rural livelihood.

Given this context, the next section looks at the GI Scenario in India. Following a brief introduction to the legal framework and status of registration, the section proceeds to reflect on three case studies – Swamimalai bronze, Aranmula Mirror and Pochampalli Ikat. The aim here is to delineate and compare the processes and examine how relevant the GI protection is to the producers in terms of access to market and enhancement in economic benefits.

3. GI: THE INDIAN CONTEXT

Until the enactment of the *Geographical Indications of Goods (Registration and Protection Act), 1999* (hereafter GI Act), there was no separate legislation which governed the use of GIs though there have been legal instances under passing off and/or unfair completion (Srivastava 2003). It is important that each GI application by the registered user (Part A) is meticulously followed by filing of (Part B) application for the recognition of authorised user. The Act has been in operation since 2003 and the GI Registry in Chennai has received applications from different categories of goods across India and abroad for registration. The Indian GI Act specifies that the GI tag can be used only by an authorised user in addition to the registered user. An authorized user, as per the GI Act is one who produces the goods in respect of which a GI has been registered. In addition, as per the Indian GI Act, any infringement action on a registered GI product can be initiated only by the registered users.

The number of GI applications filed every year ranges widely. Over the 13-year period 2003-04 to 2015-16, an average of 41 applications has been filed, with a peak of 148 applications in the year 2011-12.⁴⁶³ Compared to 2004, when GI registrations began, 2007-08 and 2008-09 have been the two years when there has been a spike in registration, with 31 and 43 applications filed respectively. Out of 320 registrations with the Indian GI registry as on March 31, 2018, there were 13 products of foreign origin. Of the registered products from India, handicrafts (including textiles) account for 62 per cent of the total products followed by agriculture (28 per cent). Manufactured and food stuff constitute 6 and 4 per cent respectively. Karnataka leads the rest of the states with 39 registrations. Karnataka (12 per cent), Maharashtra and Tamil Nadu (9 per cent), Kerala and Uttar Pradesh (9 per cent each), are the five states in the top three ranks. Rajasthan Marble is the only product that has been registered under the category of natural products.

4. CASE STUDIES⁴⁶⁴

4.1 Swamimalai Bronze

Product and socio-economic context

Swamimalai is located at a distance of 40 KM from Thanjavur and form one of the most famous art forms of Tamil Nadu. The history of Swamimalai bronze icon is several centuries old. The different kingdoms like the Cholas, Pallavas and Pandyas have contributed to the cultural heritage of Tamil Nadu. The art has continued uninterrupted till today, although the 20th century bronzes continue to be copies of the Pallava and Chola figures and have yet to develop an identity of their own. The makers of the SBI are known as sculptors or *sthapathis*. The process of making the SBI is elaborate. There are several processes involved – making of the wax model, wrapping the wax model with sand and clay mixture, burying the sand & clay structure in sand, casting of metal mix on this structure followed by removal of the cast and chiseling of the idol.⁴⁶⁵ A one feet idol would take about 15 to 20 days from the start to finish. Larger idols take more than a month or two. The entire process is done manually. Here, it is to be noted that the entire process is manual. Moreover, most importantly, the soil required for making the bronze idol is a very special kind of alluvial soil, which is available only in the river bed of Cauvery in a kilo meter range from Alavanthipuram to Thimmakudi. University level research undertaken by scholars indicate that the alluvial soil has special binding quality and thus, the GI feature of the Bronze idols lays both in the use of soil and the human skill involved in the making of the idol.

Production Process: Key actors

In the production process, four key actors could be identified. There are around 250-300 SSIs involved in the production of the craft. They either work in their own workshop or in the workshops of other master craftsmen or for the society. Most of them are members of the Cooperative Society, which buys and provides the metals. The large scale idol (LSI) maker is directly involved in the production, procurement as well as marketing of the idols unlike the SSI. The SSIs sell either through the middlemen or through Cooperative society. Poompuhar is the apex society of Handicrafts and Handlooms in Tamil Nadu and is a government enterprise. Poompuhar is also engaged in the teaching, production and marketing of the idols. Thus, there are three marketing channels: (1) Poompuhar (2) cooperatives (3) to individuals

⁴⁶³Based on the information available from the Annual Report 2016-17, The Office of the Controller General of Patents, Designs, Trademarks and Geographical Indications, Ministry of Commerce and Industry Department of Industrial Policy and Promotion, Government of India.

⁴⁶⁴ The case studies are drawn from Lalitha (2014) and Vinayan (2013).

⁴⁶⁵ For more details, see Lalitha (2014)

(against orders – could range from individual customers to institutions such as ISCON, hotel chains like Taj), retail show rooms, utensil shops. The profit margin is thus dependent on to whom the idol is sold. On an average, an artist makes 15 to 20% of the cost of the idol as net income.

GI qualification

The GI application regarding SBI was filed in the year 2006 as belonging to class 6 (common metals and their alloys) and the part A registration took place in the year 2008. The GI application was made by the Development Commissioner, Handicrafts (Ministry of Textiles, New Delhi) and the protection is renewed till 2026. The LSI (who participated in the interview) was involved in the providing information about the filing of the application for GI. With regard to initiatives from local government, it was pointed out that since Swamimalai was declared a heritage town, a fund of Rs. 1.5 crores was set aside for development and some funds from this was also used for the documentation of the GI. Most of the artisans were aware of the fact that SBI has the GI certification, but were clueless regarding the part B registration (authorized users). It was widely felt that the government should undertake workshops/symposium to educate the artisans about the GI certificate its potential. Some of the stakeholders such as LSI were of the opinion that the government should organize all the idol makers together and educate them about the GI certification and its usefulness. Different opinions prevail among the artists about the GI certificate. While the Poompuhar officials felt that GI certificate would increase the sales world-wide, a sculptor cum researcher, who was one of the respondents, was of the opinion that he is indifferent to the GI certificate as it has not made any difference to the artisans. The cooperative society has so far not engaged in any GI awareness spreading activity among the members. Nonetheless, it was pointed out by some artisans that GI can be used to prevent the unauthorized sales. According to the LSI, there are some craftsmen in Thanjavur who make idols and call it as Swamimalai idols. Such persons can be taken to task, if the part B part of the registration – identifying the authorized users of the GI certificate had been done. Similarly, idols made by the Swamimalai idol makers are easily copied by the idol makers elsewhere like the Moradabad idol makers who produce it on mass production basis. Though the Moradabad idol makers do not call their creation as SBI, yet they copy the style of SBI and because of the mass production, they compete with the SBI on price. Hence, though we cannot call this as GI infringement, because they are not sold as SBI yet there is IP violation of copying the designs. This kind of IP violations have not been checked so far, either by the artists or by the government. The respondents also said that there should be a logo for the idols of Swamimalai, which will distinguish it from the idols made elsewhere.

4.2 Aranmula Mirror

Product and socio-economic context

It is mentioned in GI application of the Aranmula Mirror that, about 400 years ago, the chief priest of Aranmula temple, himself a patron of art and craft, brought in a few craftsmen from Sankaran Koil, in Tamil Nadu to make bell metal vessels for the temple. In the process, they made an alloy which when polished shone and reflected like a true mirror. These craftsmen remained in Aranmula and continued making this metal mirror. This mirror is used as one of the eight auspicious items used in religious occasions even today. The combination of making the alloy was maintained as a secret and was known only to this few crafts men. The lineage continues even now. In making the Aranmula mirror, there are no chemicals used and the entire process is manual. It involves three main processes – preparation of the disk (where the clay from the paddy fields is used), preparation of the metal mix and preparation of the outer frame to hold the mirror (see Lalitha N 2014 for more details). Thus, the GI feature of the Aranmula mirror comes from the use of clay from the local paddy fields and in the skill of mixing the tin and copper for the preparation of the metal mix.

Production Process: Key actors

According to the president and secretary of the Parthasarathy Handicraft Society (which was formed to initiate the application), totally there are 17 artisans who are engaged in the making and selling of the Aranmula mirror. The number of producers remains limited since the craft of making the metal mirror is limited only to the two panchayats of Aranmula and Mannupuzhachery, where 9 and 8 producers are located. Out of this 15 are active, of which only two are women. Eight of these are members of the association. Indirect employment potential is therefore those workers who bring the clay from the paddy fields of Aranmula and those who prepare the clay mixture. These techniques are laborious. The other potential scope for employment is with those who make the outer frame and stand. The third important employment potential is with those who make the small carry jewellery case for these mirrors that are stitched in velvet and attractive boxes. The major marketing channels are (1) through individual shops located in the region (2) through Kairali, the state handicrafts emporium (3) to individuals/institutions against order. In this case the economic benefits are dependent on the volume of sales. For the society, the turnover ranged from Rs. 3 to Rs. 3.5 lakhs per month and the net income was between Rs. 25,000 to Rs. 40,000. For individual artisans it ranged from Rs. 1 lakh turnover to Rs. 30000 as net income.

GI qualification

The application for GI was filed in December 2003 and was granted in 2005. All the artisans both from and outside the society were aware of the GI application filing and the outcome. The Parthasarathy society was formed for the purpose of getting the GI certificate with 5 members at the time of application and now has 8 members. Recently, the society also renewed the part A certificate of Aranmula mirror (valid till December 2023). Membership fee for the association is Rs. 50. Apart from this, the society has not built any share capital among the members. The members themselves noted that very less activity takes place in the association in general and nothing particular on GI. The association does not involve

all the people engaged in the craft and is limited to a few individuals was the common refrain. It was also pointed out by the artisans that producers who make authentic mirrors do not reduce the price, but the retail shops near the Aranmula temple reduce the price and sell because they produce lower quality mirrors and hence, they do not agree to form a group. Also these sellers have agents who work for a commission and bring potential buyers to these shops. Interestingly, presently, all those artisans who are engaged in metal mirror making are related to each other and all belong to the vishwakarma caste. The president of the society said though the non-member, his brother and sister make the mirror in a different area, which does not fall in either of the panchayats mentioned in the GI application. But no action is taken because they also belong to the Vishwakarma community and they are all related to each other. The technique of making the mirror is in mixing the metals in the right proportion, which some of the artisans do in secrecy, while the president of the society said, that he does it before his workers. Yet, the technique is not copied by many because the work is laborious.

The secretary of the association said that the state government does not promote the art. He further added that UNDP offered Rs. 15 lakhs to the Association. Rs.5 lakh for documentation and the rest of the money for buying materials and to build common facility centres. This proposal of UNDP was left unutilized as there was no co-operation between the members of the association. One of the reasons for this deadlock was that besides the buying of the materials through the society, the members will also have to sell the mirror through the society at a price fixed by the members. The latter means that everybody will have to fix a uniform price for a mirror based on the size, whereas presently, all the artisans charge their own price. Hence, this proposal did not materialize. GI certificate is displayed and mentioned only by the president in his workshop and others said they mention to the buyers when it is sold individually. Some of the artisans have made a small pamphlet about them and about the art where the GI part is also mentioned and this is kept in the display box of the mirror.

4.3 Pochampalli Ikat

Product and socio-economic context

Ikat weaving has been in vogue in Nalgonda for more than a century, even though there exist ambiguities about the origin of tie and dye weaving in Nalgonda. It appears not to be indigenous to the region but learnt (Dharmaraju 2006). In post-Independent era, cooperative movement picked momentum among weavers and they also entered into silk weaving. This attracted consumers from across the country and Pochampalli developed as a centre of handloom silks in the entire country. However, there has been spate of suicides reported in Pochampalli since early 1990s (Krishnakumar 2001). The reasons were rising costs of raw materials (especially hank yarn), piling up of stock in cooperatives due to inefficiencies in the apex organization the APCO, mismanagement of cooperatives, lack of credit facilities and working capital. Today, there are no such untoward incidents, not because, things have changed for good, but, skilled artisans have changed their vocation (Vadlapatla 2011). There are three basic forms of Pochampalli Ikat, namely: a single ikat, where either warp or threads are tied and dyed prior to weaving; combine ikat, where warp and weft ikat may co-exist in different parts of a fabric occasionally overlapping; double ikat which is by far the most complex from: both warp and weft threads are tied and dyed with such precision that when woven thread from both axis and mesh exactly at certain points to form a complete motif or pattern.⁴⁶⁶ The main products include saris, dress materials and home furnishing. Both silk and cotton yarn are used but the latter mostly in the production of dress materials and home furnishing. The intellectual property of the product lies in the laborious tie and dye method used in the colouring of the yarn. It is the human skill which uses specific designs (though similarities exist in the process for Sambalpur Ikat in Orissa and Patola from Gujarat) that the certification tries to protect. During the Focus Group Discussion, weavers had pointed out that several decades ago, the water from Musi river was used for dyeing but with the pollution of Musi river, the water has been rendered unfit for use.

Production Process: Key actors and their interests

Quintessentially a household industry, handloom sector it has undergone transformations owing to colonial rule and the changes in policy environment during the post Independent era. Today, there are no watertight compartments with regard to organization of weavers. However, they are broadly organized under three institutions – co-operatives, master weavers and independent weavers. Under these institutions, there are two kinds of working systems (except independent weaver) – putting out system (household) and karkhana system (shed). In case of ikat weaving in Pochampalli, the karkhana system is not widespread. It is still predominantly a household level of organization. There are master weavers who employ 10-15 weavers, but basically, the weavers undertake tie and dye at home since it is a highly skilled work. Even in case of cooperative weavers, only the yarn is supplied by the cooperative, the tie and dye of colour is done at the household level by the individual weavers and their family. Moreover, there are ‘independent’ weavers who usually procure yarn at the market, undertake tie and dye, weave; but sell the finished product to the traders. The rise of weaving outside the home is a recent phenomenon and shows the crisis in the industry remarked the master weavers and cooperative officials during interaction. The main raw materials involved in production are: yarn – silk and cotton. In Pochampalli, there are three main sources of raw material for silk yarn: State Department of Sericulture (SERIFED), Karnataka Silk Board and private traders in Karnataka (Bangalore, Mysore) and Andhra Pradesh (Dharmavaram, Hindupur). KSB has sales depot in Pochampalli next to the cooperative society. The cotton hank yarn used by handlooms is procured through National Handloom Development Corporation (NHDC) in Hyderabad and also private traders in Hyderabad. NHDC is the main source of procurement of raw materials for cooperatives which provide

466 For a detailed account of the process of production refer Journal 2, Geographical Indications Registry, Chennai, pp. 3-6 (<http://ipindia.nic.in/girindia/journal/2.pdf> accessed on October 5, 2012)

it at a subsidized rate. Chemical dyes and colours are sourced from traders in Secunderabad while Zari is obtained from Surat and Pune. There are around 65 master weavers in and around Pochampalli who form the association Pochampalli Handloom Tie and Dye Manufacturers association. Within and outside cooperative sector there are around 2000 weavers in and around the villages of Nalgonda and Warangal who are still actively dependent on the handloom weaving as the major source of livelihood though the number has drastically reduced over the years. The major marketing channels are (1) Cooperative (2) shops of master weavers/traders. The individual weavers earned between Rs. 2000-Rs. 4000 per month (for around 6 saris). This would vary across weavers depending on the design and use of zari. The traders often impose a markup of 15-40% depending on the season (marriage, festivals) whereas irrespective of rising cost of raw material or working capital delays, the cooperatives only impose a markup of 12% on the production cost.

GI qualification

In the case of Pochampalli too, interestingly, the initiative for GI registration, like in case of Swamimalai did not emerge out of the producers i.e. weavers. In fact, the entire process of registration was facilitated under the Cluster Development Programme (CDP) of the Textiles Committee, Government of India. The Regional Office which overlooked the CDP took the lead to sensitize the stakeholders about the GI Act. To facilitate the process of registration, the Textiles Committee roped in the services of Andhra Pradesh Technology Development and Promotion Corporation (APTDC) which houses the IPR Cell of Confederation of Indian Industry (CII). In fact, the major role played by APTDC was to translate the technical information about the Pochampalli Ikat weaving into legal language. They had engaged Anand & Anand (located in New Delhi), legal consultants, to facilitate the legal process of registration. APTDC also succeeded in involving National Bank for Agriculture and Rural Development (NABARD) which had borne the costs of filing the application (around Rs. 1.5 lakhs). In fact, in order to cultivate the sense of ownership among weavers, NABARD had suggested a part of the costs to be borne by the weavers. Nonetheless, since this was a pioneering initiative and the first product to apply for registration from textiles sector, NABARD funded the entire costs – to apply under 3 classes – 24, 25, 27. NABARD has borne all the costs inclusive of expenses of workshops, meeting of the GI consultative group from the Registry, legal fees and other miscellaneous expenditure. Textiles committee had identified Pochampalli Handloom Weavers Cooperative Society (PHWCS) and Pochampalli Handloom Tie & Dye Manufacturers Association (PHTDA) as applicants for the registrations and this was conveyed to APTDC. There have been series of workshops conducted for the weavers on sensitizing them about the relevance of GI. The application was moved in December 2003 and granted in 2004.

The most important part of post-GI activities for registered products in the Indian context is registration of producers under Part B of the Act. In case of Pochampalli Ikat, only PHTDA had moved the application for registration under Part B in mid 2009 and was granted the certificate in August 2011. However, it is to be noted here that the certificate has been issued to the PHTDA and not to the individual members or the weavers working under them. The other major event that succeeded the registration was the setting up of Pochampalli Handloom Park. Given the networking during the GI registration, several entrepreneurial weavers in Pochampalli formed an association and registered a company called Pochampalli Ikat Weavers Private Limited. Located about 10 kilometres away from Pochampalli Village in Nalgonda, in Kanumukkala Village, the Park has is situated in 24 acres of land with an outlay of Rs. 47 crores. Initially the consortium consisted of 28 members (Textiles Committee 2007) and now it stands at 36 promoters who run the management of the Handloom Park. It is a joint initiative of the local entrepreneurs, State and Central Government and Textiles Committee. Under the Cluster Development Programme of the Textiles Committee this initiative was encouraged. The capital for the project was raised by the members through short term and long term loans and later by Infrastructure Finance & Lending Services Limited (IF & LS) was hired to execute the project. Nonetheless, even after 5 years of establishment, their greatest constraint is working capital. It was also noted that the awareness about the GI registration was abysmally low even among weavers who were working under the registered proprietors namely the PHWCS and PHTDA. This is alarming given the fact that the survey took place almost a decade after filing of application and the registration was due for renewal (by 2014). The FGDs with weavers in various locations (Revanpally, Jangam, Vellamla, Koyalagudem HWCS, Yellanki HWCS) indicated that while weavers were aware of the fact that there were negotiations to ‘patent’ the product, they are neither aware of the details nor were they aware that GI and patents were different conceptually.

5. 0 IMPLICATIONS FOR PROMOTING RURAL LIVELIHOODS

It is evident from all the three case studies that ‘local’, ‘terroir’ is deeply embedded either in the form of use of natural resources (such as clay) or human skill (craftsmanship either in weaving or making of handicrafts). Nonetheless, all the three case studies throw interesting facts about qualification through GI and its implications for promoting rural livelihood. While there is no doubt that there is inextricable link between geography and quality of the product, the valorisation methods differ (from use of local natural resources to traditional knowledge transferred over generations) and there has been practically no addition or improvisation due to GI registration.

The following table summarises the highlights of the three case studies discussed above.

Particulars	Swamimalai Bronze Idols	Aranmula Mirror	Pochampalli Ikat
Socio-economic factors			
Approximate number of artisans	200-500	15-20	2000-2500
Employment Potential	High	Low	High
Main Source of Livelihood	Yes	Yes	Yes
Interest of Younger generation	No	Yes*	Yes (mostly in trade)
Production related			

Use of Machinery	None	None	Low (for sizing of yarn, hand-made looms)
Volume of Production	Low	Low	High
Raw materials	Available	Available	Available
Skilled Labour	Yes	Yes	Yes
Market Related			
Domestic Market	High/Seasonal	High/Seasonal	High/Seasonal
Export Potential	High	High	High
Promotion of the Product	Self	Self	Self/State
Distribution	Self/Government	Self/Government	Self/Government /Trader
Economic benefits to the producer	Varies by artisan		Varies by design
Competition	High	Low	High
GI Related			
Use of GI	No	Yes	No
Logo for GI	No	No	Yes, but by Handloom Park
Application moved by	Central Government Agency	Association of producers	of Association of producers
GI Awareness	Low	Low	Low
Authorised user	No	No	Not used
GI Factor	High	High	Medium (Ikat weaving prevalent in other parts of India)
Economic benefits due to GI	Not achieved	Not achieved	Not achieved

Source: Compilation by Authors Note: *The average age of the present artisan would be around 35. But as of now they are unsure of their children engaging in the craft because of the nature of the work.

The socio-economic context of the three products clearly varies as evident from table above. The employment potential of the primary producers by itself is high in case of SBI and PI whereas the craft remain the major source of livelihood for all the artisans. The lack of innovations and profit margin coupled with other opportunities of employment has weaned away younger generation, but in case of Ikat it could be observed that younger generation was actively involved in marketing and trade. Moreover, minimum use of machinery make the crafts a sustainable method of livelihood based on local resources. Though over time, dependency on raw material (yarn or metals) have become commercialized, there is still a strong link between geography and the human skill involved in the production of all the three products under study. In case of Ikat, the process of tie and dye has been acquired and the technique is prevalent in different parts of India (notably in Orissa and Gujarat) and this poses a serious problem in highlighting the authenticity of the product. Nonetheless, producers, regular customers and experts can differentiate between the different types of Ikat based on geographical origin though there has been no in-depth study undertaken to distinguish these in the wake of GI certification. Here it should be noted that Sambalpur Ikat has already been registered as GI in India. Domestic market is seasonal but high for all products. Because of the uniqueness of the product, the export potential too is high though the volume of production varies. The promotional and distribution activities are solely the responsibility of the producers though occasionally as part of tourism promotion, Aranmula and Ikat are promoted by the state government agencies. The economic returns depend on the artisans and designs and also vary as per the specifications and profile of the buyer. Given the demand of these products owing to its uniqueness, there exist high competition from similar products (Moradabad idol makers, low quality mirror makers in Aranmula and elsewhere, imitation of ikat weaving by powerlooms and mills). Thus, protection of the craft through qualification is justified in terms of socio-economic context, uniqueness of product, and competition in the market. These could have been achieved with systematic efforts to identify the production chain/authorized users.

Nonetheless, the GI certification though registered as per the legal framework, was not put to potential use in case of all the products covered in this paper. In case of Swamimalai Bronze, the Development Commissioner (DC), Handicrafts (Ministry of Textiles, New Delhi) is the registered proprietor. The application had mentioned establishing an inspection body with representatives from Regional Director of DC, Chennai; Crafts Council of India; Handicrafts NGO; National Institute of Design; non-official members associated with art and craft. Thus, it was neither a territorial, sectoral or marketing strategy by an individual firm rather a policy initiative by the central government in charge of handicrafts. In case of Aranmula mirror, the application was moved by an association which was set up only for the purpose of registration and the initiative for this initially came from non-practitioners of the crafts.⁴⁶⁷ In this case, while it can be perceived as a sectoral strategy (since the number of artisans involved is very less), there has been clearly little or no collective action since there exist conflict of interests between members and non-members of the society. Even within the members of the society it was pointed out that there has been practically no discussion on GI either about drawing a code of practice or that of use of GI as a marketing strategy. The GI certification is displayed in the premises of the society but the non-members neither use it nor promote it. There was clear mistrust evident between different stakeholders. Thus, it could be seen as part of a marketing strategy pursued by some individuals who are willing to be part of the society through membership. In case of Pochampalli Ikat, though the initiative came from the quality control body at the Central level through its territorial development programme for textiles (under the Cluster Development Programme), it was the

⁴⁶⁷ See Lalitha 2014 for more details.

producer organizations which were the registered proprietors both from within the cooperative and outside cooperative sector which dominate the production process. Moreover, the role of the Textiles Committee seem to be more of a facilitator in identifying potential proprietors, funders, legal experts and other stakeholders. Nonetheless, the level of cooperation, trust and linkages between the two registered proprietors has been weak. While the private manufacturers association had obtained the authorized user certification under the Part B of the GI Act, the PHWCS remained unaware of it. In addition, the Handloom Park was unable to procure the authorized user status under the legal framework since the conflict of interest between them and the registered proprietors could not be amicably solved. Nonetheless, the initiative could be termed semi-territorial, semi-sectoral strategy and has potential for further promoting livelihood since large number of artisans are involved and the domestic and export potential of the product is high. Nevertheless, except at the behest of the Handloom Park, there has been no initiative under these proprietors to engage in brand building through use of certification or use of logo for certification.

In all the three case studies, specific to Indian context, the craft has diverse forms of organization of production. It should also be noted that in case of Aranmula Mirror, Swamimalai Bronze and Pochampalli Ikat, it is predominantly dominated by specific caste – Vishwakarma in case of the first two and Padmashalis in case of the third. While kinship can be a binding force promoting cooperation (facilitating terms of credit, supply of raw materials, marketing) it can also lead to conflict of interests. The artisans in case of Aranmula mirror categorically pointed out that they would oppose if the craftsmanship is taken up by other caste groups while the major bone of contention with Handloom Park by the weaving community is that they impart training in learning of the process of tie and dye and weaving outside the specific caste. Even in case of Swamimalai Bronze, they face stiff competition from producers in Thanjavur and Moradabad. Moreover in all three cases one could observe differences in scale of production (from small scale producers to large scale producers; cooperative versus private producers; those with huge turnovers and proper institutional mechanism from procurement of raw material to those who are dependent on external sources raw material and marketing and sell only their labour). However, 'tradition' remains an important component which would motivate different actors to be brought together and this was evident across all the three case studies. But it is not enough to promote a rural development strategy and there is need to educate the actors about the potential of collective action through qualification perhaps as an important marketing strategy which would generate rent.

In other words, lack of an institutional mechanism, which overlooks the production along various stakeholders in the supply chain, can be seen as the reason for non-use of GI in the case studies presented. There has been no effort at the level of producers to draw up a code of practice which specifies description of the product, physical, scientific; details about ingredients and raw materials; defining the process of production; demonstration of the specific quality linked to GI; demarcation of the geographic production area; labeling rules and verification and monitoring mechanism to ensure standardization. These aspects would add to the credibility of the product and sales/marketing through authorized sources alone would have also ensured in reaping economic benefits by the artisans. The case in point is the Darjeeling Tea. The entire tea produced by the recognized tea gardens (which if formed into an association of producers) is sold only through one particular channel (also easily identified through the Darjeeling Tea logo) and hence the leakage is avoided and the standardization of quality is ensured. In addition, unlike in case of European Union or Thailand, there is no logo for GI products from India except the individual logos like that of Darjeeling Tea or Kota Doria. In other words, a governance mechanism which overlooks the supply chain is a pre-requisite for the successful use of GI.

CONCLUDING REMARKS

In this paper, through case studies from India which are registered Geographical Indications, we have tried to look at the implications of such qualifications (for non-agricultural products) on rural livelihoods. It is evident from case studies that the implications are mixed. Human skills along with geographic factors play an important role in creation of reputation. De-limiting production to a geographic region, thus, becomes challenging since perhaps over centuries informal rules controlled the relations of production. The case studies point out that while the uniqueness attributed to the product are exclusively based on human skills for PI, in case of SBI and AM, use of soil, from local river bed and paddy fields (respectively) form core of production process. Irrespective of this, the reputation of PI as unique to the region remains intact since regular customers distinguish between the diverse types of Ikat (for example Sambalpuri, Patan Patola) produced in different geographical locations. While, the employment potential is high in case of PI and SBI; the practitioners were limited to (15-20) in case of AM (but remain major source of livelihood for all three products); and the economic returns varied depending on the skills of the artisans and designs both in domestic and export markets. The uniqueness of the products has led to competition from similar products - Moradabad idol makers (SBI), low quality mirror makers (AI), imitation of ikat by powerlooms and mills. Despite these, there has been no use of GI tag as marker of authenticity. This could be attributed to the GI registration being moved by or facilitated by an external agency (SBI and PI respectively) and thus, the producers (even after a decade of registration and renewal) are neither aware nor are informed of potential benefits. Rather, qualification and its ownership have led to conflict of interests among various stakeholders. In this context, it is also pertinent to point out that Part B of the Indian Act pertains to registration of authorized users of products in addition to registered proprietors Awareness about this Part of the Act remain abysmally low. In the case studies mentioned, only Pochampalli Ikat has been awarded under Part B. Even in this case it was awarded to one of the registered proprietors and it has not been awarded to individual producers under the association or the weavers who work under the member master weaver/ traders. The case studies indicate that origin qualification pre-dates the legal framework and poses serious challenge in re-organising the supply chain. Thus, identifying the products, establishing code of practices focusing on the region and quality link which in turn is supported by an

institutional mechanism to overlook the implementation and use of qualification remain the need of the hour in turning the economic assets of the region into a viable tool for sustaining rural livelihoods.

SS10.4. Rural Transformation

1630 ECONOMIC GROWTH BEYOND BORDERS: AN ANALYSIS OF RURAL TRANSFORMATION FROM VILLAGES IN UGANDA TO THE BLACK BELT IN THE UNITED STATES

ABSTRACT

In order to meet the social and economic challenges of the modern era, rural economies are evolving. Globalization and sheer necessity have forced many communities to end an overreliance on agriculture and enhance agribusiness systems. From Africa to the North America, efforts are underway to transform rural economies by expanding infrastructure, improving living standards, and diversifying production. In the South Western and Central regions of Uganda, agriculture is the main sector of employment for households. The Uganda Bureau of Statistics estimates that about 72 percent of all Uganda’s working population is employed in agriculture. Much of Uganda’s rural transformation was built on agricultural income growth that benefited poor households. According to the World Bank, poverty reduction among households in agriculture accounts for 79 percent of national poverty reduction from 2006 to 2013. The Black Belt is a region of the Southern United States where rural communities have historically faced acute poverty because of the area’s relative isolation and lack of economic development. According to the 2000 U.S. Census, the 11 states that make up the Southern Black Belt have a combined rural poverty rate of 18.7 percent, translating into almost 1 in every 5 rural residents living in poverty. Population decline in rural areas, inadequate education programs, low educational attainment, poor health care, urban decay, substandard housing, and high levels of crime and unemployment have become hallmarks of this chronically underfunded and marginalized region. This mixed methods research examines the impact of agriculture and non-agricultural activities on rural development in parts of Uganda and the United States. Through statistical and document analyses, as well as interviews and observations, this study seeks to ascertain the methods, programs, and investments necessary to promote economic independence and global interdependence among rural communities. A two-phase triangulation design is used to set appropriate quantitative and qualitative parameters and examine specific phenomena to determine if findings from disparate data sets converge upon a single understanding of the investigated research problem. During the first phase, quantitative and qualitative methods were given equal priority and all data were collected simultaneously but analyzed separately. As part of the second phase, results from data analysis efforts were examined, combined, and interpreted to determine a convergence or divergence of certain ideas. By employing a panel data model consisting of portions of select states that make up the Black Belt region in the United States observed over a fifteen-year period from 2000 through 2015; and examining statistical data from the South Western region of Uganda, this study seeks to determine the economic impacts of agribusiness and public or private investments on rural economies. Preliminary results from assessments of these different data points suggest best practices from the two countries can have a significant impact on rural communities in both regions.

1646 FARMING TOOLS AND PRACTICES AMONG SMALL AND MARGINAL HOLDINGS

ABSTRACT

Farm mechanization is a symbolic representation of transformation from traditional method to modern way of farming. In labour intensive countries, like ours, consideration of mechanization covers incorporation and utilization of improved tool, implement, machinery in enhancing workers’ efficiency and output, substituting human labor, minimizing drudgery and enhancing productivity and safety at work. However, various studies indicate input variables and approaches referring to the state of mechanization in a particular farming sector, broadly into three categories, such as machinery utilization, economic analysis and human energy expenditure. These approaches have not yet been adequately addressed for the small and marginal farm holdings that primarily depend on the conventional tools, methods and practices. Various mechanization indices that have been developed carry minimal utility among the small and marginal farm holdings. This study explores energy demand of the farmers from small and marginal holdings and elucidates their activity patterns in different crops and seasons. **Methods** - The study involved compilation of information of multiple methodological steps, covering methods of deriving mechanization status, production and energy use data from agricultural agencies, as well as generation of data from field based survey from selected regions of eastern India. Two primary crops, i.e. paddy and potato which are predominantly cultivated in the region were taken as sample crops for analysis. Field study allowed to gather data of different cropping activities, methods and tools applied, man power utilization in different activities, etc. **Results** - The studied farming areas have severely fragmented holding, limited resources and the farmers remain constrained to age-old manual methods. Overall the severity of work and energy demand of these farmers were classified as moderate to heavy in nature. Data on manual energy use pattern were further correlated with the land use and productivity over the farming seasons, indicating that the small farmers are more strained to that of mechanized sectors. Accordingly, an index of work output to energy demand with respect to the selected crops is proposed in this contribution, which may be useful for comparison of the holdings of similar dimension.

SS11.1. The future of leisure: tourism, mobility and transportation

1039 TOURIST-LED REGIONAL DEVELOPMENT IN INDIA: DETERMINANTS AND IMPLICATIONS

ABSTRACT

Globalization has led to an increase in the number of visitors from foreign destinations to various parts of the world. Tourism is an important service sector growth in developing economies such as India. There are several world class tourist locations in India such as: Taj Mahal in Agra, Forts and Monuments in Jaipur, beaches in Goa, temples in Kanyakumari, and backwaters of Kerala, Ajanta and Ellora caves in Maharashtra, and tea estates in Darjeeling. These tourist locations generate foreign exchange earnings as well as income and employment to the local population from tourists who contributes to the demand for goods and services like hotels, food, local transport and shopping centers. Tourism enhances rental income and land prices in the tourist centers. They have potential for fostering regional development and can minimize geographical inequalities among leading and lagging regions. Eco-tourism and hill station development are strategies of regional development for fostering tourism-led development in India. This entails conservation of flora and fauna, development of basic infrastructure, decentralization of accommodation facility, and increasing number of affordable hotels. Given this overview the purpose of this research is to address the following four research questions: (1) What are the trends of tourism in India during the past decade (2003-2013)? (2) What are the determinants of tourist-led-regional development in India? (3) Can tourism-led-development lead to decrease in regional inequality in India? and (4) Can a typology of geographical tourist enclaves be identified in India? This research will employ a mixed methods approach to identify the determinants of tourist development in India at the regional levels. Data will be collected from the following documents from the year 2003-2013 from: Indian tourism statistics and indicators for socio-economic development variables will be collated from Statistical Yearbook of India, and Selected SocioEconomic Statistics of India. Secondary data from these sources will be put in excel format which will be used for mapping trends, converting data into shape files which can be read by a geographical information system (GIS) software such as ArcGIS and for preparing maps and conducting statistical analysis. These maps will reveal spatial changes and the data will be utilized to run exploratory data analysis. Further regression and spatial regression approaches will be used to identify determinants of tourist-led- regional development and rural-urban variations in tourist development in India.

1202 IMPACT OF TOURISM INDUSTRY ON INDIAN ECONOMY: AN ANALYSIS OF GULMARG AND PAHALGAM TOURISM CENTERS IN JAMMU AND KASHMIR STATE

ABSTRACT

It is general perception about tourism industry that it is a social and cultural exchange activities sector but it has been changed at very large extent in many respects in the era of globalization because diverse tourists activities have been increased across the countries which led to increase inflow of tourists and revenue. Both developed and developing countries are injecting huge investment in tourism industry. Therefore, it becomes a largest and fastest growing industry of the world. The present study has estimated impact of tourism industry on Indian economy at macro level by using time series data of post reforms period and found that foreign exchange receipts from the tourism industry significantly contribute to gross domestic product, employment and infrastructure in terms rail, road and civil aviation . This study has also selected and Gulmarg and Pahalgam tourism centers at micro level in Jammu and Kashmir state on economic, natural and political grounds and found that tourism sector contributes more than three-fourth share to the revenue of the state at the time of independence but political condition in the state become worst and had severely affected tourism industry which has put adverse effect on peace, employment generation as well as the GDP of the State during last four decades. Both central and state governments are trying to establish tourism industry as main occupation for the generation of employment to the growing unemployed population of the state in the last few decades resulting the tourism industry in the state again emerged as a growing Industry. This study investigated the impact of tourism industry at micro level by using primary data and found that there is a positive impact on the income, employment and infrastructure development in tourist center Gulmarg and Pahalgam.

1112 WELLNESS TOURISM PARTICIPATORY GOVERNANCE: A COMMON POOL RESOURCES APPROACH

ABSTRACT

The global growth currently observed in wellness tourism (Yeung and Johnston, 2015) opens opportunities for development of rural areas where resources for the attractiveness of these travellers can be found. As Smith and Diekmann (2017) systematize, natural assets, landscapes or local cultural values complement the spa-related services based on thermal water to fulfill their needs and motivations. The region of East Hokkaido has the resources to undertake innovative initiatives within this tourism segment, as observed by Romão et al. (2017) and acknowledged by an official report (Government of Japan, 2017). These resources can be framed within the concept of “Common Pool Resources”, usually indivisible and with boundaries difficult to delineate, and characterized by subtractability and nonexcludability (Briassoulis, 2002). Problems of overuse, degradation, lack of incentive for preservation or unequal appropriation of benefits often emerge (Dietz et al., 2003). A strategy of diversification of wellness tourism services oriented to regional sustainable development implies sustainable use of territorial resources, socio-economic benefits for local communities and participatory management process, involving the relevant stakeholders: accommodation and spa-service managers, institutions in charge of natural parks, cultural and educational facilities, and representatives of local residents, including indigenous Ainu communities, whose cultural values can contribute to differentiate the destination (Romão et al., forthcoming). In this paper, a governance model based on the principles for governing sustainable resources proposed by Ostrom (2008) is proposed, implying definition of boundaries, equivalence between benefits and costs, collective-choice arrangements, systematic monitoring and mechanisms for conflict resolution. This governance model considers international guidelines for utilization of natural and cultural resources in tourism (UNWTO, 2001; UNESCO, 2013), along with coordination with Destination Management Organizations being implemented in accordance to national policy guidelines. These guidelines point out wellness services, natural resources and cultural as tools for economic revitalization of rural areas in Japan (Government of Japan, 2013 – 2016).

SS11.2. The Future of Leisure: Tourism, Mobility and Transportation

1127 TOURISTS' IMPORTANCE AND SATISFACTION EVALUATION: THE CASE OF SELECTED TREKKING ROUTES OF KUMAON HIMALAYAS, UTTARAKHAND, INDIA

Shomini Biswas

Department of Geography, University of Calcutta

INTRODUCTION

There is growing evidence that customer satisfaction is a driving force behind firm's business competitiveness and performance (Parasuraman et al., 1985, 1988; Zeithaml et al., 1996). This is absolutely true in the case of tourism, where there is a wide application of concepts, models and tools aimed to evaluate customer satisfaction. It is recognized in fact that, in order to identify the strengths and the weaknesses of a tourist destination and to improve its competitiveness, it is essential to "listen to the customer". Satisfaction is commonly considered the best indicator of the state of health of tourism, an industry that is difficult to evaluate in quantitative terms. Satisfaction, even for tourism, as well as for other industries, is also directly linked to the loyalty of "clients" and, therefore, to the sources of competitive advantage.

Tourist satisfaction essentially indicates the result of relationship between tourists' expectations about the destination based on their previous information and image of the destination (pre-travel expectations) and their assessment of the outcome of their experience (post-travel experiences) at the visited destination (Pizam, Neumann, & Reichel, 1978; Neal & Gursoy, 2008). It is a feeling generated both by cognitive and emotional aspects of tourism activities, as well as an accumulated evaluation of various components and features of the destination visited (Wang, Zhang, Gu, & Zhen, 2009). As tourist satisfaction influences tourists' behavioural intentions and plays a vital role in destination competitive advantage, it has attracted many academicians' interest and a large number of studies have focused on this aspect with regard to various tourist destinations throughout the world (Pizam et al., 1978; Baker & Crompton, 2000; Kozak & Rimmington, 2000; Yoon & Uysal, 2005; Wang & Qu, 2006; Cracoli & Nijkamp, 2008; Alegre & Garau, 2010; Chen & Chen, 2010; Marcussen, 2011)

Although there is a wide array of literature on mass tourism satisfaction analysis and destination management, documenting importance and satisfaction among trekkers, nature-based and adventure tourists is limited. Moreover the Uttarakhand State of India has received poor coverage in literature, despite having the excellent tourism attractions. Hence this paper adopts the trekkers'/ecotourists' perspective and it proposes the Importance-Performance (IPA) as a tool for evaluating trekkers' satisfaction levels arriving at selected trekking routes of Kumaon Himalayas, Uttarakhand. Information on the importance and performance of destination attributes in overall tourists' satisfaction enable recommendations on improving the quality of tourism offerings and services of the trekking routes and better management of the services provided to the trekkers visiting the areas. The present study contributes in the area of trekkers'/nature-based tourists' satisfaction by providing an empirical relationship between the performance of destination attributes and overall tourist satisfaction.

LITERATURE REVIEW

Enhancing tourist satisfaction is one of the primary functions of tourism destination and a prerequisite for the development of strategies leading to destination's improved attractiveness and competitive positioning (Dmitrovic et al., 2009). Although tourist satisfaction is a personal judgment, the understanding of tourists' satisfaction is necessary forevaluating the performance of destination, improving products and services offered, promoting tourism offerings effectively to target markets, gaining better destination image, and determine repeat visits and predisposition for recommending the destination to others (Kozak & Rimmington, 2000; Yuksel, 2001; Yoon & Uysal, 2005; Chi & Qu, 2008; Meng et al., 2008). Satisfied tourists normally recommend better tourist destinations to others or express their appreciation about the destination and are keen to visit again and vice-versa (Baker & Crompton, 2000; Kozak & Rimmington, 2000).

Interests in the application of consumer satisfaction to tourism research dates back to the 1970s (Pizam, Neumann and Reichel 1978), and the literature has grown considerably in recent years (Bowen 2001; Kozak 2001; Master and Prideaux 2000; Millán and Esteban 2004; Wong and Law 2003). Current literature has indicated that measuring and managing tourist satisfaction is critical to the sustainability of a product, an attraction, an activity or a destination (Sirakaya et al. 2004). Many tourism scholars (Hwang, Lee and Chen 2005; MacKay and Crompton 1990) have applied the service quality (SERVQUAL) model, developed in the management field (Parasuraman, Zeithaml and Berry 1988), to measure tourism satisfaction. However, satisfaction is generally deemed to be more affective or emotional than quality or cognitive (Iacobucci, Grayson and Ostrom 1994). Satisfaction is also distinct from either price or value, in that they might equally exist without an intimate structural interdependence (Bowen 2001).

The context of this study is nature-based tourism and trekking therefore findings from studies conducted in natural areas are briefly summarized here. Bowen (2001) measured satisfaction of a small group of tourist to Malaysia's Taman Negara National Park. He applied other theories relevant to management (services marketing) including performance, attribution, emotion and equity, and concluded that tourist satisfaction consists of a multitude of parameters and no single parameter would fully explain tourist satisfaction. Satisfaction level o backpackers with different attributes of accommodation in Youth Hostel was studied by Nash (2006), where levels of satisfaction exceeded the levels of importance attributed to the range and quality of facilities.

As noted earlier, research on nature-based tourists' satisfaction is very limited. This research applies the "importance-performance" construct in measuring the discrepancy between pre-travel importances attributed to lodge-related services and facilities, and perceived satisfaction level after the travel experience in selected trekking routes of Bageshwar District of Uttarakhand. The focus of the study was to identify key areas of satisfaction and concerns that tourists expressed regarding their overall trip and services received in the trekking routes under study.

OBJECTIVES

- + To evaluate nature-based tourists'/trekkers' importance and satisfaction levels at Pindari, Sundherdunga and Kafni trekking routes of Bageshwar district of Kumaon Himalayas, Uttarakhand with the help of IPA or Importance-Performance analysis.
- + To identify key areas of satisfaction and dissatisfaction and concerns that tourists expressed regarding their overall trip and services received during their stay.

THE IPA SCHEME

The IPA is a tool in line with the expectations-performance approach to the measure of quality perceptions and it is well documented in the marketing literature (Ennew et. al, 1993; Slack, 1994; Matzler et al., 2003); it is commonly used to provide directions for making strategic marketing decisions. Although the use of IPA lost favour in the last few years as consequence of the development of more complex quantitative methods (Duke, Mount, 1996), since this approach was proposed by Martilla and James (1977), academic literature is replete of studies which provide empirical application in several service settings, such as transportation (Huang, Hsu, 1996), banks (Joseph et al., 2005), universities (Pike, 2004), hospitality (Janes, Wisnom, 2003) and tourism (Fuchs, Weiermair, 2003). In particular, it has been argued that «for tourist destinations with rather little market research experience, Importance-Performance Analysis in its purest form can be used as a very powerful tool in marketing planning» (Hudson and Shephard, 1998).

It has been observed that looking at satisfaction and importance values separately is ineffective in assessing the success of a particular tourism destination in meeting tourists' needs. Hence both the values together are regarded to give interesting results. IPA employs a simple graphical approach to compare the mean score for 'perceived importance' of various attributes with the corresponding 'satisfaction rating' using a two-dimensional grid, where each quadrant can be summarized into a specific suggestion for management (Figure 1). In particular, poor performance on extremely important dimensions indicate high priority in intervention for improvement (Concentrate here quadrant); excellent performance on highly important features represent opportunities for gaining or maintaining a competitive advantage (Keep up the good work quadrant); slightly important features that are excellent in performance imply that resources would be better employed elsewhere (Possible Overkill quadrant); finally, fair performance on slightly important features suggest that it may not be necessary to focus additional effort to these attributes (Low priority quadrant).

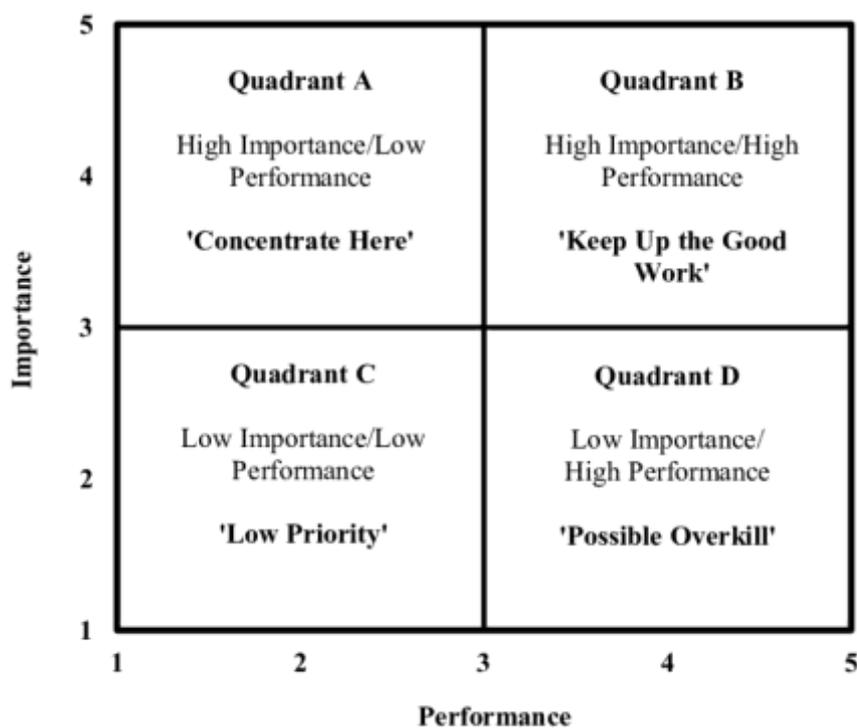

Figure-1: Importance-Performance Analysis

IPA has been proven to be a popular management tool and is well documented in various tourism studies (Oh, 2001; Fuchs & Weiermair, 2003; Zhang & Chow, 2004; Aksu, Icigen, & Ehtiyar, 2010; Ziegler et al., 2012; Chen, 2013; Lai & Hitchcock, 2015). It provides easy understanding of the drawbacks and strong points of a particular tourist destination and provides for easy management at various levels.

METHODOLOGY

The Study Area:

Trekking in India:

The last half of the last century has seen a dramatic rise in the development of travel and tourism in the world. While mass tourism dominated the sector, a niche market has always been involved in more nature and adventure oriented travel and tourism. However, the last few decades has seen a dramatic change in tourism with a shift towards more sustainable tourism. While this market is still niche and limited in numbers, it is growing rapidly. Much of the nature tourism market emanates from North America and Europe and is directed at pristine natural locations such as Asia and South America. Nepal, as the home of the Greater Himalayas, sees the majority of mountaineering and adventure tourism. Uttaranchal, located strategically near Nepal and with the Himalayas has great potential for development, in the present scenario, especially as a trekking destination.

Trekking in Uttarakhand:

Trekking in Uttarakhand can be categorized as either that related to adventure trekking or pilgrimage. While pilgrimage travel is more related to mass tourism, it constitutes the larger segment of trekking tourism to the State. While many of the pilgrimage routes don't require physical trekking, of the 27 popular and predominant treks, at least 7 (Gangotri, Kedarnath, Yamunotri, Badrinath, Chandrasilla, Devi Darshan and Panch Kedar) are pilgrimage treks or extensions of pilgrimage treks. Most of the adventure treks in Uttarakhand are popular both in the domestic and the international circuits. The majority of treks are located in Garhwal but the more remote and pristine treks are found in Kumaon.

Located in the eastern part of Uttarakhand, the Himalayas of Kumaon are one of the most underrated and picturesque in the country attracting tourists from all over the world. Among all the glaciers of Kumaon region, the most stupendous and well known are the Pindari, Sundherdunga and Kafni. The trekking routes leading to these three aforementioned glaciers are well known as well. The present study focuses on the three trekking routes and the visiting nature-based tourists/trekkers were surveyed.

The most accessible glacier in Kumaon region, Pindari is located at 3820m in Patti Malla Danpur of Bageshwar District. The glacier is 3 km long and 0.25 km broad and is connected to the southwestern slope of the outer wall of Nanda Devi Sanctuary. The main peaks near the glacier that adds beauty to the trekking experience are the Nandakot (6880m), Nandakhat (6611m), Pawalidwar (6663m), Baljuri (5922m), Changuch (6322m). The route to Pindari Glacier has government rest houses and local homestays at convenient sites.

The Kafni Glacier lies towards the left of Pindari valley below Nandakot. The main peaks near the glacier are Nandakot (6860m) and Nand Bhanar (6104m). This region is rich in wildlife and wildlife enthusiasts are frequent here. There are no rest houses beyond Dwali and tents or caves are used to spend the nights. The route to Pindari and Kafni Glaciers is common till Dwali (Fig.).

Sundherdunga comprises of two glaciers, Maiktole and Sukhram and the main peaks near to the glaciers are Tharkot (6100m), Mrigthuni(6856m), Maiktole (6804m).The route to Sundherdunga is the same as Pindari and Kafni till Khati village (Fig.). Each of the trails are about 40 km to 80km through deep gorges, fast flowing rivers, colourful villages and high mountain scenery.

The catastrophe that occurred on 16th June, 2013, in the wake of pre-monsoons in Uttarakhand affected everything, primarily the tourism sector of the state given the fact the tourism sector is one of the major sources of income of the people there. Although there has been more destruction in the Garhwal region, the Kumaon region remains underemphasized in terms of the loss that occurred. Apart from closure of the main points of touristic interests, all trekking routes were closed for 2 years since the disaster. Since trail routes are mostly amidst natural surroundings with narrow passes, snowbound regions and forested areas, they were highly damaged due to the torrential downpour. The trails have been constructed and mended but with the changing patterns of precipitation in the form of rain and snow and changing patterns of temperature there has been frequent changing of the trails, melting of the snowbound regions resulting in exposure of trenches and deep gorges which are difficult for trekkers to overcome. Hence annual frequency of trekking groups has dropped to a significant level. This is another reason why the tourists' satisfaction levels visiting these places are important for further destination management of the region.

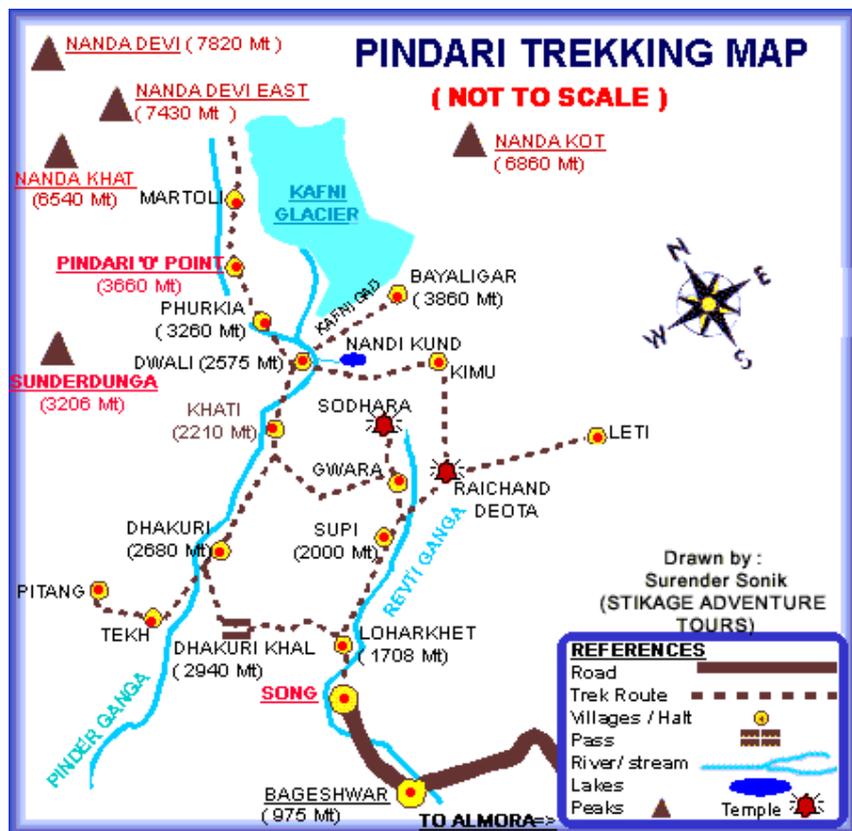

Figure-2: Study Area

Data Collection:

Importance and satisfaction variables related to nature-based, adventure-based and rural tourism were selected through direct interviews conducted with local tourism entrepreneurs, tour guides apart from consultations with a number of visitors. In addition, surveys of previous literature were also considered, for example, - Kozak and Rimmington (2000) in Mallorca, Spain, Nepal (2007) in Annapurna, Nepal, Chi and Qu (2008) in Arkansas, USA and Aksu et al. (2010) in Antalya, Turkey were studied and included in the survey instrument.

The sample population of the survey is 129 domestic and overseas trekkers who have stayed and trekked through any of the three trekking trails under study. The survey was conducted face-to-face using self-administrated questionnaires after the monsoon season in September- October, 2017. Tourists were approached at selected locations of the trails and also at Bageshwar (transit hub) according to convenience. 135 questionnaires were filled by respondents out of which 6 of them were excluded from the study as they were unreliable and improperly answered. The survey questionnaire consisted of demographic profile of the respondents, travel behaviour and tourists’ importance-satisfaction attributes of the destination. Respondents were asked to indicate their level of agreement on a five-point Likert scale ranging from 1 (Strongly disagree) to 5 (Strongly agree) against the 33 importance-satisfaction attributes on the survey questionnaire. The 33 attributes were related to weather conditions, uniqueness of the destination, quality of facilities, motivation factor and accommodation factors.

DATA ANALYSIS AND RESULTS

Demographic Profile and Travel Behaviour:

The sample shows dominance in male respondents (60.45%) although in case of overseas tourists’ sample male respondents comprise of 50%. The highest percentage of trekkers are in the age bracket 25-34 years, the least found in the above 45 years bracket. 58.13% are married and 27.13% of the respondents visited with their spouse and majority of the sample visited in a group of 3-6 persons. 48.20% of the sample did not hire any local support from guides and porters. Regarding the country of origin 74.41% (96) respondents were domestic and rest were overseas tourists who came from North America, various countries of Europe, countries of Asia-Pacific and South America.

Table-1: Demographic Profile and Travel Behavior of respondents (N=129)

Importance-Performance Means of Destination Attributes:

In order to obtain the IPA Scheme descriptive statistics and mean of the scores were performed in Table-2, showing the levels of importance and performance of the 33 destination attributes.

Table-2: Importance-Performance Means of Destination Attributes

Variables	Importance	Performance	Mean Difference
Weather and Accessibility	3.91	3.41	-0.25
Favourable weather and climate	4	2.3	-0.03
The destination is free from air and noise pollution	4.1	4.23	0.13
Availability and adequateness of transportation facilities	3.9	3.82	-0.08
Completeness of roads and road signage to destination	3.98	3.65	-0.33
Easy accessibility of hotels and lodges	3.74	3.66	-0.08
Telecommunication facilities near tourist destination	3.34	3.26	-0.08
Condition of trekking routes till destination is good	4.34	3.00	-1.34
Uniqueness of Destination			
Uniqueness of Destination	5.066	4.16	-0.056
Tranquility and panoramic view of natural environment	4.83	4.85	0.02
The wilderness and undisturbed nature	4.76	4.67	-0.09
A rich spiritual and cultural heritage	3.44	3.52	0.08
Variety of tourist attractions	4.13	3.92	-0.21
Protected cultural and natural resources	3.95	3.91	-0.04
The destination is unique and authentic	4.22	4.12	-0.1
Quality of Tourist Facilities			
Quality of Tourist Facilities	3.77	3.52	0.168
Quality & hygiene at tourist place, accommodation & eateries	3.95	3.78	-0.17
Availability of competent tourist guide	3.56	4.57	1.01
Maintenance of tourist attractions	3.8	3	0.14
Cleanliness & maintenance of public convenience facilities	3.72	2.9	-0.02
Availability of leisure and recreational activities	3.23	2.5	0.07

Uncrowded and unspoiled destination	4.4	4.38	-0.02
Accommodation related amenities 3.88		3.71	-0.17
Availability of bedroom options	3.5	3.2	-0.3
Good toilet facility	4.6	4.1	-0.5
Good shower facility	4.8	2.2	-2.6
Cleanliness of lodge and surrounding area	4.03	4.5	0.47
Good views of mountains/scenery	4.74	4.8	0.06
Host friendliness	3.6	4.62	1.02
Good local food	3.1	3.6	0.5
Reasonably priced	4.35	4.25	-0.1
Attached bathroom	2.23	2.14	-0.09
Tourist Motivation Factor	4.424	4.4	-0.024
Hospitality and friendliness of local people	4.8	4.82	0.02
Safety and security	4.55	4.3	-0.25
Availability of information center	3.7	4.13	0.43
Diversity of flora and fauna is high	4.82	4.73	-0.09
Adventure factor is high	4.25	4.02	-0.23

In order to examine tourist satisfaction with destination attributes, mean scores of all attributes were plotted on the IPA matrix as shown in figures of 3 to 6. For each IPA matrix, placements of axes on the grid were calculated through the grand mean of the given factors. Tourists' perception and importance values were plotted on the four quadrant grid that were formed based on the mean scores of importance performance ratings. Each attribute was then assessed by locating in the appropriate quadrant. Each quadrant suggests a different response from the tourism management and destination marketing strategy point of view.

Weather and Accessibility:

Quadrant B which is the 'Keep up the good work' quadrant includes the attributes which are the destination is free from air and noise pollution, availability of transportation facilities, easy accessibility of hotels. Low performance but high importance attributes including in quadrant A which is 'Concentrate here' were favourable weather and climate and condition of trekking routes till destination, which proves that trekkers were not quite satisfied with these. Low priority attribute in quadrant C was telecommunication facilities near tourist destination which proves that for the telecommunication facilities in the trekking trails was not something trekkers expect.

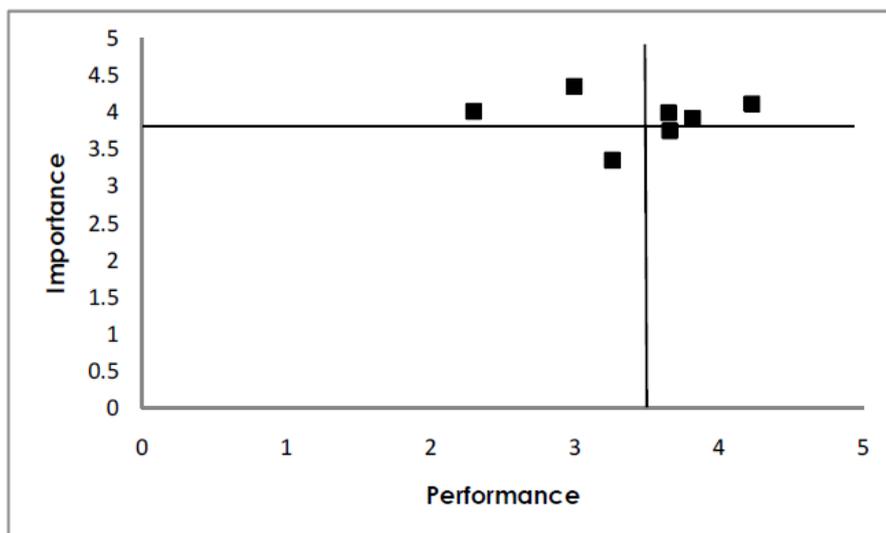

Figure-3: Weather and Accessibility

Uniqueness of Destination:

In case of uniqueness of destination tourists were satisfied with almost all attributes with are related to undisturbed nature, panoramic views and uniqueness of the destination. These were in the high importance and high performance quadrant. The low importance and low performance attribute was rich spiritual and cultural heritage included in the 'low priority' quadrant.

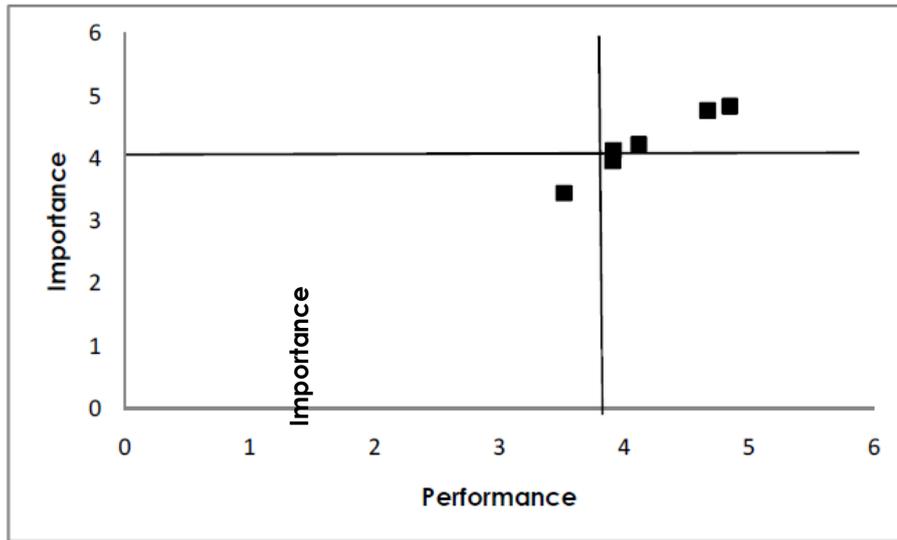

Figure-4: Uniqueness of Destination

Quality of Tourist Facilities:

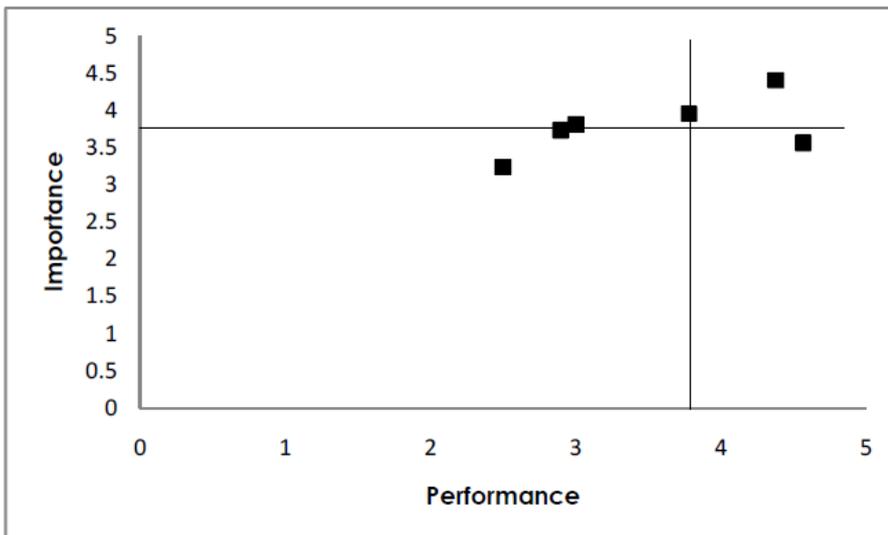

Figure-5: Quality of Tourist Facilities

Here the low importance-high performance attribute was the availability of competent tourist guides which proves that the region has good guides although trekkers have kept it on low priority. Cleanliness and maintenance of public places and lodges and maintenance of tourist places were included in the ‘concentrate here’ quadrant whereas unspoiled and uncrowded destination was included in the ‘keep up the good work’ quadrant proving the pristine nature of the destinations.

Accommodation related Amenities:

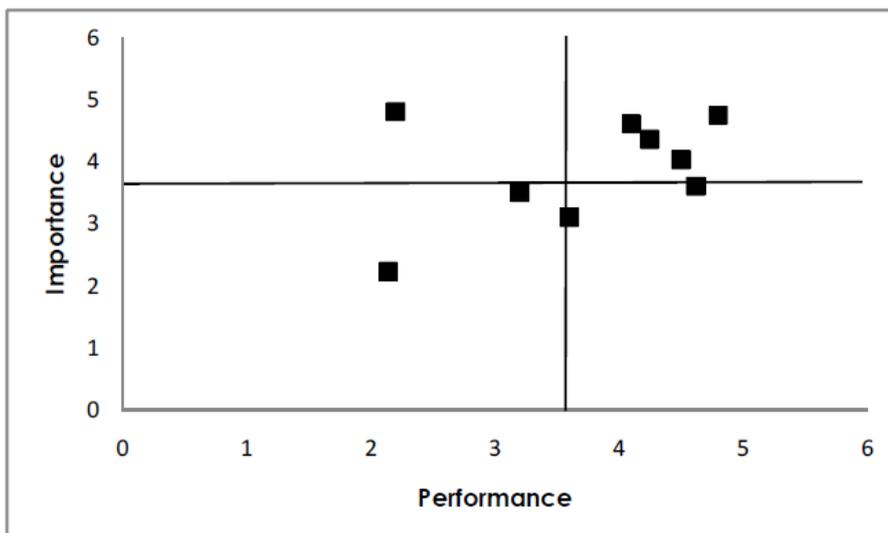

Figure-6: Accommodation related amenities

The low priority and low performance attributes in accommodation related amenities are attached bathroom and availability of bedroom options. The 'concentrate here' quadrant included shower facility which indicates that shower facility was clearly high priority but low performance. The low importance but high performance quadrant included good local food which was not of particular interest to the trekkers but performed well. Good views, reasonable prices and good toilet facility was in the 'keep up the good work' quadrant as the trekkers were satisfied with these.

Travel Motivation:

Friendliness of locals and hosts and diversity of flora and fauna were included in the 'keep up the good work' quadrant as these were high importance-high performance attributes. The other attributes like availability of information centre and high adventure factor were low priority-low performance attributes.

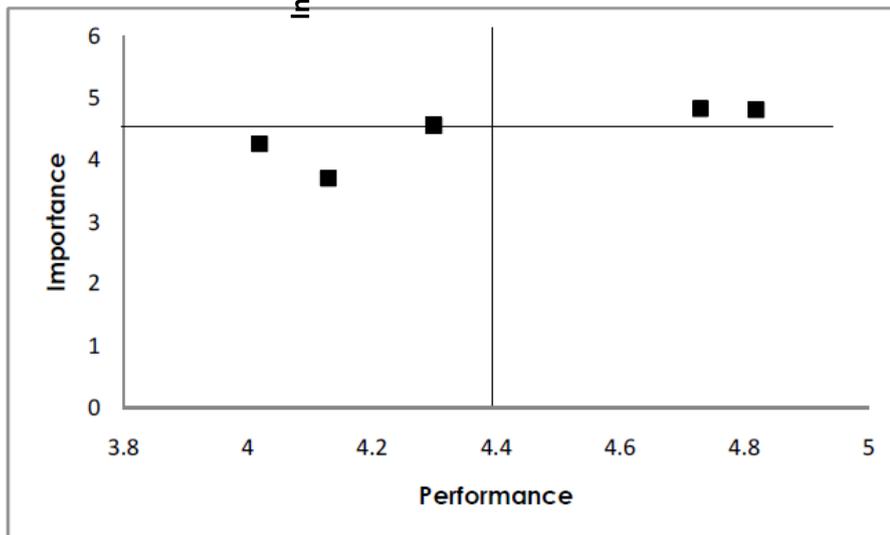

Figure-7: Travel Motivation

CONCLUSIONS AND IMPLICATIONS

This study has significant implications both for practitioners and for academics. From the management prospective our results may provide a clear guidance for the improvement of tourist offer, by identifying the main area of intervention according to the tourists' perceptions. In particular, in the case of Pindari, Sundherdunga and Kafni trails, policy makers should devote more efforts to the enhancement of better trail conditions, safe accessibility and transportation facilities, better roads and better signals on the trails, better shower facility. Such services are rated high in importance so they are perceived as relevant determinants of tourism/trekking experience. Although favourable weather and climate are uncontrollable but high on importance in the tourism industry. In terms of pristine, undisturbed and unexplored, the three trails are excellent and government should continue to keep it as uncrowded as possible.

From the research prospective, this study supports the adoption of the IPA as an alternative/integrative framework for evaluating tourist satisfaction. Such framework can be utilized in further research on tourist satisfaction and destination management in case of alternative tourism and ecotourism. Tourists' loyalty to a destination can only be strengthened through a positive total experience. A high quality nature-based tourism experience can only be ensured if immediate attention is paid to improvements in areas of concern.

ABSTRACT

This paper examines the impact of slot restrictions as a determinant of scarcity rent. Previous studies on this subject have a common limitation: they could not explicitly examine the effects of slot restrictions on airfare. To overcome that limitation, this paper took advantage of an exogenous regulatory change, the removal of slots at Newark Airport in October 2016. The results from the difference-in-differences estimation suggest that after the slot removal at Newark Airport, the average fare on routes to or from Newark decreased by about 2.8% compared to the average fare on routes to or from the two other slot-controlled New York-area airports. The estimation results from modified models suggest that the key driver lowering airfares on routes to or from Newark after the slot elimination was carriers other than the dominant carrier at Newark, though even the dominant carrier, United Airlines, was challenged by competition on relatively high-fare routes. Overall, the estimation results suggest that slot restrictions limit the effect of competition on airfare. Future research should focus on better understanding how to enhance competition on fares by improving the accessibility and transparency of the secondary slot-trading market or by replacing slot restrictions with market-based measures, such as congestion pricing and a slot auction mechanism.

Keywords: Entry barriers, price competition, airline industry

1 INTRODUCTION

This paper investigates the impact of slot restriction as a determinant of scarcity rent, i.e., markup on fares resulting from airport capacity shortages. Scarcity rent can arise at capacity-constrained airports when airport charges (e.g., landing fees) at the airports are lower than the market clearing price at which the level of demand would be in balance with the airport capacity available. In reality, it is widely believed that many congested airports charge carriers less than the market clearing price, and many carriers are taking advantage of this situation. Indeed, it is assumed that carriers often maintain their fares at the highest level the market will bear and make excess profits by exploiting the scarce airport slots (Starkie, 1998; Burghouwt et al., 2017). The scarcity rent is therefore transferred to carriers, not to passengers.

The effect of entry barriers, including airport slots, on the amount of scarcity rents has been studied extensively (Abramowitz & Brown, 1993; Borenstein, 1989; Ciliberto & Williams, 2010; Dresner et al., 2002; Evans & Kessides, 1993; Gayle & Wu, 2013; Morrison, 2001; Peteraf & Reed, 1994; Snider & Williams, 2015; Van Dender, 2007). However, no previous study has explicitly examined the effects of slot restrictions on airfare. This paper estimates the specific effects of slot restrictions on airfare by taking advantage of an exogenous regulatory change, the removal of slots at Newark Airport in October 2016.

I use a difference-in-differences strategy to estimate the impact of the elimination of slot restrictions at Newark Airport on airfare. The data are carrier-route-level quarterly unbalanced panel data that are constructed from the DOT's DB1B data for the period between the first quarter of 2016 and the second quarter of 2017, which includes three quarters before and after the slot removal at Newark Airport. The treatment group comprises routes to or from Newark Airport, and the control group consists of routes to or from the two other New York airports, John F. Kennedy and LaGuardia Airports, both of which were slot-controlled during the analysis period.

The base estimation results suggest that the average fare on routes to or from Newark Airport decreased by about 2.8% compared to the average fare on routes to or from the two other slot-controlled New York airports after the elimination of slot controls at Newark Airport. The estimation results from the modified model suggest that the key driver lowering fares on routes to or from Newark Airport after the slot elimination was carriers other than the dominant carrier at Newark Airport. Also, the results of estimation from a quantile regression approach suggest that the dominant carrier, United Airlines, may have been able to take advantage of its dominant position at Newark Airport and charge a premium ticket price on relatively low-fare routes even after the slot removal, even though it has been challenged by growing competition especially on relatively high-fare routes.

The paper is organized as follows: Section 2 summarizes the results of previous studies. Section 3 provides some background on slot restrictions at US airports, especially those in the New York area. Section 4 describes the estimation models, methods, and data that were used. Section 5 reports the estimation results and robustness checks, followed by a discussion in Section 6. Section 7 concludes with some policy implications of the analysis.

2 PREVIOUS STUDIES

The effect of entry barriers, including airport slots, on the amount of scarcity rents has been studied extensively. For example, Borenstein (1989), in one of the seminal papers on scarcity rent or fare premiums in the airline industry, estimated the effects of various forms of market power on airfares and found a significant fare premium at hub airports due to the market power arising from being a hub. Borenstein (1989) also found the presence of scarcity rents at some congested US airports. However, he did not explicitly examine the effects of slot restrictions on airfare. Indeed, Borenstein (1989) used airport dummies to estimate the amount of scarcity rents at congested airports. The estimated coefficients

of airport dummies represent not only the effects of scarcity rents due to slot restrictions, but also the effects of unobserved airport characteristics such as the availability and control of airport gates. As a result, the estimation indicates that significant positive “scarcity rents” are identified for both slot-constrained (O’Hare) and non-slot-constrained (Atlanta, Denver, Cleveland) congested airports.

A similar problem persists in the studies of Abramowitz & Brown (1993), Dresner et al. (2002), Gayle & Wu (2013), Morrison (2001), Peteraf & Reed (1994), and Van Dender (2007). These studies use slot-controlled airport dummies to identify the presence and magnitude of scarcity rents at slot-restricted airports. Unfortunately, this approach also could not fully differentiate slot-specific effects from unobserved airport- fixed effects on airfares because slot restrictions remained in effect at slot-restricted airports during all the periods these studies covered. Although the estimation results of these studies suggest that airfares are higher in markets that include slot-restricted airports as an endpoint, it is not clear whether and to what extent the higher airfares are due to the slot constraints.

Ciliberto & Williams (2010) and Snider & Williams (2015) made the most recent important contributions to the study of hub premiums, or scarcity rents. Indeed, these studies revealed that factors such as control of gates is a crucial determinant of hub premiums. This finding is an important update to Dresner et al. (2002), who found a similar result with respect to gate constraints and utilization. However, neither Ciliberto & Williams (2010) nor Snider & Williams (2015) could measure the magnitude of scarcity rents derived from slot restrictions because the fixed effects of slot-controlled airports were differenced out in their studies.

3 BACKGROUND ON SLOT RESTRICTIONS AT NEW YORK-AREA AIRPORTS

To overcome the limitations of the previously mentioned studies, this paper takes advantage of an exogenous regulatory change, the removal of slots at Newark Airport in October 2016. On March 18, 2008, the Federal Aviation Administration (FAA) proposed placing a temporary limitation on scheduled flight operations at Newark Airport. The airport has historically experienced a significant number of delays compared to other airports. The on-time performance at Newark Airport deteriorated in the 2000s. According to the FAA, the percent of on-time gate arrivals within 15 minutes of the scheduled time decreased from 70.66% in 2000 to 63.97% in 2006 and to 61.71% in 2007. The average daily count of arrival delays greater than one hour increased from 54 in 2000 to 79 in 2006 and to 93 in 2007. In addition, it was anticipated that carriers might try to add still more operations at Newark Airport because of an operational limitation at nearby John F. Kennedy Airport (73 FR 14552).

On May 21, 2008, the FAA issued an order that placed temporary limits on scheduled operations at Newark Airport to mitigate congestion and delays. Under the order, the FAA established hourly limits of 81 scheduled operations during the peak period. The order took effect on June 20, 2008 (73 FR 29550). Similar orders were issued and took effect at LaGuardia Airport on January 1, 2007 (71 FR 77854), and at John F. Kennedy Airport on March 30, 2008 (73 FR 3510), due to increasing congestion and delays. Therefore, the US Department of Transportation (US DOT) and FAA considered a longer-term and comprehensive approach to slot management at the New York-area airports (i.e., John F. Kennedy, LaGuardia, and Newark). On January 8, 2015, the agencies proposed a set of alternative rules that replaced the orders limiting scheduled operations at the three airports. During the review process of the comments received on the proposed rules, United Airlines and Delta Air Lines entered into controversial slot transactions on June 16, 2015. One transaction was a so-called slot lease agreement pursuant to which Delta would lease United 24 Newark slots for \$14 million. Although it was called a “slot lease agreement,” the lease was long term and automatically renewable. Thus, it was intended to effectuate a permanent transfer of the slots to United. The other transaction was a separate slot lease agreement pursuant to which United leased 30 slots at Kennedy Airport to Delta, also for \$14 million. This lease was also long term and automatically renewable, and thus it was intended to effectuate a permanent transfer of the slots to Delta. The latter transaction closed in June 2015 (US DOJ, 2015).

The former transaction was challenged by the US Department of Justice (US DOJ), however, because it allegedly posed a significant risk of anticompetitive harm to passengers using Newark Airport. At the time when the transaction was proposed, United controlled 73% of the slots (i.e., 902 of the 1233 allocated slots) at Newark. If United’s proposed acquisition of 24 slots from Delta were allowed to proceed, United would have a market share of approximately 75% of the Newark slot market and a correspondingly high share of the Newark air passenger service market. The US DOJ alleged the following:

United is already exercising this monopoly power, and has long been able to extract a “Newark premium” for its service. Indeed, airfares at Newark are among the highest in the country and service ranks among the worst... Through the proposed transaction and other actions, United is monopolizing and/or maintaining and enhancing its current monopoly over the markets for Newark slots and for scheduled air transportation in Newark... (US DOJ, 2015)

This is why the US DOJ brought an antitrust case against United and Delta.

At the same time, after the imposition of temporary limits on scheduled operations at Newark Airport, the FAA reviewed operational and performance data on an annual basis and found that scheduled demand was routinely below the hourly limits of 81 scheduled operations set by the order. Considering the results of the demand and capacity analysis, on April 1, 2016, the FAA announced that it decided to eliminate slot restrictions at Newark Airport. The elimination of slot restrictions became effective on October 30, 2016. In response to the impending regulatory change, on April 4, 2016, United terminated the slot lease agreement dated June 16, 2015. Based on United’s decision, the US DOJ dismissed the case on April 6, 2016 (US DOJ, 2016).

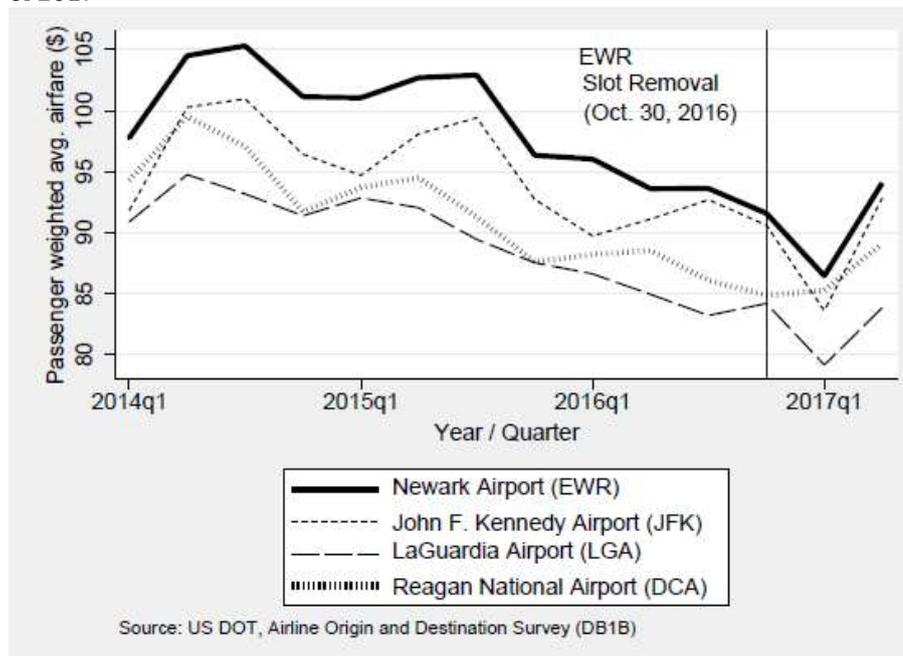

This paper takes advantage of the regulatory change, i.e., the elimination of slot restrictions at Newark Airport, to identify the presence and magnitude of scarcity rents due to the slot constraints at Newark Airport.

4 MODELS AND DATA

This paper uses a difference-in-differences strategy to differentiate slot-specific effects from unobserved airport-fixed effects and estimate the impact of the elimination of slot restrictions at Newark Airport on airfares. The data are carrier-route-level quarterly unbalanced panel data that are constructed mainly from the DOT's Airline Origin and Destination Survey (DB1B) data for the period between the first quarter of 2016 and the second quarter of 2017, which includes three quarters before and after the slot removal at Newark Airport. The treatment group comprises routes to or from Newark Airport, and the control group consists of routes to or from John F. Kennedy and LaGuardia Airports, both of which were slot controlled during the analysis period. By using the difference-in-differences approach, we can uncover systematic differences between slot-controlled airport and non-slot-controlled airport on airfares by explicitly controlling for airport fixed effects.

However, the key identifying assumption of the difference-in-differences strategy is that airfare trends would be the same in both groups in the absence of treatment, i.e., slot removal. Figure 1 plots the passenger-weighted average airfares (deflated by CPI-U) on routes to or from the four slot-controlled airports, Newark, Kennedy, LaGuardia, and Reagan National Airports, for the period from the first quarter of 2014 to the second quarter of 2017. The average airfares on routes to or from the four airports show a similar trend before the slot removal at Newark. The average airfares on routes to or from the three New York airports dropped sharply after the slot removal. In contrast, the average airfare on routes to or from Reagan National Airport slightly increased after the slot removal. Figure 1 provides visual evidence that the three New York airports have a common underlying trend, but Reagan National does not follow the common trend. Although the figure does not provide clear visual evidence that the slot removal at Newark induces a sharp deviation from this trend, it suggests that Kennedy and LaGuardia Airports may provide a good measure of counterfactual average airfares at Newark Airport in the absence of slot restriction.

Figure 1 Passenger weighted average airfare at EWR, JFK, LGA, and DCA: the first quarter of 2014 to the second quarter of 2017

4.1 Models

I estimate two models that allow arbitrary correlation between unobservable factors affecting airfares (including airport fixed effects) and explanatory variables in any time period. The first includes carrier-route fixed effects, which control for unobserved time-invariant differences across carriers and routes that would cause a systematic difference in airfares. In fact, carriers and routes may vary with factors such as the brand image of a carrier and the attractiveness of the location of an endpoint airport. The second model allows correlation between explanatory variables and time-invariant carrier-route characteristics, but with carrier- and route-specific trends. In this model, each carrier on each route has its own time trend, which may affect airfares (Cf., Heckman and Hotz, 1989; Papke, 1994; Wooldridge, 2010).

As will be explained in Section 4.2, the models include two potentially endogenous variables relating to competition as regressors. While a structural approach or an instrumental variable approach may be more desirable for dealing with the potential endogeneity of competition, this paper takes a reduced-form approach and uses lagged endogenous variables as predetermined variables because of the difficulty of finding valid instruments. Although the endogeneity bias could reduce the size of the competition effects, Gayle and Wu (2011) show that such bias is small in their study, which accounts for endogenous entry in airline markets.

The first model is given by Eq. (1):

$$\ln piodt = \theta t + \alpha EWRod + \beta REMOVALt + \gamma EWRod * REMOVALt + xiodt\delta + viodt \quad (1)$$

where $viodt$ is $ciod + uiodt$ (the unobserved fixed effects + the time-varying error).

The subscripts $i, o, d,$ and t represent carrier, origin, destination, and time. The dependent variable, $piodt$, is the passenger-weighted average fare calculated on a route/carrier/quarter basis, which is deflated by the quarterly average of monthly CPI (1982-84=100) (Source: US DOT, Airline Origin and Destination Survey (DB1B); US DOL, Consumer Price Index – All Urban Consumers). Newark Airport dummy, $EWRod$, represents a route that includes the airport as an endpoint. As mentioned previously, the elimination of slot restrictions at Newark became effective on October 30, 2016. In addition, the US DOT's DB1B consists of quarterly data. Thus, the dummy $REMOVALt$, which identifies the period after the slot removal at Newark Airport, equals 1 for the period after the fourth quarter of 2016. $EWRod * REMOVALt$ is an interaction term between these two dummies, $EWRod$ and $REMOVALt$, which is intended to capture the effect of the slot removal at Newark on airfares on routes to or from Newark.

The model includes a linear common trend, θt , and an array of control variables, $xiodt$. The error, $viodt$, is the composite error term, decomposed into $ciod + uiodt$. The fixed effect, $ciod$, captures all unobserved, time-constant characteristics of carriers and routes, such as the customer loyalty of carriers and the prestige of the location of endpoint airports that affect $piodt$. The error, $uiodt$, is the time-varying error. It represents unobserved factors that change over time and affect $piodt$. I assume that the error, $uiodt$, is uncorrelated with explanatory variables. However, pooled OLS is biased and inconsistent if $ciod$ and explanatory variables are correlated. Thus, Eq. (1) is first-differenced to eliminate $ciod$, unobserved carrier and route characteristics, and the resulting Eq. (2) is estimated by the pooled OLS:

$$\Delta \ln piodt = \theta + \beta \Delta REMOVALt + \gamma \Delta EWRod * REMOVALt + \Delta xiodt\delta + \Delta uiodt \quad (2)$$

where we use the fact that $\theta t - \theta(t - 1) = \theta$ and $(ciod + uiodt) - (ciod + uiodt-1) = \Delta uiodt$. The Newark Airport dummy, $EWRod$, and the unobserved time-constant effect, $ciod$, are differenced out. The coefficient of $\Delta REMOVALt$, β , represents the effect of the slot removal at Newark Airport on airfares on routes to or from airports other than Newark (i.e., routes to or from airports used as a control group). The coefficient of the interaction term ($\Delta EWRod * REMOVALt$), γ , captures the effect of the slot removal at Newark on airfares on routes to or from Newark compared to the airfares on routes to or from airports assigned as a control group. If slot restriction is a source of scarcity rent, the coefficient γ should be negative and statistically significant. The coefficient β could also be negative and statistically significant if the slot removal at Newark Airport has an indirect competition-enhancing effect on routes to or from airports adjacent to Newark Airport.

The second model, the carrier/route-specific trend model, is given by Eq. (3):

$$\ln piodt = giodt + \theta t + \alpha EWRod + \beta REMOVALt + \gamma EWRod * REMOVALt + xiodt\delta + viodt \quad (3)$$

where, again, $viodt$ is $ciod + uiodt$ (the unobserved fixed effects + the time-varying error).

The second model allows the explanatory variables to be correlated not only with time-constant carrier and route characteristics, $ciod$, but also with carrier- and route- specific trends, $giod$. In this model, aggregate time effects, θt , are allowed in addition to carrier- and route-specific trends. As with Eq. (1), we first-difference Eq. (3) to obtain Eq. (4):

$$\Delta \ln piodt = giod + \Delta \theta t + \beta \Delta REMOVALt + \gamma \Delta EWRod * REMOVALt + \Delta xiodt\delta + \Delta uiodt \quad (4)$$

where we again use the fact that $giodt - giod(t - 1) = giod$ and $(ciod + uiodt) - (ciod + uiodt-1)$

$= \Delta uiodt$. Eq. (4) is the standard unobserved effects model, which can be estimated by the fixed effects model.

Both models assume that slot removal at Newark has the same effect in each quarter after the removal. This may be too restrictive; the impacts of the slot removal could change over time, as suggested in Figure 1. Thus, in the robustness checks in Section 5, I relax this restriction and replace the slot removal dummy with three dummies for each quarter after the removal.

4.2 Data

The paper uses quarterly unbalanced panel data constructed on a carrier-route basis mainly from the US DOT's Airline Origin and Destination Survey (DB1B) data for the period between the first quarter of 2016 and the second quarter of 2017, which includes three quarters before and after the slot removal at Newark Airport. When constructing the data set, I define a market as directional travel between a pair of airports, following Borenstein & Rose (1994) and Snider & Williams (2015). I keep only one-way or round-trip travel in the data set, following previous studies such as Evans and Kessides (1994), Ciliberto & Williams (2010), Brueckner, et al (2013), and Snider & Williams (2015). In other words, the data set excludes open-jaw itineraries, in which a passenger's return flight is from a different airport than the passenger arrived to and/or a passenger does not return to the origin airport of his or her outbound flight. Also excluded are (1) tickets involving a non-reporting US carrier flying within North America or a foreign carrier flying between two US points, (2) tickets that are part of international travel, (3) itineraries with more than one marketing (or ticketing) carrier on a directional trip, which are known as interline tickets (in contrast, itineraries with a single marketing carrier but multiple operating carriers are included in the data set), (4) tickets flagged by the DOT as those with questionable fare value (e.g., extraordinarily high fares), (5) tickets with fares greater than \$2,500 or less than \$25, (6) tickets with fares in the bottom or top fifth percentile in their quarter, and (7) tickets with more than six coupons for round-trip itineraries and three coupons for one-way itineraries.

The dependent variable in our estimation models is each carrier’s passenger- weighted quarterly average fare on each route deflated by consumer price index for all urban consumers (CPI-U) (log-transformed). Following previous studies, the models include the following control variables (as components of the *xiodt* vector): (1) quarterly total number of carriers serving the market; (2) Southwest’s presence dummy, which is 1 if Southwest airlines is present at the origin or destination of the given route, 0 otherwise;

(3) log-transformed market distance (miles); (4) number of coupons in the market; (5) indicator of operating carrier change, which is 1 if the given itinerary involves more than one carrier, 0 otherwise; (6) indicator of round-trip, which is 1 if the given itinerary is round-trip, 0 otherwise; and (7) log-transformed quarterly total number of employment at route endpoints.

Several previous studies have included other variables in the estimation models, such as flight frequencies and number of passengers, which are constructed from the US DOT’s T-100 data. In this paper, however, considering the difference between the DB1B and the T-100 data, the estimation models do not include these variables constructed from the T-100 data. While the T-100 comprises non-stop segment data (i.e., direct flight data), the DB1B contains flight itinerary data, including not only direct flight data but also any connecting flight data. Thus, the T-100 data show poor coverage of itineraries included in the DB1B data. This makes it practically impossible to construct and include, e.g., a variable that represents flight frequencies of connecting flights in the estimation models. In general, increased competition results in lower airfares. Hence, negative coefficients would be expected for the two competition variables, the quarterly total number of carriers serving the market and the Southwest’s presence dummy (Source: US DOT, Airline Origin and Destination Survey (DB1BMarket); US DOT, T-100 Domestic Segment (All Carriers)). As suggested above, these competition variables are potentially endogenous. Indeed, markets with high fares due to lack of competition may be attractive targets for low-cost carriers. To deal with this reverse causality, which may bias the estimates, I use lagged endogenous variables as predetermined variables. The use of lagged competition variables has an additional advantage: It makes the analysis more realistic. Carriers’ route structures are relatively fixed in the short term. It usually takes more than a few months to launch new routes. Indeed, one carrier says “the lead-time for launching routes is normally 12-18 months” (British Airways, 2016). Thus, it is difficult for carriers to change their route structures immediately, even if the average fare on the given route increases due to lack of competition. In this sense, using the lagged competition variables is more realistic than using the competition variables in the current quarter, which suggests that a change in the average fare on the given route has an immediate and contemporaneous effect on carriers’ route entry and network configuration decisions.

Fares are usually higher for long-distance itineraries. Therefore, the log- transformed market distance variable should have a positive coefficient (Source: US DOT, Airline Origin and Destination Survey (DB1BMarket)). The greater the number of coupons, the higher the fare will be, because the greater number of coupons means that the itinerary includes multiple flight-legs, which could lead to higher fare. Hence, the coefficient of the variable representing the number of coupons will be positive (Source: US DOT, Airline Origin and Destination Survey (DB1BMarket)). A negative coefficient is expected for the operating carrier change variable. Indeed, other things being equal, an itinerary operated by one carrier is better for passengers in terms of service quality than an itinerary involving multiple operating carriers (Source: US DOT, Airline Origin and Destination Survey (DB1BMarket)). A round-trip ticket is typically cheaper than two one- way tickets. Accordingly, the round-trip dummy should have a negative coefficient (Source: US DOT, Airline Origin and Destination Survey (DB1BMarket)). Finally, the coefficients of the log-transformed quarterly total number of employment at route endpoints should be positive because the volume of business travel can increase as the employment level increases (US Bureau of Labor Statistics, Quarterly Census of Employment & Wages).

5. ESTIMATION RESULTS

5.1 Main results

Table 1 presents descriptive statistics for the data set, and Table 2 reports the results of estimating the first-differenced versions of the common trend model (Eq. (2)) and the carrier/route-specific trend model (Eq. (4)). The first column of Table 1 shows the estimation results from the common trend model without aggregate time effects (year and quarter fixed effects). The coefficient of $\Delta REMOVAL_t$, the period after the slot removal at Newark dummy, is negative and statistically significant. In our data set, the control group consists of routes to or from the two other New York airports, John F. Kennedy and LaGuardia Airports, both of which were slot-controlled during the analysis period. Thus, the coefficient suggests that the average airfare was decreased on routes to or from Kennedy and LaGuardia Airports after the removal of slots at Newark Airport. This may be due to an indirect competition-enhancing effect derived from the slot removal at Newark Airport. The coefficient of the dummy representing slot removal at Newark is also negative and statistically significant. The result seems to suggest that scarcity rent arose at Newark Airport during the period when temporary limits were placed on scheduled operations. However, Eq. (2) does not control for the time fixed effects. Hence, the impact of indirect competition and the amount of scarcity rent may be overestimated.

Table 1 Descriptive statistics

	Mean	SD	Min	Max
Δ Passenger weighted average fare calculated on a route-carrier-quarter basis, deflated by CPI-U (log-transformed)	0.00575	0.182	-1.281	1.258
$\Delta REMOVAL_t$: Period after the slot removal at Newark: 1 after the fourth quarter of 2016	0.167	0.373	0	1

Standard errors in parentheses are clustered by carrier and route. The data set is an unbalanced panel. The Slot restriction at Newark Airport was removed on October 30, 2016. Aggregate time effects (quarter and year dummies) are omitted for brevity. All variables are first-differenced.

+ p < 0.1, * p < 0.05, ** p < 0.01, *** p < 0.001

To control for the time fixed effects, year and quarter dummies are included in Eq. (2). The estimation results, which are shown in column 2 of Table 2, indicate that the absolute values of the coefficients of $\Delta REMOVALt$ (the period after the slot removal at Newark dummy) and $\Delta EWRod *REMOVALt$ (the slot removal at Newark dummy) become smaller. However, the negative coefficient of $\Delta EWRod *REMOVALt$ is still statistically significant. The result suggests that the effect of competition on airfare was limited at Newark Airport by the slot restriction. Indeed, scarcity rent arose at Newark Airport during the period when temporary limits were placed on scheduled operations, and the scarcity rent was transferred to carriers, not to passengers. As a result of slot removal, the average airfare on routes to or from Newark Airport dropped by about 2.6% compared to the ones on routes to or from Kennedy and LaGuardia Airports. Interestingly, the coefficient of $\Delta REMOVALt$, the period after the slot removal at Newark dummy, is also still negative and statistically significant. The result can be interpreted as indirect evidence that adjacent competition generated by the slot removal at Newark Airport had a negative impact on the average fare on routes to or from Kennedy and LaGuardia Airports. Indeed, the average airfare on routes to or from the two slot-controlled New York airports dropped by about 3.7% compared to the period before the slot removal at Newark Airport.

Most of the control variables have the expected signs but are not necessarily statistically significant. The negative and statistically significant coefficient of the quarterly total number of carriers serving the market suggests that an additional competitor leads to a 0.7% decrease in the average airfare on routes to or from the three New York airports. The coefficient of the Southwest presence dummy has an expected negative sign. However, it is not statistically significant.

Although the presence of Southwest Airlines at route endpoints could be a potential competitive threat for the incumbent carriers on the given route, the threat may not be substantial enough for the incumbents to lower their airfare if Southwest Airlines does not enter the route. The variables of market distance and the number of coupons have positive and statistically significant coefficients as expected, though the coefficient of the latter variable is significant only at the 10% level. The negative but statistically insignificant coefficient of the operating carrier change variable suggests that an itinerary involving multiple operating carriers is potentially unattractive for passengers compared to an itinerary operated by one carrier, though its unattractiveness is not as important as other factors, such as whether a flight is round-trip, that would lead to a lower fare. As column 1 of Table 2 shows, the coefficients of the quarterly total employment at route endpoints was positive and statistically significant when year and quarter fixed effects were not controlled for. However, column 2 of Table 2 indicates that the coefficients turn statistically insignificant when year and quarter fixed effects are controlled for. The aggregate time fixed effects may absorb the effects of the employment variables.

5.2 Robustness checks

To check the robustness of the above estimation results, I also estimate the carrier/route-specific trend model (Eq. (4)), which allows the explanatory variables to be correlated not only with time-constant carrier and route characteristics, but with carrier- and route-specific trends. The estimation results are shown in column 3 of Table 2. The overall pattern of the estimation results remains the same. This time, the fare-reducing effect of the slot removal at Newark gets slightly larger. Indeed, the results suggest that the average airfare on routes to or from Newark Airport lowered by about 3.2% compared to that on routes to or from the two other New York airports. In addition, the coefficient of the dummy for the period after the slot removal at Newark is again negative and statistically significant. This suggests that the average airfare on routes to or from Kennedy and LaGuardia Airports decreased by about 3.4% compared to the period before the slot removal at Newark.

Eq. (4), however, does not control for carrier-specific time and seasonal fixed effects. Thus, carrier-specific year and quarter dummies are included in Eq. (4) to control for carrier-specific time and seasonal fixed effects. Column 4 of Table 2 shows that coefficients of three variables (i.e., the number of carriers serving the market, the period after the slot removal at Newark, and the number of coupons) become statistically insignificant. In particular, the coefficient of $\Delta REMOVAL_t$, the dummy representing the period after the slot removal at Newark, becomes smaller in its absolute value and is no longer statistically significant, albeit still negative. The estimation results presented in columns 1 through 3 suggest that adjacent competition generated by the slot removal at Newark Airport had a negative impact on the average fare on routes to or from Kennedy and LaGuardia Airports. This impact of adjacent competition seems to be absorbed by carrier-specific time and seasonal fixed effects. In contrast, the coefficient of $\Delta EWRod * REMOVAL_t$, the slot removal at Newark dummy, remains negative and statistically significant, which suggests that the average airfare on routes to or from Newark Airport is about 2.8% lower than that on routes to or from Kennedy and LaGuardia Airports.

Overall, the estimation results suggest that the slot restriction at Newark Airport had a negative effect on competition, which created scarcity rents that were transferred to carriers, not to passengers. Put differently, the additional competition created by the slot removal at Newark competes scarcity rents away. The adjacent competition generated by the slot removal at Newark Airport may have lowered the average fare on routes to or from Kennedy and LaGuardia Airports. However, this adjacent competition effect disappeared once the carrier-specific time and seasonal fixed effects were controlled for.

6 DISCUSSIONS

6.1 Which carrier was the key driver lowering airfares?

As pointed out in Section 3, Newark Airport is a hub airport for United Airlines. As of June 2015, United controlled 73% of the slots at Newark Airport. Carriers' reaction to the removal of slot controls at Newark may have differed depending on whether they were dominant carriers or not. Indeed, incumbent fringe carriers or new entrant carriers or both would aggressively compete with dominant carriers by lowering airfares, increasing flight frequencies, and launching new routes. Dominant carriers may respond aggressively to competitors on competitive routes. However, if the dominant carriers control access to the airport facilities, such as gates, they can deter market entry of competitors and may not necessarily need to lower their airfare even after a slot removal. In sum, the key driver lowering airfares may not have been the dominant carrier, but rather incumbent fringe carriers or new entrant carriers.

The above estimation models, Eqs. (2) and (4), assume that all carriers react to the slot removal at Newark in the same manner. Because of this strong restriction, Eqs. (2) and (4) could not identify the key driver lowering airfares on routes to or from Newark Airport after the slot removal. To relax this restriction, the dummy representing slot removal at Newark is divided into two groups, one including only the dominant carrier, United Airlines, and the other including other carriers. Eq. (5) is the common trend model, and Eq. (6) is the carrier/route-specific trend model. UA_i and $OTHER_i$ stand for United Airlines and other carriers, respectively.

$$\Delta \ln p_{i0dt} = \theta + \beta \Delta REMOVAL_t + \gamma 1 \Delta EWRod * REMOVAL_t * UA_i + \gamma 2 \Delta EWRod * REMOVAL_t * OTHER_i + \Delta x_{i0dt} \delta + \Delta u_{i0dt} \quad (5)$$

$$\Delta \ln p_{i0dt} = g_{i0d} + \Delta \theta + \beta \Delta REMOVAL_t + \gamma 1 \Delta EWRod * REMOVAL_t * UA_i + \gamma 2 \Delta EWRod * REMOVAL_t * OTHER_i + \Delta x_{i0dt} \delta + \Delta u_{i0dt} \quad (6)$$

+ p < 0.1, * p < 0.05, ** p < 0.01, *** p < 0.001

The first two columns of Table 3 show the estimation results obtained from the common trend model without and with aggregate time fixed effects (quarter and year dummies). Both results suggest that the key driver lowering fares on routes to or from Newark Airport after the slot removal was carriers other than the dominant carrier at Newark Airport. For example, column 2 of Table 3 suggests that, after aggregate time fixed effects are controlled for, the average airfare of United on routes to or from Newark Airport decreased by about 1.7% compared to that on routes to or from Kennedy and LaGuardia Airports, whereas the average airfare of carriers other than United is about 2.9% lower than that on routes to or from the two other New York airports. Column 3 of Table 3, which presents the estimation results obtained from the carrier/route-specific trend model, indicates that the overall pattern of the results remains the same. However, if we allow the explanatory variables to be correlated not only with time-constant carrier and route characteristics but also with carrier- and route-specific trends, the fare-reducing effect of Newark slot removal for United slightly decreases (1.6%). In addition, it is statistically significant only at the 10% level. In contrast, the fare-reducing effect of Newark slot removal for carriers other than United increases (-3.9%) and is statistically significant at the 0.1% level. As column 4 of Table 3 shows, the fare-reducing effect of Newark slot removal for carriers other than United is still statistically significant (-3.7%) even after controlling for carrier-specific year and quarter fixed effects, but the same effect becomes positive and statistically insignificant for United.

Although the null hypothesis that the coefficients of $\Delta EWRod *REMOVALt*UAI$ and $\Delta EWRod *REMOVALt*OTHERi$ are equal is not rejected for columns 1 and 2 of Table 3, it is rejected at the 5% level for columns 3 and 4. This partially supports the hypotheses that carriers react differently to the slot removal at Newark Airport and that the key driver lowering fares on routes to or from Newark Airport after the slot removal is carriers other than United Airlines.

6.2 Does the dominant carrier's fare premium persist even after the slot removal at Newark Airport?

The above results are interesting and do not run counter to common expectations. But they are slightly puzzling. Indeed, the positive and statistically insignificant coefficient of $\Delta EWRod *REMOVALt*UAI$ (the slot removal at the Newark for United dummy) is counterintuitive. Even though United has enjoyed a competitive advantage derived from its dominant position over other carriers at Newark Airport, it would be forced to react to increasing competition after the slot removal. However, Eqs. (5) and (6) impose the restriction that the slot removal has the same effect in each quarter. This may be too restrictive because the effects of the slot removal could change over time. Hence, Eqs. (7) and (8) relax it:

$$\begin{aligned} \Delta \ln \text{piodt} = & \theta + \beta_1 \Delta \text{REMOVAL1t} + \beta_2 \Delta \text{REMOVAL2t} + \beta_3 \Delta \text{REMOVAL3t} \\ & + \gamma_1 \Delta \text{EWRod} * \text{REMOVAL1t} * \text{UAI} + \gamma_2 \Delta \text{EWRod} * \text{REMOVAL2t} * \text{UAI} \\ & + \gamma_3 \Delta \text{EWRod} * \text{REMOVAL3t} * \text{UAI} \\ & + \gamma_4 \Delta \text{EWRod} * \text{REMOVAL1t} * \text{OTHERi} + \gamma_4 \Delta \text{EWRod} * \text{REMOVAL2t} * \text{OTHERi} \\ & + \gamma_4 \Delta \text{EWRod} * \text{REMOVAL3t} * \text{OTHERi} \\ & + \Delta \text{xiodt} \delta + \Delta \text{uiodt} (7) \end{aligned}$$

$$\begin{aligned} \Delta \ln \text{piodt} = & \text{giod} + \Delta \theta + \beta_1 \Delta \text{REMOVAL1t} + \beta_2 \Delta \text{REMOVAL2t} + \beta_3 \Delta \text{REMOVAL3t} \\ & + \gamma_1 \Delta \text{EWRod} * \text{REMOVAL1t} * \text{UAI} + \gamma_2 \Delta \text{EWRod} * \text{REMOVAL2t} * \text{UAI} \\ & + \gamma_3 \Delta \text{EWRod} * \text{REMOVAL3t} * \text{UAI} \\ & + \gamma_4 \Delta \text{EWRod} * \text{REMOVAL1t} * \text{OTHERi} + \gamma_4 \Delta \text{EWRod} * \text{REMOVAL2t} * \text{OTHERi} \\ & + \gamma_4 \Delta \text{EWRod} * \text{REMOVAL3t} * \text{OTHERi} \\ & + \Delta \text{xiodt} \delta + \Delta \text{uiodt} (8) \end{aligned}$$

Eqs. (7) and (8) are extensions of Eqs. (5) and (6) with the dummy representing the period after the slot removal at Newark, *REMOVALt*, replaced by three dummies for each quarter after the removal. *REMOVAL1t* equals 1 for times *t* within one quarter of the slot removal at Newark, and 0 otherwise. *REMOVAL2t* and *REMOVAL3t* equal 1 for times *t* within two and three quarters, respectively, of the slot removal at Newark, and 0 otherwise.

Table 4 reports the estimation results obtained from the common trend model without and with aggregate time fixed effects (columns 1 and 2) and the results obtained from the carrier/route-specific trend model without and with carrier-specific year and quarter fixed effects (columns 3 and 4). The results from the common trend model (columns 1 and 2) show that the fare-reducing effect for carriers other than United persists at least two quarters after the slot removal. Besides, the results from the carrier/route-specific trend model (columns 3 and 4) indicate that the effect persists three quarters after the slot removal. While the null hypothesis that the coefficients of $\Delta EWRod$

$*REMOVAL1t*OTHERi, \Delta EWRod$ $*REMOVAL2t*OTHERi$ and $\Delta EWRod$

$*REMOVAL3t*OTHERi$ are equal is rejected at the 1% level for columns 1 and 2 of Table 4, it is not rejected for columns 3 and 4. The test results suggest that the fare-reducing effect for carriers other than United persists after the slot removal at Newark, but it does not seem to change over time.

Interestingly, the estimation results again suggest that the slot removal at Newark Airport does not have the same fare-reducing effect for United as for other carriers. The results obtained from the common trend model (columns 1 and 2 of Table 4) suggest that during the first quarter after the slot removal, United’s average airfare on routes to or from Newark Airport was lower by about 1.7% to 2.0% compared to that on routes to or from Kennedy and LaGuardia Airports. However, during the second quarter after the slot removal, United’s average airfare on routes to or from Newark Airport was higher by about 3.1% to 3.4% than that on routes to or from the two other slot-controlled New York airports. The results obtained from the carrier/route-specific trend model (columns 3 and 4 of Table 4) further suggest that United’s average airfare on routes to or from Newark Airport was not lower than that on routes to or from Kennedy and LaGuardia Airports during the three quarters after the slot removal. Rather, the results from the carrier/route-specific trend model suggest that during the second and third quarters after the slot removal, United’s average airfare was about 5.5% to 6.9% higher than that on routes to or from the two other slot-controlled New York airports.

These results suggest that United could still take advantage of its dominant position at Newark Airport even after the slot removal. United’s market share at Newark calculated on the basis of domestic passengers carried was 69.8% in 2015. Although slightly decreased, it was maintained as high as 67.9% even in 2017, i.e., a full year after the slot removal. In contrast, at Kennedy and LaGuardia Airports, the largest carrier, Delta Airlines, had only about a 40% market share in terms of passengers carried in 2017: 40.1% at Kennedy and 41.7% at LaGuardia (Source: The Port Authority of NY & NJ, December Traffic Report, 2015-2017). As several previous studies have pointed out, airport dominance enhances a carrier’s ability to charge higher fares (Borenstein, 1989; Ciliberto & Williams, 2010; Evans & Kessides, 1993; Peteraf & Reed, 1994; Snider & Williams, 2015). The persistence of United’s “fare premium” after the slot removal may be due to its control of critical airport facilities such as gates at Newark Airport.

6.3 How did United react to the slot removal at Newark Airport?

It is understandable that the dominant carrier’s fare premium would persist even after the slot removal because of its control of airport facilities such as gates. However, it is not necessarily clear whether United could charge a fare premium on all routes to or from Newark Airport. How did the dominant carrier, United Airlines, and other carriers react differently to the slot removal at Newark Airport?

To examine whether United’s average fares were uniformly higher on all routes, I re-estimated the modified estimation model using a quantile regression approach. Fixed effects quantile regression is an active area of research (Abrevaya and Dahl, 2008; Canay, 2011; Galvao & Wang, 2015). Unfortunately, there seems to be no established method for estimating quantile regression with fixed effects at present. Thus, I estimate the Eq. (5) (i.e., the common trend model with aggregate time fixed effects) with carrier-specific quarter and year fixed effects using a simultaneous quantile regression method.

Table 5 Estimation results

Common trend model with carrier specific year and quarter fixed effects	(1) Q = 0.1	(2) Q = 0.2	(3) Q = 0.3	(4) Q = 0.4	(5) Q = 0.5

The results of the re-estimation reveal some interesting features of United's and other carriers' reactions to the slot removal at Newark Airport. The nine columns of Table 5 show that all coefficients of Δ EWRod*REMOVALt*OTHERi have negative signs and are statistically significant except for the 0.9 quantile coefficient. In addition, the quantile coefficients of Δ EWRod*REMOVALt*OTHERi are relatively similar across the quantiles: they range from about -1.96 (the 0.8 quantile coefficient) to about -3.17 (the 0.6 quantile coefficient), which suggests that carriers other than United responded to the slot removal at Newark Airport by reducing the average ticket prices on routes to or from Newark Airport by about 1.94% to 3.12% compared to those on routes to or from the two other New York airports. In contrast, the coefficients of Δ EWRod*REMOVALt*UAI have negative signs for the upper quantiles (those at or above the 0.5) but positive signs for the lower quantiles (those at or below 0.4). The 0.1, 0.2, 0.7, 0.8, and 0.9 quantiles, which

range from -0.0931 (the 0.9 quantile) to 0.0834 (the 0.1 quantile), are statistically significant at or below the 5% level. The results suggest that United responded to the slot removal by increasing the average ticket prices by about 5.71% to 8.70% at the lower quantiles (0.1 and 0.2) of the conditional fare distribution, while simultaneously lowering the average ticket prices by about 3.79% to 8.89% at the higher quantiles (0.7 – 0.9) of the conditional fare distribution compared to the average ticket prices on routes to or from the two other New York airports.

Overall, the above estimation results suggest that United Airlines may have been able to take advantage of its dominant position at Newark Airport and charge a premium ticket price on relatively low-fare routes even after the slot removal, even as it was being challenged by (possibly growing) competition, especially on relatively high-fare routes.

7 CONCLUSIONS

This paper examined the impact of slot restriction as a determinant of scarcity rent, i.e., markup on fares resulting from airport capacity shortages. Previous studies on this subject have a common limitation: they could not explicitly examine the effects of slot restrictions on airfare. To overcome this limitation, this paper employed the exogenous regulatory change, i.e., the removal of slots at Newark Airport in October 2016. The results from the difference-in-differences estimation, in which the treatment group comprises routes to or from Newark and the control group consists of routes to or from the two other slot-controlled New York airports, suggest that the average fare on routes to or from Newark Airport decreased by about 2.8% compared to the average fare on routes to or from the two other slot-controlled New York airports after the slot removal at Newark Airport. The estimation results from a modified model and a quantile regression approach suggest that the key driver lowering fares on routes to or from Newark Airport after the slot elimination is carriers other than the dominant carrier at Newark, i.e., United, though it is challenged by competition on relatively high-fare routes.

In sum, the estimation results imply that (1) scarcity rent arose at Newark Airport during the period when it was a slot-controlled airport; (2) the scarcity rent was transferred to carriers, not to passengers; and (3) the fare-reducing effect of Newark slot removal was stronger for the non-dominant carriers than for the dominant carrier, United; however, (4) even United seems to have lowered its ticket prices on relatively high-fare routes to or from Newark Airport, perhaps due to growing competition after the slot removal at the airport. Put differently, at slot-controlled airports, slot restrictions limit the effect of competition on airfare, and the scarcity rent is not transferred to passengers. If this situation is considered inequitable, future research should focus on better understanding how to enhance competition by improving the accessibility and transparency of the secondary slot-trading market (Fukui, 2010, 2012, 2014) or by replacing slot restrictions with market-based measures, such as congestion pricing or a slot auction mechanism (Brueckner, 2009; Gillen & Starkie, 2016; Starkie, 1998). The latter measures will transfer scarcity rents from carriers to the government, which could be used to increase airport capacity and competition among carriers.

1187 TOURISM, MOBILITY AND TRANSPORTATION: CHANGING SPACES IN LISBON (2007-2017)

João Rafael Santos

CIAUD, Lisbon School of Architecture, Universidade de Lisboa, Rua Sá Nogueira, Pólo Universitário do Alto da Ajuda, 1349-055 Lisboa, Portugal, jrs@fa.ulisboa.pt

ABSTRACT

The city of Lisbon has been witnessing a strong growth in the tourism sector, being the 2nd fastest growing city destination in Europe, from 2009 to 2016 (Global Destinations Cities Index - GDCI/Mastercard), with an increase from 5,6 million visitors (hotel stays) in 2009 to 11 million in 2016 (National Institute of Statistics, Portugal). This growth is the combined result of a number of factors, among which a reorganization of the European and global tourism markets, the opening of various low-cost airline routes to Lisbon and the perception of a friendly and warm-welcoming destination, combining a local flavour of tradition with an increasingly cosmopolitan urban beat. On the other hand, this increase in tourism cannot outlook major transformations in the city's infrastructural and spatial amenities, among which 1) transport infrastructure, 2) mobility services and 3) public space systems.

The paper addresses the recent change (since 2007) in these three systems, highlighting urban and infrastructural projects in which meaningful interplays between tourism and mobility can be found.

Keywords: touristification, mobility infrastructure, public space, urban regeneration, Lisbon

1 INTRODUCTION

This paper outlines the emerging fields of relationship between tourism and recently developed projects of infrastructure, mobility and public space in Lisbon. This discussion stems from previously developed lines of research regarding Lisbon's urban and metropolitan morphogenesis and its relationship with large scale infrastructural networks (Santos, 2012).

The discussion will be structured in three parts. Firstly, an overview of the recent trends in the Portuguese spatial development framework, its urban policies and funding. This outline establishes the responsibilities and decision levels in which urban development and mobility-related policies occur. In this field, urban policies have been focusing on public space and infrastructural projects, not so much on housing and economic activities, since the early 2000's. Municipalities have a strong role in urban planning, but limited resources to guide or control private investment. Public expenditure is, therefore, seen as an initiator, triggering follow-up dynamics, with considerable investment on public urban networks.

Secondly, a mapping of urban transformations in the three above-mentioned systems is presented, emphasising the areas where improvement in mobility nodes and public space intersect to drive tourism attraction upwards. This mapping is accompanied by a short overview of relevant projects associated with the change in international and metropolitan transport hubs, the regeneration of the city's waterfront and the public space improvement in the hilly inner-city districts.

Finally, a third part concerns the main threads of discussion regarding the critical issues raised by the recent paths of urban change. A fragile social fabric in the older city districts is faced with gentrification and touristification – much of it as the result of new and improved mobility and public space amenities. The city's public transportation networks (i.e. metro, river boats, trams and historical funiculars) – faced with budget cuts and service downgrade during the recent economic and financial crisis – are increasingly sought by tourists and incapable of providing adequate service to local users.

Nevertheless, considerable positive effects can be underlined when transport and public space projects are spatially intertwined to deliver quality urban spaces. Either a circumstantial or more permanent trend, tourism growth has triggered challenges but also new opportunities in Lisbon. A fundamental question open for debate is how tourism-oriented mobility products (i.e. tuk-tuk, amphibious vehicles, Segway-type personal movers) can feed-back as smart solutions for everyday's urban mobility.

This paper's specific contribution links the spatial apparatus of metropolitan scale infrastructure with the smaller scaled fabric of Lisbon's central city districts. The focus on public space projects, associated with those of heavy infrastructure, provide the common ground between the morphological approach, post-network criticism and their linkages with specific patterns of urban life – in this case, tourism. An in-depth analysis of Lisbon's tourism is intentionally left behind in the discussion, as the main thematic focus stems from infrastructural space. Tourism, however, is a field from which a timely discussion regarding future prospects for Lisbon's urban development can emerge. Tourism can be approached as a commercial product but also as spatial package with which multiple actors are engaged.

2 POLICY FRAMEWORK FOR URBAN REGENERATION IN PORTUGAL (2007-2017)

With most of housing in central Lisbon in private hands, the municipality's investment in urban regeneration is mainly focused on infrastructure and public space. This focus also stems from national and EU guidelines, in which public funding in recent years has been directed to environmental qualification and promotion of soft mobility. Such approach, in which physical interventions are prioritised can be better described as urban revitalization initiatives (Balsas, 2007, Mendes, 2013a). National policies on urban development during the late 1990's and early 2000's included a line of investment in

the upgrade of spatial, environmental and mobility systems in several cities (MAOT, 2000; SEAOT, 2008). According to Baptista (2013), this investment – labelled *Polis Program* – is embedded in a Welfare State rationale:

“its focus on public-led intervention, public space for public use, and disciplining of private developers, makes sense in the context of a state apparatus that was still thinking of itself as “modernizing” toward a “European” welfare ideal already in decline elsewhere in the EU and the world at large. With its impetus to extend the benefits of modern city living to a greater number of urban citizens, to fix urban problems, and to use the powers of the state to redistribute social goods and stimulate social cohesion, the Polis Program constitutes an exemplar of state intervention within a welfare logic that seeks to be a corrective to the logics of capitalist accumulation.” (Baptista, 2013: 600).

From 2008 onwards, and according to new EU funding guidelines, the national urban policies framework is adapted in order to foster social cohesion, inclusion and local partners involvement criteria. In Lisbon, the Municipality establishes as policy priorities the reversion of a four-decade-long demographic loss trend, the attraction of younger inhabitants, and the promotion of inclusion, innovation and creativity through strategic initiatives (Carta Estratégica de Lisboa – Lisbon’s Strategic Charter: CML, 2009a), urban planning (Plano Director Municipal – Municipal Master Plan: CML, 2012) and local interventions (CML, 2009b, UPM, 2009 e 2010, Mendes, 2013b).

Along with the major restructuring and expansion of the underground network in the late 1990’s came the opportunity to redevelop major plazas and squares. *Rossio* and *Praça da Figueira* were the first to be renewed, with underground parking spaces, new pavements, lighting, furniture and trees, with a more generous approach to pedestrian space. After a first generation of piecemeal interventions (Balsas, 2007: 248), a more consistent and systemic approach to public space improvement can be detected, especially after 2006 (CBC, 2006; CML, 2008; Salgado, 2012; CML, 2016). *Frente Tejo, SA*, a specific purpose public agency, is established by the Government to lead a large scale urban revitalization project in the riverfront (Conselho de Ministros, 2008).

3 MAPPING CHANGING SPACES OF MOBILITY, PUBLIC SPACE AND TOURISM IN LISBON (2007-2017)

The last decade can be seen as a stage of transition in Lisbon’s metropolitan infrastructural strata to what it was called the layering of a *connective fabric* (Santos, 2012). At the city scale, this fabric is established through: 1) the introduction of complex intermodal transport nodes and 2) the development of well-connected patches of urban development bridging or regenerating spatial and functional gaps in the metropolitan fabric.

3.1 The connection of metropolitan nodes in the central districts

Transformations at a local level in the city of Lisbon began to be sensed as the underground system is expanded and connected to the railway, the airport, and to river and bus terminals in a number of new intermodal stations. Public space qualification and urban renewal projects started to be programmed in the areas adjacent to these new stations, taking a role in the framing of a better balanced and cohesive urban structure.

Specifically relevant to tourism, the downtown and riverfront transport hubs of *Terreiro do Paço*, *Rossio*, *Cais do Sodré* and *Santa Apolónia* played a key role in redefining the city’s urban flows. These transport hubs were simple terminals of river traffic and railroad lines, without proper connection to other urban networks. Since the late 1990’s, they were connected to the underground network defining the first step towards an efficient mobility network in the city central districts. More importantly, they provided a qualified spatial apparatus for commuters, city users and tourists in some of the noblest areas of the city such as the riverfront and the city’s main plazas.

The underground station of *Baixa-Chiado* was also an important landmark for bringing that network to the hitherto declining commercial heart of Lisbon. It offers two entrances: one at the downtown district (*Baixa*), the other at the *Chiado* hill. Over the station, one of the most cherished department stores that had burnt down in the late 1980’s – as the result of declining commercial tradition – was refurbished as a new shopping mall while maintaining a remarkable urban and architectural integrity. The station and shopping mall became popular links between the districts’ lower and upper levels, driving a lasting commercial revival, both for Lisboners and tourists.

The investment in these transport nodes was a meaningful departure from decades of very limited public and political concern with the commercial and urban attractiveness of Lisbon’s central districts. The 1970’s and 1980’s were mainly shaped by powerful centrifugal trends towards suburban axes, accompanied by strong population loss in the inner-city neighborhoods.

The 2011 census has shown, however, a slight tendency of demographic recovery in the most central districts, associated with a new type of residents: young singles and couples, with above average income and attracted to the trendy urban scene. This recovery cannot be properly assessed without a broader perspective on other urban activities, in which tourism is clearly playing a role as a trend-setter in recent years. On one hand, tourist accommodation has increased in number and diversity, its quality being widely acknowledged. On another hand, public space and other urban amenities have also been systematically upgraded and renovated, offering the needed infrastructure to support residential, working and tourist city users. Public space, together with heavy mobility infrastructure, can be said to be a key driver of urban regeneration in central Lisbon. The following section briefly outlines this recently upgraded public space system.

3.2 The improvement in the public space system associated with urban attractors

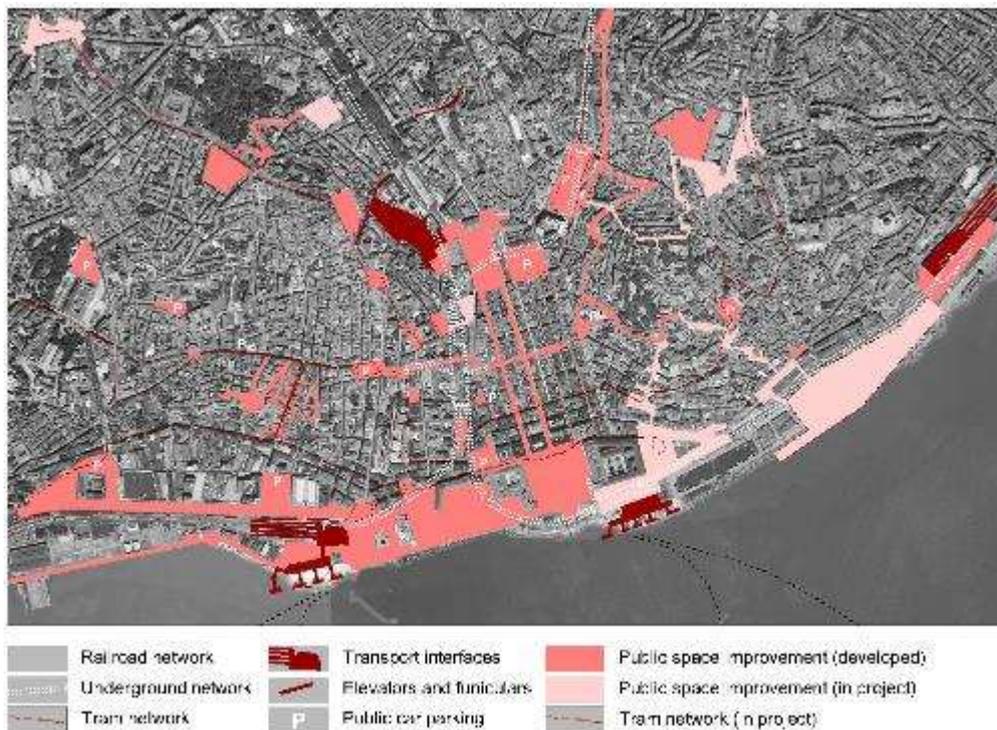

This process has extended to other open spaces, defining an increasingly coherent network of qualified public space, of which one can trace three main systems:

- the riverfront system (Figure 1): *Cais do Sodré – Ribeira das Naus – Terreiro do Paço – Campo das Cebolas – Santa Apolónia*;
- the garden and belvedere system: *Príncipe Real – São Pedro de Alcântara – Graça – Senhora do Monte*;
- the street and square system: *Santa Catarina – Bica – Chiado – Baixa- Rossio – Martim Moniz – Mouraria – Castelo – Alfama*

Figure 1: The riverfront system in 2014. Source: <http://portugalfotografiaaerea.blogspot.com>

The upgrade of these systems (Figure 2) during the last fifteen years had a clear impact in the spatial attractiveness of some of the city's most outstanding places, but more importantly, established a continuous and coherent public realm system. Other than the UNESCO listed monuments of Belém (Jerónimos Monastery and Torre de Belém), Lisbon best touristic offer comes from the diversified character of its urban fabric, from the sensual relationship with topography and from the dialogue with the Tagus river. On the other hand, the overall upgrade of such public realm system had a clear impact on the everyday life in central Lisbon, with a sharp increase in commercial and leisure-related offer.

Drawing by the author

Figure 2: public space and transport infrastructure projects in central Lisbon, since 2000.

In fact, most of these public space improvements were accompanied by the development of food & beverage establishments and some fashion retail stores. This commercial profile reveals a clear prevalence of visitor-oriented commerce, either from outside (tourists) or from the metropolitan area. The reinforcement of pedestrianized spaces was accompanied by the building of several multi-level parking areas, some of them under large squares, in a process not exempt from controversy (Balsas, 2007). Just as happened with the patterns of commercial change, these parking facilities were mainly targeted at visitors. As it will be discussed in the following chapter, the appropriation of these renewed spaces didn't necessarily translate in benefits to local residents or traditional city uses. Notwithstanding an

undeniable urban spatial qualification, these improvements were also the drivers of a new pattern of use and flow, in which tourism and leisure were clearly favoured in terms of urban amenities or the involvement of local communities.

Finally, they share the relationship with heavy infrastructure: underground stations, underground car parkings and recently upgraded public realm in the vicinity. Despite controversy in terms of management regime and public amenity privatisation, these cases remain, however, as evidence of a rather successful strategy to associate urban attractors with the public space system, maintaining some democratic balance in its use and appropriation. Far from thematised enclaves so often seen in other *touristified* cities, Lisbon’s public space maintains a clear Mediterranean character, in which continuity and some sort of functional promiscuity stand as the fundamental city structure.

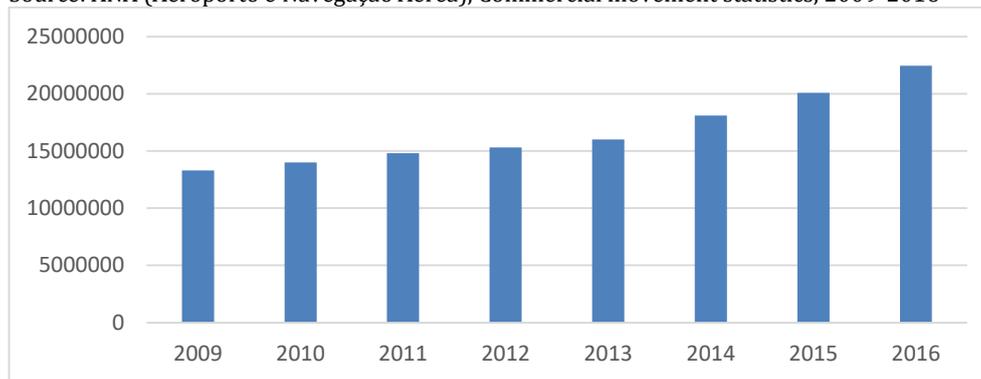

4 CRITICAL ISSUES: GENTRIFICATION, TOURISTIFICATION AND THE PROVISION OF PUBLIC SPACE AND MOBILITY AMENITIES

4.1 The emerging tourism landscape of Lisbon

After initial flagship projects with high international visibility, such as the 1994 European Capital of Culture, the 1998 International Exhibition and the 2004 European Football Championship, Lisbon became an increasingly sought tourist destination in the European scene. These projects brought considerable change to the city’s infrastructure and spatial amenities, with a strong commitment to the valorisation of urban heritage, public space and cultural venues. International visibility combined with attractive local conditions (relatively affordable prices, mild climate, strong identity, remarkable heritage and landscape sites, friendliness and safety, diversified and cosmopolitan leisure and nightlife offer) resulted in steady increases in the number of international visitors, visible both in the growing airport attractivity (Graph 1) and in the number of hotel stays (Graph 2). Since 2009, tourism sector in Lisbon has increased at an average level of 6% per year with European markets remaining as the main origin of visitors (55%), despite increasing numbers from Brazil, Russia and China (ATL, 2012, 2013, 2015).

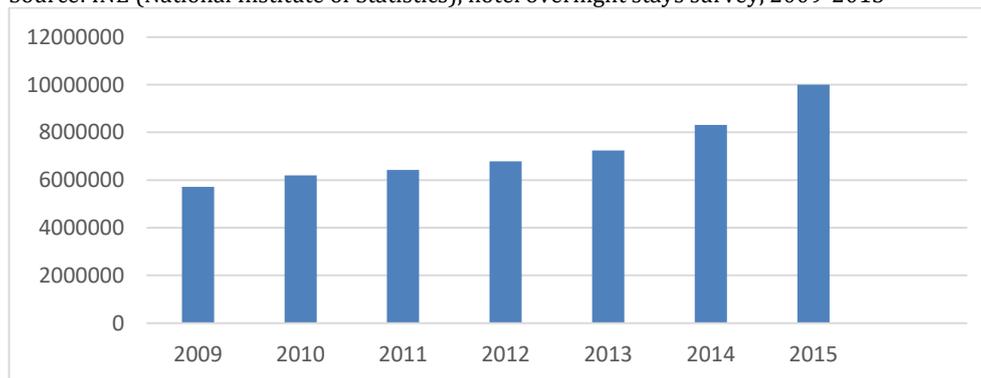

Graph 1. Passenger movement in Lisbon airport.

Source: ANA (Aeroporto e Navegação Aérea), Commercial movement statistics, 2009-2016

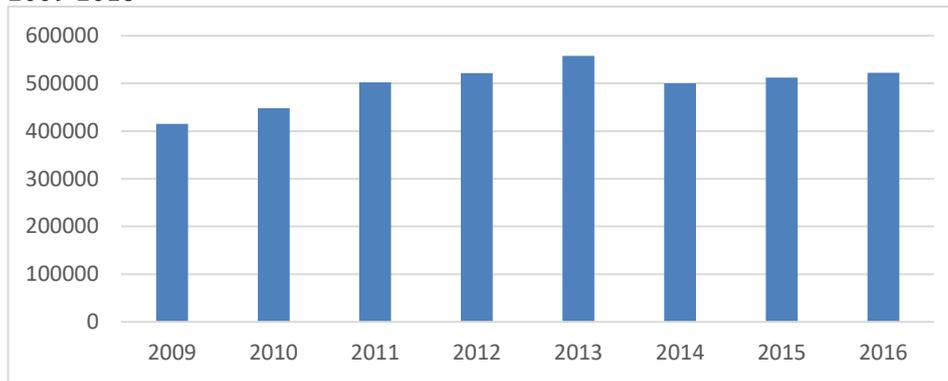

Graph 2. Overnight stays in Lisbon (city).

Source: INE (National Institute of Statistics), hotel overnight stays survey, 2009-2015

Additionally, specific tourism niches began to take shape and grow as major vehicles of attraction: the cruise ship market (Graph 3), the low-cost airline operators, the hostel and *bnb* sectors (JLL, 2015). City-breaks are currently the most important tourism category in Lisbon, taking advantage of easy access, while maintaining the rather unique blend between European and Mediterranean culture. One interesting issue is discussing Lisbon’s touristic performance is related to the severe austerity context it is going through, namely since 2011. Tourism is virtually the only major sector in Lisbon in which high growth rates can be observed. It is, however, a growth that must critically observed, namely in its long-term perspective. Current offer, despite acknowledged as innovative and attractive to urban visitors, remains targeted at a rather lower economic strata of visitors. Lisbon’s position in term of economic value remains distant from other cities with comparable numbers.

Graph 3. Cruise ship movement in Lisbon port. Source: APL (Administração do Porto de Lisboa), Port activity statistics, 2009-2016

Tourist offer are mainly centred on conventional city landmarks, such as the historical districts and the monumental area of Belém, but has been successful in diversifying to other stems of attraction, such as the immaterial cultural heritage (*Fado*, popular festivities, creative hubs, renewed impetus on local associations), the riverfront and other outstanding landscape sites (the city's belvederes or the out-of-town landmarks of Sintra and Cascais), or the less massified activities related to wine production, horse riding, bird watching, nautical and other open air activities, all of which gaining prominence in the metropolitan outskirt regions.

4.2 The overload of infrastructure

Coming out from decades of poorly developed mobility network, Lisbon's major improvements in this field shadowed other less visible trends of overload. The extension and interconnecting of major railroad, underground, river traffic and airport networks in the city increased its overall capacity significantly, despite a strong pressure from private car and individual motorization.

Aside from the large-scale infrastructures, such as the airport and its limitations in terms of future expansion, other local infrastructures are facing increasing levels of overload because of tourism development. Some major attractions in Lisbon are precisely associated with traditional modes of transportations, as is the case of three funiculars and one lift dating from the late 19th century, or the *ex-libris* fleet of yellow tram cars. Riding them without a previously purchased ticket is now almost three times more expensive than before. Long queues, delayed stops in popular locations, and overloaded vehicles push local users away. Yet, they are crucial in maintaining this ageing network in terms of financial sustainability, after many years of line closing and replacement by bus lines.

As previously seen, mobility investments are targeting the connections in central districts, especially in the hilly areas, together with the upgrade of public and pedestrian space. However, the interesting side of this investment is being confronted with growing conflict from new forms of transport, especially tailored for tourists (Bloomberg Business, 2015, Público, 2014 and 2015b): *tuk-tuks* that run noisily in the narrow city's streetscape; the tour buses taking and leaving hundreds of cruise ship passengers in central squares for local excursions or dinner at one of the many *fado* restaurants; the queuing taxi cars waiting for the opportunity of a tourist ride.

While legitimized by a consensual discourse on public space improvement, restriction of private car traffic in the central city or decrease of air pollution control, many of the above discussed initiatives led by the municipality resulted in conflictive side effects in other areas of the city. Traffic restrictions in outstanding sites such as *Baixa* and *Terreiro do Paço*, diverted urban traffic to neighbouring districts which, in turn, fail to accommodate the increased pressure. Additionally, the surge of new amenities attracted visitors from other parts of Lisbon and from its metropolitan area, often using their own car. This phenomenon is can be especially seen at night and weekends, when public transport becomes a far less convenient alternative. The impact of spatio-temporalities of tourism, leisure and urban attraction in urban infrastructure seems too difficult to grasp and anticipate. Their state of constant flux offers, however, an opportunity to devise new levels of service (i.e. mobility) that better suits the needs and demands of a wider metropolitan realm, while taking advantage of recent investment in heavy infrastructure.

4.3 The vision behind strategic infrastructural investments

A critical area, in which future development is being reassessed under wider political visions, is the one relating to the heavy metropolitan infrastructures: the airport, the port and the railroad system. Notwithstanding its overarching complexity, the short-term change in national infrastructural policies has had – and will continue to have – important repercussions on the evolution of the country's capital city. The role tourism and its stakeholders play in this equation is critical. Two examples reveal this dilemma.

After a five decade-long debate regarding the development of a new international airport 40 km from Lisbon, current decision points to the improvement of existing facilities, taking full advantage of its capacity. The cost-benefit debate has often been assessed in terms of geo-strategic reasoning (Lisbon as a new hub for Africa and South America) and spatial development (the new infrastructure as a driver of regional economic and urban balance in Lisbon metropolis). However, the presence of an airport right in the middle of the city stands as a major argument for current tourism market. Easy and effective connections enable the city-break market associated with a friendly, easily manageable human scale of the

metropolis. Privatization and liberalization in airport and airline market, along with the support of low-cost bases, come together to shape the future configuration of global connection and indeed the spatial pattern of Lisbon metropolis.

The second example comes from the port. Being a multi-terminal port in various locations in both banks of the River Tagus, the port is at cross-roads in terms of the future of city terminals. With major cargo terminals located in very central areas of Lisbon, the competition of scarce space resources is having direct impact in port and municipal decision-making. Unlike many other waterfront cities, Lisbon has kept a vision of a working port city, favouring the maintenance of cargo operations in the city. This approach has not been consensual and considerable debate and claims have been made regarding the need to return unused port spaces to the city. Vast areas of landfill have been redesigned as public space for leisure, culture and commercial amenities, though far from some of the well-known Anglo-Saxon experiences. Prospects regarding the increasing presence of cruise ships and the relocation of large cargo terminals for new urban uses are still far from clarified. Yet, they provide a test-bed to assess the interplay of these different stakeholders.

5 CONCLUSIONS

Taking Lisbon as a test-bed for a leveraged approach to urban tourism, mobility and public space can be said to play a meaningful role as a common ground to overcome and go beyond strict confrontation between city residents and visitors. When considered as common ground, mobility and public space are key contributors to make the city as a value in itself. Instead of competition-driven rationale, in which cities are seen as *quasi-enterprise* entities fighting for a prominent position in the global arena, the argument of a strong relationship between public space improvements and the upgrade of trans-scalar metropolitan connectivity can be seen as a socially aware alternative.

In what urban planning is concerned, the planning of public space upgrade and improved mobility connections as part of a robust network of shared spaces remains as a valued approach to a democratic and socially equitable city. Unlike other approaches in which infrastructural and public space development occur under a rather focused economic rationale, Lisbon's initiatives have maintained relatively high levels of concern with various strata of city users, going beyond the strict duality of tourists vs. residents. Recent project can hardly be accused of single-mind concern with tourist markets as many of the city's most cherished places were in need of renewal and qualification. Despite an obvious increase of touristification and gentrification processes in the inner city, urban infrastructure policies provide a fair basis for urban development, improving both the quality of access and the quality of urban landscape. If undesired trends are to be fought, then other levels of urban policy must be enforced – namely in terms of private activities, accommodation and quality of service.

1643 AN APPROACH TO UNDERSTAND PEOPLE'S EXPECTATION FOR DESIRED WALK-ABILITY IN URBAN SPACE CASE STUDY: GARIAHAT, KOLKATA

Suparna Dasgupta, Joy Sen

Indian Institute of Technology Kharagpur, suparnadasgupta0@gmail.com

ABSTRACT

Benefits offered by a walkable public space are many folds. An understanding of the multi-folded benefits has led to a shift of paradigm in development of cities as whole and public spaces within cities, specifically. Today, cities are increasingly becoming more “people centric” and “pedestrian oriented”. But pedestrians take individual decisions within a space. Similar decisions taken by many individuals generate flow patterns reflecting a collective aspiration pattern. Therefore, for making public spaces better in terms of quality of life, is extremely necessary to observe pedestrian space in terms of these collective activity pattern and aggregate user expectations and then, draw meaningful relationships between people and spaces.

Street vendor encroachments make these spaces further complex and multifunctional. On one hand, decreases the width of sidewalk makes pedestrian environments dense and congested and on the other hand, it adds on to the diversity, safety and increases the involvement in space.

The paper documents and explores a specific case of Gariahat, Kolkata in depth, the activities and processes, which takes place within a pedestrian walk and then identifies the elements, components and sub-components, which shape the place. Then it draws meaningful and desired relationship between the spatial structure, organizational pattern of elements, functionality and people's expectation from space. The results provide an insight in creating a stronger linkage between the collective ecosystem of people and space in planning and redesigning encroached public spaces with high pedestrian volumes.

Keywords: the collective ecosystem of people and space, “people centric” and “pedestrian oriented”, walk-ability in urban space

1 INTRODUCTION

The benefits offered by a walkable physical environment ranges from personal health to development of local economy or reducing dependency on fossil fuel. These benefits have raised a concern throughout the world to create adequate conditions for walkability. Walking is the oldest, cheapest and pollution free mode of commuting. It is also the only mode for economically weaker sections. In India, about 3% of pedestrians are captive users, while 72% road users do not have access to private vehicles (Pendakur, 2000). This generates both physical, social and economic need to plan spaces for pedestrian. But most of the developing countries including India has Informal vendors along the pedestrian walks; though every-one agrees to the fact that It offers livelihood to low or minimally skilled or educated urban and sub-urban population, indeed they play a dual role in these spaces- they make these spaces congested, inadequate for people to walk, yet making them diverse, providing safety through “eyes on street” and essentially provides a supply of goods and services. Therefore, the presence of a street vendor signifies a particular need which remains unserved by the formal sector. Presence of a group of vendors would definitely mean both a collective demand of goods and services and Through a cases-study of a particular node and a stretch of road, this paper tries to find out the pedestrian expectation from space some of the essential services provided by these vendors to enhance the quality of pedestrian walk. This paper finally links these identified (unserved) demands to direct a vision towards policy planning of urban pedestrian spaces.

The first part of the paper shares the preliminary understanding of people starting off as “pedestrians”- their considerations before and during the journey.

The paper is further divided into the following parts:

Urban Context of Gariahat- which gives a brief introduction to the urban character of Gariahat

Methodology- this part briefly describes the details regarding the sample size, the methodology of data collection.

Analysis of Spaces-the analysis acknowledges the fact that the need of individual user is combined to form a collective demand of service from spaces. Therefore, for the purpose of analysis individual need and demand from space is assessed at various scales starting from individual user level to the site level.

Discovering the Links and directing towards the vision-This part of the paper identifies the present state of problems, spatial and planning limitations and finally attempts to link the user needs and expectation to the vision so that there is a “win-win” situations for all.

Finally a Conclusion drawn from the study

1.1 An understanding of the pedestrian Space

A person who walks is a pedestrian. A part of any journey is always performed on foot. The pedestrian activities can be classified at three different levels: *Strategic level, Tactical level and Operational level* (O. Marina, 2011). At Strategic level, a person decides the nature of activities to be performed the choice of area and the broad order of activities. This is predominantly dependent on the landuse and urban functions. These are beyond the control of an urban designer. At Tactical level, takes short term decisions taking into account the surroundings and relative movement pattern of people

and vehicles. At this level, the route choice, order of activity is decided depending on the configuration of streets, street character and other area level determinants. While at the operational level, a pedestrian takes instantaneous decisions depending on both area level determinants as well as the immediate surroundings. At this level, there is maximum interaction between pedestrians and the built environment. Thus, above two levels can be controlled through design strategies. Therefore, for designing a “pedestrian friendly environment” or policy framing for a pedestrian friendly city, a combination of both top down and bottom up approaches are required.

But, being regarded as a mode of transportation, design and policy planning for walkability has traditionally been a quantitative process; therefore, it has been mostly addressed in terms of pedestrian flows, density, intensity of usage etc. The paper demonstrates a methodology, how, with minimum direct intervention, the quality of space can be improved, just by augmenting elements and supporting the activities and processes. Finally, it also shows how these decisions can help in better decision making and policy formation with respect to improving quality of pedestrian space in densely encroached pedestrian walk. For the purpose of a demonstrative example, a densely encroached pedestrian walks at Gariahat, in Kolkata, India is selected.

2 DOMAIN OF INTEREST

Pedestrian walk is a part of public space dedicated to walking. These are the interfaces where the buildings meet the city environment. It links the “private” to the “public” and so it is called is the most “important urban public space” or the “vital organs” of a city. (Jacobs, 1961). Jan Gehl points out that these spaces essentially serve three major purposes. They provide accessibility and connectivity; act as a meeting place, and a market place.

Sir Christopher Alexander, in his seminal works *The Pattern Language*; & *The Timeless Way of Building*, describes a similar methodology to create “livable “spaces. The process of evolving a “form” from its context. By “form”, the author means the interfaces which need to be changed or redesigned & by “context” the author means the things which would remain constant & shape the form. This is done by the linking present user-activity-pattern & the physical & non-physical context which surrounds it. Then analyzing the course of future development, projecting the future needs and finally, directing the course of development towards a vision. This method is used as a tool to identify the user requirements at the *Site Level* (overall Gariahat area) *Area Level* (built environment around schools, colleges, Waiting Areas, On Street Parking, & Intermediate Paratransit (IPT) stops), and Individual User Level. Finally, these were combined to form a vision for policy formation regarding pedestrian walks in Kolkata

2 URBAN CONTEXT OF GARIAHAT

Image Courtesy: Wonobo.com

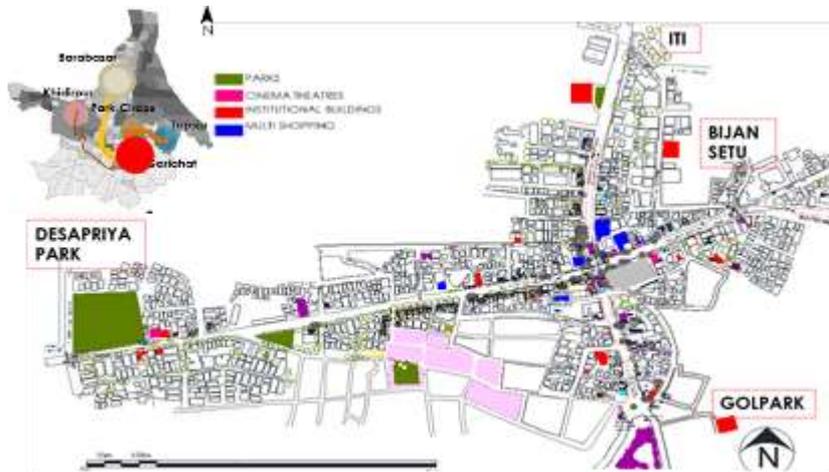

Figure 119: Street View of Gariahat represents buildings with porticos, louvered windows

The city of Kolkata has expanded from North to South and Gariahat marked the southern edge of the city. It was a home to the “wealthy middle class” way back in 1930’s. The houses had huge entrances with plinth stairs and large porticos overhang verandas, and wooden louvered windows -typical features of architecture of Bengal. These façade elements along with the small scale urban design elements like small temples, type of trees, nature of shops-all contribute to the continuum of space which connects it to areas in north of Gariahat like Rashbehri, Hazra etc. These elements have contributed to walkability, encroachment and pedestrian experience within a sidewalk- particularly Gariahat area. For this paper, Gariahat refers to the intersection of Leela Roy Sarani (North South) and Rashbehari avenue (East West) while the boundaries are marked by Bijan Setu bridge in the east Desapriya Park in the west; the North- South boundaries is marked by Golpark & Ballygaunge Shiksha Sadan School respectively.

2.1 Street Conditions at Gariahat

Physical observations at gariahat reveal vehicular congestions in the carriage ways, encroached pedestrian walks with minimal space available for walking and pedestrians forced to walk out of the pedestrian walk

3. METHODOLOGY

Map 1: Map Representing Gariahat in Urban Context of Kolkata

The methodology consisted of identifying the individual user level requirements identifying the area level requirements, comparing them with the existing standards and finding the gap areas and finally designing strategies for augmenting

3.1 Mapping and Data Collection

Data collection was done from the month of October-December with attention to festival like Diwali, Christmas-New-Year, & Holi. A quick reconnaissance was done to map the spatial structure, typology of permanent shops, typology & nature street vendor encroachment and Photographic & video graphic recordings at important junctions in Gariahat. This was followed by a questionnaire based primary Survey of street vendors and pedestrians, collection of secondary data like ward demographics and an expert opinion survey to understand the current situation and direction of future growth. The data obtained was then co-related to the areas, spaces, adjacent building and landmarks.

The findings of the survey are represented in form of sketches, maps, diagrams and tables. Street Vendor Encroachments considerably reduce the effective width of a footpath. An extensive survey on nature, ownership, relocation intent, of the street vendors have been done, which however remains beyond the scope of this paper. This paper only presents the urban design related issues regarding walkability and pedestrian experience of space. The following set of maps represent material specific details of encroachments, along with the density of encroachments.

3.2 Survey Locations and Sample size

The survey was conducted at all important nodes along the main road & internal streets within the specified boundaries.

Street Vendors	Pedestrian Survey
Total no of street vendors mapped=1049 For sample survey, Confidence level taken to be: 95 % Confidence interval is taken as + 5 Sample size -285 Proportioned in ratio of their occurrence	Pedestrian survey has been done on all important nodes, four times a from day, for 10 samples each & for all sides of Gariahat crossing, 20 samples four times a day, both on all week days & holidays & special occasions like Diwali, Christmas, New Year amounting to a total No. of 480 pedestrian surveys

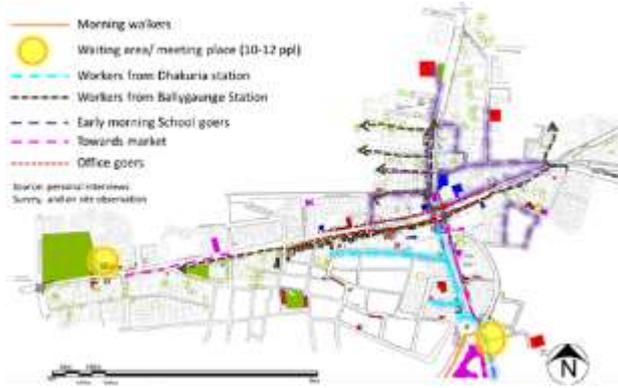

3.3 Findings from the Survey

The main objective of the survey was to provide a combination of qualitative and quantitative measure to assess a pedestrian space.

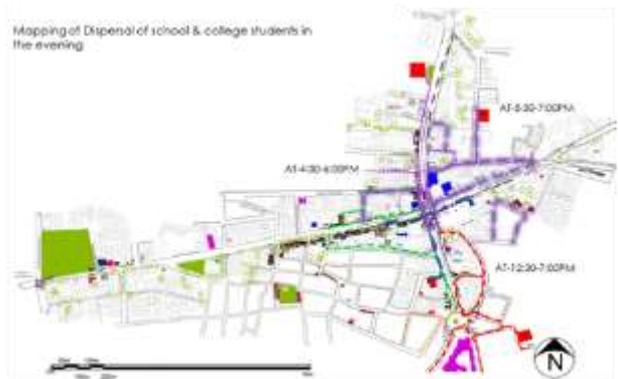

4. SITE LEVEL ANALYSIS OF SPACES

4.1 Maps representing Pedestrian Density Pedestrian Purpose of Visit

Video graphic surveys were performed at varying time intervals all important junctions on all six-working days, Sundays and some special occasions like Diwali, Christmas, New year, to obtain pedestrian volumes. Following maps summarize the nature of pedestrian demand from the space. A set of pedestrian surveys were conducted at Morning_6:30, 8:30, 11:30 and Evening 6:30 and at night 8:30 to obtain pedestrian density & purpose of visit.

Map 6a: Map Representing Pedestrian Density and Purpose of Visit during morning Hours

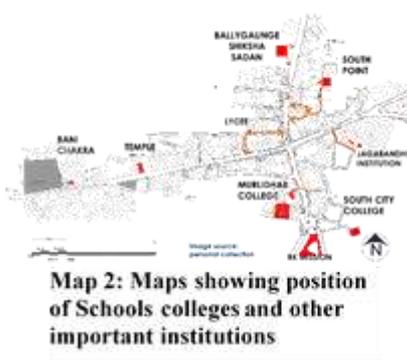

Map 6b: Map Representing Pedestrian Density and Purpose of Visit during Evening Hours

4.2 Quantitative Demand from Pedestrian Space

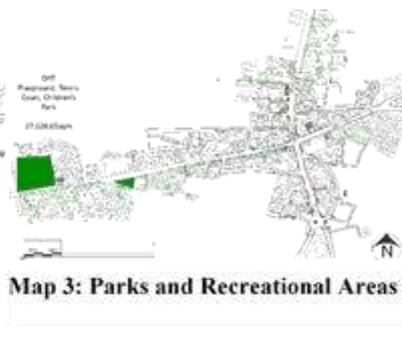

The maps as well as the table represent there is a clear correlation of pedestrian density and nature of space usage to the encroachment pattern, onset of shops etc. Overlapping Effective Width (width of clear space available for walking) to the pedestrian maximum density patterns we can quantitatively assess a space in terms of Pedestrian Level of Service (PLOS). The flowing map represents the PLOS at main roads of Gariahat.

4.3 Analysis of User requirements at Landuse and Network Structure level

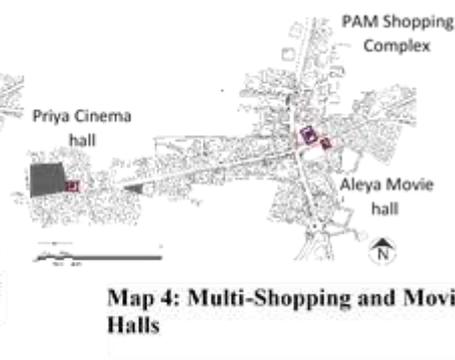

Urban Landuse is the key determinant the nature of relationship of people to the city. In this section, Gariahat the spaces which generate pedestrian activities are individually taken into consideration. The north-south roads from Gariahat crossing to Golpark is intercepted at various points by the internal roads (with very low vehicular density) which diagonally join the East - West roads. Houses along these streets belong to the low-income groups. They act as principal offsite storage areas for informal shops.

Map 2: Maps showing position of Schools colleges and other important institutions

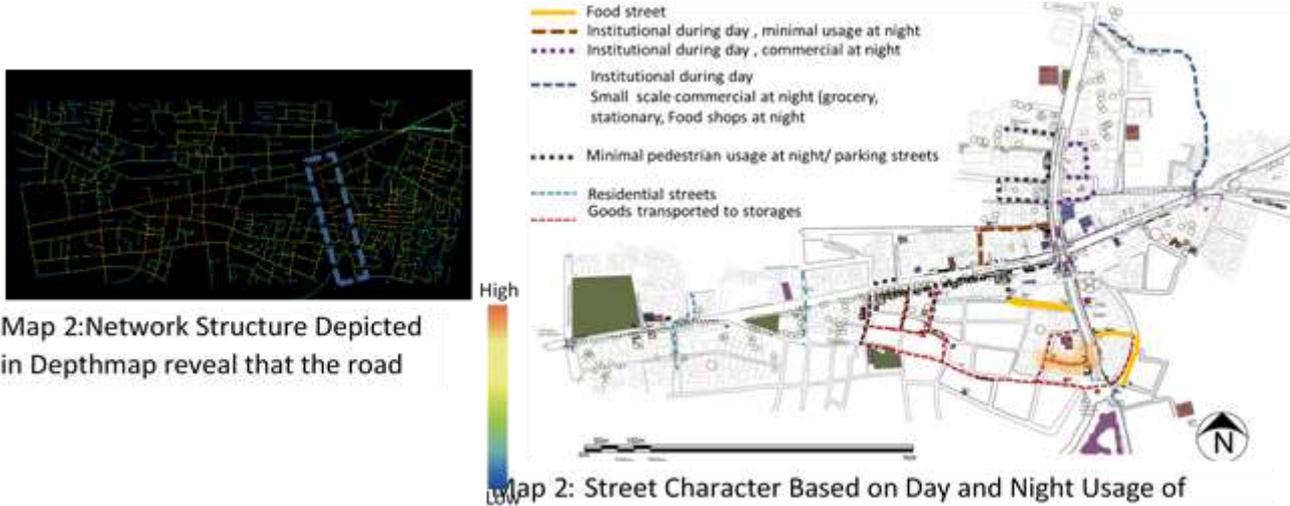

Map 3: Parks and Recreational Areas

Map 4: Multi-Shopping and Movie Halls

4.4 Analysis of User requirements at Street level

Connectivity structure and use of spaces

Character of streets

Gariahat is was principally a residential area at its inception which is being upgraded to commercial and mixed-use developments A number of city level services like fire stations, neighborhood level services like rationing shops are located in this area. Since a number of public buildings are located in this street the area has developed into zone of informally encroached food vendors.

The streets which are primarily institutional remain unused during the night. Therefore, the landuse structure of some of the streets adjacent to schools have been upgraded to alternative uses like boutiques, hobby classes etc. (source: primary survey)

There is minimal activity in the residential streets especially during the night. The streets are predominantly used for on-street parking.

The internal roads display a typical residential character, though, gradually being upgraded to mixed used with commercial at the ground floor. There streets are wide and relatively used lesser and can be used to Opportunities creating Variations, interchange of spaces/ increasing interactions

4.5 Area Level Analysis of Spaces

4.5.1 Identified Areas with special zones in Gariahat which attract a different type (and volumes) of pedestrian interactions

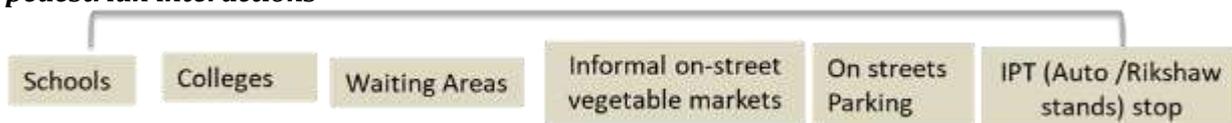

Table 54: Discovering Area Level Pedestrian Requirements and their links to the individual level & Site Level Determinants

Areas	Location plan	Recognition of the conflicts and Pedestrian expectation from Sidewalk
-------	---------------	---

<p>Schools</p>	<p>Traffic Calming Measures at intersection</p> 	<p>Waiting Areas for parents. Adequate car parking for Pooled cars Adequate buffer of pedestrian walks from main roads. <i>Observations reveal that at places, informal vendors act as a buffer, obstructing access to the main road.</i> Use of Elements in the areas that link the main road to the kids</p>
<p>College</p>		<p>Spaces for waiting & Snacks. <i>This need is served by the informal vendors of the area, who would particularly gather during starting or end of college times</i></p>
<p>Waiting Areas</p>		<p>The important landmarks act as waiting areas of the pedestrians. <i>The informal vendors provide for seating areas along with tea and snacks shops in zones (1-5) while formal food and beverage counter are provided at zone 6</i></p>
<p>On Street Parking</p>		<p>Majority of internal roads and parts of Main road (Leela Roy Sarani) are used for on-street parking signifying high demands of on-street parking <i>These spaces can be provided with parklets thereby providing opportunities for waiting areas as well as accommodating on-street parking</i></p>
<p>Intermediate Para-transit (IPT). Stops-Auto & Rikshaw Stops</p>		<p>Parked Auto-rikshaws make in accessible, leading to pedestrian waking on vehicular Road Low Vehicular Density</p>

4.6 Individual User Level Analysis of Spaces

To obtain the individual user level requirements a Revealed Performance analysis on Likert scale analysis was performed at every important intersection regarding their opinions on safety, shading and protection from monsoon, dedensification (removal of Street Vendors), basic services like toilets and drinking water, way findings, Night Illumination, and urban design improvements like beautification, street furniture. The results suggested that they feel safe in general safe in these areas while maximum amount of improvements was required in terms of shading and monsoon protection followed night illuminations and urban design improvements and dedensification strategies.

5 DISCOVERING THE LINKS AND DIRECTING TOWARDS THE VISION

Tasks	Findings	Vison
<p>Activity Pattern & space usage pattern Analysis (individual spaces)</p>	<p>The onset & typology of goods offered for sale bear a relationship to the pedestrian dynamism on streets Density of street vendor varies from inner core, (the crossing-) outwards</p>	<p>Relocation of working area, (wherever possible -like flower Vendors) but display counters remaining</p>

Carrying capacity of streets & pedestrian walks	Both pedestrian walks & vehicular roads are congested. A Vehicular Level of Service Analysis conducted on the carriage way suggested that the No scope for shrinking of vehicular road to increase foot path width	Increasing width of foot path only at nodes
Analysis of space usage along main road	Spaces lack waiting areas & transitional spaces	Integrating waiting areas within the sidewalks, at nodes Elements to lean on, while standing,
Analysis of space usage along internal streets	Internal roads of Gariahat are wider, have very low pedestrian & vehicular density	Directing street vendor towards internal roads
Street vendor change typology of goods offered for sale according to the change in market demand	The change particularly takes place in identified stretches (e.g.) in case of Gariahat, K.M.C (Kolkata Municipal Corporation) market entrance to Golpark is the place which takes major part in seasonal diversity & has the most no. Of people who keep on changing the material typology offered for sale.	Urban design detailing

7 CONCLUSION

In India, there is a high rate of population growth, high level of unemployment with the presence of low educated low skilled people. Street Vending can act as a symptomatic solution to these problems meanwhile, adequate measures for long-term plans like education, skill development or infrastructural development in rural areas can take place.

The results show that the street vendors serve a local demand of the pedestrians and thus, pedestrians and the street vendors share a symbiotic relationship with each other. in India, there are functional overlap in public spaces. This makes it very difficult for planners and designers to comprehend spaces. Decomposing spaces in terms of pattern hierarchy (Site level, area level, Street Level and User Level) and linking them to adequate solutions.

INTRODUCTION

Nishii (2014) 1) reviewed studies on tourism-related travel behaviors in Japan after the 1990s and divided them into three main streams that are characterized by their side-by-side comparisons. As indicated in **Figure 1**, the first stream is called transportation planning and policies in tourist areas. Various approaches to tourist travel demand forecasting methods have been developed for transportation planning and policy making, whereas tour based trip chaining models and activity-based approaches have been applied to tourists' travel behavior data as well as traditional trip based and discrete choice models. Moreover, travel demand management measures have been implemented to reduce traffic congestion in major tourist areas during annual peak periods. The area development involving tourism (ADIT) was established during the second stream, specifically, in the beginning of the 2000s. The ADIT studies aimed to promote attractive tourist areas while taking into consideration the preferences for the spatial scales of the targeted areas. The focus of these studies, however, has changed from transport-sector oriented themes to area development themes that involve tourism. This shift implies that we must face further challenges when evaluating the effect of area development measures not only with respect to the increase in the number of visitors but also with respect to the sustainable local economic growth in the area. The ADIT is featured as part of the tourism destination based approach in which area restoration and area revitalization are achieved through tourism-related policies and projects in the targeted areas. Accordingly, although it is noted that consistency between the goals of area development and tourism destination policies is required in destination-based approach, in some cases, it is determined that the goal of the tourism destination policy is not always compatible with that of achieving the sustainable development of the targeted areas. This may be caused by the fact that there exists both spatial and temporal divergence between tourism destination policies and area development planning. Based on the diversification of tourism-related travel behavior studies, this study is devoted to developing an area marketing and management approach (AMMA) as a third stream.

Figure 1 Diversification of tourism studies in Japan

The AMMA is comprised of four basic components, namely, area, tourism, area marketing and area management, and incorporates certain specific features (Nishii (2009) 2)). The first of these is concerned with the system in which area marketing and area management are comprehensively linked. The second feature, however, which is more essential to the AMMA, explicitly expresses the separation of area and tourism while simultaneously highlighting the separation of tourism from the tourist area and

the separation of area from the tourist area. This is because the AMMA is capable of targeting not only tourists/visitors but also local residents as important actors in the sustainable development of the tourist area. From a problem-oriented perspective, it is also expected that this separation contributes to a

better understanding of comprehensive area development measures and policies. Nishii (2012) 3) has criticized Umekawa (2012)'s 4) definition of the ADIT as follows: "As shown in the word, that is to say, 'ADIT (area development involving tourism),' it is clear that both 'tourism destination policy & planning' and 'area development policy & planning' should be discussed in a comprehensive system. It is also necessary for us to clarify how we define the relationship between

‘tourism’ in the targeted areas and its effect on the ‘area development.’ This therefore means that we need to eradicate ambiguous issues on tourism destinations such as, the subject(s), the target(s), the measures and their evaluation viewpoints.”

Based on the above statement by Nishii (2012), this paper aims to identify basic issues on managing tourism destinations in relation to urban and regional planning from the perspective of the AMMA. This paper consists of four sections. Following this introductory section, the second section introduces the basic concept of area management in the AMMA and identifies some essential prerequisites for area management in the ADIT. In the third section, the concept of the tourism area life cycle (TALC) is introduced. The TALC model proposed by Butler (1980) 5) and the acceptance capacity in a tourist area

has often been the subject of debate. The model, which expresses the growth curve in the targeted tourist area, focuses on the annual trend of the number of visitors to the area(s) and divides it into several stages, namely, exploration, involvement, development, consolidation, and stagnation. The TALC, which significantly influences strategic destination management, incorporates destination planning as well as destination marketing (see Butler (2006) 6), Butler (2011) 7) and Morrison (2013)8)). This means that as one of the prerequisites for the sustainable management of the area, we must identify at which stage of the TALC the targeted area should be positioned. Furthermore, we must discuss which orientation drives the marketing and management of tourism destinations. Especially, in the case that the targeted area is positioned as a stage of stagnation, the roles and missions in the strategic management area are important for the sustainable development of the area. Finally, the tourism statistical analysis of the TALC is intended for a typical wellness-tourism destination, i.e., onsen tourism in Japanese, Noboribetsu in Hokkaido. The TALC analysis aims to provide useful information for discussing how to organize destination management/marketing organization (DMO) and what missions should be identified as part of the DMO for each tourism destination. In the conclusion of this paper, basic challenges regarding the DMOs of the onsen tourism destinations are discussed.

THE FRAMEWORK OF THE AMMA

Figure 2 graphically depicts the AMMA as consisting of area, tourism, area marketing and area management. The ‘Area’ is classified into several levels of hierarchical spatial structure according to the spatial spread as shown in **Table 1**. The table provides an example of a classification of the spatial scale of the targeted area(s). While this table corresponds to the case of tourism-related transportation planning in general, the AMMA is therefore required to include a variety of survey and analytical methods depending on the spatial spread of the targeted areas.

Table 1 Classification of tourism-planned areas by scale level

Level	Scale of area	Name of plans	The expected effects of road network improvement
I	Nation-wide unit	Nation-wide plan	Improvement of airline access may increase potential of inbound tourism.
II	Regional block	Wide area excursion plan	Gaining the ascendancy over wide area excursion may lead up to the formation of an attractive route.
III	Tourist region	Tourist region formation plan	Formation of the tourist region stretching over more than one prefecture promotes the endogenous development with increasing both LOS in transportation and tourism demand.
IV	Tourist area	Tourist area plan	Smoothing mobility in the tourist area may give tourists satisfaction.
V	Tourist spot	Tourist spot plan	Walk trail improvement in a tourist spot makes the excursion more attractive.

On the other hand, for the purpose of our discussion, the term tourist area is divided into two areas, namely, one is the area as a destination for tourists and the other is the area as a city/region for local residents and workers. Thus, the separation of area and tourism is explicitly expressed. It also highlights the separation of tourism from tourist area just as it does the separation of area from tourist area (see Nishii and Goulias (2016) 9)).

Furthermore, it is emphasized that the AMMA incorporates both area marketing and area management in a comprehensive system. From a methodological perspective, the method of area marketing is regarded as a short-term tool for triggering tourist demand in the area. In contrast, that of area management is concerned with relatively long-term decision-making with respect to sustainable area development. For example, the task of area marketing is to analyze the market to explore what would be an effective strategy of increasing both the attractiveness of and the sales for the targeted areas. Conversely, area management aims to develop a sustainable system in which such a marketing strategy will affect the area(s) in the years and decades to come.

This figure also displays the general challenges related to our AMMA. Some of these challenges will be discussed and focus on how to identify basic challenges to area management in the ADIT from the AMMA link with urban and regional planning.

Figure 2 A framework of the AMMA and its challenges

BASIC CONCEPTS OF THE AREA MANAGEMENT IN AMMA

While the definition of a managing area(s) in the AMMA is based on that of managing a corporation/firm, there is a difference with respect to the number of stakeholders. This is because there exist various types of stakeholders who commit themselves to area management when considering the spatial spread of the targeted area(s). Managing the area(s) is therefore defined as follows: To achieve the goal of business activities within the area and perform them smoothly requires that four manageable area-oriented resources, such as humans, goods, money and information, be procured and combined. However, managing the area can also be defined as the activity in which comprehensive strategies should be developed and promoted for area marketing (see Nishii (20167) 10)).

Let us here compare area management as defined above with destination management as defined by Morrison (2013), He defines it as follows: “*Destination management is a professional approach to guiding all of the efforts in a place that has decided to pursue tourism as an economic activity. Destination management involves coordinated and integrated management of the destination mix (attractions and events, facilities, transportation, infrastructure and hospitality resources)*” referring to the definitions of the UNWTO (pp6-7).

Hence, it is noted that while a tourism destination is originally defined as a simple unit of a tourist place, the spatial range of the geographic area can cover from the largest country to the smallest states, territories, regions and cities. He further emphasizes that “*there is a variety of destinations in the world and an enormous range of DMOs are involved*” (p4). While ‘*all of the efforts*’ corresponds to ‘*the destination mix (attractions and events, facilities, transportation, infrastructure and hospitality resources)*’, it also means that “*effective destination management requires a strategic or long term approach based upon a platform of destination visioning and tourism planning*” (p5) and that “*destination management is accomplished through specialized organizations, known as DMOs, and they can coordinate many stakeholders to achieve the destination’s vision and goals for tourism*” (p5).

Two essential prerequisites for area management in the ADIT are identified. The first clarifies the importance of the role of tourism destination planning to manage the areas over the long term. This suggests that area management in the ADIT should be positioned so that it includes long-term tourism destination planning. Morrison (2013) further introduces the definition of destination management roles as proposed by the Destination Consultant Group (denoted DCG), namely, planning and research, marketing and promotion, leadership and coordination, partnerships and team building, community relations, and product development. **Figure 3** presents a variety of missions with respect to area management that consider process as part of the mission. Moreover, due to its broad definition, tourism destination management is followed by the process of tourism destination planning, which suggests that the policy-making decision process with respect to tourism destinations is a comprehensive system composed of long-term tourism planning, marketing and management that includes the continued monitoring and evaluating of the outcomes of tourism destination policies and measures.

When aiming to achieve sustainability in tourism destination development, the basic strategy in our area management approach is to change the patterns of production and consumption and find a way to avoid trade-offs between economic growth and environmental loading in critical areas. Thus, area management requires long-term tourism planning as part of the decision-making process (Nishii, Furuya and Romao (2017) 11)).

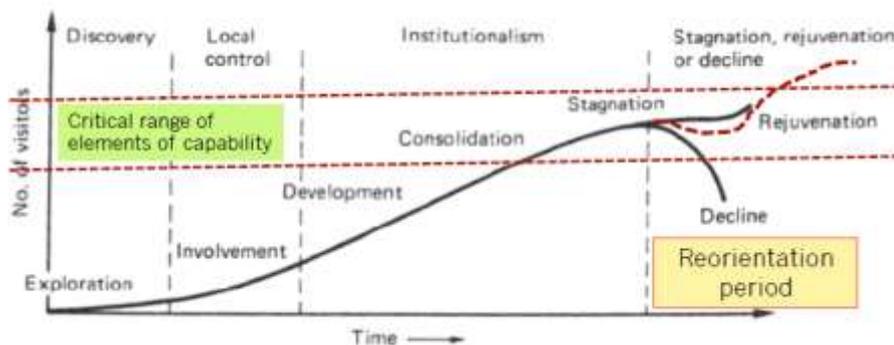

Figure 3 Missions of tourism destination management

The second prerequisite is to explicitly consider the TALC when managing tourism destinations. The concept of Butler's TALC model is introduced as a growth curve of the annual trend of the number of visitors to the area(s). The model allows us to explore in which stage of the TALC the targeted area is actually positioned.

These two prerequisites are linked given that the TALC significantly influences the strategic destination management and that the preceding destination planning process could identify the challenges related to the reorientation of the targeted area.

TOURISM AREA LIFE CYCLE (TALC) FOR THE AREA MANAGEMENT

The concept of the TALC of targeted areas was first proposed by Butler (1980). As presented in **Figure 4**, the cycle can be expressed as an S-shaped growth curve. When focusing on the annual trend of the number of visitors to an area(s), it can be divided into several stages, namely, exploration, involvement, development, consolidation, and stagnation. Zmysolny (2011)12) introduces Getz (1992)'s claim that *"the concept of the destination life cycle has apparent potential to advance the theory and practice of tourism planning, particularly as a conceptual framework within which long-term changes can be forecasted and strategies for land use, economic development, and marketing can be harmonized."* Additionally, the TALC significantly influences strategic destination management, which incorporates destination planning and destination marketing (see Morrison (2013)).

Source: Butler, 1980. 'The concept of the tourist area life-cycle of evolution, implications for management of resources, Canadian Geographer, 24(1), 5-12.

Figure 4 The tourism area life cycle (TALC)

The concept of the TALC embraces a perspective common to the limits of economic growth in tourism destination as argued by Mishan (1969) and Beckerman (1974) and which Hirsch (1978) referred to as social limits to growth (see Urry (1995)13)). Their arguments were concerned with the economic growth limits that were caused primarily by the overcrowded tourism destination. The maximum feature of the proposed TALC model was to assume that the carrying capacity of a resort represents its evolution by applying the product life cycle (PLC) to that of a tourism destination. The TALC model is also intended to represent a general concept of the resort life cycle by focusing on its evolutionary nature and to allow tourism destinations during the stagnation period to avoid moving into the decline period either by applying appropriate market intervention strategies or resource management. However, it is further noted that the causal structural approach, in which both external (marketer side) and internal (tourist side) determining factors are explicitly postulated, has not been applied to the modeling of such an evolutionary transition in chronological order. Martin and Uysal (1990)14) discussed the factors impacting the stagnation stage and the following decline of a destination. Conversely, Pornphol and McGrath (2010)15) suggest that there may be a benefit in implementing the TALC as an advisory expert system. They also claim, *"a number of tourism and hospitality researchers have reported on instances of*

where different rejuvenation approaches have been tried and they and others have also specified classification schemes and frameworks for the various types of rejuvenation strategies.” Accordingly, once entering the stagnation stage, there exist a variety of strategic rejuvenation approaches in tourism destination management. Furthermore, such diversification is the result of both internal and external factors that determine the market circumstances in tourism destinations.

Lumsdon (1997)16 suggests that tourism destinations appeal to different markets according to the corresponding stages of the TALC under the assumption that a primary segment of visitors play a leading role in the economic growth of the tourism destination. He further emphasizes that such an assumption is based on the concept of the PLC, i.e., diffusion of innovations by Rogers (1962).

Two principal perspectives regarding the concept of the TALC since the 1990s require summation. The first perspective focuses on the difference between the PLC and the TALC such that the heterogeneity of tourism services is distinguished according to general goods and services. The services instantly supplied at the tourism destination have specific characteristics, whereas locational goods depend not only on the historical and cultural backgrounds but also on the spatial spread of tourism destinations developed by cooperating with the surrounding areas and the higher levels of governments. Thus, it is noted that, as there exists a variety of TALC patterns, it is difficult to assume a standardized pattern of economic growth in tourism destinations. Finally, it is also necessary to cautiously observe their transitions over time by making full use of a retrospective approach.

The second perspective concerns the diversified situations that occur during the reorientation period of the TALC. Such diversification covers situations that range from decline to stability to rejuvenation. In the case of the TALC, tourism destination marketers rarely intend to withdraw from their own markets but rather intend to reorient forward to the post-stagnation stage. Nonetheless, it is not always advisable to forecast situations based on a general business model because the types of destination management strategies that should be implemented vary, and thus, their results also vary from case to case depending on the circumstances specific to identified targeted area. That said, a better understanding of the actual situations of the TALC in the targeted tourism destinations results in better decisions with respect to area management strategies.

AN EMPIRICAL ANALYSIS OF THE TALC IN ONSEN TOURISM AREAS

Romao et al. (2017) 17) defined the concept of onsen tourism as follows. “...a varied set of products, services and activities are required for the attraction and satisfaction of wellness travelers. At the spatial level of the establishment, apart for the accommodation facilities, these services normally include diverse spa-related services (massage, different water treatments, aromatherapy, beauty care, etc.), other facilities for health-oriented activities (gyms or sports facilities) or the supply of healthy food. Other wellness activities identified in the literature relate to the spatial level of the destination, including hiking, biking, open-air sports, enjoyment of natural landscapes, or cultural and educational activities, including the interaction with local communities and their specific values.”

He also introduced the concept of new-toji tourism. The Japan Tourism Agency in Japan defines this term as follows: It is “a combination of the traditional Japanese onsen experience with other educational and recreational facilities, by defining various programs of activities oriented for relatively long stays and based on the surrounding nature, local history and culture or high quality food, aiming at a physical and mental rejuvenation, while promoting the interaction with local communities.”

As Noboribetsu is one of the typical onsen tourism destinations in Hokkaido, it is important to explore the trend of the number of visitors to Hokkaido, as this trend clearly determines the changes in the TALC in Noboribetsu over time. Because this explorative analysis is based on the AMMA, the spatial spread of Noboribetsu areas is assumed to form the stratified structure of onsen tourism destinations that cooperate with the surrounding areas. This assumption suggests that there exists the Hokkaido bloc, which is positioned as the upper spread of the Noboribetsu tourism destination such that the Noboribetsu onsen area plays a core role as the wellness tourism destination, which is then followed by the surrounding small-size tourism areas.

Figure 5 presents the trend regarding the number of visitors to Hokkaido from 1960 to 2016 based on the data obtained from the Department of Tourism in Division of Economics of Hokkaido and their referred comments. It is apparent that the number of visitors to Hokkaido increases or decreases due to the macro-environmental factors that determine the various types of external events that occur over time.

As Johnston (2006) 18) noted, “macro-structural conditions (roughly synonymous with external events) are important ontologically because they function as structures, meaning they constrain or enable development from outside – the role of climate in eco-succession, for example.”

As presented in **Table 2**, the macro environmental factors are listed and the external events that occurred during the period are classified into several categories, including the components of the PEST analysis, natural phenomena, and value and norm-consciousness. The table indicates that a variety of macro factors clearly determine the changes in each stage of the TALC. Because the TALC entered the stage of development in the early 1970s, the increase in the number of visitors has been accelerated by the upward factors. These factors include the following:

- + strong economic growth (the bubbled economy from 1980 to 1990) as a macroeconomic factor,
- + opening of the Aomori-Hakodate tunnel (1988),
- + increase in domestic direct flights (1995, 1996, and 1997), and

+ entry of AIRDO as a social-capital factor.

However, even during the development -stage, i.e., from the early 1970s to the end of the 1990s, via the bubbled economy, the downward factors significantly influenced the decline in the number of tourists to Hokkaido. Specifically, the factors are mainly concerned with the natural phenomena in Hokkaido:

- The eruption of Mt. Ushu (1977 and 2000),
- The earthquakes on Okushiri Island and southwest offshore (1993), and
- The unusual/unsettled weather (days and seasons) (1981, 1983, 1993, 1995, 1996, and 1999).

Other downward-factors include:

- The end of the bubbled economy (1991) and the depression in the economy in Hokkaido (1993 and 1999), and
- Marine EXPO '75 in Okinawa, which was a microenvironment factor related to the competitive tourism market.

Since the 2000s, as tourism destinations have entered the stages of either consolidation or stagnation in the TALC, both upward and downward factors have impacted the fluctuation in the number of visitors to Hokkaido. Specifically, with respect to upward factors, they are mainly concerned with the macroeconomic issues, which include:

- + The strong yen-rate (2013) and economic growth (2014),
- + The new entry of SKYMARK (2006) into service and the increase in international direct-flights (2015),
- + The entry of DOTO expressways into service (2012), and
- + The opening of Hokkaido Shinkansen (to Hakodate; 2016).

In addition, the political factors related to the governmental tourism planning and policy, which the Japan tourism agency has promoted since the early 2000s, and the changes in preferences for inbound tourism for Asian tourists with respect to the tourists' needs and wants include the following:

- + An increase in inbound tourism to Hokkaido (2001-)
- + Visits to the Japan campaign (2004-) and the visa-relaxation policy (2004),
- + The Hokkaido tourism campaign (1999 and 2012), and
- + The Aomori-Hakodate destination campaign (2016).

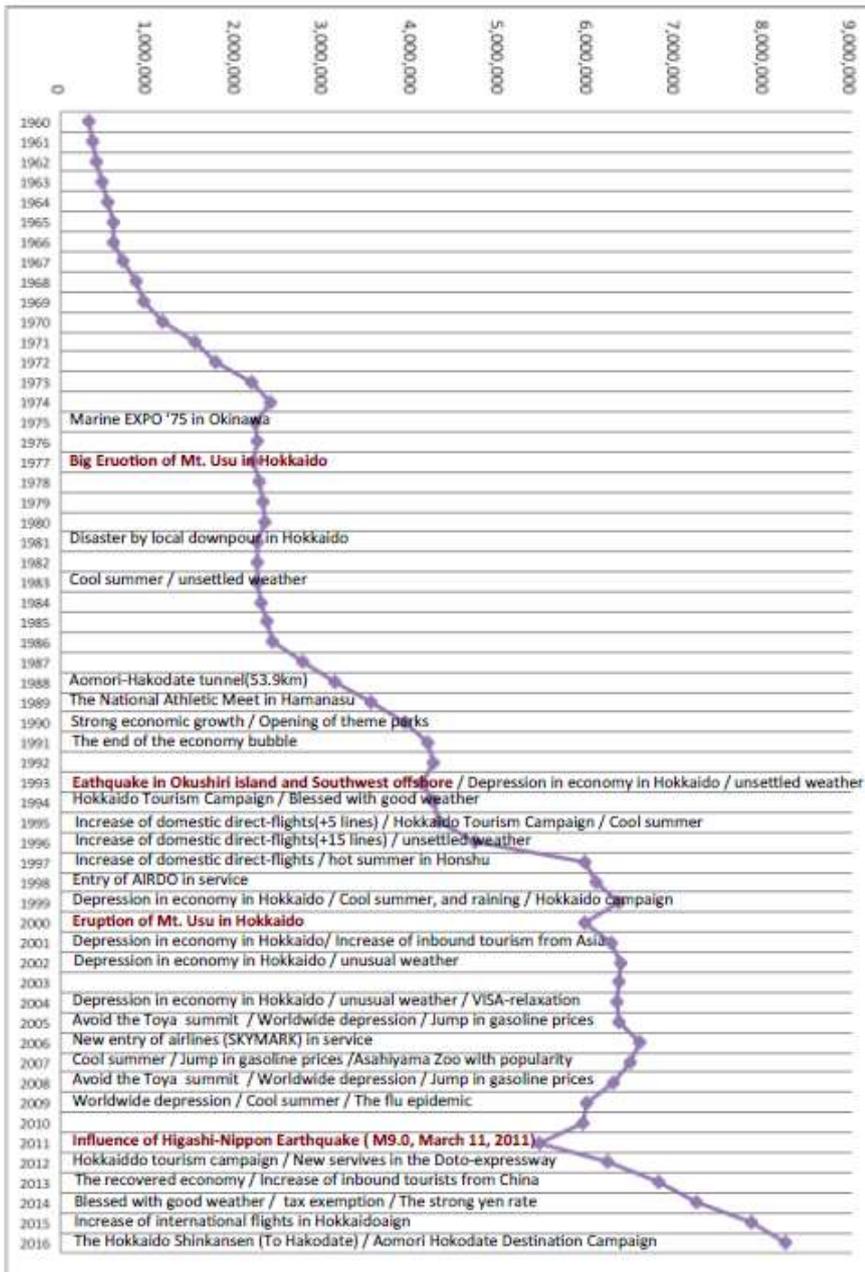

Conversely, the downward factors that determine the fluctuation during the 2000 to 2016 period are extremely similar to those in the previous period, i.e., the 1970s to the end of the 1990s:

Among the natural phenomena in Hokkaido, the downward factors are as follows:

- The influence of the earthquake in the Higashi-Nippon areas (2011.3.11), and
- The unusual/unsettled weather (days and seasons) in 2002 to 2004, 2007, and 2009.

The following socio-economic situation/external events are also listed as additional downward factors:

- The depression in Hokkaido (1993 and 1994 to 2004) and worldwide depression (2008 and 2009),
- Increase in gasoline prices (2007 and 2008),
- Terrorist attack in the US (2001.9.11),
- The Toya summit (2008) avoidance, and
- The flu epidemic (2009).

Figure 5 Trend regarding the number of visitors to Hokkaido

Table 2 The factors determining trends regarding the number of tourists to Hokkaido and the leading events and phenomena over time

Spatial level	Environmental Factors / Categories / Items		The leading events and phenomena (referred by Tourism Department in Hokkaido)		
		Items	- downward	+ upward	
Outside of Hokkaido	Political	Law/Regulation/Tax/Subsidies	Immigration/Visa-relaxation/Tax-Free	* Tax exemption (2014) / + Visa-relaxation policy (2004)	
			Governmental Tourism Promotion Policy & Planning	* Visit JAPAN Campaign (2004-)	
	Economic	Macro economic factors	Economic trend/economic growth rate	- Worldwide depression (2008, 2009) / - Depression in Hokkaido (1993, 1999-2004) / - Jump in gasoline prices (2007, 2008) / - The end of the bubbled economy (1991)	* The strong yen rate (2014) / + The recovered economy (2013) / + Strong economic growth (the bubbled economy) (early 80s - 1990)
			Prices / Consumer price tendency		
			Stock prices / Exchange market		
	Social	Population movements	Change over the years		
			Trend on the aging society with fewer children		
		Social Capital (infrastructure)	Improvement of transportation system		* The Hokkaido Shinkansen (2016) / + Increase of international flights in Hokkaido (2015) / + Increase of inbound tourists from China (2013) / + New services in the Doto-expressway (2012) / + New entry of airlines (SKYMARK) in service (2006) / + Entry of AIRDO in service (1998) / + Increase of domestic direct-flights (1995, 1996, 1997) / + Aomori-Hokodate tunnel (1988)
			Changes in way of life (income, welfare, healthcare, leisure time, etc.)		
	Social Situation	Serious accidents/ Conflicts/Infectious diseases	- The flu epidemic (2009) / - Avoid the Toya summit (2008) / - Terrorist attack in US Sep.11 (2001)		
	Techno-logical	Information-oriented society	Innovation of information technology		
		Technological Innovation	Patent / Innovation of Tourism Industry Management		
	Natural Phenomena	Natural Environment Resource	Conservation of the natural environment		* Registration of Shiretoko as World Nature Heritage (2005)
			Natural disasters (Earthquake, eruption, typhoon, etc.)	- Higashi-Nippon Earthquake (2011) / - Eruption of Mt. Usu in Hokkaido (1977, 2000) / - Earthquake in Okushiri island and Southwest offshore (1993)	
			Unusual/unsettled weather / Ideal weather for traveling	- Cool summer / - unsettled weather (1981, 1983, 1993, 1995, 1996, 1999, 2002-2004, 2007, 2009)	* Blessed with good weather (1994, 2014) / + Hot summer in Honshu (1997)
	Sense of value/ Norm consciousness		Items		
		Tourists' Needs / Wants	Changes in preferences on destinations for domestic tourists		
Changes in preferences on destinations for inbound tourists				* Increase of inbound tourism from Asia (2002)	
	Diversification of tourists' sense of value	Creation of new-typed tourism		+ Film location site tourism (1999)	
		Development/ Rediscovery of tourism resources	+ Asahiyama Zoo with popularity (2007) / + Steam Locomotive services (1999)		
	Effect of Tourism Marketing Strategies	PR/ Campaign / Promotion / Branding for Hokkaido tourism		* Aomori Hokodate Destination Campaign (2016) / + Hokkaido tourism campaign (1994, 1995, 1999, 2012)	
Micro-Environment Factors					
	Micro-environment	Market environment of tourism industry (supply side)			
		Competitors, Distributors, Competing products	- Marine EXPO 75 in Okinawa	* The National Athletic Meet in Hamanasu (1988)	
	Inbound tourism environment	Micro-environment of Tourism market in Asia			

Figure 6 shows the trend regarding the number of visitors to Hokkaido by access mode. The figure indicates that the overall trend depends on the number of visitors who arrive via airlines. Furthermore, it is notable that the fluctuation in the number of airline visitors has dominated the trend during the last thirty years, which corresponds to the 1986 to 2016 period.

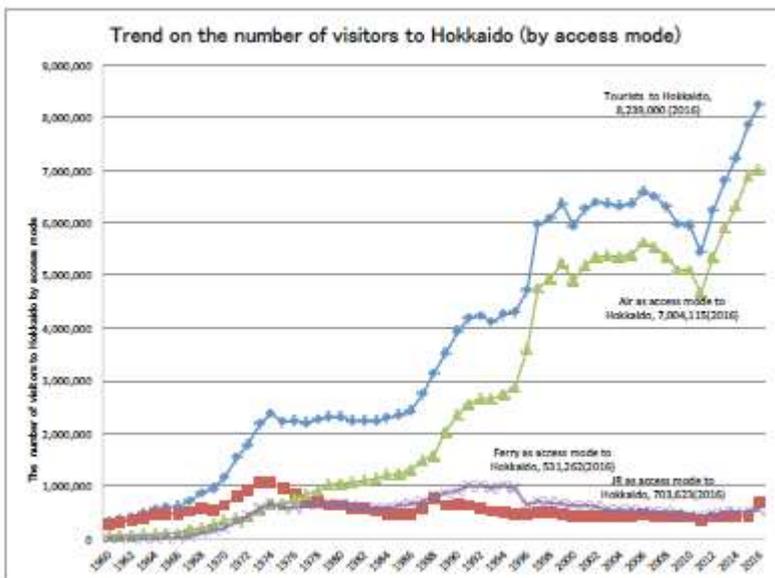

Figure 6 Trend regarding the number of visitors to Hokkaido (by access mode)

The trend regarding the number of visitors to Noboribetsu onsen-tourism destinations is introduced herein, with Figure 7 revealing the TALC in Noboribetsu compared with that in Hokkaido from 1960 to 2016.

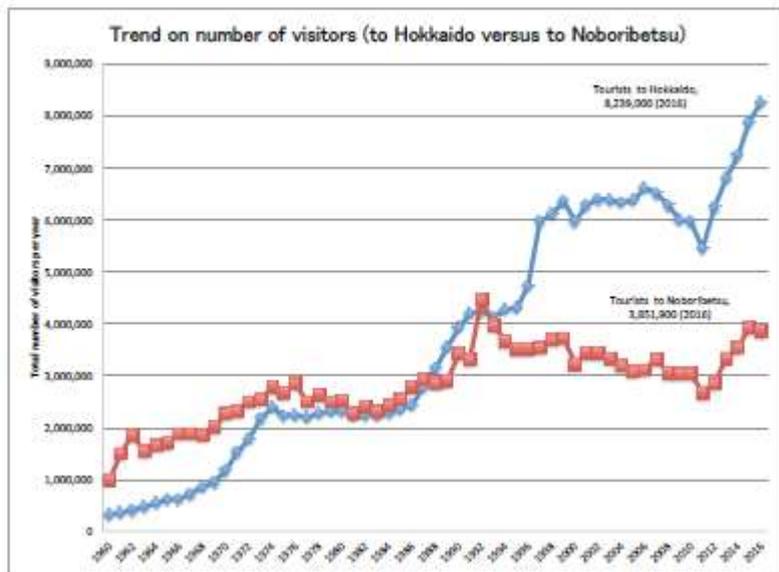

Figure7 Trend regarding the number of visitors to Hokkaido versus those to Noboribetsu)

This figure indicates that the TALC in Noboribetsu differs from that in Hokkaido. Considering that the Noboribetsu area is a traditional onsen tourism destination of Hokkaido with more than a one-hundred year history, the stage of consolidation started in the beginning of the 1960s, whereas the stagnation stage began in the mid-1970s. Thus, it is noted that before the mid-1980s, the number of visitors to Noboribetsu exceeded the number of visitors to Hokkaido.

Figure 8 reveals the trend regarding the number of tourists to Noboribetsu compared to those outside/inside of Hokkaido. With respect to the Noboribetsu tourism areas, the number of tourists from outside of Hokkaido was far below that of tourists from inside Hokkaido prior to 1971, even during the consolidation stage. After entering the stage of stagnation, however, there was only minimal fluctuation until 2011, albeit the drop in 2000, which was the result of the eruption of Mt. Usu in Hokkaido, is regarded as an exceptional year. Since the Higashi-Nippon earthquake in 2011, the number of visitors to Noboribetsu from both outside and inside Hokkaido has been smoothly increasing, although the number of visits to Noboribetsu from inside Hokkaido has fluctuated rather substantially.

As indicated in **Figure 9**, it is notable that the fluctuating pattern in Noboribetsu since 2012, i.e., after the Higashi-Nippon earthquake, is similar to that of other major onsen tourism destinations, such as Beppu in Oita and Atami in Shizuoka. These patterns are characterized by their unstable and undulating fluctuations.

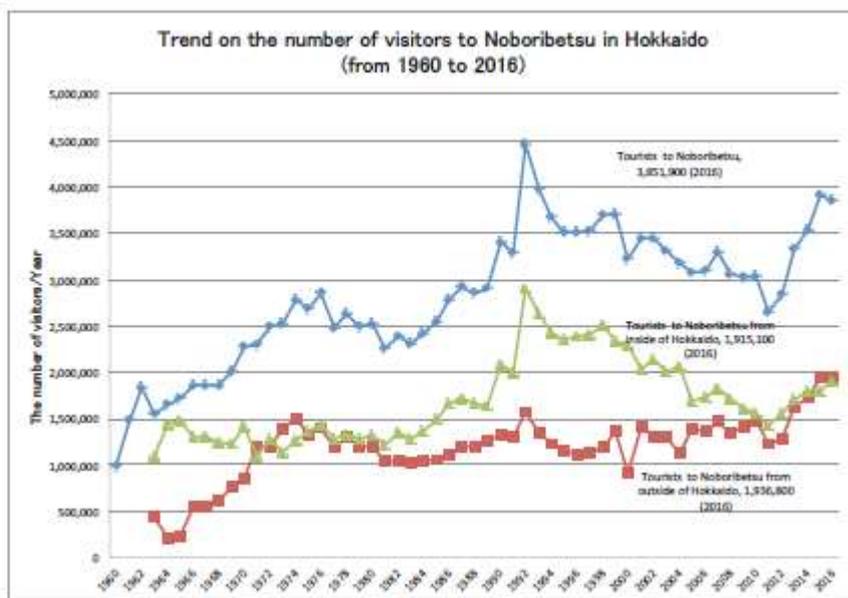

Figure 8 Trends regarding the number of visitors to Noboribetsu (from inside/outside of Hokkaido)

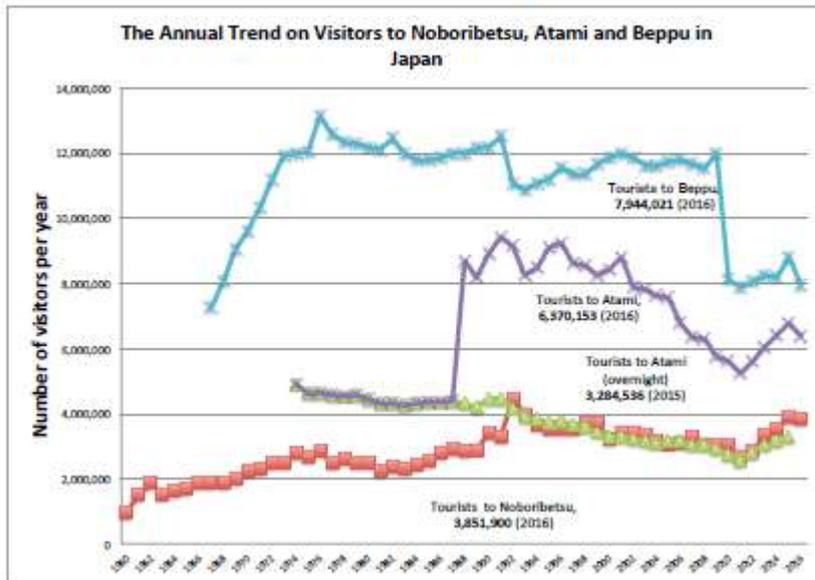

Figure 9 Comparison of the number of visitors to Noboribetsu, Atami and Beppu

DISCUSSION

This paper identifies basic issues regarding the managing of tourism destinations in relation to urban and regional planning from the perspective of the AMMA. After introducing the concept of area management in the AMMA, we identify two essential prerequisites for the area management in the ADIT. The first is to clarify the importance of the role of tourism destination planning with respect to the long-term management of the areas. This emphasizes that area management in the ADIT should be consistent with the long-term tourism destination planning. Accordingly, a comprehensive system of the process composed of long-term tourism planning, marketing and management that includes the continued monitoring and evaluating of the outcomes of tourism destination policies and measures must be developed. The second prerequisite is to explicitly consider the TALC in managing tourism destinations. It is assumed herein that the TALC significantly influences strategic destination management, which incorporates destination planning as well as destination marketing. The trend regarding the number of visitors to Noboribetsu in Hokkaido was empirically analyzed with a focus on the macro-environmental factors that determine various types of external events that occur over time.

Hence, it is evident that the challenges facing the Destination Management/Marketing Organization (DMO) in onsen-tourism destination based on the empirical results of the TALC in Noboribetsu are important. Especially, based on the results obtained from the TALC analyses, it is necessary to garner relevant information when discussing how to organize the DMO and when identifying the missions and roles of the DMO with respect to each of the stages of the TALC in Noboribetsu.

The factors that determine the trend regarding the number of visitors to Noboribetsu are confirmed, which is further defined under the condition that the spatial level is within the targeted areas. As presented in **Table 3**, the factors are divided into four categories, namely, those related to the environmental aspects of tourism destination, the core services, the supplementary services and the area management strategies.

Table 3 Factors determining the trend of the number of visitors to the onsen-tourism destination (Noboribetsu)

Spatial level	Environmental Factors / Categories / Items		
Within the targeted areas (Noboribetsu)	The Environment Factors Surrounding The Areas		
	New entry / Competitor in surrounding wellness tourism destinations		
	Partnership/ Cooperating with the surrounding wellness tourism destinations		
	Core services	Spa/Resort services	Spa/Resort service facilities (quantitative)
			Spa/Resort service facilities (qualitative)
	Supplementary services	Lodging services	Lodging service facilities (quantitative)
			Lodging service facilities (qualitative)
		Eating & drinking /Amusement services	Eating & drinking/Amusement service facilities (quantitative)

Area Management (by the DMOs)	Tourism destinations marketing	Promotion/ PR / Campaign/ Branding / marketing-mix strategies	
	Tourism destinations management	Sustainable area-development strategies	

The DMOs clearly play an important role in managing tourism destinations while also determining the fluctuating pattern during the stage of stagnation in the TALC.

Hori et al. (2016)19) conducted a comparative analysis of Beppu, Noboribetsu and Atami by focusing on how to cooperate and co-product among the local governments (city office), tourism-related organizations (tourism association, chamber of commerce and NPO) and private sectors (store/private business owner communities) and on how they have developed and promoted their activities in the DMOs in Noboribetsu.

Table 4 presents an overview of the DMOs in Noboribetsu as well as their activities during the last twenty years. The definition of a DMO in Noboribetsu is not the same as that of the DMO in general (defined by the UNWTO and the DCG (Morrison(2013)) because the DMOs in Noboribetsu are organizations created primarily by the Noboribetsu city office. These existing DMOs in Noboribetsu are characterized by an initiative in which the city can exercise leadership in the decision-making process as it relates to destination planning. The diversified situations in the reorientation period of the TALC in Noboribetsu, however, remain to be understood. Such diversification covers a broad range of situations from decline to stability to rejuvenation. That said, the outcomes from destination management strategies also vary from case to case depending on the circumstances specific to the targeted area(s).

Accordingly, one of the important challenges is to identify how these strategies can be combined to achieve effective rejuvenation in Noboribetsu. Hence, it is essential that the DMO expand into a broader-based organization that enables cooperation and collaboration with the surrounding areas and involves a variety of stakeholders in Noboribetsu. This requires the identification of the imagined future vision of the spatial spread of the onsen-tourism destinations as attractive area. As previously mentioned, the AMMA is expected to be beneficial given that the comprehensive framework has the capability of integrating the area-formation issue with that of the sustainable area-development.

Considering such a broad-based DMO, the development of tourism plans and policies is regarded as important. Mason (2016) 20) introduces Richie and Crouch (2003)'s view, 'it is an intellectual process that uses information to create macro-level decision making to develop the type of destination that is viewed as desirable.' It is evident that the Noboribetsu city office and the partners play major leadership roles in creating their own master plans and policies for the ADIT within each city-based

DMO. Following and consistent with the destination planning process, these DMOs have specific missions with respect to tourism destination management, as presented in **Figure 3**. Mason (2016) indicates, 'destination management is more of a micro-level process, in which all stakeholders carry out organizational activities, on a day-to-day basis, in a macro-level vision contained within the policy and planning.' In addition, when focusing on sustainable area development during the period of stagnation in the TALC in Noboribetsu, one of the challenges was to have the analytical ability to develop both the destination marketing and management policies necessary to shift the stage of the TALC toward rejuvenation.

Table 4 Overview of the DMOs in Noboribetsu and their activities (From 1995 to 2015)

Name(Type) of the DMOs	Year	Content	Outcome	
Noboribetsu Tourism Association	Since 1995	PR & Promotion for Ttourists from Eastsouth Asia	Increase of foreign tourists in 1996 and its acceleration	
Noboribetsu-Shiraioi Tourism Liaison Council	Established in 2002	These DMOs cover the broader tourism destinations to PR & Promotion for both domestic and international visitors to Hokkaido	The effect of PR & promotion strategies is effective for foreign tourists	
Noboribetsu-Toya Broad Tourism Areas Council	Established in 2009			
Meeting for Hokkaido Shinkansen xNittan Region Strategies	Established in 2013			
Noboribetsu city (Department of Tourism and Economy)	Settled in 1996	Noboribetsu Grand Design over 50 Years Ahead	As a comprehensive grand design for land use patterns, the area getting close to nature for green-tourism (forest therapy) & marine-tourism, Tourism & recreation area for convention tourism and natural resources area as eco-tourism	
	Settled in 2006	The second Master Plan in Noboribetsu 2006-2016		The numerical target of he number of visitors to Noboribetsu in 2016 was achieved: The target is 4.0 millions in 2016 from 3.2 millions in 2004 and the result in 2015 was 3.91 millions.
		•To differentiate the attractiveness of tourism with that in other tourism destinations • To bulid up the complex industrial bases resolving around the toursim industry		
Muroran Technology Center (owned by Noboribetsu, Muroran and Date cities)	Started in 2003	Projects for promoting new creation of manufacturing	Support for development of tourism-related products and improvement of package design	
Noboribetsu city (Department of Agriculture, Forest and Fishery)	Started in 2008	The improvement project of farm-stay typed recreation activities	The project originally intended to commercialize a dairy farmer experience. But, because of anxiety of foot-and-mouth disease, its purpose is to establish the sixth industrial sector.	

Noboribetsu Branding Promotion Council (Noboribetsu Commerce Group+Tourism Association+the Chamber of Commerce in Noboribetsu and the NPO in Noboribetsu)	Settled in 2009	Established the recommendation system of the Noboribetsu branded products and commercialization of local products	
Store-owners' Community in front of the Noboribetsu station	Started in 2010	Tourist Information Office called 'Oni-navigational station in Noboribetsu'	Tourist information guidance and Sales promotion of products from Hokkaido
NPO: MOMONGA-CLUB	Established in 2002 and Conversion into a corporation in 2005	•Operation of Nature Center Forest Mining • Projects for promoting the area-development •Support projects for nature-based tourism • Children care and human resources development	
Noboribetsu Active Guide Association B-NAG	Started in 2005	Nature tour as an eco-tourism	A trial of the autonomic coproduction typed management
The Local Economy Promotion Conference for Small and Medium-sized Companies	Settled in 2013	•How to live a self-sufficient life •The flow patterns of visitors to Noboribetsu •The returning of the profits of tourism industry to other industries	

Note: The DMOs and the contents are summarized by the author with referring to the description of Hori (2016)'s paper.

1446 CENTRALIZED VS DECENTRALIZED TOURISM POLICIES: A SPATIAL INTERACTION MODEL FRAMEWORK

ABSTRACT

The choice of centralizing tourism policies at the national level or, on the contrary, of decentralizing them at the local level is widely discussed in the literature, which highlights the related pros and cons. In fact, the simultaneous role of originator and attractor of tourism of each spatial unit may imply a range of complex and competing interests at various geographical scales. In particular, in a framework of regional competition, a central (national) policy may be necessary to offset or coordinate the clashing regional interests. We stress that more profound insights into the problems and challenges of (de)centralized tourism policies can be gained by examining the national-regional choice, and in particular by using as a modelling framework, the 'normative' spatial interaction model.

1318 CARTOGRAPHIC SOLUTION FOR PROMOTING MOUNTAIN TOURISM IN INDIA

ABSTRACT

The diversified topography alongwith mesmerizing beauty, mystery and serenity of mountain environment attract tourists to experience thrilling adventure, spiritual well being within natural and socio-cultural environment thereby generating 15-20% of annual global tourism. Mountains of India are of no exception which not only rejuvenating pleasure respite and relief from sultry tropical monsoon climate but also bloomed with adventure, spiritual and eco-tourism. Whatever the nature or destination, tourists need some guiding solutions to find out their point of interest, available infrastructure facilities, topographic information in an unfamiliar destination. Map is one such cartographic solutions that help the tourists as useful reference to explore the destinations with a proper overview encompassing an idea of the destination and its neighbourhood. NATMO, being a pioneer mapping organisation is continuously working in this field with the help of advanced technologies like high resolution images, GPS, GIS etc. and come up with several publications like Adventure tourism, Trekking and Tourism, Environment and Tourism - Northern India, Tourism Infrastructure-Northern India, Tourist Guide Book along with DPMS, GMS and tourist maps of different places which are of great demand among the tourists. In this paper two different Mountain environment in the Himalayan Mountain Region have been selected with a brief overview of two different tourists attractions. Sikkim, being a part of the North-Eastern hilly states of India lies in Eastern Himalaya and always attracts tourists for adventure and natural beauty. In 2016, total 740763 domestic tourists and 66012 foreign tourists visited Sikkim. Kedarnath in Uttarakhand State of India lies in the Western Himalaya region well known for pilgrimage or spiritual site. Every year nearly 3 lakh tourists visit this place for its spiritual and natural attraction. However the devastating flood of 2013 reduces the number of tourist to 40000 by 2014. Afterwards Government initiation like infrastructure facilities and introduction of helicopter services further increased the number of tourists to more than 3 lakhs by 2016. The new route via Rambara and Linchauli is now a major trek route to reach Kedarnath which will start from Gaurikund with a total length of 19 km. NATMO has prepared a new map showing new route to Kedarnath aligned with the Govt initiatives to bring back resilience in Mountain tourism as well as Uttarakhand State tourism. Key Words : Adventure Tourism, Pilgrimage Tourism, Sikkim and Kedarnath

1262 IS ICT IMPROVING ACCESS TO ACTIVITIES? A CASE STUDY OF MUMBAI, INDIA

ABSTRACT

Overall wellbeing and quality of life of individuals living in an urban area depends on the freedom they get to participate in society, by allocating time in different activities that fulfill both their production needs (activities such as work, education etc.) and consumption needs (activities such as shopping, leisure activities etc.). Institutional lack of access to opportunities created as a result of various social exclusion factors such as transport disadvantage, poor housing conditions, illiteracy, unemployment, and income poverty curbs this aforementioned freedom. However, the current rise in the use of information and communication technologies (ICT) among the urban populace has the potential to make a number of activities more accessible with minimum rise in cost. Keeping this trend in mind, this study aims to analyze the effects of ICT on social exclusion by investigating its impact on activity participation behaviour. A time use study was conducted in the city of Mumbai (Municipal Corporation of Greater Mumbai-MCGM area), collecting 1205 samples representative of Mumbai's social disparities. 46.6% of all the samples were from informal housing settlements (such as slums or chawls). Activity participation and time allocation behaviour of individuals were observed for two days (entire 24 hours) i.e. one weekday and one weekend day along with details on travel and ICT usage. The interrelationships between ICT usage and various socio-economic parameters, along with its impact on different activity types were tested using structural equation modelling (SEM). SEM are a set of simultaneous equations which are ideal for the objectives of this study as it combines factor analysis with regression and path analysis to provide confirmatory results. The SEM analysis aided in the testing of interrelationships between different factors (such as 'access to ICT', 'reduced mobility, 'physical access') and various socio-economic parameters (such as income poverty, poor housing conditions). It was observed that 'access to ICT' had a significant negative relationship with income poverty and physical access. Meanwhile, staying in informal housing settlements related positively with access to ICT. This finding substantiated the optimism surrounding ICT usage and its potential to cut across certain disparate segments. In addition, the effect of these factors were tested on activity participation behaviour. The effect of ICT was observed to be most prominent in case of leisure activities with significant substitution in leisure trips, whereas the effects were not significant in case of mandatory activities. The findings of this study indicate towards the physical space dependent nature of mandatory activities and the scope of improving access to leisure opportunities through ICT based policy interventions. Moreover, the study was helpful in identifying exclusion in different types of activities and how various segments of population have varying levels of exclusion. The same could be used for targeted and focused policy interventions.

SS11.4. The Future of Leisure: Tourism, Mobility and Transportation

1644 SPATIAL ACCESSIBILITY TO AIRPORTS IN TURKEY: EVALUATING THE CHANGES OVER TIME

ABSTRACT

There certainly is a relation between spatial accessibility and transportation infrastructure, so it is critical to investigate the changes in spatial accessibility caused by the changes in transport infrastructure (especially airports, highways, metro lines and high-speed railways) over time. How the policy changes in air transport and new airport investments effect spatial accessibility, and consequently travel behavior is the main drive for this study. The nature of air transportation in Turkey changed after 2001 with two important amendments. Firstly, the airlines were entitled to determine the ticket prices for domestic flights in 2001. Secondly, all obstacles for private airline companies were removed in 2003, and the domestic flight market has been completely liberalized. As a result of this, the number of air passengers and the rate of air transport passengers in interurban travel passengers dramatically increased. In addition, the number of active airports went up from 25 to 52 within twelve years. These developments brought the airport transportation into prominence, so accessibility to airports. The aim of this study is to investigate the changes in accessibility to airports between the years of 2000 and 2014 for each district in Turkey. Within this scope, firstly we will determine the boundaries and estimate the population of catchment areas of each airport in the years of 2000, 2007 and 2014 according to maximum covered travel time using ArcGIS Network Analyst program. Secondly we will reveal districts accessible from at least an airport within 30, 60 and 120 minutes travel time, and districts that inaccessible within two hours in the years of 2000,2007 and 2014. So, we will trace the effects of newly activated or built airports on the catchment areas of the other airports and accessibility to these airports. After that, we will estimate the regionalization index of each airport comparing the catchment area population with the number of domestic passengers by the years of 2000, 2007 and 2014. Finally, we will use a location-based method including gravity-based formula to measure the spatial accessibility of each district to the airports within the catchment area of two hours travel time. The main findings of the study give clues about the future policy directions. Despite the fact that last airport openings reduced maximum covered distance especially in the northeastern part of Turkey, and consequently have shrunk the catchment population of the airports, the regionalisation indexes of airports located in regional centers and hub cities increased because of increase in the number of air passengers in the given time period. Airports located nearby the main hubs could not achieve to increase air passengers and regionalisation indexes although some of them have big catchment populations. Airports located in sparsely populated areas have similarly low regionalisation indexes. This also affects the accessibility degrees of districts, which are in the catchment areas of these airports. As a conclusion, distance to main hubs and the total catchment population of airports have combined effects on the number of air passengers and accessibility degrees of districts in Turkey.

1355 HIGH-SPEED RAIL IN DEVELOPING COUNTRIES: WHICH USE IN TERMS OF TOURISM MOBILITY?

ABSTRACT

In January 2017, there were 37,343 km of high-speed lines (HSLs) in the world, with a further 15,884 km under construction; almost 36,000 km were planned worldwide for completion by 2050 (UIC, 2017). By favouring mobility, these lines are used to develop exchanges between cities and sometimes with other countries, in the case of transnational lines, and more broadly to foster economic development. It is the case in terms of tourism. But the potential indirect effects (or wider impacts) of high-speed rail (HSR) on tourism are difficult to assess and not automatic (Albalade et al., 2015, Bazin et Delaplace, 2013, Delaplace and Bazin, 2017 for a review). But this is an issue that needs to be re-examined, as 21st-century rail has so far been characterized by network extensions in developing or emerging countries (China, Turkey) and by projects in many others (India, Brazil, Morocco, Malaysia, Egypt, etc.). These high-speed lines take shape in very different socio-economic contexts from those of developed countries. Income inequalities are higher than they are in developed countries (World Bank, 2016). Indeed, as shown by Kuznets in 1955, during the take-off period, growth is highly unequal because only a small percentage of the population benefits from the growth of national income induced by this industrialization. Moreover, income inequalities are linked to spatial inequalities that increase with growth and development (Kim, 2009, Kanbur and Venables, 2005). What are the consequences in terms of tourism? Can the issue of potential increases in tourism mobility be addressed in the same way in both sets of countries? In developing countries in particular, two key issues are to know who is using these lines. Does everybody have access to high-speed rail in developing countries? Are its uses and clients the same as in developed countries in terms of tourism mobility? Is tourism equally developed in developing country as in developed countries, especially concerning domestic tourism? Do factors such as low income and greater inequalities, which characterize these developing countries, influence the way transport infrastructure is used for tourism mobility? The aim of this article is to show that in terms of tourism mobility high-speed rail could induce more inequalities in developing countries than in developed ones, not least because its uses differ spatially, economically and socially. This article suggests analysing a less-developed issue concerning the effects of high-speed rail, namely the issue of spatial, social and economic inequalities linked to high-speed lines. Our analysis will be illustrated by the cases of different countries and their willingness to develop tourism (Turkey, China) and some investigations concerning the future line in Morocco.

SS11.5. The Future of Leisure: Tourism, Mobility and Transportation

1285 PERCEPTION OF NATIVE JAPANESE TO PROMOTE HALAL FOOD BUSINESS IN JAPAN, A CASE STUDY ON KUSATSU CITY, SHIGA PREFECTURE

MD Arifur Rahman

Graduate School of Economics, Ritsumeikan University, Email: reach2arif99@gmail.com

ABSTRACT

Though the concept of Halal is generally concerned with the values of Muslim consumers, it has regarded a fast-growing brand over the world. Consequently, halal food business nowadays has immense potentiality in capturing non-Muslim as target market because of two distinctive reasons – safety and health aspects of halal foods and rapid acceptance of halal within the global population through the process of acculturation. Although perceptions of Muslim consumers are studied in a few research studies but there is shortfall of research works regarding perceptions of Japanese non-Muslims towards halal food retailing in countryside areas of Japan. Therefore, the main purpose of this study was to understand the views of Japanese consumers to promote halal food stuffs in Kusatsu city, Shiga prefecture. This research also focused on to know the challenges for retailing halal food products in this rural area of Japan. The data were collected from Japanese citizens of Kusatsu city of Shiga, Japan through interview survey. However, five key themes had been emerged after analyzing the contents of interview survey such as – knowledge about halal food, need of halal certification, quality of existing halal food, willingness to know about halal food and prospects of halal food. In addition, it was found that majority of respondents showed positive attitudes towards halal food products when they are asked about health benefits of halal foods. This study also identified considering halal as a religious custom is the main reason to show little interest of local consumers towards halal food. In addition, this research identified that the biggest challenge for willingness of local people to adapt with halal food in Japan is dearth of awareness and limited information on what is halal and how to prepare halal food. It was also found that description of products' ingredients only in Japanese language which is a key challenge for Muslim travelers in this area to find Muslim-friendly foods in retail shops. In this term, using international language beside local language can be a good solution for promoting Muslim-friendly foods in such countryside areas of Japan. Therefore, it can be conceived from the overall study that non-conventional strategy can be a suitable approach for food retailers in this rural area for promoting halal food stuffs among Muslim and non-Muslim consumers. For instances, food marketers can promote the health benefits of halal food stuffs for human being which can be called halal science and economic aspects of halal food retailing such as – contribution of halal food stuffs in local tourism value chain which can further play an immense role in the development of rural economy of Japan. In addition, this research keenly intends to propose halal food products as an alternative food for native Japanese which can further contribute to attract inbound tourist specially from middle east and international students from Muslim countries.

Key word: Halal Food, Halal accreditation, Value chain, Halal science

JEL Classification: L66, L83

1. INTRODUCTION

1.1: Background of the Study

Halal is an Arabic word which means permissible or lawful for human being. Though the concept of halal generally adopted by most of the food industries in Islamic countries, many of the food companies in non-Muslim countries have also adopted this in their business practices because of the elevated attribute of Halal concept (Haque, et. al., 2015). However, the halal has become the World's fastest growing brand mainly because of two reasons: first, Halal food is considered as cleaner, healthier and tastier (Alam and Sayuti, 2011); and second due to the tremendous acceptance of halal within the global population through the process of acculturation and assimilation (Ayyub, 2015).

Japan is still lagged the development of effective Halal food value chain comparing with other east Asian nations mainly because of its homogeneous ethnocentrism as an insular country (Eto, 2016). In this regard, Japanese food retailers should have a close eye on promoting halal food stuffs that can contribute in enriching halal tourism and attracting Muslim travelers in Japan. Nevertheless, the participation of Japanese companies in this sector is still very low compared to other global players because of some drawbacks, but the reasons behind these drawbacks are yet unrevealed which is the basic motivation of this research. This is a primary research which is aimed to expand step by step following different empirical approaches in the life-time career of author. Therefore, the fundamental objective of this study is to understand the views of native Japanese consumer to promote halal food products in countryside areas of Japan such as Kusatsu city of Shiga prefecture. Thus, the objective of this study can be met by answering following questions:

RQ1: what is the perception of Japanese consumers towards promoting halal food stuffs in Kusatsu, Shiga.

RQ2: what are the drawbacks for promoting halal food products in this countryside area of Japan?

1.2: Why is Japan

Important dietary changes have emerged over the World during last few decades. Besides, millions of Muslims are travelling and settling to non-Muslim industrialized countries in quest of labor or work and are living among communities with dissimilar dietary habits (Rahman 2014). The aforesaid global turns are also observed in one of economic superpower – Japan. Also, Japan is thriving towards the development of effective tourism value chain. Tourism sector of Japan has contributed 7.4% of total GDP in 2016. The performance of this sector can be enhanced sharply in the Japanese

economy by creating and adding more values. But the unique food culture of Japan is one of reasons to become unattractive destination for travelers including Muslims. In this regard, developing an effective halal food value chain might be a strong operative mean to increase the influx of visitors from foreign countries including Muslims. Sakurai (2003) cited that immigrants from neighboring country such as Korea, China, and the Philippines, along with those from Muslim countries such as Pakistan, Iran, and Bangladesh, came to Japan in considerable numbers in the 1980s. However, Japan represents a non-Muslim country with a significant Halal industry development (Adidaya, 2016), but the development of Halal food value chain is still lagged in Japan compared to other East Asian countries due to reluctance of Japanese society in religion.

1.3: Motivation of this Study

It is observed that recently halal food stuffs are available in some shopping malls of Kusatsu city which is unusual comparing with other rural areas of Japan. Also, Kusatsu International Friendship Association (KIFA), a sister concern of Kusatsu City Government Office, has included halal foods in its international cultural exchange programs. Consequently, such movements of food retailers to promote halal food products locally and initiative of local government of Kusatsu city have created awareness among ordinary citizens about halal foods and some of them are keenly interested to know more about halal. For this reason, this research is aimed to understand the perceptions of native Japanese to promote halal foods more extensively in this rural area which can work as the guideline for local food retailers for their regional strategic plan.

2: HALAL FOOD BUSINESS IN JAPAN

Japan represents a non-Muslim country with a significant Halal industry development (Adidaya, 2016). Now there are 97 Halal shops throughout 31 out of 48 prefectures in Japan where only 66 shops are recorded by Islamic Center Japan and author took help from some halal shopkeepers in Tokyo for counting rest of shops whereas this number was only 55 throughout 27 out of 48 prefectures in 2014 (Yusof and Shutto, 2014). It is also indicated in the website of Islamic Center Japan that 64 halal restaurants and 9 halal certified organizations are working over the country. But compared to other East Asian countries, Japan is late in addressing the Halal market due to less interest in religion in Japanese society (Halal Challenge Project, 2013). Muslim often find it is difficult to travel or line in Japan while keeping their belief and consuming only Halal foods, though Muslims represents only 0.18 percent of the Japanese total population (Adidaya, 2016). In this regard, Japan Food Industry Center (2009) pointed out that Halal is a sensitive issue as it is associated with religion. In addition, Japan and Islam are not closely related compared to other religions such as Buddhism and Christianity. Japanese may see Halal as part of Islamic requirements; hence it becomes too complex to be associated with. It is perhaps complexities and sensitivity in Islamic rules that have been shying the Japanese food companies away from venturing into this sector. Besides, the concept of Halal does not apply only to the product and process, but also throughout the firm's value chain. This will require a major overhaul for the firm to coordinate, standardize and control its value chain. On the contrary, countries of high certainty avoidance cultures such as Japan tend to avoid risk and ambiguity and prefer incremental innovations, where each step is small and ambiguity is more easily kept under control (Hofstede, 2001).

However, a consumer survey results suggested that most Japanese consumers have not heard about Halal and are not interested in learning about Halal (Shazlinda, 2008). But it is reality that nowadays concept of halal food is mushrooming in Japan. Halal is becoming a new trending topic, and it covers not only food and drinks but is more widely applied to other aspects such as tourism, pharmaceuticals and cosmetics. Therefore, it is very promising that Japan will be able to create effective value chain of halal food since local government, academicians and other stakeholders of Japan are working relentlessly to conceptualize the importance of the development of halal food value chain which can play further prospective role to build competitive advantage of Japanese tourism business.

3. METHODOLOGY

A qualitative method, i.e. interview survey was used to achieve the objectives of this study. This research mainly focused on primary data that had been collected through a semi-structured questionnaire. All the items in the questionnaire primarily focused on understanding the perception of Japanese consumers towards halal foodstuffs in Kusatsu city of Shiga, Japan. Kusatsu city is selected as study area for this research since halal food is increasing more and more in the local shopping malls and native Japanese of this area is becoming interested to hunt knowledge about halal. Data was collected from the ordinary Japanese shoppers. In this perspective, evening time was selected to reach customers easily since most of Japanese shoppers visit shopping malls after their official work. For this study 25 native Japanese shoppers were interviewed randomly who belonged to the resident of Kusatsu city. Finally, contents of interview were coded, categorized and summerized. Authors conducted interview in two sessions where in first session authors represent religious view of halal food products which results were quite general and similar with some previous studies such as findings of Ayyub (2015). On the other hand, focusing on health and economic view of halal food stuffs produced different results from similar research studies.

4. RESULTS AND ANALYSIS

Five key themes were emerged after abstracting the feedback of informants such as knowledge about halal food, importance of halal certification, quality of existing halal food, willingness to know about halal food and prospects of halal food in local vicinity of Kusatsu. Hereafter, some essential variables are categorized under emerged themes to propose recommendations for food traders in this area of Japan. The outcomes of systematic analysis of field survey data are briefly discussed one by one as follows.

4.1: knowledge about halal food

There were number of observations provided by the respondents that could exhibit their thought-provoking perceptions regarding Halal foods. It is found that most of the respondents (n= 31) are familiar with the taste of halal food and they have positive approach about halal food stuffs though they don't have literal knowledge about Halal which is very common as non-Muslim.

For instance, Kimiko, one of Japanese housewives, responded about the "taste" of halal foods:

"I don't know what is halal and recently I have been familiar with the concept of halal. The taste of foods which I consumed before was delicious and I want to eat it again. However, I think Halal food is spicy and sometime sweet."

Rie mentioned that *"I only know the name of halal. I didn't have opportunity to consume halal dishes. However, I taste some snacks with halal logo from Lamu (a local shopping Mall) which does not give me different experience from non-Halal snacks, but the taste was good."*

Takaba, an employee of a private organization, talked about "availability" of halal foods in locality - *"I have some knowledge about halal and I often visit some shops near me where halal food products are sold. Taste of halal is little different from non-Halal foods since it comes from different culture. However, availability of halal foods in Japan can ensure perfectness for Muslims residents and it can attract more tourists for enjoy sightseeing in Japan."*

It can be said from aforesaid opinions that majority of respondents are unaware about the term "Halal" which is quite general, but this countryside Japanese citizens have complete positive impression about taste of halal food. In addition, most of respondents perceive halal food promotion in this rural area as an effective tool for attracting Muslim travelers. Indeed, optimism of local respondents towards developing halal food value chain is an obvious indication of cultural diversity in such a countryside area of Japan.

4.2: Awareness about quality of existing halal food

Halal food is recognized as a global brand for its distinct quality and safety in modern business era. In this regard, Said et. al., (2014) cited that halal food stuffs certainly confirm the protection of human beings and any foods or drinks which may cause harm to the human body and health is forbidden even if there is no prohibiting legal evidence. Consumers now are seriously conscious in their food selection and physical health concerns. Many studies (Sawari, et al., 2015; Azeez, 2013; Techathuvanan, et. al., 2010; Ayyub, 2015) worked on quality of Halal foods and health concerns of consumers. It is noticed from this study that most of respondents (n = 33) are intensely concern about food quality though they could not distinguish the quality of halal food and non-halal food thoroughly whereas few consumers (n=6) consumers gave references that they are well informed about the quality of halal food and they are interested to see halal Japanese foods in future.

Hidetomo mentioned about "freshness and cleanliness" of halal foods:

".... I am not informed about the cleanliness of Halal meat or other Halal foods. Even I am not aware about the health impacts of pork or alcohol and I don't want to be concerned about it since I don't have any allergy regarding those foods. But, I don't think Halal food is really healthier than conventional food."

Takahiro commented on "attribute" of halal meat which is *"..... no, I don't know about the quality of halal food and even halal meat. But I have heard that halal meat does not contain any blood and it is more fresher and cleaner. I am interested to know more about it. If I found the truth about its superiority regarding quality, it is also better for me to live healthier."*

Michihito, described the "shelve life" of halal foods as follows

"I have little experience about halal food and the quality of it since I attended in some halal programs in Kyoto and Osaka apart from Kusatsu city. I am aware about the cleanliness and safety issue of halal food and meat which can be preserved for long time than conventional meat. Also, I don't want to think about the negative impact of non-Halal meats, specially-pork and alcohol, because sometimes it gives me amazing taste. In a word, I don't want to miss it, but surely I will taste halal food."

However, Daichi explained his observation the "usefulness" of halal food for human body in the following way:

"I was first inspired by one of my Muslim friend to eat halal foods and noticed very good taste of those foods. After that I was self-motivated to know more about halal culture and read some articles about it. Now, I do believe it is not a matter of religious activity. But acute halal food is good for sound health since it is scientifically proved that actual halal foods don't contain any harmful ingredients of human body."

So, it can be summarized from the field study that many respondents (n=15) have knowledge about the quality of halal foods and meat though they are non-Muslim. It is also noticed that most of respondents are interested to know more about the quality of halal and they want to learn the scientific approach of halal meat though the comprehensive reasons behind their interest is unrevealed. On the other hand, few informants have very good concept about the quality of Halal food. Some previous studies also support that non-Muslim consumers are also aware about the quality of halal foods, for example – research conducted on halal food in UK context by Ayyub (2015).

4.3: Willingness to know about halal food

The process of adaptability with new culture is simply called acculturation. More specifically, acculturation is the process of one cultural group adopting the beliefs and behaviors of another group. However, Wibowo and Ahmed (2016) traced

acculturations as one of the key factors to emerge halal food value chain among non-Muslim consumers. As a result, acculturation of halal food among different cultures increases the acceptability of halal food stuffs among non-Muslims (Ayyub, 2015) which ultimately can work as a by-product of halal tourism value chain. So, this study also intends to understand the willingness of Japanese people towards acceptability of halal food stuffs in rural area. The following responses are evident about how Japanese non-Muslims are being acculturated with halal-culture successively.

Nakano commented on “availability” of halal food in his neighborhood as *“Halal foods are rarely found in my area. But I have experience to taste it which gave me the taste of different culture. However, if I got chance in future I want to have more experience of Muslim foods and also want to refer my friends to introduce with this food culture.”*

Minoru reacted about “the religious” aspect of halal food as follows – *“I don’t have idea about halal. But, I do believe consumption of halal food is perfectly the reflection of Muslim culture which I don’t like and I don’t want to recommend any of my friends about it. However, if halal food contributes in our economy, then necessary agents can think to promote this culture.”*

Mariko is a community leader who work and deal with foreign people also replied about “availability” of halal foods in local market from her own career experiences as *“Food stuffs in Muslim family and restaurants are spicy which is quite different from Japanese food. But as I have heard many Japanese foods also can be in the form of Halal food which is an utmost prospective mean to have a new trend of our economic development. I had opportunity to enjoy halal foods several times and in my sense ... foods were delicious though some were not. So, I think number of Halal restaurants in our locality must be extended for the convenience of Muslim travelers. However, I want to recommend halal food products not only my friends but also local government to create an effective chain for halal food business.”*

It was evident from the aforesaid responses that most of the informants are familiar with halal culture and they are immensely cordial to welcome halal culture in their vicinity. In addition, ongoing acculturation process of halal foods in this countryside locality can be a strong driving force for acceptability of halal culture among Japanese consumers in near future. However, effective and timeous campaign about ongoing acculturation process towards halal foods can increase the awareness about halal food stuffs among non-Muslims and sufficient awareness about halal concept can encourage local food retailers of Kusatsu city to develop effective value chain of halal food.

4.4. Importance of halal certification

Halal accreditation is necessarily required for manufacturers to satisfy the need of customers and authentic halal certification in this regard contains paramount value for customers. Author noticed from the local shopping malls and online halal shops, as a regular halal product consumer, that Japan has different halal certification bodies whose standards differ from one to another. In this context, Elsrag (2016) pointed out that there is ongoing confusion about halal standards because of different national and international halal accreditation bodies over the world and the majority of halal food is being produced in non-Muslim majority countries and these foods are certified by independent halal certification bodies that operate with little regulatory oversight. Therefore, halal certification is one of prime challenges towards the trustworthiness of brand loyalty of halal. However, this issue had been brought up by the following responses.

Kyoko, a staff of Japan post office, mentioned about “diverse logo” of existing halal foods as *“I don’t have knowledge about Halal certification. uuuummm.... I saw many products with halal logo but logos are different which is bit confusing to me. I don’t know whether these products have different taste or different standards. [...] want to taste one by one.”*

Junko commented on “halal accreditation body” of a neighboring city as follows *“I have heard about one Halal authorization body in Kyoto though I don’t have detail idea about functions of this body..... perfect adjustments and standardization need to be made for acute accreditation process.”*

Minako, staff of a shopping mall, responded about “halal brand” as *“Halal is a less promoted brand in this local area. In our shop, many halal products are from Brazil and some are from Malaysia and local manufacturers. But we see halal logo is different even in term of a specific country. So, it seems diverse quality of halal brand.”*

However, it can be concluded from the above responses that the local consumers are conscious about reliable halal accreditation body which should be trusted by both Muslim and non-Muslim consumer. In addition, proper and timely initiatives from government can ensure the reliability of halal certification which can be an effective tool for keeping confidence and trust of consumers towards local halal food stuffs.

4.5. Prospects of halal foods in local market of Kusatsu

Halal culture is not a new phenomenon in Japan though the concept of halal is booming gradually over the country (Yusof and Shutto, 2014). However, Adidaya (2016) mentioned that Japan represents a non-Muslim country with a significant halal industry development, but the development of halal food value chain is still lagged in Japan compared to other East Asian countries due to reluctance of Japanese society in religion. In this study, most of the respondents were optimistic to see the halal boom in this local area of Japan for the sake of developing competitive tourism industry and creating advantageous environment for immigrants. Explanation of some respondents are given below.

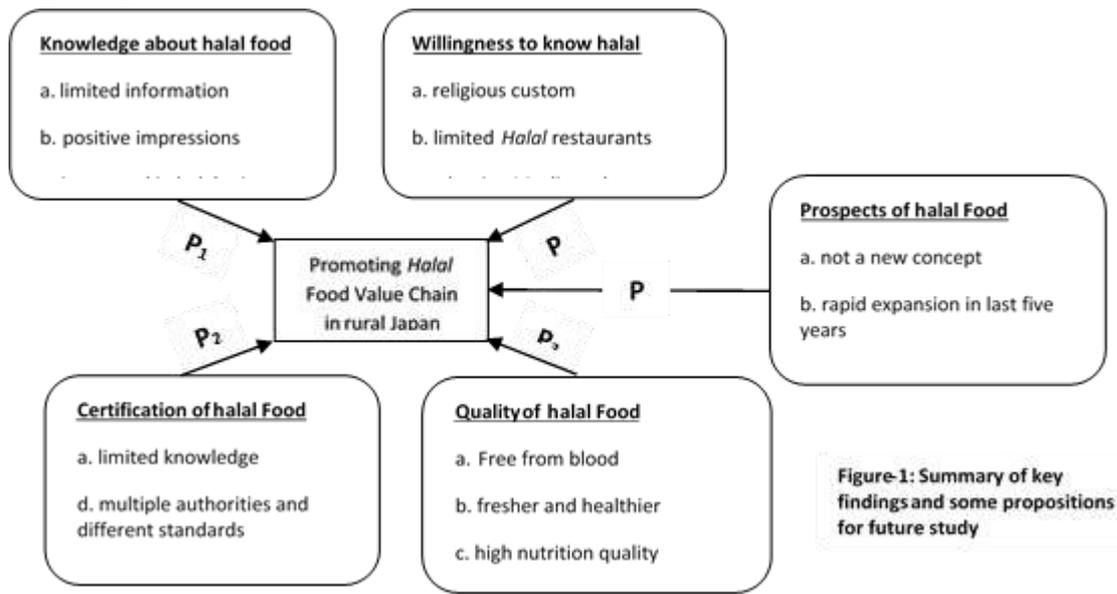

Sugimachi, staff of KIFA, mentioned the “economic” prospects of local halal foods as *“May be.... Japan has prospects to develop halal food business. It would be auspicious for local economy if the purpose to attract tourists from Islamic countries, but for Japanese consumes it would not be suitable.”*

Kimiko, housewife, explained that *“I cannot figure out the future of halal business in Japan since I cannot conceptualize the real purpose and benefit of halal food business in Japan. As far I know it is useful for Muslim residents... that’s it*”

Murakami opined about the prospective contribution of halal foods in *“local tourism”* as follows *“I hope developing effective chain for halal food can be useful for tourists in Japan including Muslims. But I think Muslims and Japanese have different concept about food safety and standard. So, this contradiction about purification and cleanliness among Japanese and Muslim people can be a threat for developing effective value for Halal food in Japan.”*

Therefore, it was found from the field survey that majority of respondents are in favor of developing halal food chain in the selected rural area of Japan and local people is interested to be aware about both upstream and downstream perspectives of halal food supply chain. And, effective halal food chain in such a country side area can be a long-awaited phenomenon for travelers in Japan.

The following framework represents the key findings after abstracting the key themes of this study which can be empirically examined in future:

5. CONCLUSION AND IMPLICATIONS

It is noticed during field survey that when authors represent religious view of halal foods, then respondents did not show much interest on halal food which is very general aspect as non-Muslim consumer. However, respondents felt fascination to participate in halal discussion when authors focus on health and economic view of halal food stuffs. This study revealed some essential results in perspective of its predefined objectives. However, this research uncovered five emerging themes which influencing the perceptions of Japanese non-Muslims towards promoting halal foods in the local market of Kusatsu city such as knowledge about halal food, importance of halal certification, awareness about the quality of existing halal food, willingness to know halal and prospects of halal food in local market of Kusatsu. In this regard, first, this study identified that Japanese consumers still cannot make decision about consumption of halal food because of limited information and reluctance to know about halal as a religious aspect. Proper awareness programs about halal food can remove the negativity about halal foods. Thus, knowledge of halal directly affects the purchasing decision of Japanese non-Muslims in this rural area of Japan which is consistent with the findings of Aziz and Chok (2013). Second, it is found that native Japanese consumers in this area are highly conscious about the quality of food products but they cannot make difference between the quality of halal food stuffs and Japanese traditional foods since the term *‘Halal’* is less promoted and ordinarily popular among local people which is relevant with the findings of Adidaya (2016). But, it is evident that halal foods are fresher and healthier than non-halal foods (Verbeke et al., 2013). However, it is revealed from the field study that halal restaurant of Kusatsu and online shops of halal food in Japan is keeping non-halal foods and beverage in restaurant and uncertified halal foods in online halal shops which is completely contradictory with the standard of acute concept of halal. It is also found that there is no unique halal certified foods in local shopping malls and most halal products are imported from Brazil, Malaysia, Thailand and local food manufactured which is the indication of quality variation. Consequently, this situation is creating confusion among both Muslim and non-Muslim consumers in Japan.

However, it can be conceptualized from this study that non-conventional strategy can be best method for food retailers in this rural area to attract both Muslim and non-Muslim consumers towards halal food stuffs. For instances, food marketers can promote the health benefits of halal food stuffs for human being which can be called halal science and economic aspects of halal food retailing such as – contribution of halal food stuffs in local tourism value chain which can further play an immense role in the development of rural economy of Japan. In addition, local food promoters can try to apply the concept of halal in Japanese traditional foods such as Ramen, Sushi, Miso soup etc. with special savory taste of Japan like – umami (Gabriel et. al., 2018 and Kawai et al., 2012). Furthermore, local food retailers can produce Muslim – friendly foods and every food stuffs also should have English version of food ingredients beside Japanese version since creating unique halal certification body in Japan is one of major challenges for promoting halal food stuffs domestically

and internationally which creates always confusion about the authenticity of halal. Therefore, continuous study on value chain analysis of halal food business can be an effective tool for local food marketers to create competitive advantages for prevailed halal food stuffs and for onward development of halal food value chain in Kusatsu city of Japan.

6. LIMITATIONS AND FURTHER STUDY

This is a primary research study on promoting halal food business in a rural area of Japan and outcomes of this study is one of life-time career goals of author. As a result, further research is essentially needed for its gradual expansion which can be implemented by empirical tests of five emerged themes and their contribution on creating competitive halal food value chain in such a rural area of Japan. Due to time constraints, research had to follow nonprobability sampling and only managed small samples for in-depth interview. Further research can be expanded following an effective tool of probability sampling and covering a large sample size. Also, this research is confined within the responses of native Japanese consumers in a rural area of Japan. But, further research can include immigrant non-Muslims in Japan beside native Japanese to avoid biasness which can further produce more attracting and interesting results for learners in value chain analysis of halal food business.

1030 GASTRONOMY: WOULD IT BE A LOCAL ECONOMIC DEVELOPMENT TOOL IN TURKEY?

ABSTRACT

Gastronomy has gained distinctive attention as a tourist destination, and it has become one of the substantial parts of the tourism. Local authorities benefit from gastronomy as a tourism development tool to energise the local economy. Gastronomy enables cities and regions to increase their competitive economic edge, and it represents significant opportunities for cities and regions to expand economic growth and job creation as well as being essential to reduce economic imbalances among regions. The policies on gastronomy tourism should not be considered as isolation from geographical indication as there is a vivid relationship between geographical indications and gastronomy tourism. Today, Turkey has more than one hundred geographical indications in products and hosts many national/international food festivals. So far, there is no any gastronomy tourism strategy that prompts the potential. Although Turkey has an excellent gastronomy culture, it is unable to convert its potential into opportunity. There may be various reasons behind Turkey's failure to exploit gastronomy tourism as a development means. The most prominent of these is that there is no organisation structure, which would bring related stakeholders around one table, lack or insufficiency of regional and national strategies as well as promotions. This situation sabotages the ability to use the resources efficiently. This study is aimed to draw a roadmap basing on Turkey's inefficacy to utilize gastronomy as a local economic development tool. Accordingly, interviews with institutions, development agencies, municipalities, chefs, culinary schools, and researchers, the ministry of culture and tourism and researchers that have relation with the topic are conducted. The primary advantage regarding gastronomy is the fact that Turkey hosts a wide range of products and techniques thanks to its multicultural background. Both the differences between regions and the authenticity of local cuisines demonstrate that this potential persists. Besides, the existence of over 100 geographical indications proves to be an additional potential for the culinary culture. It is also a major weakness is the common perception that gastronomy tourism is only about "dining". In order to reduce regional disparities in Turkey and to ensure economic sustainability, it is necessary to improve projects and set targets in gastronomy tourism, and to implement these projects and targets effectively.

1326 FOOD SUPPLY NETWORK IN A TOURISM REGION

ABSTRACT

As one of the leading service sector many developing countries take advantage of the economic gains of tourism, make efforts for the development of the sector. Apart from the direct economic contributions through wages, tourism positively affects the local and regional economy through the demand on other sectors. Supply networks which is mentioned as backward linkages in literature, are studied within the scope of secondary economic effects. Accordingly, tourism facilities demand products and services in order to maintain their core services, thus they create economic opportunities for suppliers. The local involvement in tourism sector is explained by supply relations between tourism and local entrepreneurs which provide various goods and services to tourism facilities. Furthermore it is also observed positive effects on human capital with factors such as the development of entrepreneurship, the acquisition of knowledge and experience, the development of institutional relations and the increase of trust between actors. The supply network of products and services is created by backward linkages within the cluster, whereas many tourism clusters have strong linkages with related sectors such as agriculture and textile. Hospitality firms are the main actors of tourism clusters, which demand products and services and creates economic opportunities for supplier firms, both in and outside of the region. In this context, the costs of products and services in hospitality sector are highest in food and beverage departments, so the analysis of the supply network of the hotels can provide critical findings in terms of regional relations. Aim of this study is to identify the fresh fruit and vegetables supply network of tourism and to explore the effects on the agricultural sector through their supplier relations in the scope of secondary economic impacts. Research questions are as follows: Who are the actors in the tourism-agriculture linkages and what kind of network occurs in terms of geographical extension? What are the effects of tourism on the supplier firms? A cluster of tourism and agricultural linkages that formed by fresh fruits and vegetables distribution is identified and the effects of hospitality sector on the development of agricultural distributors (middleman) is discussed within the framework of local development literature. Moreover, the geographical distribution of agricultural suppliers would provide to explore spatial dimension of networks. The research is conducted in Alanya, which is one of the most important destinations of Turkey, owing to its natural attraction, accommodation capacity and long season period. Data is collected through semi-structured interviews with the suppliers and middleman of fresh fruit and vegetables. 47 out of 63 firms participated in the study. Mixed method is applied for in-depth understanding of the tourism-agricultural linkages. Effects of tourism on agricultural sector is analyzed by non-parametric tests and elaborated with the interviews. Results show that hotels are important customers for supplier firm or middleman of fresh fruit and vegetables, and tourism generates strong linkages and enhances the supply of agricultural production within and outside of tourism region.

1498 RELIGIOUS PROXIMITY AS A FACTOR FOR OUTBOUND TOURIST CHOICE DESTINATION

ABSTRACT

This paper engages with religion, as a classical measure of culture, and its impact on tourist choice destination. The first objective of the paper is to test whether religious distance outperforms alternative types of cultural and geographical proximity in determining the short term movement of people in a gravity model. At a next step, our second objective is to cross-check how this relationship between tourist flows and religion relates to flows in migration and trade. On one side, we want to examine how religious distance affects economic growth in the Balassa-Samuelson setting of difference in prices across countries. On the other side, we want to see how religious gravity predicts the longer-term movement of people towards countries. To perform our research, we collected a unique dataset for the period 1995 – 2015 for all countries in the world, available from the United Nations World Tourist Organization and World Development Indicators from the World Bank. To quantify religious distance, we employ a specialized index, elaborated by Dow et al. (2016). We use panel data methods and Granger causality test to triangulate the analysis on the direction of the examined effects. In this process, we check if tourism is a channel for cultural (religious) distance effect on migration and trade flows. The implications from our research come to highlight that the warning posed by both Balassa and Samuelson that tourism is a major source of price differences across countries holds today in the framework of increased movement of people. And in both processes, religious distance might be a major and classical but so far neglected factor in understanding tourist destination choice with importance for other economic effects.

SS12.1. Transforming Metropolitan Regions: Ideas and Examples

1306 TRANS-SCALAR AND MULTI-DIMENSIONAL APPROACHES IN URBAN PROJECTS: AN OVERVIEW FROM LISBON METROPOLITAN AREA

ABSTRACT

Particularly after Expo 98 large scale urban regeneration project, in which a former industrial area gave way not only for the 1998 world exhibition, but also to a new lively mixed-use urban district at Lisbon’s waterfront, new expectations arose regarding public space quality, establishing a new benchmark level. Resorting to various follow- up urban and environmental regeneration programmes, mostly funded by European Union, other Portuguese cities developed various projects aimed at improving urban environment and mobility. A selection of such projects in Lisbon’s Metropolitan Area (LMA) is to be presented in the paper, highlighting their role in driving a trans-scalar and multi-dimensional rationale within a clear metropolitan framework. Since 1998, a stage of transition in Lisbon’s metropolitan infrastructural strata can be acknowledged. After considerable efforts in delivering large scale motorway, railway and transit/subway systems, a new generation of urban projects is helping introduce a softer realm of public space and urban amenities in both central districts and peripheral areas. This stage resulted in the layering of what can be called a connective fabric (Santos, 2012). This fabric is established through: 1) the trans-scalar recombination of various mobility, supply and communications networks; 2) the development of well- connected patches of urban development bridging or regenerating spatial and functional gaps in the metropolitan fabric; and 3) the introduction of landscape and intermodal interfacialities in nodal spaces. Municipalities are the key players in setting up programs targeted at urban heritage districts, environmental qualification and promotion of soft mobility. Some address mostly spatial quality issues, other include economic regeneration goals, others relate both existing and new streets as part of a complex urban reconfiguration process. The paper outlines a selection of recent urban projects in LMA, identifying and discussing a number of criteria related to trans-scalar and multidimensional approaches. Preliminary results point out to common trends, shared by the various projects, which can be the basis for further discussion and comparison with international cases, namely: - a diversification of locational criteria, acknowledging the need to provide spatial quality in more recently developed territories; - the laying of coherent linear spaces, either through metropolitan roads or blue and green corridors and their intertwined combination; - the reconfiguration of arterial circulation systems at various scales, including publictransport nodes and road re-networking; - the development of increasingly compatible and shared spaces between pedestrians and cars; - a predominant strategy to concentrate public resources mostly on public space and public facilities, acting as a driver of subsequent private-led investment.

1290 AN INVESTIGATION TO DETERMINE THE IMPACT OF THE REGULATORY FRAMEWORK ON THE SUPPLY OF THE AFFORDABLE HOUSING IN PUNE CITY*Chinmay Satbhai***ABSTRACT**

The supply of affordable housing (AH) is influenced by the existing regulatory framework. Planning regulations seldom impose costs on the housing, decreasing its affordability to the majority of the populace, particularly in developing country like India. As AH shortage continues to grows, there exists a greater need to investigate the impact of various regulations on its supply. Regulatory framework includes the urban land planning regulations (land use distributions and zoning, land subdivision, etc.) and the building and site planning regulations (FSI, ground coverage, height restrictions, minimum parking and open space stipulations, etc.), as well as, which act together impacting the optimum use of the urban land leading to consequences on the housing supply. The study develops a two level spatial analysis methodology to investigate the impacts of regulations on the AH supply and to determine the critical factors which have cost embellishments on the overall housing price. In the macro level, a neighborhood in Pune is analyzed for the regulatory impacts on AH supply, while the impact on the cost and the quantity of AH is investigated, in the micro level analysis, by analyzing the AH situation in Pune. As a part of micro level analysis, the comparative scenario analysis is performed by generating two alternative layouts for the same site - one with the existing regulations and another by proposing modifications in the regulations. The study demonstrates that the cost of AH dwelling unit can be reduced by 26.17% and the overall supply of AH could be increased by 79.15%, if the regulatory framework is revised based on the insights from the study. It is suggested that the regulations must be critically scrutinized for their appropriateness in the local contexts of individual cities. The empirical evidence provided by such studies, aspire to be instrumental in paving way for the timely regulatory reforms, creating enabling environment for an increased AH supply in our cities.

Keywords – Affordable housing shortage, regulations, multi-level spatial analysis

1 INTRODUCTION

Provision of shelter and security, in the form of housing, has always been the objective of any civilized society. Adequate provision of housing is directly linked to the economic and social development in the country. Strong forward and backward linkages across more than 250 ancillary industries have been associated with the housing sector in India (National Housing Bank 2014). Reports suggest housing and real estate sectors being second largest employment generation in India. In spite of studies establishing the importance of the provision of housing, many developing economies (incl. India) struggle to fulfill this task. The urban housing scenario in India is characterized by a large number of low-income group populations who correspondingly have low levels of housing affordability (the EMI usually considered as not more than 30% to 40% of monthly income). Contrastingly, this large segment of the society is catered minimally by the formal housing market creating a large deficit of affordable housing (AH) for lower income populations. Multiple factors play a crucial part in the situation, but many studies agree on the role of regulatory framework influencing the supply of AH (Kim 2010). The study provides evidence of the extent of the impact of the regulations on the supply of AH in Pune. The paper starts by discussing the AH scenario in India, followed by brief discussions on the regulatory constraints in its provision in section one. The second section discusses the selection of the case of Pune city followed by the third section providing a brief review of the past studies in this domain. The fourth section discusses the research methodology adopted and the performed multi-level spatial analysis is discussed in the fifth section. The sixth and the final section concludes discussing the suggestions to improve AH supply in Indian cities.

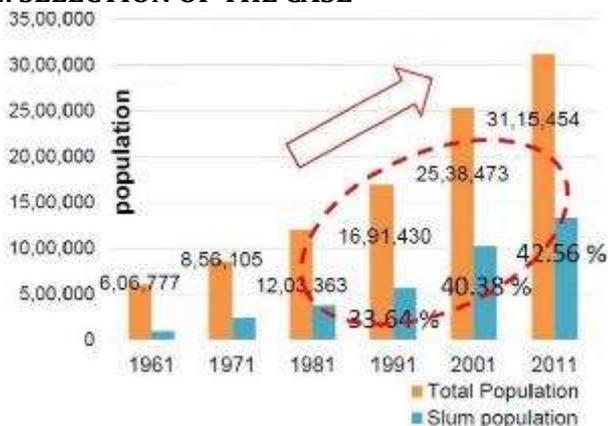

1.1 AH Scenario in India

The rise of the urban population has been unprecedented and we have more than half of the world population living in the urban areas (United Nations 2014). The scenario in India has also witnessed a huge population growth and transformation with regard to rural to urban population in the past couple of decades. The country today is poised at 31.16% and 68.84% with regards to its 1.21 billion population distributed in urban and rural areas respectively (Census of India 2011). Efforts in India to tackle the provision of housing throughout the five-year plans (1951 – 2017) have been extensively documented (National Housing Bank 2005). During all these years and efforts, the role of government evolved from being the provider to the promoter, then to the facilitator and finally being the enabler. But these efforts still proves to be inadequate particularly in the light of the urban housing shortage figures in India. The urban housing shortage in the year of 2012 was estimated to be 18.78 million dwelling units with almost 96% in the EWS and LIG categories, i.e. affordable housing (AH) segment (NBO (TG-12) 2012). Many factors (demand side as well as supply side factors) play a crucial role in the rise of the housing shortage in India. Large immigration to the urban areas, rapid nucleation of families and the changing demographic structure of the urban society, and aspiration for an urban lifestyle, etc. bolster the demand for AH in our cities. But, contrary to the rising demand, supply constraints limit the provisions of AH. Rising land and construction costs, labour costs, accessibility to housing finance and credit facilities, unavailability of appropriately located urban land, lack of appropriate infrastructure, and regulatory barriers in our cities are attributed as major supply-side constraints in the provision of AH (PSN Rao 2012; Jones Lang LaSalle 2012; Gopalan & Venkataraman 2015; Patel et al. 2017). The regulatory constraints in the provision of AH are the main focus of this paper.

1.2 Regulatory constraints in the provision of AH

The regulatory framework is the tool for the implementation of the urban policy. These are exercised primarily for ensuring the basic standard and quality of living, in order to maintain safety and security in the neighborhoods and to recognize the existing local externalities (Quigley & Rosenthal 2005). Regulatory frameworks include the land use regulations, the infrastructure standards and finally the building regulations (Bertaud 1988). The land use regulations include the subdivision of the urban land, the width of the access roads, the densities to be achieved, etc. The infrastructure standards are primarily to set the benchmark for service provisions (water supply, sewerage networks, drainage networks, etc.), the minimum levels of quality for the type of materials and construction standards. The building standards are principally attributed to the design guidelines, the height restrictions for the building, the ground coverage, and marginal open spaces standards, the minimum necessary standards for the sanitary and electrical fixtures, etc. In the recent years, newer regulations are introduced to attain the sustainability goals like the rainwater harvesting, encouraging the renewable sources of energy, appropriate construction technology, etc. (Patel et al. 2017). In this way, regulations are also utilized as tools for mainstreaming the newer and appropriate necessary techniques and methods. Regulations although exercised with the best of intentions for the betterment of the overall comfort, health, and safety of the neighborhoods, also triggers the limiting supply of urban land and its inefficient use. The widespread effects generally result into the rise in the cost of both, the land as well as the built property on it (Sivam 2002; Bertaud 2010; Clarke Annez et al. 2010; Gandhi 2012; Patel et al. 2017). This increased cost of the residential properties has a direct consequence on the supply of AH in the urban areas, both due to actual cost rises and in terms of induced effects resulting in the overall value appreciation of the residential neighborhoods. Apart from this many of the regulations are also ‘remnants’ of the archaic British system, which calls for a critical evaluation in contemporary times (Mehta et al. 1989).

2. SELECTION OF THE CASE

Source: Draft DP Pune 2007-2027, Housing survey in 2010 - MASHAL

Figure 120 Total population of city along with slum population (Pune)

One of the major cities in western India, the city of Pune ranks seventh in India and second in Maharashtra with regard to its population. The municipal limit of the city boundary encapsulates an area of 244 sq km and has an overall density of 4300 persons per hectare (pph). The city has witnessed an alarming and rapid growth of slums in the past few decades, with an estimated 42.56% of the total populations being slum dwellers in the year 2011. The case study area of Pune city was selected based on three prime criteria. These are a large AH requirement, the presence of a robust real estate market and current phase of undergoing regulatory reforms in the city. These will be discussed in brief in the following text.

Alarming and rapid increase in the slum population is the striking reality of urbanization in Pune. The population of the city rose from 16.91 lacs in 1991 to 31.15 lacs in the year 2011. Correspondingly the slum population rose from 33.64% to 42.56% of the total population during the same period (See **Erro! A origem da referência não foi encontrada.**) (DP 013). There exist a total of 564 slums in Pune city which are home to more than 2.2 lacs of households. There exist a strong possibility that the slum population might grow further and reach a stage where half of the city’s household reside in the slums (Lall et al. 2008; Shekhar 2012).

Secondly, Pune city has the presence of a robust real estate market. Strong market demand is one of the primary determinants of housing prices (Nelson et al. 2002). Thus the existence of a strong demand is quintessential for such study. Also equally important is the presence of a large number of suppliers, negotiating this strong demand to create a healthy housing market scenario. Since the past two decades, Pune city has witnessed a strong economic growth and upsurge in the housing demand owing to its IT, manufacturing and educational infrastructure (Joshi 2014; Krishnamurthy et al. 2016). Due to these reasons, Pune’s real estate market is characterized by a diverse, strong and robust supply (Krishnamurthy et al. 2016).

Finally, the city of Pune is currently undergoing the phase of regulatory reforms making new modifications to the current rules and regulations (Khape 2017). Political will and the current positive environment in this regard makes the study an appropriate, relevant and timely contribution to the ongoing narrative.

3. LITERATURE REVIEW

The literature review which would be presented in the following texts predominantly forms the part of contemporary theories and studies linking the role of regulations and the supply of AH. The formal modes of AH supply range broadly

in the three domains, developed by the public or government agencies, the non-market AH segments or cooperatives, and the AH developed by the private developers (Ram & Needham 2016). The AH developed by the government or those subsidized by the public agencies includes the transitional housing, assisted self-help housing, social housing and other institutional practices. In the cooperative and the privately developed formal housing market segments, rental AH and the ownership AH are the sub-types. Studies, as well as the existing shortage figures, suggest the inadequacy of the government subsidized AH segment as well as the non-market or the cooperative modes of the AH supply, pointing towards reinforcing the efforts for removing constraints in the AH supply by the private developers.

As history suggests, many countries deliberately set high regulatory standards in order to discourage large rural to urban migration (Thomas 2002). Studies also direct the origins of the Indian regulatory systems in the spacious British standards, which were set in different times and had a very different purpose than those which are required for AH in the contemporary times for Indian cities (Mehta et al. 1989). Many unrealistic standards have caused the rampant spread of slums in our cities. A study from the African country of Tanzania clearly demonstrates that by having generous planning standards and regulations only 3900 lots of AH were permissible which when appropriately modified resulted in having around 15000 AH lots (Lusugga Kironde 2006). Suggestions to modify the restrictive regulatory practices which trigger the unauthorized residential formations must be prioritized, and private sector must be enabled to participate in the AH delivery (Ogu & Ogbuozobe 2001). Similar opinions regarding higher roles for private players in urban land management, assembly, along with the construction and delivery are also recommended by the Indian studies (Sivam et al. 2001).

Regulations very often influence the supply of AH in Indian cities. This AH supply has to comply with range of regulations which includes ownership and land title issues, the time and the complex procedures for the conversion of agriculture land use to the urban developable land use, zoning and regulations related to the land subdivision, variety of site planning regulations which prescribes the minimum road widths, the minimum lot sizes, the marginal setback, the overall densities (FSI), minimum parking stipulations, and so on (Patel, B., & Phatak 2014). Studies also remark about the direct influence of the regulations in the increased cost of AH within the formal AH supply mode (Annez et al. 2012; Patel et al. 2017). Only a smaller quantum of the AH requirements is catered by the formal markets due to these hindrances, and the remaining demand remains out of the formal supply. This encourages the informal supply to hold ground and forces the large AH requirement to live in the slums and squatters. Studies also link the formation of slums with the existing regulatory framework which limits the AH supply, across different cities of the world (Lall et al. 2006; Lusugga Kironde 2006). In order to gain the urban citizenship, better educational facilities, better employment opportunities, triggered by their aspirations, the poor sections of the society compromise on their health and living standards (Cardoso 2002). The failure of the formal system which is fenced by the regulatory constraints results in the formation of slums and the city fails to absorb its residents within its formal AH supply mechanism. A large section of the society being forced to live in the slums, most often also results in the encroachments over the significant and fragile environmental lands, for e.g. the riverbanks, the hill slopes and the lake shores, etc.

Many studies argue for the revision of the regulations which cause the inflationary effect particularly in the provisions of the AH. Modifying and providing relaxations in the regulatory frameworks increases the efforts to enable the access to the needy sections of the society in the formal AH supply (Mehta et al. 1989; Payne 2005; Arnott 2009; Annez et al. 2010; Bertaud 2010; Kala Seetharam Sridhar 2010). Adverse impacts of the regulations on the AH supply results in two manners. Firstly, the time required for the cumbersome regulatory processes, and stipulation of minimum standards cause the price of the AH to rise (Malpezzi & Mayo 1997). Price elasticity of AH supply is reduced due to regulations, which results in the lower steady-state construction levels and reduces the market responsiveness to demand shocks (Mayer & Somerville 2000). Studies also demonstrate and quantify the possibility of an increase in the AH supply, if regulations are modified appropriately, without compromising on the safety and quality of life parameter (Bertaud 1988; Patel et al. 2017).

The major inferences drawn from the study above are presented in the following texts. Regulations impact the AH supply (both quantity and their price) across different economic geographies. Secondly, there exists a greater need for empirical evidence due to the heterogeneous nature of housing studies, and characteristically local and distinct nature of regulations of each place. The market AH supply, primarily developed by the private developers must be mainstreamed and constraints in its provision of AH should be removed. Finally, it can be inferred that planning regulations impact the AH supply on various spatial levels and multi-level spatial methodology for such studies should be adopted.

Figure 121 Macro level area delineation (neighborhood layout) in Kothrud

4 RESEARCH METHODOLOGY

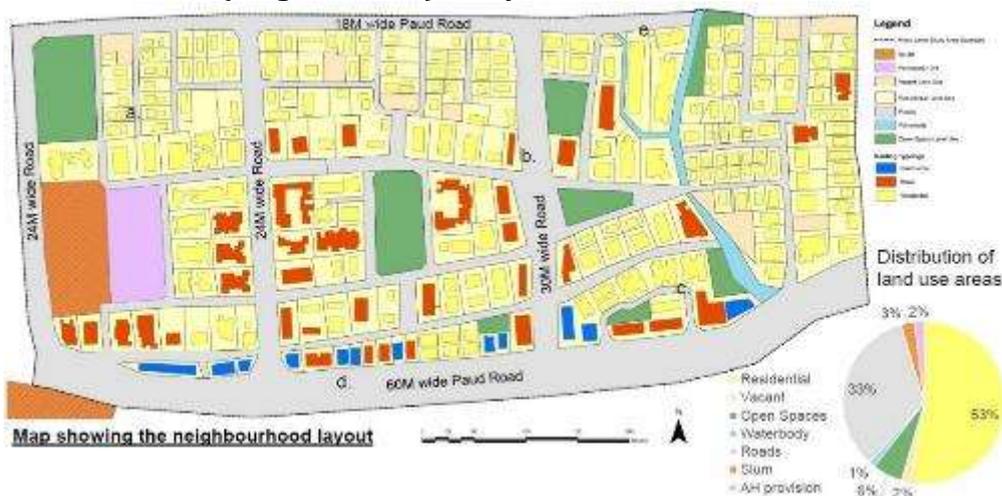

The presented literature review clearly establishes the fact that regulations have a causal link with regard to the AH shortage. But many consider it more than a factor of restricted serviced land supply or low FSI provisions (Bertaud 1988; Glaeser & Gyourko 2003; Bertaud & Brueckner 2005; Brueckner & Sridhar 2012; Patel et al. 2017). Taking a cue, from these researchers, the study embarks on to provide empirical evidence from the Pune city in investigating the impacts of regulations on AH supply by employing multi-level spatial analysis methodology. The study aims to find the extent to which the AH supply is impacted by the regulatory framework in Pune city.

5 MULTI-LEVEL SPATIAL ANALYSIS

The multi-level spatial analysis includes the macro (neighborhood) level analysis and a micro (project design) level analysis. The macro area was delineated based upon certain criteria. These criteria for the delineation of the macro spatial area were three in number. The first and the foremost criterion was the location of the neighborhood to be in the ward where there exist more requirement for the AH than what is being supplied as the AH provisions by the Draft Development Plan (2007-27). Kothrud ward was identified as one such ward within the city which have more requirement for AH than what is supplied in the ward by the city DP. The second criterion was to select the neighborhood in the zone which consist major lower income group (EWS and LIG) population. As per the ‘Socio-economic census’ of Pune, the wards were shortlisted which had relatively higher percentages of the lower income group population. The third criterion was that the neighborhood has to have predominantly residential land use. Based upon the qualification in all the three criteria, a residential neighborhood in Kothrud area of Pune was selected as the macro level area for the multi-level spatial analysis (See Source – Prepared by *author*, Pune Draft DP (2007-27)

Figure 121). For the micro-level analysis, a typical AH scenario was generated for housing a population of 3000 households, based upon the existing regulations of DCR-2013 Pune. Then an alternative scenario is generated after modifying certain regulations in order to perform a comparative analysis of the areas, costs, and the regulations. Suggestions for modifications in the regulatory framework are suggested based upon the insights of the study.

5.1 Macro-level (Neighborhood) Analysis

Source – Prepared by *author*

Figure 122 Map showing the neighborhood layout (macro level analysis) along with land use distribution

The residential neighborhood in Kothrud is the area selected for performing investigations of impacts of regulations on AH supply in the neighborhood. After the primary survey verification, a spatial map of the neighborhood was prepared and investigated for its composition of land uses (See Source – Prepared by author

Figure 122). The various land uses which exist in the layout are residential (53%), road network (33%), open spaces (6%), slums (3%), AH provisions (2%), vacant (2%), and waterbody (1%). It can be inferred that the area under the road networks is considerably higher than that prescribed in the URDPFI guidelines (MoUD 2014). The guidelines prescribe the road area percentages to be 12-14% in the case of large cities, and 15-18% in the case of metro cities. Within the layout of the neighborhood, the supply of the residential land is constrained due to large areas under roads. The building uses within the neighborhood were also investigated by undertaking field visits and verifications. Among all the building uses, the exclusively residential building use category was observed to be maximum (81.2%), followed by the mixed building use category (14.3%), and minimum presence of the exclusively commercial building use category (4.5%).

Source – Prepared by author

Figure 123 Distribution of the residential supply within the neighborhood

The residential supply in the neighborhood was analyzed by first classifying it under two categories, the organized residential supply (multi-family dwelling apartments) and the individual residential supply (usually single or extended family dwelling) (See Source – Prepared by author

Figure 123). Organized residential supply utilizes 58% of the total available residential area in the neighborhood and individual residential supply utilizes the remaining 42% of the available residential area. It could also be noticed that the organized residential supply contributes to around 80% of the total floor supply while the individual residential supply contributes to only around 20% of the total floor supply (See Table 55). Thus, it can be inferred that the organized residential supply fare better in terms of the delivering more floor area by utilizing the lesser land area. In other words, the organized residential supply is more efficient in FSI utilization than the individual residential supply.

Also, the organized residential supply is observed to be developed upon bigger plots, compared to individual residential supply which utilizes smaller plots (See Source – Prepared by author

Figure 124). The study infers that if the plots are bigger in size, they offer a greater chance of being developed as organized residential supply, and better consume the permissible FSI. In the neighborhood analysis, it has

been observed that the permissible FSI for the entire neighborhood is one, which implies that equal floor area could be provided as of the total plot area. But contrary to the permissible FSI, certain plots having the residential land use, are observed to consume lesser FSI than the permissible one. This can be spatially illustrated as a map of FSI consumption (See Source – Prepared by author

Figure 126). The study super-imposes the classified organized residential supply, the building heights and individual residential supply along with the FSI consumption map, to infer that the organized residential supply is more probable of being developed on the bigger plots, of consuming the permissible FSI and they achieve so by building more number of stories (See Source – Prepared by author Figure 126).

Table 55 Utilization of the land area and floor areas among the organized and individual residential supply

Utilization of land and floor areas		
Particulars	Organised supply	Individual supply
No. of premises	97	157
Land area (Ha)	8.33 (58%)	6.06 (42%)
Floor area (Ha)	12.02 (80%)	3.09 (20%)

Land area, Individual supply, 42%

Land area, Organised supply, 58%

Floor area, Individual supply, 20%

Floor area, Organised supply, 80%

■ Organised supply
■ Individual supply

Source - Prepared by author
 Figure 124 Map showing the average range of sizes of residential plots along with the type of residential supply

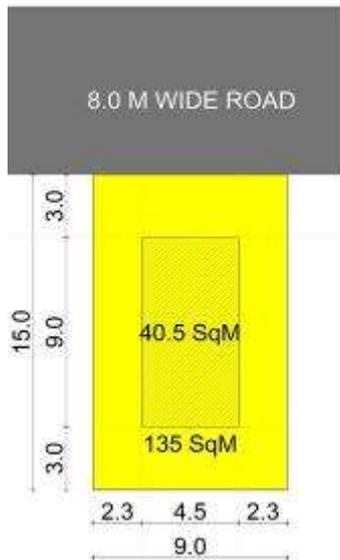

Source - Prepared by author
 Figure 125 Map showing the FSI utilization of the residential supply along with the building height

The study further poses an important question for self-exploration. ‘Why are the smaller plots not being able to consume the entire permissible FSI?’ One of the important observation in their defense is the fact that most of these smaller sized plots have individual residential supply developed upon them. Hence a prominent reason for not consuming the permissible FSI is owing to the resident's preferences and/or choice and their socio-economic status. But this constraint in the complete utilization of the permissible FSI can also be attributed to an impact of the existing regulations.

5.1.1 Demonstration – The collective impact of regulations

A simple demonstration is illustrated which clearly indicates the collective operation of the regulations which makes it impossible to consume the full permissible FSI. This is true in the case of smaller plot sizes and could be one of the reasons for low FSI utilization of the individual residential supply category (See Source – Prepared by author Figure 126). To demonstrate this fact, a smaller plot of 9m width and 15m depth is considered which is accessed from an 8m wide road. As per the DCR-2013 for Pune city (PMC 2013), the permissible FSI, the front, side and rear setbacks, and the building height is regulated if the plot is accessed by a road having a particular width and the area of the plot falls under a certain category. Thus in our case demonstration, the plot comes under the following categories. Access road width < 12m width, plot size is in between 125 sq.m. to 250 sq.m. For these, the setbacks to be left are, 3m in front and rear and 2.25m in the side. The permissible maximum FSI is one, permissible maximum ground coverage is 50% and the permissible maximum height of the building is 10m (PMC 2013). If these conditions are met, the ground coverage achieved is 30%, the area of single floor plate is 40.5 sq.m, and only three stories could be constructed (due to the building height restrictions). Hence the resultant FSI consumed is only 0.7 as against the maximum permissible FSI of 1. Thus it could be inferred that the collective impact of regulations pertaining to the access road widths and height restrictions on the building, and the marginal open space regulations do not allow the building (particularly on smaller plots having a size range between 125 to 250sq.m.) to consume complete permissible FSI.

Source – Prepared by author

Figure 126 Demonstration of the collective impact of regulations on FSI utilization

5.2 Micro-level (Project Design) Analysis

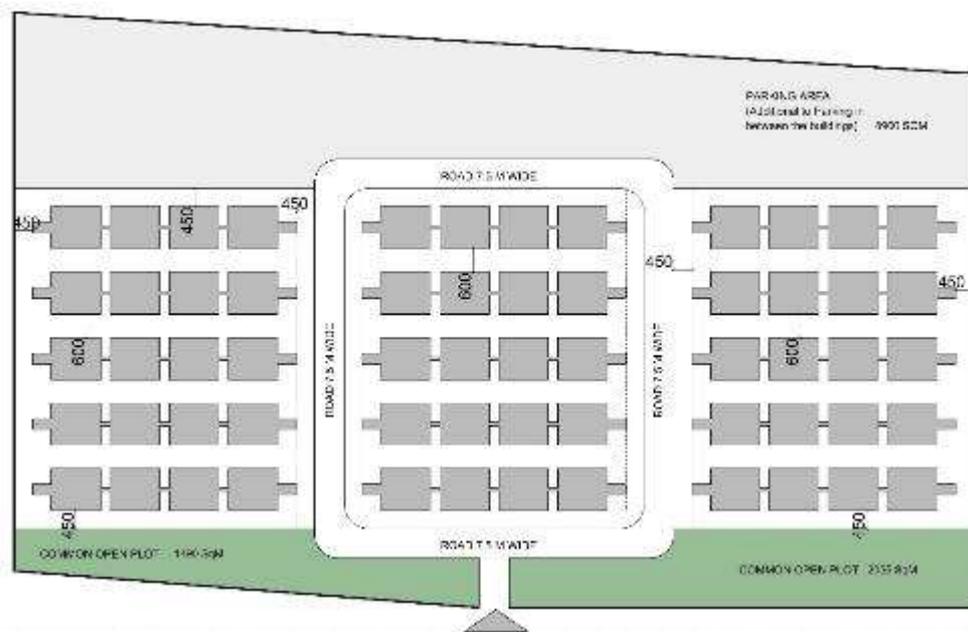

Generation of typical and alternative scenarios and performing the subsequent comparative analysis is often a method adopted in such studies (Bertaud 1988; Patel et al. 2017). Following the same methodology, the micro-level (project design) analysis was performed. Here, site visits to AH projects were undertaken in order to comprehend the site planning, building layouts, and residence designs. Also, the lifestyle of the user group (EWS and LIG) were studied upon. Based on the primary observations, typical and alternative scenarios for an AH project were generated based on the existing (DCR 2013) and the modified regulations, respectively. The two AH layouts are then compared for the provision of total dwelling units, the cost of a single dwelling unit in both the layouts and finally with regard to the regulations which are responsible for the change.

5.2.1 Scenario generation (typical and alternative) and major considerations

As mentioned above the two layouts were generated, first is the typical layout generated in accordance with the DCR 2013, and the second generated after modifying some critical identified regulations. These two are represented in the following figures (See Source – Prepared by author

Figure 127, Source – Prepared by author

Figure 128).

Source – Prepared by author

Figure 127 Original layout design of AH generated in accordance with prevalent regulations

Source – Prepared by author

Figure 128 Alternative layout design of AH generated after modifying regulations

The alternative layout is generated by employing an iterative process to achieve the low cost, high-value solution, essential for the feasibility of the AH projects (Woetzel et al. 2014), without compromising on the safety and appropriate quality of life parameters.

The major important considerations are listed below, based upon which the two layouts were compared.

The total number of tenements – In the typical AH layout, which is generated in accordance with the DCR 2013 (existing regulations), 960 tenements are accommodated which are distributed in 60 buildings of four stories each. In the alternative layout designed after modifying and relaxing certain byelaws, 1720 tenements could be accommodated which are distributed in 86 buildings of five stories each. By employing much more compact layout and increasing the story of each building, the alternative AH layout utilizes the site area prudently.

Road width – The regulations stipulate the minimum width of the roads as 6m for the running length of 75m. Beyond the length of 75m up to 150m, the regulations stipulate the width to be increased to 7.5m. The basic premise behind this considers the appropriate volume to capacity ratio of the roads and correspondingly increases the widths to increase its carrying capacity. But the primary investigation in such AH projects, as well as documented studies (Patel et al. 2017), clearly indicates the low purchasing powers of the target groups cannot afford and do not possess vehicles for which the increased width of the roads is a thoughtful consideration. Hence the alternative layout keeps the road widths as 6m up to the length of 150m acknowledging the low vehicle possession in AH projects. Also, this increases the setbacks from the roads to 5.25m in the alternative layout, from the initial 4.5m in the original layout. This added space adds on to the off-street parking space for the two-wheelers and occasional three-wheeler the users possess.

Recreational open space – It is mandatory to provide 10% of the total site area as recreational open space as per the DCR 2013 of Pune city. As much as possible, the regulation suggests this ROP be provided in a single location. But the regulation also states that for the site area more than 5000 sq.m, this recreational open space can be provided in more than two places. One such place must accommodate 50% of the total mandatory recreational open space (PMC 2013). The minimum area of this recreational open space is to be 300 sq.m. In the alternative layout, the minimum dimension and size requirements are relaxed. Also, the total area of recreational open space is distributed, so that these areas generate greater social interaction among neighbors and creates more utility to the households (See Source – Prepared by author

Figure 128).

The parking provisions – The regulations stipulate provision of one parking space (comprising of one car, six scooters, and four bicycles), for every two AH households. Area required for these is 28.5 sq.m. Also, the DCR states that it is mandatory to provide extra space for 5% of the total parking space required as visitor's parking space. Thus the total parking area demanded as per the original layout is 13608 sq.m. After accommodating parking requirements in the 6 meters wide spaces between the buildings as well as the on-street parking, 8900 sq.m. of the additional parking space is provided (See Source – Prepared by author Figure 128). Primary survey verifications performed shows presence of two-wheelers, some three-wheelers and no or rare presence of cars in AH projects. In the alternative layout generated the required parking can be parked in the spaces around the apartments. Stipulating minimum parking requirements in the AH projects in such form is inappropriate and these AH projects have different needs pertaining to parking, which must be provided for (for an e.g. rickshaw, tempos, etc.).

Building height and access road width – The regulation of Pune city makes a restriction on the building height to be 10m for the buildings which have their access road widths less than 12m (PMC 2013). In the alternative layout, the access road widths for the residential buildings are 6m. Hence, it becomes imperative to restrict the building height to three stories high, if 3m of clear habitable room height is to be maintained. The alternative layout creates buildings with five

stories. The total height of the building thus reaches to 15.5m. Walk up apartment typology of design has been utilized in the layout to achieve a low-cost high-value solution as the regulations make it mandatory to install lifts (adding the costs of AH development) beyond the building height of 16m.

Floor space index (FSI) – In the original layout generated according to the regulations of Pune, several contributing regulations briefly discussed above, come together and makes the consumption of the FSI to 0.85, not even achieving the maximum permissible limits of 1. In the alternative layout after relaxing some key regulations as briefly discussed above, and by building more quantity of the dwelling units, the FSI consumed is 1.5.

5.2.2 Comparative analysis

The particulars of comparisons are represented in the table below (See Table 56). The area comparisons consider the FSI consumed on the site of AH, the average land consumed, the recreational open space (ROP) achieved, etc. Compared to the original layout, land consumed by each tenement in the alternative layout is reduced by 44.20%. In the alternative layout, the total built-up area on the same site is increased by 77.55% compared to the original layout. It was possible to build intensely on the site after modifying the key FSI regulation to 1.5 from existing 1 in order to achieve 1720 tenements against 960 tenements (79.16% increase) as per the original layout. Similarly, after modifications in the regulations of recreational open space (ROP), it is observed that an increase in the quantity of ROP by 75.3% could be achieved. As mentioned above, this also improves the quality of these spaces and these utility value to the households.

Table 56 Area comparisons

Particulars	Layout in accordance with DCR 2013, Pune	Layout in accordance with modified regulations	Change (%)
Total plot area (sq.m.)	34055	34055	
Total built-up area (sq.m.)	33917.4	60221.5	77.55
FSI consumed on site	0.85	1.5	76.47
No. of floors	G+3	G+4	25
Total tenements	960	1720	79.16
Tenement areas			
a) Carpet area (sq.m.)	27.6	27.6	
b) Built-up area (sq.m.)	30.87	30.62	-0.8
c) Gross built-up area (sq.m.)	35.33	35.01	-0.91
Average land area consumed by each tenement (sq.m.)	35.47	19.79	-44.20
Ground coverage utilized	24%	35%	45.83
Recreational open plot (ROP)	10%	17.53%	75.3
Percentage of land under a dedicated parking	26.13%	0%	
<i>Source – Prepared by the author</i>			

Then followed are the cost comparisons considering the land costs, the construction costs, soft costs (registration and stamp duty), to finally arrive at the total cost per tenement in both the AH scenarios (See Table 57). Total costs for both the layouts are estimated and compared. The costs compared includes the land costs, the construction costs including developer’s profit, and the soft costs which include the registration and stamp duty. Land cost component per tenement comes to Rs. 5.32 lacs in the original layout (960 tenements), which is reduced by 44.18% to Rs. 2.96 lacs per tenement in the alternative layout (1720 tenements). Transaction charges add an additional 6% in the state of Maharashtra. The state government of Maharashtra charges stamp duty at the rate of 5% and sale deed registration at the rate of 1% of total cost. Transaction cost component per tenement comes to Rs. 53,124 in the original layout, which is reduced by 26.91% to Rs. 38,825 per tenement in the alternative layout. Overall the total cost component for a single tenement in the original layout is estimated to be Rs. 9.38 lacs and Rs 6.85 lacs in the alternative layout designed after modifying certain regulations. The overall cost for every tenement is reduced by 26.91%, from original to alternative layout.

Table 57 Cost comparisons

Particulars of cost comparisons	Layout in accordance with DCR 2013, Pune	Layout in accordance with modified regulations	Change (%)
General Details			
Built up area each tenement (sq.m.)	30.87	30.62	-0.8
Total built-up area (sq.m.)	33917.4	60221.5	77.55
Total no. of tenements	960	1720	79.16
Gross built up area per tenement	35.33	35.01	-0.91
Land cost (a)			
Total plot area (sq.m.)	34055	34055	
Land cost per unit area (Rs/sq. m.)	15000	15000	
Total land cost for the entire plot	5108.25 lacs	5108.25 lacs	
Land cost per unit area of built space (Rs./sq. m.)	15061	8483	-43.67
Subtotal a: Land cost per tenement	5.32 lacs	2.96 lacs	-44.18
Construction cost including profits (b)			
Construction cost per sq. m. of gross built-up area	10000	10000	

(Rs./sq. m.)			
Subtotal b: Construction cost per tenement	3.53 lacs	3.50 lacs	-0.91
Transaction (stamp duty and registration) charges(c)			
Stamp duty @ 5% of land and construction cost (a + b)	44270	32354	-26.91
Registration charges @ 1% of land and construction cost (a + b)	8854	6471	-26.91
Subtotal c: Total charges per tenement	53124	38825	-26.91
Total cost per tenement incl. land, construction, and transaction charges (a+b+c)	9.38 lacs	6.85 lacs	-26.91
<i>All costs are in Indian Rupees (Rs.).</i>			
<i>Source – Prepared by the author</i>			

Based upon the discussion above, the study recommends modifying key regulations, exclusively in an AH project, pertaining to the provision of the recreational open spaces (ROP), the quantity of parking, the building height and finally the permissible FSI. The alternative layout which improves the supply of AH does not change the existing marginal open space or setback regulations and the amenity space regulation and these are not modified. The comparison of the regulations (DCR 2013 and the suggested modified regulations) can be summarized in the table below (See Table 58).

Table 58 Comparison of regulations

Comparison of regulations		
Regulation	DCR 2013	Modified regulations
Maximum allowable FSI	1	1.35
Minimum area of recreational open plot (ROP)	10%	15%
Criteria	1 place with min. 50% of the total ROP	Not specified
Minimum size of ROP (sq.m.)	300	Not specified
Internal road widths for road length (75 m upto 150 m)	7.5	6
Height restrictions for Road<12M wide	10	15
Amenity Space	15%	15%
MOS (F-S-R)	As per DCR	As per DCR
Parking	1 parking space per 2 tenements = 28.5 sq.m. / 2 tenements	Appropriately specified (for e.g. - 1 parking space per 3 tenements)

Source – Prepared by author

6 CONCLUSIONS

Regulatory framework does influence the overall quantity of AH supply as well as has an inflationary effect on the price of AH. The study demonstrates by performing a multi-level spatial analysis, the phenomenon of multiple regulations restricting the possibilities of consuming complete permissible FSI. The macro-level analysis of the neighborhood clearly illustrated these inabilities of consuming complete permissible FSI, particularly of the smaller plot (< 250 sq.m) which are accessed from lower width roads (<12m wide). The micro-level analysis demonstrates the existence of the possibility of increasing the supply of AH in Pune city, provided regulations are appropriately modified. The key regulations which the study identifies are pertaining to the road widths, the building height restrictions, the recreational open space stipulations, the parking requirements, and finally the overall FSI limitations. Care has been taken throughout the alternative scenario generation to not compromise on the safety and quality of life parameter. The study reveals the possibility of cost savings of about 26.91% per tenement could be achieved and an overall supply of AH could rise by 79.16% if the regulations suggested are appropriately modified. In doing so, the study also clearly indicates that building more intensely on the site does not necessarily compromises the living quality and encroaches upon the open spaces. On the contrary, an increase in the recreational open spaces to the tune of 75.3% could be achieved if designed appropriately. Most of the cities across India, are grappling with the issue of AH shortage and are simultaneously also in possession of such restrictive regulations. In the given situation where the AH shortage problems seem to get bigger and stronger by every passing year, such regulation must be critically scrutinized and evaluated for their appropriateness in the local context of individual cities. The empirical evidence provided by such studies, aspire to be instrumental in paving way for the timely regulatory reforms, creating an enabling environment for an increased AH supply in our cities.

1481 COMMUTATION OF SCHOOL CHILDREN IN CONTEXT TO GEOGRAPHICAL SPACE OF URBAN SCHOOLS AND NEOLIBERAL REFORM IN THE CITIES

Meenakshi Kumari

Research Scholar, CSRD, JNU, New Delhi, India, Email – meenakshi.moti@gmail.com

ABSTRACT

Due to the urbanisation and the irrational manner in which space has been appropriated in the city, the possibilities for unequal and biased distributions of schools within big cities clearly exists. If schools are so located that they are not within negotiable walking distance from the place of habitation, they cannot effectively serve the population they are meant for. Urban reform not only ceases public hands rather also redefine the geographical space and distribution of public services and its accessibility at large. This paper explores the distribution of schools in Bangalore and its availability to children. And resulting commuting pattern of school children. The distribution is depicted using School Report Card 2014-15 data. The commuting pattern has been analysed in terms of distance, mode of travel and time taken from home to school and is based on primary survey in two localities in Bangalore comprising data of 130 school going children. The study concluded that commuting is more passive in nature and least cases of active commuting observed. The demand for international schools is the main factor leading to the commutation of school children to far off places which is inferred from the flow diagram.

Keywords: Commutation, Urban Schools, Travel mode, Geographical space, Neoliberal reform

CONCEPTUALISING URBAN REFORM AND URBAN SCHOOLING

Cities (including their suburban peripheries) have become increasingly important geographical targets and institutional laboratories for a variety of neoliberal policy experiment. (Lipman, 2011). Urban reform in cities usually follow the neoliberal path, which in a way, ceases the hand of public sectors and provokes the private sectors in regulating public services such as infrastructure, health and education etc. As schools play a pivotal role in sustaining the new global economy (Marie & August, 2005), privatisation of education has become the vehicle which further moves on the path of neoliberal ideology. Urban education has become more a trade-off commodity where corporate school reform is more evident. Like the city, urban schools have undergone neoliberal revolution also referred as corporate school reform. Neoliberalism is a kind of new configuration of capital and state power where market values and corporate and financial interests have come to dominate all aspects of state governance and social life. The ultimate aim of the corporate school reform is to dismantle public school in cities all across the country and create a corporatized for-profit system. (Means, 2014). Thus, investment on schooling by private corporate in private schools is selective to the high branded and reputed schools of ICSE boards which demand an extremely high school fee.

In neoliberal processes, privatisation is making strong place in urban education where corporate invest their money on private schools and argue that public schools lack resources and competition in market. This is how neo-liberalism has come to describe a new configuration of capital and state power, whereby market values and corporate and financial interests have come to dominate all aspects of state governance and social life. (Marie & August, 2005) The neoliberal development of the city is followed by differential development of the territory within the city at different pace.

Public Schools are becoming 'warehouses' and 'dumping grounds' for the students with the greatest needs, from the most disadvantaged backgrounds. (Means, 2014). Public schools and idea of neighbourhood schools are disappearing in the process of urban reform. It reconfigured the geographical distribution as well as management of the schools. Now the accessibility gets defined both on locational as well as socio-economic grounds. So, the idea governing that who gets what where and how is complete mess in urban scenario. The private schools are mushrooming in strategic locations of the city and their demand is high where parents are sending their children to far off places. Commutation of school children in cities and related issues are common in cities.

SCHOOL LOCATION AND ACCESSIBILITY

Accessibility of schools is considered as the first option which acts as the determining factor for the children to attend school without any barrier. Location of schools comprises several factors. Socio-political factors, size of the area, and economic opportunity in an area in urban space attract the location of schools as per the demand of the majority in particular area. If schools are so located that they are not within negotiable walking distance from the place of habitation, they cannot effectively serve the population they are meant for. This is the outcome of unequally funded urban public schools in cities which creates inequality. Accessibility involves movement in space and thus implies the relative ease, or difficulty, in negotiating the distance between the two given points. In terms of schooling to impart education to children, the attributes of accessibility flow directly from the decision of locating school vis a vis the residential location of the population to be served. Thus, Geography of distribution in space or among territories defines as '*who gets what and where*' and how the spatial inequality penetrates into geographical pattern of distribution of different population group in different areas. In this way the schools' location are strategically planned and segregated in nature. As Coleman (1966) pointed "inequalities are justified only if they provide advantage to the unprivileged in society or if they benefit all".

The idea of neighbourhood school has been incorporated in Right to Education ACT, which demarcates limits of neighbourhood in distance norms as 1 km for children in class I-V and 3 Km for children in VI-VIII. It is yet far in translating these concepts into practice. A good quality school is often compensated by commuting distances by children.

There are also cases where there are no state-run schools in the vicinity of the neighbourhood. These kinds of situation lead to the commutation of school children to far off places every day. This is how the idea of common /neighbourhood school system has been circumvented by ruling political elites in an eminently hostile environment. (Velaskar, 2010).

STUDY AREA AND METHODOLOGY

Bangalore has emerged as a 'Silicon Valley' and 'city of the future' in the last five decades; where this small town has metamorphosed into an internationally known city. Bangalore is becoming a multiply divided city where both social and geographical barriers are reinforced. There are large numbers of international schools which are coming up while on the other hand educational opportunity in poverty areas raises a central question to its availability and their functioning (LER, NIAS, 2002). According to a survey by IBM, commuter pain index that ranks the emotional and economic toll of commuting in cities worldwide has revealed that Bangalore stand 6th in the index all over the world and 1st in India. (IBM 2011). Traffic and congestion is very high in this city which creates problems for general commuters as well as children too. With the establishment of IT sector and development to reach global level, the city has transformed largely over the last three decades. And it has given way for neoliberal agenda to work in all spheres including education.

The paper dealt in two sections. First is geographical distribution analysis through maps using data of School Report Card 2014-15. Second part is based on primary survey which has been conducted in the city of Bangalore. The survey has been conducted in two different localities i.e. Indraprastha colony in Gottigere (Locality 1) ward and Wellington Paradise in Singasandra ward (Locality 2).

Plate 1: Location of Study Area

Source: Google Earth___ Localities

The sampling was mostly of snowball character and had selected only those households which comprises school going children. A total of 101 households have been surveyed which consists of information of 130 school children. A structured questionnaire has been prepared and parents were targeted to answer these questions. Further, the data has been analysed in SPSS and also flow diagram has been depicted through GIS.

FINDINGS AND ANALYSIS

The distribution of these schools shows a geographical variation which shows location specific biasness. There is a divide between core and periphery. High concentrations of schools are in central core areas while the peripheral areas have thinner distribution of schools.

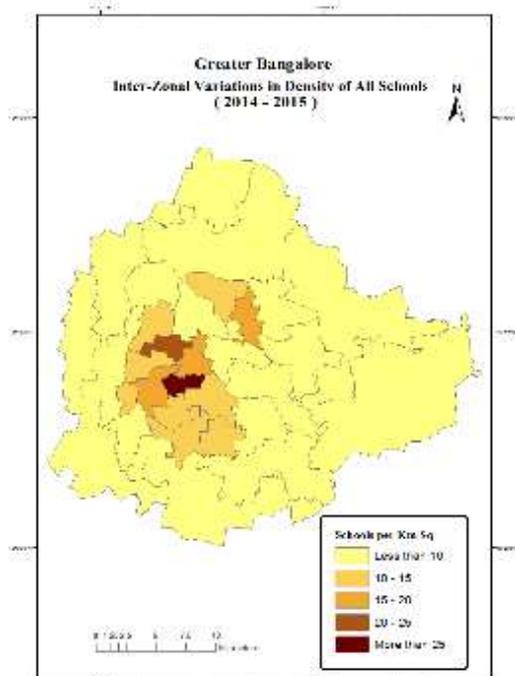

Although the cluster level distribution of schools is difficult to show in maps, but it is observed from data that out of 140 clusters 25 clusters have only 5 or less than 5 schools and 32 clusters have less than 10 schools. 54 clusters have 20 to 40 schools in each cluster and 29 clusters consist of more than 40 schools in each cluster. So, there is a huge gap in the distribution of schools at local level.

As the base unit of the study is carried out at inter-zonal level which is constituency level comprising wards within its boundaries; the distribution of schools at city-zonal level and the school availability has been analysed. The study at inter-zonal level enables to evaluate the distribution and its access to the population.

The Greater Bangalore has a whole of 5.96 schools per sq km. The density of all schools shows there is complete segregation between the core and the peripheral areas. The phenomena are very similar to other cities also, where the high concentration is found in centre of the city which disperses towards the edge of the city. Dhanpal (1981)⁴⁶⁸ also found similar distribution pattern of schools in Delhi. Thus, it is observed that centrality in a city is important factor for allocating schools. The distribution is not for the goodness or to benefit the clients but it is guided by the legitimacy of the decision process or the fairness of the allocation system in the city. The rising value of markets in the central city also attracts schools in large numbers. In cities, economy has been liberalised and welfare has not, Nicholas (2005), and thus distribution is also justified based on economic rationality not on equity principles. Competitiveness of attracting schools is higher in central part of the city than the peripheral city zone.

⁴⁶⁸ Unpublished Document, CSRD, JNU.

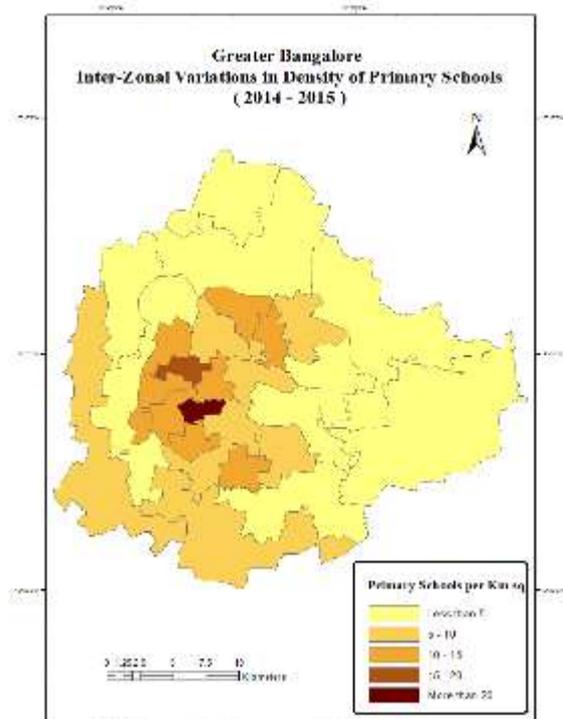

Figure 129

In 2 and 3, it is evident that the distribution of primary schools is better than the distribution of upper primary schools. In both cases of primary and upper primary school density, higher density is found in the core of the city and lowest in the peripheries. The Upper primary schools are very less in all the zones it means there is limited scope of upper mobility from primary to upper primary schools. As, it is observed that, peripheral areas have low density in upper primary schools, it means commutation of school children in peripheral areas to central city zones may increase. It is very true that independent upper primary schools not preferred by both parents and teachers and so integrated primary and upper primary schools are important providers of elementary education. Varghese and Mehta (1998).

In figure 4, The central part of the city has high density for both private and government schools; while peripheral zones show low density in both types of schools. This also creates a situation of commutation of school children. Since children do more prefer private schools, so they are travelling far off places towards the centre of the city from low density peripheral zones.

Figure 130

This creates biasness in the school location in the city. The central part of the city has better supply of schools. The school providers are economically driven and choose the central part of the city for marketing purpose. It drives children from central as well as peripheral areas.

Figure 3

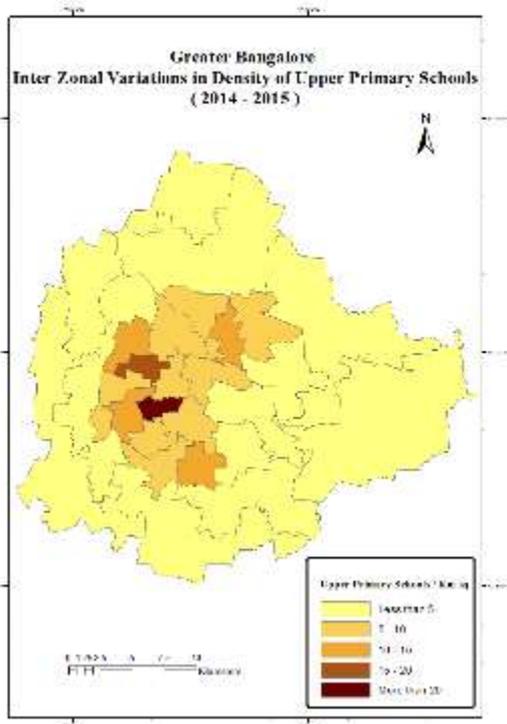

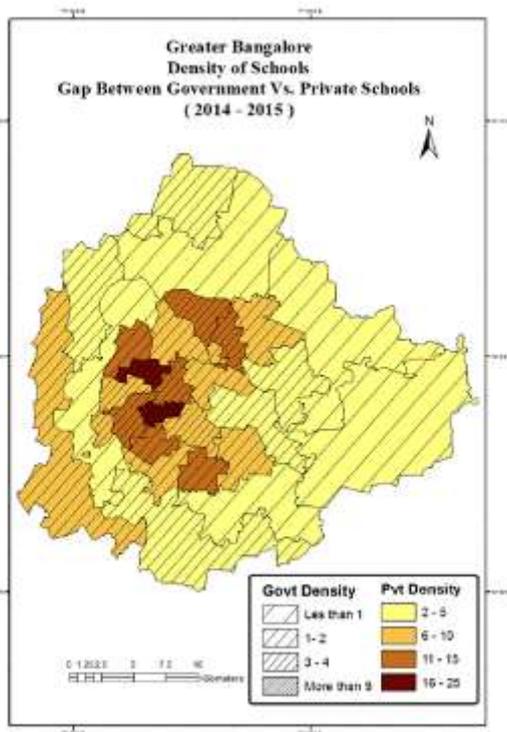

Figure 4

COMMUTING OF SCHOOL CHILDREN IN BENGALURU: ANALYSIS AND FINDINGS FROM SURVEYED DATA IN TWO LOCALITIES.

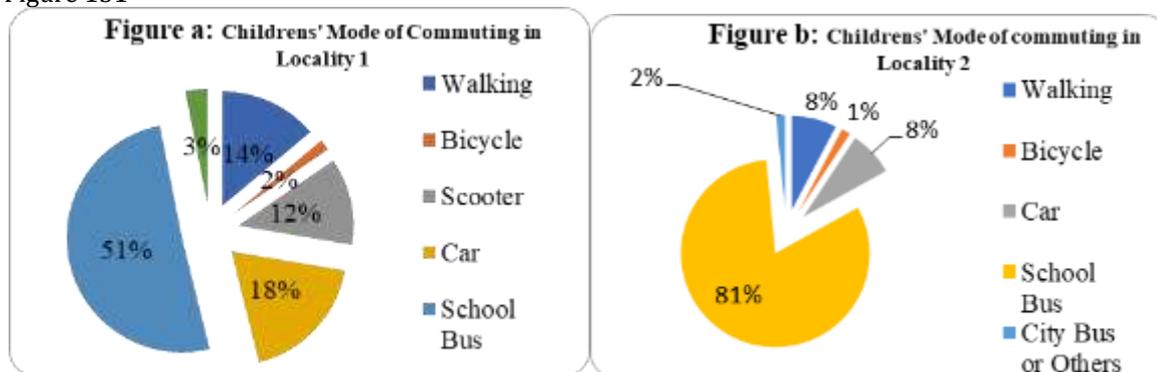

In both the localities, majority of the school children goes to private schools. Here private schools include all types of private schools like low fee private schools, private aided schools and private unaided schools. The categorisation of all these types of schools is not possible since the respondents have not that much idea about the schools. In Gottigere locality, 92% children attend private schools and 8% goes to Government schools in nearby localities. In Singasandra region, the preferences for private schooling is more; where 95% children goes to private schools and rest only 5% children prefer government schools. This connotes various level of deprivation in the city. Since there are no good government schools in the vicinity of the locality, parents prefer to send their children to private schools in nearby areas or also accept to compensate good education with far distances. Whole Bangalore South Region has no Central

Government schools like Kendriya Vidyalaya, or good public school which are performing better. The Government schools are in vernacular medium, which has no second or third language in English medium. Cities are melting pot, where more immigrants are coming to the city from different areas; they want their children to learn and communicate in English. The vernacular medium especially for migrants as well as local from kannada people also prefer good communication skill in English medium for their children. All the government and private schools promote Hindi as a language subject. Medium of instruction, thus play important role in the selection of schools in south Indian cities with various types of language mix and difficulty in comprehending other regional (vernacular) language by some other groups. The present era of liberalisation and globalisation, where English language is considered as main communicating skill demanded highly in the market; and thus, people prefer ICSE Board of schools for their children especially by the affluent group of the society. The State Board is the least preferred board in the city. Since the state board consists of huge syllabus and also contains language as a bar for them, so very few children go to state board schools. While survey, many of the parents proposes arguments against state board syllabus that their syllabus is lengthy as well as very outdated and does not match with contemporary syllabus and skills which are highly demanded in market.

COMMUTING PATTERN

As above it was observed that the type of school and boarding of school is inclining more towards the private school and ICSE schools. These schools are rarely located in the vicinity as government schools. People are promoting intentionally or unintentionally the market driven schooling system. Instead of realising the deprivation of good public schools in the vicinity, parents' 'school choice' demands school of high status and send their children to far distances. There are different modes of travel to school by children, which ranges from private or self-mode to private school buses and public transport system.

Figure 131

Active mode of travel to school has a very depressing picture in both the locality. This could be due to changes in urban form and parents' notion of safety which hinders more bicycling as mode of travel to school for children. This contrasts sharply with the neighbourhood school vision and expectation of letting children attend schools close to homes and encourage walking and bicycling to school. (Badri, 2013) Majorities of children travel to school by school buses in both the locality. It is the most commonly used modes of transportation of school children in the city. Since majority of the schools (private) provide school buses, which are responsible for escorting children to and from school, parents prefer school buses as safest mode of commuting for their school going children. Self-mode like scooter and car are less preferred mode in the city because it again adds extra work load for parents. This could also be due to mismatch between route to work for parents and route to school for children. The difficulty of coordinating work and school schedules likely explains the mode shifting to private buses. (Mcdonald & Aalborg, 2009). Also, it could be attributed to the early start of schools which may not match working hours of offices. Some parents who send their children to school by car put their arguments against school buses that they charge high fees for school buses which are not affordable to them. There are also proportions of children who travel to school by public transport like city buses and auto rickshaws, which contribute together 3% and 2% in Gottigere and Singasandra respectively. It further claims the high school fees together with bus fees becomes a burden on parents and thus affects mode of commuting of children belonging to different types of society. This is the way where school fees get tightened and government provide subsidy to the school buses up to Rs. 12000 per year.⁴⁶⁹

Distances of school from home is also a critical factor governing the mode of transportation for children as perceived by parents. (Mcmillan, 2007). There is a capacity limit to walk and bike to some distances for children, which determine or influence the mode of commuting. As the distances increase, the mode of transportation Of children shifts from 'active commuting' to school bus or car. The distances travelled by children also depend on the path followed, and since it was not possible to know the path through parents and also inability to take information about route to school, the distances used in this study is taken from the survey data as parents responded and also cross checking it with Google maps.

Children travelling time to and from school also depends on mode of travelling and vice versa. But in cities travelling time has not been much important since bus became the choice of travel for majority of the children. On the one hand, longer distances could be easily travelled in less time; on the other hand, route to school also results in longer time of travel even for shorter distances.

⁴⁶⁹ As informed by the school bus driver in the locality which is valid for the whole city for private school buses.

Commuting Pattern of children in Singasandra locality is also similar in nature where a very low proportion of children are going to government school like GHPS located in the locality. Schools like Lawrence High School and Cambridge Public School located towards the centre near HSR residential Layout are perceived as big schools for affluent class.

More than 10 to 15% children from the locality are going to these schools. Also, Chaitanya Techno School and Christ academy are the most reputed schools, where children and parents are proud to be a part of these schools. Schools located in Electronic city are also more in demand. Although there is Delhi Public School located where children and parents are proud to be a part of these schools.

Table 1 Distance Wise Mode of Commuting Among School Children taken to travel. It has been further categorised to different mode based on distances and time.

Gottigere		Walking	Bicycle	Car	Scooter	School Bus	City Bus or Others
	1 km or less	50.0%	0.0%	0.0%	25.0%	25.0%	0.0%
	1 - 3 km	17.2%	3.4%	17.2%	17.2%	44.8%	0.0%
	3 - 5 km	0.0%	0.0%	0.0%	0.0%	100.0%	0.0%
	5 - 10 km	0.0%	0.0%	33.3%	4.8%	57.1%	4.8%
	15 - 25 km	0.0%	0.0%	0.0%	0.0%	66.7%	33.3%
Singasandra							
	1 km or less	100.0%	0.0%	0.0%	0.0%	0.0%	0.0%
	1 - 3 km	0.0%	10.0%	0.0%	0.0%	80.0%	10.0%
	3 - 5 km	13.3%	0.0%	13.3%	0.0%	73.3%	0.0%
	5 - 10 km	0.0%	0.0%	10.7%	0.0%	89.3%	0.0%
	10 - 15 km	0.0%	0.0%	0.0%	0.0%	100.0%	0.0%

where children and parents are proud to be a part of these schools. Schools located in Electronic city are also more in demand. Although there is Delhi Public School located at 8 to 9 km, but very less proportion of children goes to this school. It may be due to strict admission criteria in these schools.

Active mode is not promoted by the parents because there are no sidewalks or path constructed in the city for walking and bicycling and also lack neighbourhood aesthetics as proposed by others. (Badri, 2013). Not only this, little awareness about road guidelines among children also contribute to the fact strongly. The culture of active commuting is negligible in the city since metropolitan city (public) rarely or do not care for the children while children are crossing the roads, this affects parents decision on allowing their children for active commuting to school. (Badri, 2013). The walkers together with the children going to school by car and scooter are escorted with their parents. Most of the respondents informed that parents accompany their children in catching the bus and also take their children to the bus stand or the area where bus stops to collect all the children of the locality if there is less space for stopping bus to their door step.

Table 2 a: Grade wise Mode of Commuting - Gottigere

Grades	Walking	Bicycle	Car	Scooter	School Bus	City Bus or Others
Primary (I - V)	13.7%	2.0%	21.6%	15.7%	47.1%	0.0%
Upper Primary (VI - VIII)	11.1%	0.0%	11.1%	0.0%	77.8%	0.0%
Secondary (IX - X)	20.0%	0.0%	0.0%	0.0%	40.0%	40.0%

Table 2 b: Grade wise Mode of Commuting - Singasandra

Grades	Walking	Bicycle	Car	School Bus	City Bus or Others
Primary (I - V)	9.1%	0.0%	5.5%	83.6%	1.8%
Upper Primary (VI - VIII)	0.0%	0.0%	25.0%	75.0%	0.0%
Secondary (IX - X)	0.0%	16.7%	16.7%	66.7%	0.0%

Source: Primary Survey Data

In Both the localities, School buses are the most preferred mode of transporting children among all grades. The situation is very critical where primary school children are send to school by buses which can lead to exhaustion of child’s energy and which will reduce their physical activity too. It is observed in the survey that if a household has more than one child than younger children will follow to same school and same mode of commuting as the elder one.

As it is defined in Kothari Commission Report that primary school children should attend school located within 1 km distance and Upper Primary children should attend within 3 Km distance. It can be seen from above tabulation 4.6 (a) and 4.6 (b) that there is no such distinction is followed in the city for particular group of children. It means that distances are not the deciding factor as per the neighbourhood school concept denotes it. The parents’ notion of sending children to school of their choices is more important than to the nearby schools as per the distance norm. The busing system in private schools encourage parents to send their children to remote areas schools without considering any other factors of distances travelled by children.

Active commuting is hindered because of National Highways which is very busy and less secure for children to walk and cross the roads. Although, service road and subways are available on the highways, they are very risky for school children.

The parents' notion of sending children to school of their choices is more important than to the nearby schools as per the distance norm. The busing system in private schools encourage parents to send their children to remote areas schools without considering any other factors of distances travelled by children.

It can be said that, distances are being violated to greater extent in cities to avail good education. Good education and status are compensated with distances commuted by children. This gives a sorry picture of children belonging to lower income level as they are not able to afford bus fees and thus find difficulty in sending their children to those schools. Parents also have perception that sending children to nearby area is more difficult than distant schools since buses are provided easily to them. The social and economic inequity reinforces schooling inequality among children.

Table 3a: Grade wise distances travelled by children in Gottigere

Grades	1 km or less	1 - 3 km	3 - 5 km	5 - 10 km	15 - 25 km
Primary (I - V)	9.8%	47.1%	5.9%	37.3%	0.0%

COMMUTING PATTERN OF CHILDREN FROM LOCALITY TO DIFFERENT TYPES OF SCHOOLS

Commuting pattern in Gottigere represents both the direction of flow of children and also the strength of children attending different types of school. Government school in this map is named as GHPS, which we can see that it is located within the locality of 1km. But the children flow to that school is very less i.e. 6.2% only. While at the same distance a private CBSE school is located where about 12.2 % children from the locality are attending that school, most of them go to that school by walking under the supervision of their parents. ICSE schools like Podar international school and Ryan international schools attract a good proportion of children about 12.3% and 7.7% children respectively to each of them. The highest demand is seen in PSBB international school, which is again an ICSE English medium school; about 23% children are attending that school. All the children going to PSBB are from elite class and their parents take pride in sending their children to a school which is reputed as number one school in the locality. This school is located within 7 km on an average from this locality and all children are going to this school via school bus paying a fare of Rs. 12000 per year. These ICSE schools are located at such locations which are easily accessible via Banerghatta road and also Nice road in less than 30 minutes. There are also various schools located in the centre of the city and are calling good proportion of children.

Commuting Pattern of children in Singasandra locality is also similar in nature where a very low proportion of children are going to government school like GHPS located in the locality. Schools like Lawrence High School and Cambridge Public School located towards the centre near HSR residential Layout are perceived as big schools for affluent class. More than 10 to 15% children from the locality are going to these schools. Also Chaitanya Techno School and Christ academy are the most reputed schools, where children and parents are proud to be a part of these schools. Schools located in Electronic city are also more in demand. Although there is Delhi Public School located at 8 to 9 km, but very less proportion of children goes to this school. It may be due to strict admission criteria in these schools.

Figure 5

Figure 6

CONCLUSION

The inequality in accessibility and availability of schools is very remarkable in geographical space in cities. This inequality can be attributed to the centrality of the zones or the market strategies working among clientele of providers. Both the geographical distributions of schools and availability of schools have been analysed. The results show differential distribution in schools with high concentration in centre of the city and shows thinner distribution in peripheral regions. The disparities in the school provision in terms of school availability are also misleading, as they are not commensurate with the population in that age group. It means there is least concern of school education in the city. School location is strategically planned so that it can create good market to match demand. It has little concern of equity in imparting quality education to all.

The section which analysed commuting pattern among school children contend with the idea of urban reform and changes in the city which does not provide appropriate space for commuting of school children. It is found that active commuting is least preferable even among those travelling to lesser distances. Busing in cities is highly demanded for mode of commuting among school children. The risk factor vis a vis notion of safety among parents is an obstacle, which does not allow children to commute by walking and cycling. The city does not provide safer route to school. Commuting flow diagram highlights the demand of different schools in the locality and distances travelled by children. Most of the children travel to larger distances of 10 to 15 km. The schools located at far off places are reputed international schools.

Distances are not that important factor of commuting among school children. In cities, modes of commuting are available sufficiently and thus have least constraint on commuting longer distances. Good education and status are compensated with distances commuted by children. Good education and status are compensated with distances commuted by children. Children belonging to lower income level find difficulty in sending their children by bus as they cannot afford bus fees. Bus fees are also an extra burden on poor parents. Parents also have perception that sending children to nearby area is more difficult than distant schools since buses are provided easily to them. The social and economic inequity reinforces schooling inequality among children. Commutation of school children poses a question to neighbourhood school. Children are travelling longer distances to attend good schools. The choice of schools by parents here are important factor affecting commutation of school children. It is obvious from the results that it is not the availability of the schools in the vicinity that matters, rather than the parental school choice decides that which school they choose for their children. It may be far from home or may be nearer to home.

So, there is need of urban planning which are children centric too and that children are taken care of in all these aspects.

1684 THE PRIMACY OF THE TERRITORY IN TRANSPORT DEMAND MODELING

ABSTRACT

Over the last three or four decades, extensive research work has been conducted worldwide to develop and expand the existing array of modelling methods and techniques to estimate patterns of passenger demand for all types of public transport systems. More recently, particular attention has been paid to the study of passenger demand for metro and light rail systems in urban and metropolitan areas. This paper presents an innovative model, developed on a GIS platform, and designed to estimate, through regression techniques, the average daily passenger demand at each and every stop of the rail network of a metro system. All the empirical work was carried out on the Light Rail System serving the Oporto Metropolitan Area, with a total population close to 1.5 million inhabitants. This 67km long metro system is in operation for 15 years now, and accounts with a comprehensive and detailed statistical database of the evolution of the effective levels of passenger demand in this time period. All the modelling process was based on the understanding and quantification of the complex relationships between the actual demand – we called it, in this case, Structural Demand - at each stop of the railway system and a selection of a restricted number of spatial variables. These are associated with land use patterns of human occupation in the vicinity of each stop, such as residence, employment and major traffic generator activities, as well as with the strategic location of each particular stop within the rail network, measured in terms of access to employment along the line (or lines, in case of a junction), and in both directions, from that same stop. The results produced by this Structural Demand Model were surprisingly accurate when compared against the actual data available to characterise the real levels of demand in the existing rail network. Indeed, given the accuracy of the results produced by the regression model, with a surprisingly high R2 of 0.884, the model was then used to assess the likely levels of demand associated with an investment decision in the expansion of the existing metro system. A number of alternative new lines and possible extensions of existing lines were then assessed. Based on the forecasts of the structural demand levels produced by the model for each alternative, a short list of new lines to be built was selected and subject to political scrutiny and public discussion. The model proved to constitute an important input to the subsequent decision making process. Indeed, a satisfactory balance was reached between all the evidence produced by the application of the Structural Demand Model and the local and metropolitan political objectives and priorities. At moment the expansion project of the Oporto Light Rail System is already at the design stage and the construction works of one new line and the extension of another one are expected to start next year. The total budget is estimated to reach close to 300 million Euros.

SS12.2. Transforming Metropolitan Regions: Ideas and Examples

1573 OTTOMAN URBAN POLICIES: ISTANBUL EXAMPLE

ABSTRACT

Istanbul had become part of Ottoman Empire in 1453. When Turkish first entered, population of the city had been 50.000. This number rose to 700.000 in a few years by making Istanbul the most crowded city of Europe and West Asia. For centuries it was the capitol of economics, social life and administration of the Empire and then Republic of Turkey, although the last moved to Ankara after republic is established, yet importance of the city did remain. This study aims to elaborate what kind of settlement policies had been carried out in Ottoman cities through Istanbul example. Establishment of social-cultural facilities, guild organizations, repopulation of the city, characteristics of newly constructed neighborhoods and legal regulations will be discussed. In addition to physical characteristics of the settlements how religious and nomad background of Turkish people had affected on urban policies and architecture in these lands will be discussed.

1678 ESTIMATION OF SELECTED COMPONENTS OF CONGESTION COST ALONG SELECTED STRETCH OF ROAD IN KOLKATA MUNICIPAL CORPORATION

ABSTRACT

The roads of most cities, particularly, metro cities weren't engineered for today's traffic densities and Kolkata too is no exception. Though the growth rate of the city is only 4.1per cent yet Kolkata Municipal Corporation (KMC) records the highest car density (1,421 cars per sq. km. total area of the city) and second highest car ownership (61 cars per 1,000 residents with regard to total population) in India. Compared to the global standard of 30% of designated road space for Tier I cities the road space is only 6-8 per cent for Kolkata. This is what has created a great congestion chaos in way of accommodating a mixed traffic flow ranging from hand pulled rickshaws to trailers. A surprising manifestation of traffic, however, is not always by huge count of cars plying towards their destination rather it's their individual nature of manoeuvring that lowers the vehicular speed of 'others'. It gradually adds up the travel time incurred by commuters and pollution count along the halting points along with ever increasing occurrences of accidents. Thus the objectives of the study is to assess the losses in terms of opportunity cost and operating cost along the selected stretch of road and put forward strategies to reduce such losses to contribute to a city's economic productivity. The methodology adopted has been calculation of value of travel time index, planning time index, lane length duration index, Congestion Index to adjudge the efficiency of the corridors under consideration. As mobility is inversely related to congestion, corridor mobility index further helps to assess the critical nature of the prevalent congestion scenario and based on this the value of opportunity and operating cost is calculated. In order to capture the relationship under consideration the data has been statistically analysed and cartographically represented. Keywords: congestion, opportunity cost, operating cost, congestion index, and travel time

1053 SPATIAL AND ECONOMIC CHALLENGES OF NEWLY FORMED CAPITAL REGION: A CASE OF ANDHRA PRADESH CAPITAL REGION

Prashanti Rao

Architect and Urban Planner

ABSTRACT

The spatial delineation of Andhra Pradesh Capital Region (APCR) brought new challenges for balanced growth in this region. As per an Andhra Pradesh government proposal, it has been planned to link a 30 mandals in Krishna and 26 mandals in Guntur districts along both sides of the holy Krishna River. This plan reflects the varied economic attributes within the region. Though, the agriculture is the main part of economy in Krishna and Guntur region, there are many other small and large industrial clusters that exist within the region, which also contribute to the economy as a secondary sector. Apart from this, tourism contributes in the tertiary sector with a valuable additional role in economy generation. The physical features of the region like forest, river, hilly region and proximity to sea coast also develop spatial challenges for balanced growth. At the same time the regional connectivity through airways, railways and water ways acts as a catalyst for the development of secondary and tertiary sector. Hence, this paper is focussing on the identification of positive and negative constraints for the balanced growth in the economic sector while it also proposes a few initiatives to strengthen income generation.

Key words: APCR, Balanced growth, Economic sector and Physical features and Spatial challenges

BACKGROUND AND RELEVANCE

The basic principle of formation of capital Regions in India is shifting to linguistic priorities. The formation of capital regions many a times face problems of uneven land distribution, land acquisition, loss of income resources, if not planned and delineated properly. The change in existing administrative boundaries and launching of new schemes and regional development project creates imbalance in growth. Hence it is very essential to identify the growth parameter both physical and fiscal. In order to understand the growth dynamism Andhra Pradesh Capital Region (APCR) has been selected for study concern. As most of the population is dependent on agriculture in Andhra Pradesh. Since the major part of land, which is acquired by the government, is agricultural land, this acquisition of agricultural land leads to loss of livelihood. The Andhra Pradesh Capital Region is the area covering the proposed Andhra Pradesh capital city along with nearby metropolitan areas and small towns around it. On 2nd June 2014, the north-western portion of the state was bifurcated to form a new state of Telangana. The entire region is under the jurisdiction of the AP Capital Region Development Authority (APCRDA). Amaravati is the proposed planned capital city. It is located on the southern banks of the Krishna River in Guntur District, within the Andhra Pradesh Capital Region. The location chosen for the Capital City is in the vicinity of Vijayawada and 20 km from Guntur. It falls in Thullur, Mangalagiri, and Tadepalli mandals of Guntur District with an area of 217.23 sqkm.

Table 59 Demographic Profile of Andhra Pradesh Capital Region

Demographic Profile							
As per census 2011	Area (sqkm)	Population	% of AP Population	Literacy rate /100 population	Sex Ratio/1000 population	Urban Population %	Rural Population %
State							
Andhra Pradesh	160205	49386799	-	67.6	966	14618493 (29.6)	34768306 (70.9)
Krishna District	8727	4529009	9.17	73.7	992	1847835 (40.8)	2681174 (59.2)
Guntur District	11391	4889230	9.90	67.4	1003	1657449 (33.9)	3231781 (66.1)
APCR	8603	5873588	11.89	63.1	1001	2753745 (46.88)	3119843 (53.12)

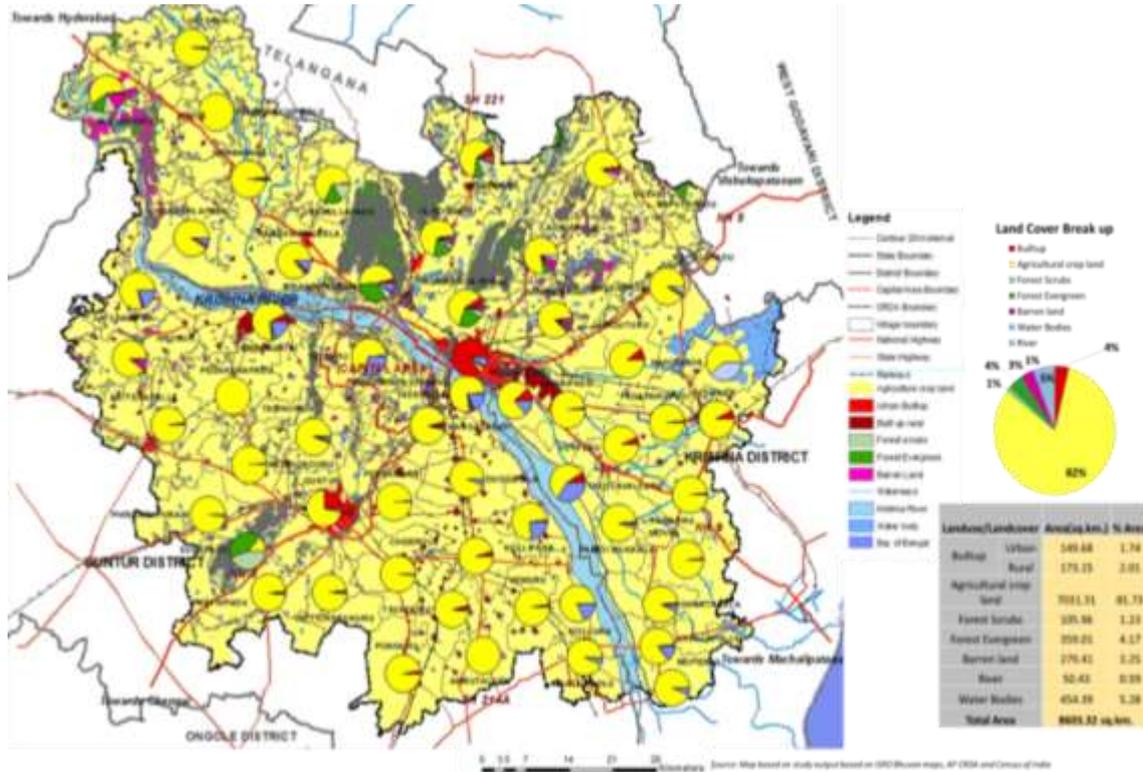

Source: APCRDA

The urban population within APCR has witnessed a rapid increase. The urban population in the year of 1991 was 16,98,224. This population in the course of next 10 years increased to 20,20,560. As per the Census of India 2011, the urban population of APCR was found to be 27,53,745. The population decadal growth rates from 1991–2001 was observed to be 18.98% and the population decadal growth rate from 2001–2011 was observed to be 36.29%, almost double the previous decade. The rural population within APCR has not increased rapidly as compared with the increasing urban population. The rural population in the year of 1991 was 29,99,546. This population in the course of next 10 years increased to 32,24,266. This increase in urban population is the result of people shifting from outer rural areas into the inner urban area. This increase will lead to an enhancement in the requirement of land, income opportunity and other basic infrastructure.

ECONOMIC BASE

Agriculture is the main part of economy in Krishna and Guntur region. Paddy, Grams, Cotton and Chilies are the major crops in both districts. In Krishna district, 10 industrial estates are developed by APIIC and 2 are private estates in Guntur. There are 11 industrial estates, 3 autonagar and 2 shopping complexes. Clusters in Krishna district include industrial,

handloom, handicraft and handloom clusters. Industrial clusters include food processing cluster, pharmaceutical cluster, rice mill clusters, textile cluster, auto component cluster, furniture cluster, burnt lime and lime stone clusters and foundry activities. Handicraft clusters comprises kalamkari printing, toy and puppet making, embroidery, stone carving and brass and bell metal. Land cover map shows that 102.36 sqkm area is agricultural crop land which is 82% of total APCR area. This clearly states that the major population is dependent on agriculture 53.12% population.

Map-1 Landuse Landcover Map of APCR

MAJOR ECONOMIC SECTORS

There are three major sectors within the Economic Sector – they are primary, secondary and tertiary sectors. The sub sector, which comes under these sectors are given in Figure 1. Tertiary sector contributes majorly in the domestic product of the Capital Region. Secondary sector contributes the least in the domestic product of the Capital Region. The domestic product of the secondary sector has increased in 2014 when compared to 2013. The region has potential for various industries. The per capita income in the capital region has increased by 8.8%. When we compare the per capita income of the Capital Region, then we find that it has higher value compared to per capita income of the country (India) and the State (Andhra Pradesh). Vijayawada Urban has highest MDP but a very low PCI.

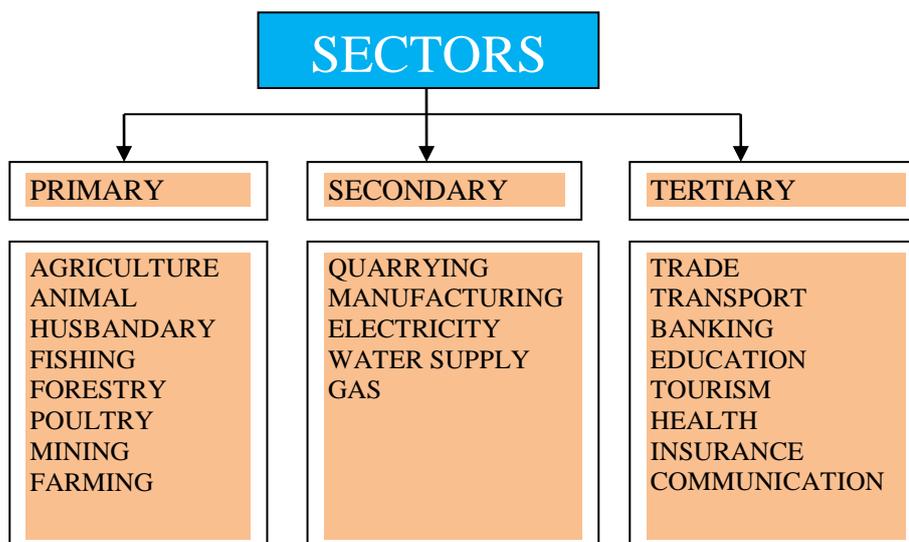

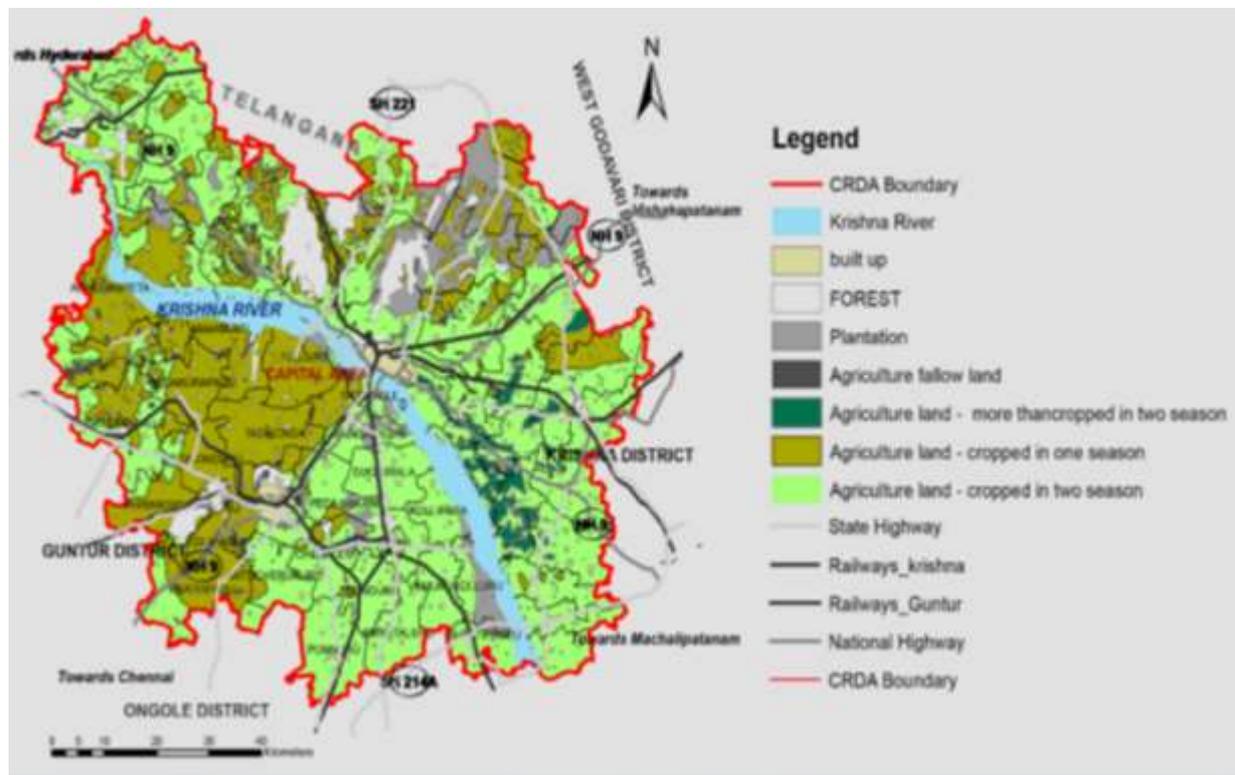

Figure 1 Major Economic Sectors

This is because the population of the mandala is the highest. Similar is the case for the observation of Guntur. Most of the mandalas, which has high MDP, has major share of activity as tertiary. Mandalas which have primary sector as their major activity, has the least MDP. Also these mandalas have lower population, which might be due to the lack of job opportunities, which leads to migration.

I.PRIMARY SECTOR

Andhra Pradesh is predominantly an agricultural state. Nearly two-thirds of the labour force in the state depends on it for their livelihoods. Yet the share of agriculture in the state income dropped below 20%. The state is adversely placed with respect to both soils and rainfall, which are the key resources for agriculture. The agriculture sector is the important sub-sector of the primary sector in Andhra Pradesh. Agriculture has been a way of a life and continues to be the most important livelihood of the masses. Stabilization and augmentation of productivity assume critical importance, given the limited area scope for increasing under cultivation of various crops and the contribution of district towards paddy production was 606135 tons in the year 2013–2014 and area under cultivation was 268072 hectare. Maize is another main crop with a production of 548722 tonnes. Guntur district is famous for the chillies production while the Krishna district is famed for the mango crop.

Map-2 Cropping pattern in APCR

II. SECONDARY SECTOR

The secondary sector consists of five different sub-sectors, according to which the analysis is done in this regional study. These sub-sectors are Mining and Quarrying, Construction, Manufacturing (Registered), Manufacturing (Un-registered) and Electricity, Water Supply and Gas.

The main objectives of this sector are as listed below:

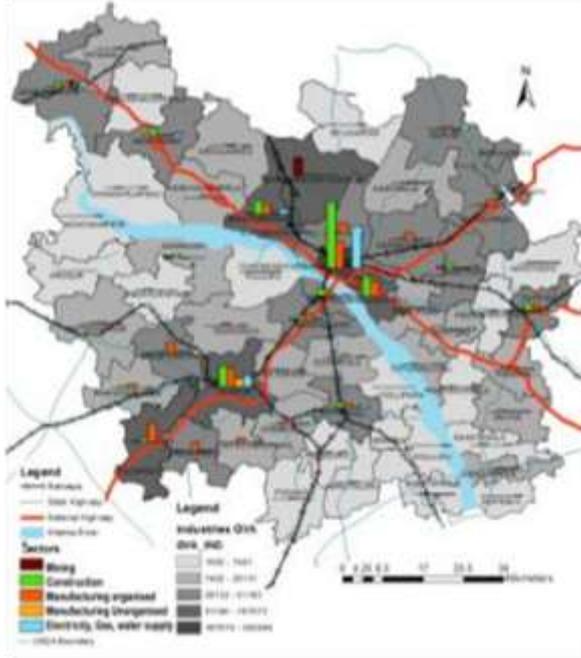

- Understanding the existing scenario, impact and potential of industries in the region.
- Identifying potential and thrust area for the development of the region by utilizing its natural and human resource.
- Preparing strategic plan for the economic development in secondary sector for the region.

The Mandala with the highest Gross Value Added (GVA) contribution in the industries sector is Vijayawada Urban. One of the major urban centres in the region, it has increased developmental activities. This is the likely reason; it has the highest share in the construction industry. The maximum numbers of industries are also located in the same Mandala of Vijayawada Urban. There are a total of 54 large and medium scale industries in the region. The classification of these industries has been done according to global industry classification standard. In both the districts under the APCR it can be seen that most of the industries are situated near the National Highways. This might be due to convenient logistics and transportation facilities. Some of the industries are located near the Krishna River. More number of large and medium scale industries are situated in the developed mandals of Ibrahimpatnam, Edlapadu, Jaggiahpeta. More industries can be observed in the Krishna District as compared to Guntur District. There are a total of 5380 factories registered in the APCRDA region. There are 107405 people employed in these factories. The Ministry of Environment, Forest and Climate Change (MoEFCC) has developed the criteria of categorization of industrial sectors based on the Pollution Index which is a function of the emissions (air pollutants), effluents (water pollutants), hazardous wastes generated and consumption of resources. In Krishna: majorly industries fall into the orange category followed by red, green and very few white.

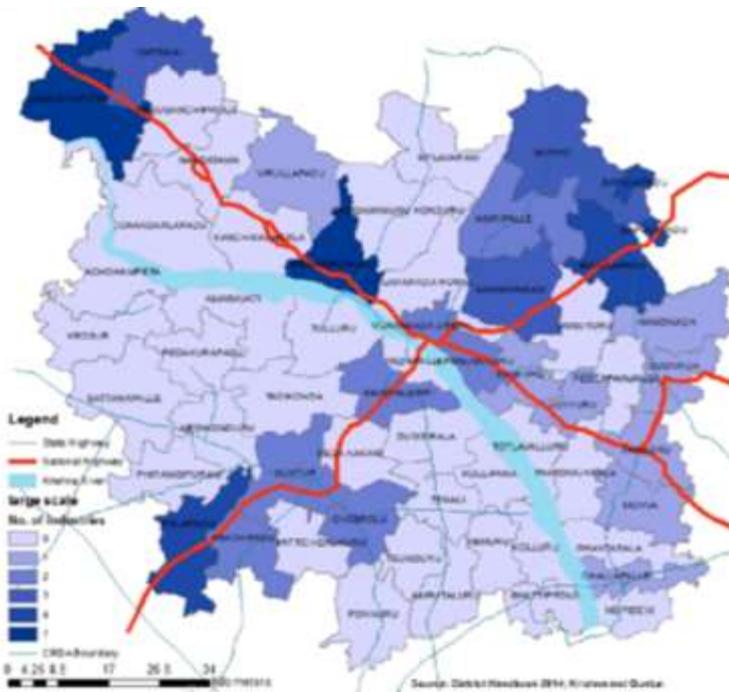

Table-2 Type of industries in Vijayawada and Guntur

Type	Vijayawada	Guntur
------	------------	--------

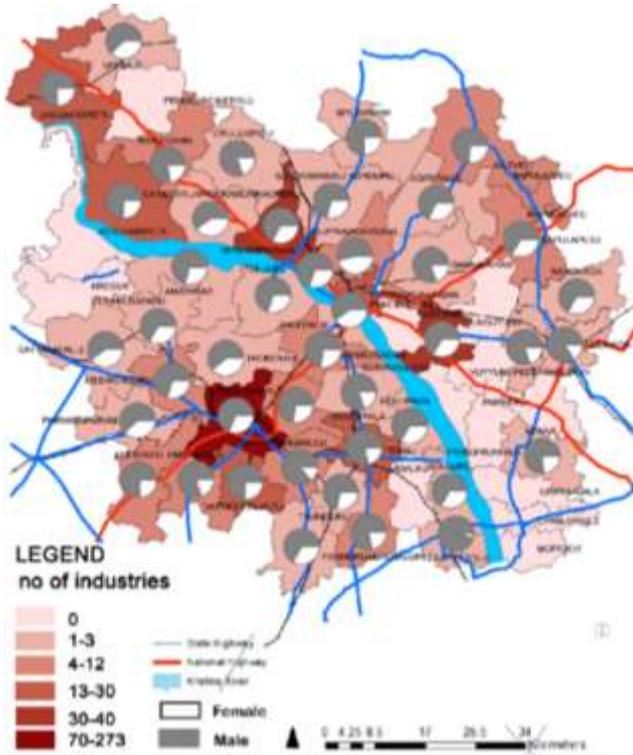

Red	Textile, oils and material industries	Ibrahimpattanam, Jaggayyapeta, & Vijayawada urban mandals	Materials, sugar, power generation	Atchampet, Kolluru, Tadepalli, Kollipara mandals
Orange	Tobacco and beverages	Ibrahimpattanam, Penumuluru, Vijayawada Urban, Vijayawada Rural, G.Konduru, Kanchikacherla.	Cattle & Aqua Feed, Printing of posters, photo offset process, Solvent extracted oil	Medikonduru, Guntur, Edlapadu, Chebrolu mandals
Green	Cotton and agro based	Ibrahimpattanam, Penumuluru, Vijayawada Rural, Gannavaram.	Cotton and Agro based	Guntur, Mangalagiri, Tenali mandalas

Map-3 GVA of Secondary Sector Along With Its Different Categories

Map-4 Small scale Industry of APCR

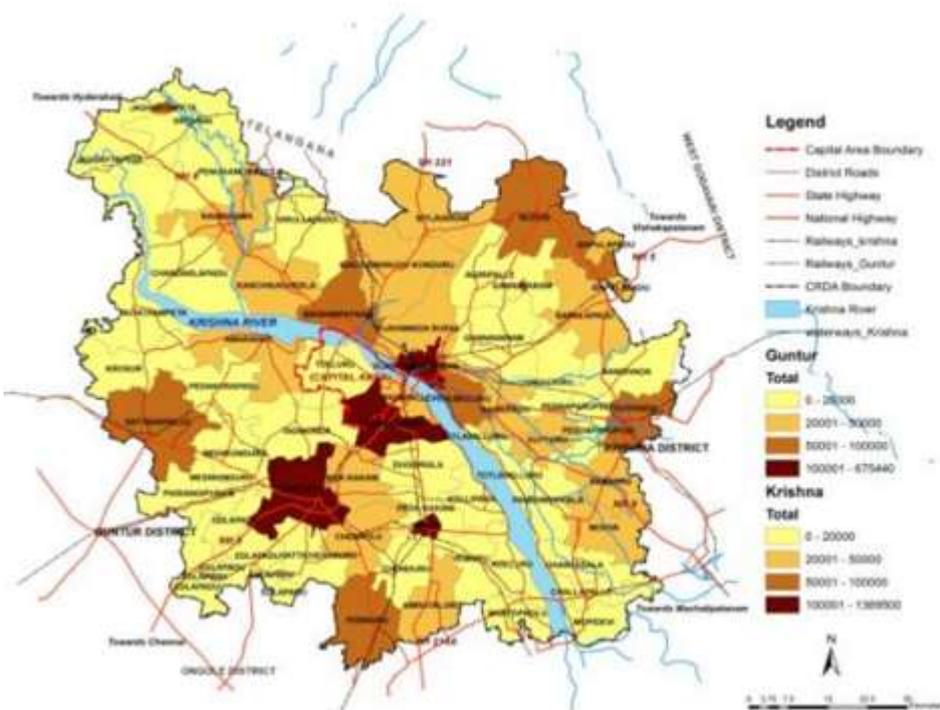

Map-5 Large and Medium Scale Industry of APCR

There are many different kinds of small scale industries in the APCRDA region. The total number of registered SSI units in the region is 610 (2014). The number has increased from 361 in 2012. Out of the 610, Guntur has 384 SSI units and Krishna has 226 SSI units (2014). About 10636 people are employed in the small scale industries out of which 70% is the male population whereas only 30% is the female population working in SSI units.

III. TERTIARY SECTOR

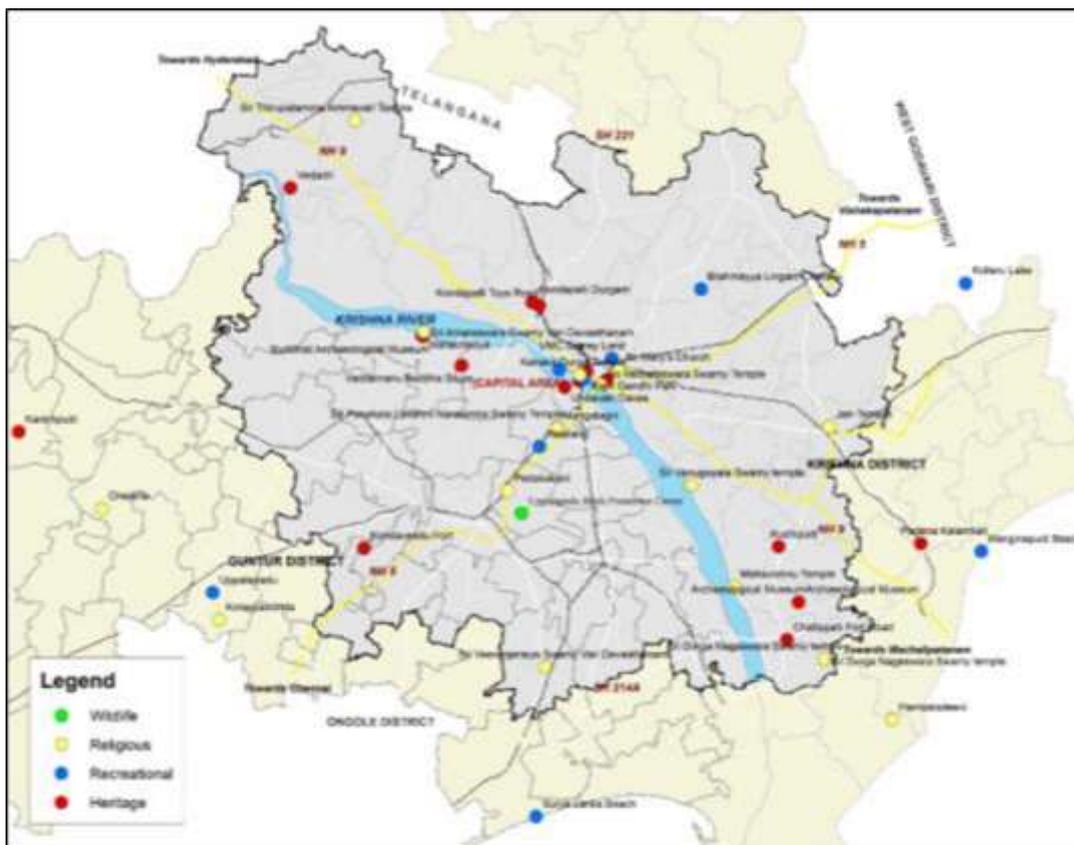

The tertiary industry is one of three industry types in a developed economy, the other two being the primary, or raw materials, and secondary, or goods production, industries. As an economy becomes more developed, it shifts its focus from primary to secondary and tertiary industries. The tertiary sector includes service industry and it holds high importance among all sectors. The tertiary sector of economy involves the provision of services to business as well as final consumers. The sub-sectors of tertiary sector are Trade, Hotel and Restaurant, Railways, Transport by other means & storage, Communications, Banking & Insurance, Real Estate and Professional services, Public administration and Other services: tourism, etc.

MAP-6 Distribution of GVA of Tertiary sector of APCR Mandals

Tourism is the most prominent territory sector. Andhra Pradesh has been one of the highest visited states in the country. In 2012, the consolidated state of AP was the highest visited state by domestic tourists. In 2013, the new state of AP was the 3rd most visited state in the country by domestic tourists accounting for 8.6% share to total domestic arrivals in India. However, in terms of foreign tourist arrivals, AP stands 18th in the country with a share of about 0.35%. The progress brought by tourism industry over the period of time. The growth has been increasing steady from past few years in terms of GSDP.

- Krishna and Guntur districts offer a lot of sites of heritage and cultural significance. The culture of Krishna district is mostly traditional in rural places and moderately modern in Vijayawada. Krishna district has 59% share in the tourism and Guntur district has 41%.
- It is also famous as the birthplace for Indian classical dance named “kuchipudi”.Guntur District has a dams and waterfalls along Krishna River in the end many Buddhist and Hindu temples. Most of these key heritage and cultural destinations fall in the Capital Region.
- Krishna district stands on 2nd position from all 13 districts of AP state for domestic tourists in 2016. Krishna district has increased 94% and 65% in comparison to 2014, while Guntur increased by 52% and 10% in 2015 and 2016 in comparison to 2014.

MAP-7 Tourist spots in APCR

There are 56 mandals in APCR out of 56 mandal tourist locations are in 17 mandals. Out of them **Vijayawada urban** mandal has 7 tourist location, **Amravathi mandal** has 4 tourist locations, **Penamaluru** mandal has 3 and rest 14 mandal has 1 tourist locations each. **Vijayawada urban, Ibrahimpatnam** and **Jaggayapeta** have highest Heritage tourist spots from all mandals. **Penamaluru**, has the highest Religious tourist spots from all mandals. For the Foreign tourist Kanak Durga temple then followed by, Kotappakonda, Mangalagiri are most visited religious tourist locations. **Vijayawada urban** has highest Recreational tourist spots from all mandals.

CHALLENGES

I. POSITIVE CONSTRAINTS

As region is rich in culture and tradition there are lack of traditional industries, for example Kondapalli toy making is prevalent in the area. The growth rate is good only in a few selected mandalas, the developed regions of Guntur and Vijayawada has seen considerable amount of growth as compared to other mandalas, so these areas served as major economic areas and have burden of migrating population and their requirement.

Due to favourable climate, location and topography there is potential of new industries like:

Table 3 List of the potential of new industries

Agro-based Industries	Rice,Poha, Oil Mills, Dairy Products based on Milk, Papad / Pickle, Grinding & Packing of Spices, Mango Jelly and Jam.
-----------------------	--

Mineral-based Industries	Quartz grading, Fly Ash bricks, Cement lattices, grills etc., Cement based particle board, Cement concrete pipes, Mosaic flooring tiles.
Livestock based Industries	Egg trays, Poultry feed, Meat processing, animal feed, Buttons from cattle horns, Wool carding and knitting
Fisheries	Feed, Fish oil, Fish meat cubes, Processing, Packaging of fish/shrimp

II. NEGATIVE CONSTRAINTS

- I. Even after having rich culture very meagre textile industries are there. The region is rich in agricultural resources but a very few agro based industries are found in the region. Lack of traditional industries – Kondapalli toy making is prevalent in the area As the region will start developing exactly like capital region there will be no scope of new textile or agro based industry and burden will be increased on other source of income and employment which will lead to imbalanced economy. Mandals in Guntur district contributing less in trade and commerce sector as compared to mandals in Krishna district. Sector burden is more towards Vijayawada urban and Guntur city. It needed to be shift towards other mandalas located at APCR boundary.
- II. The tourist arrivals were reduced in year 2013 due to the bifurcation of the city, as there were many riots and the growth took few years to recover tourist back in state as previously. APTDC is looking for the overall Andhra Pradesh tourism, and district tourism departments only concerned with their respective districts just like Krishna & Guntur tourism department. There is no **Act/Policy** which will mandatory for all Hotels, Travel Agents, Tour Operators, Tourist Guides, Tourist Taxi Operators, water sports operators and Dealers etc. There is no **Act/Policy to protect and maintain** the tourist places from deterioration and **preserve** their tourism potential like to protect Kondapalli Fort, Kondaveedu Fort etc. There is no act/policy/guideline for **watersports activities guidelines** on Krishna river & to reduce water pollution. There is no guidelines for proper signage and everything is written in telegu which is very difficult for other tourists outside from Andhra Pradesh.

CONCLUSION: A WAY FORWARD AND STRATEGIES FOR BALANCED GROWTH OF APCR

Strategies to convergence not only the schemes within the department but also converge the various sectors and the actors who are working to help the farmers in the Andhra Pradesh capital region.

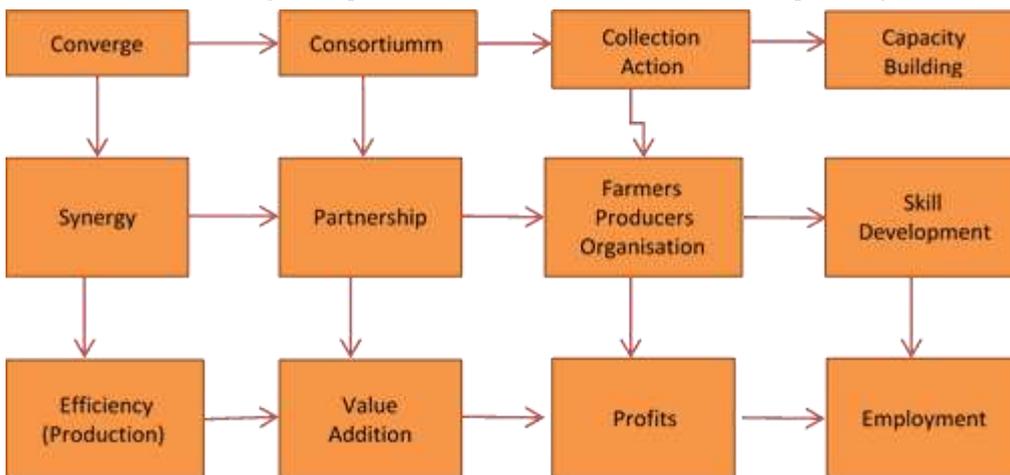

Figure 2 Schematic Strategies for the balanced economic growth

Through convergence, consortium, by building the partnerships including public private partnerships and collective action of the various actors (e.g, farmers’ producer organizations) and improved well being of our farmers through capacity development. The final goal of achieving the increased production through increased efficiency, increased profits, through value addition and enhancing the employment opportunities through skill development will be achieved as depicted in the above Figure. For achieving this growth, the mission will need to innovate the technologies, partnerships, institutions and enabling policies through convergence of schemes, departments/sectors, resources through improved communication and convergence of minds of various actors for enhancing the efficiency through use of ICT, science-led interventions, value addition and market linkages as depicted in the following diagram. The important strategy in addition to the above mentioned components, the mission will target increasing the awareness, ensuring the effective delivery systems for knowledge and inputs; processing by adopting value chains and market linkages and ensuring enabling policies and institutions along with effective and regular monitoring mechanisms at all the levels.

PROPOSED STRATEGIES FOR SECONDARY AND TERTIARY SECTOR

Based upon analysis of both primary and secondary sector two sectors were identified namely agriculture based and mineral based. As the region is rich in agricultural resources (rice, chillies, maize, and cotton) and abundant limestone is found in a part of the region. Related industries based on these such as rice mills, spice parks, textile mills, and cement industries have been proposed.

A. Agro Based Industries:

The region is rich in terms of agriculture-resources and it is historically called the "Rice Bowl of India" and continues to be the largest producer of Rice in the country. The region is also the leading producer of cash crops like Tobacco, Groundnut, Chillies, Turmeric, Sugarcane and Maize. It produces some of the finest varieties of fruit like mango, grape, guava, sapota, papaya and banana.

I. RICE MILL

Rice mills concentrated only in Vijayawada mandal. Rice mills are appropriate for the achieving the objectives as:

Labour intensive work – employment generation

Staple for over half of the world population – huge demand

Issues faced by rice mills industries

Uneven rainfall

Lack of proper storage and warehousing

Lack of adequate agricultural training

Inadequate infrastructural facilities (Roads, Transport, etc.)

Less integrated large and small scale industries

Potential clusters and reasons for selecting the above mandals are as follows:

In Krishna region of APCR :Vuyyuru, Kankipadu, Unguturu, Pedaparupdi

In Guntur region of APCR :Chebrolu, Ponnuru, Amrataluru, Tsunduru

Raw material availability: the mandals where yield of rice is high and has not been utilised to its full extent in the industries.

Availability of supporting services: water availability for the industries is important on daily basis, accessibility for importing and export, power supply. These mandals have sufficient water availability through the already existing water bodies and good railway and roadway connection.

Availability for labour: these mandals have more population of non-workers, the upcoming industries will generate and create employment opportunities for them.

Proximity to urban centres: the mandals have proximity to the markets to sell the products manufactured in the industries and also to the existing warehouses to store the produce.

a) Cluster level benefits:

- Evolution of common infrastructure for all cluster SMEs in the form of common marketing yard, common testing laboratory.
- Creation of a proactive consortium that will continue to add value to the cluster units.
- Various training programmes including a month long growth programme to promote exports.
- Creation of integrated SSI.

II.SPICE PARK

The Regional crop specific Spices Park is a well-conceived approach to have an integrated operation for cultivation, post harvesting, processing for value addition, packaging, storage and exports of spices and spice products. The Spices Park will ensure better pricing for the produce by eliminating intermediaries from the supply chain system currently followed locally for trading of spices. The facilities available in the Spices Park can be utilized by the farming community for selling their produce directly to the exporters by improving the quality of the products. Hence, the farmer community will get premium prices for their produce. The production of chillies is abundant in the southern part of the region. This needs to be exploited, i.e. further developed for suitable activities.

CLUSTER IDENTIFIED

Tsunduru, Amrataluru, Chebrolu, and Tenali These consist of the mandals rich in raw material as well non workers. Also less developed mandals such Tsunduru and Chebrolu.

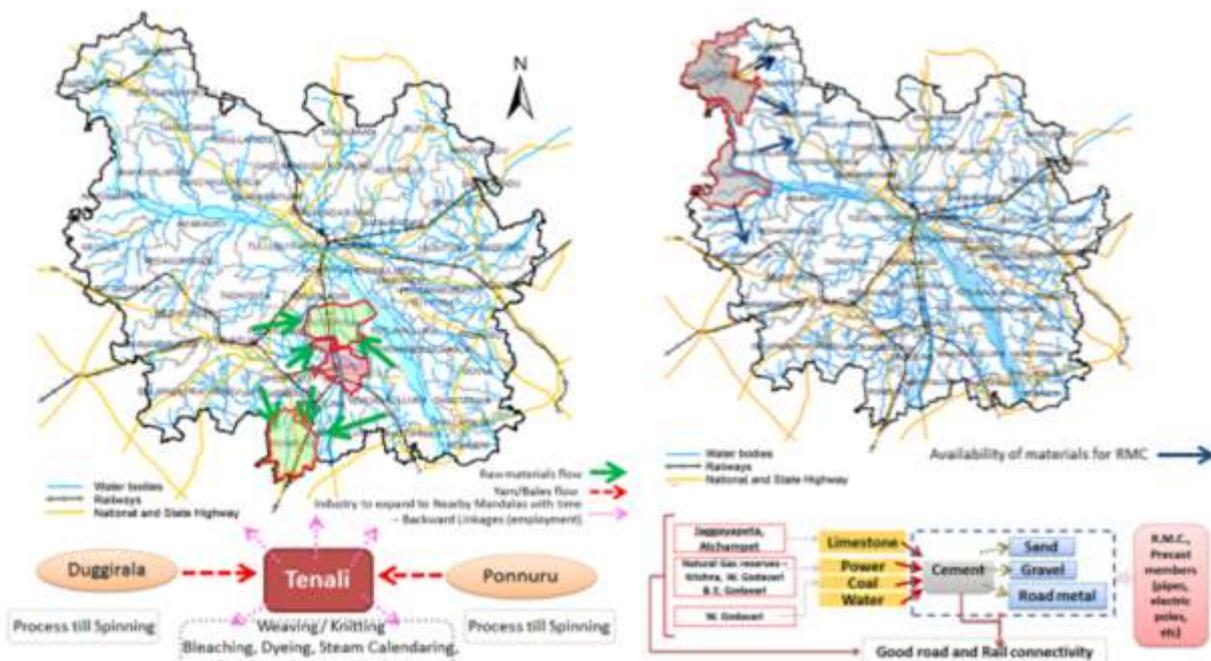

FIGURE-4 Identified Cluster For Spice Park

III.COTTON TEXTILE AND CEMENT INDUSTRY

An Integrated Textile Park at Tenali on is proposed to promote textile industry in Andhra Pradesh. This envisage 100 small scale industries relating to garment manufacturing, weaving, packaging and other accessories manufacturing units

in association with A.P Spinning Mills' Association (APSPA), AP Cotton Association and Guntur Ginners' Welfare Association.

MAP-7 Textile Park and Cement Industry

FIGURE-3 Linkages between different stakeholders

POLICY INTERVENTIONS

Special incentives package could be offered to the manufacturing units proposed to be set up in the rural areas located in high priority and priority zones. This could combat the high cost involved in development of the supply chain management, infrastructure development and manpower development.

Manpower training and skill development: State Government has established 'Anchor Institute' for sectors such, Food and Agro based, Mines and Mineral based and textiles. Industrial association/industry members should be involved in entire process of establishing and running of the anchor institutes so that they gain industry acceptance and market leadership easily.

Access to finance and administrative support: Reserve Bank to encourage commercial banks to lend credit to the industrial units located in rural areas or backward districts. As a special incentive 2% interest subsidy could be offered to the loans offered to the industrial units in rural areas.

After observing existing resources; natural and infrastructural, selection of Mandals for infrastructural updating, policy level proposals and environmental recommendations for a sustainable growth; we can foresee in the livestock sector like employment generation, economic betterment and environmentally conscious growth being fulfilled till 2037. To avoid spatial disparities and economical imbalance in future this is the right time to develop secondary and tertiary sector to achieve sustainable growth which will not lead to haphazard development and stabilize economic growth throughout the region. To reduce burden on Vijayawada urban it is important to distribute industrial development and economic opportunities throughout the capital region so that potential of different areas can be used.

ACKNOWLEDGEMENT

I would like to acknowledge the students of MPUR 2017 Batch of SPA Bhopal students for data collection and GIS Map Preparation. As the whole study is based on primary and secondary data available from the departments, hence in references only department names were mentioned.

ABSTRACT

In this article, the research work focuses on the analysis of the “dark matter” that embodies the city, not always visible yet constant, and looks into possible visions of development, new urban concepts and planning methodologies to better understand the metamorphosis of the city’s body. In order to do this, we propose to address some of the phenomena resulting from the urban sprawl and the emergence of diverse space categories in that evolution process. We analyze, from a historically-conceptual point of view, the roots of the Functionalist City and the adoption of zoning as an urban planning model and operative system of land use, closing the chapter with a critical analysis to current constraints of this urban model. The article concludes with the presentation of some new concepts that have come to be explored by contemporary urbanology, bearing in mind the diversity and heterogeneity which characterize the new territorialities formed within metropolitan areas.

Keywords: urban sprawl, city, urbanism, metamorphosis, territory.

INTRODUCTION

In this article we develop the concept of metamorphosis of the urban body of cities, as an adaptation process characteristic of the built environment and the social fabric. The adaptation and transformation of urban forms are constant metamorphic processes in cities, with characteristics that give rise to a renewed urban body resulting from its adequacy to each historical cycle, or as a result of natural or man-made disasters.

These changes manifest themselves more evidently in big cities, by the impact of the early 20th century new industrialization and urbanization phase, as result of the transposition into the urban planning of Frederick W. Taylor’s (1856-1915) theories about the need to increase the efficiency and competence of organizations, and the principles of mass production conceived by Henry Ford (1863-1947).

This radical process of urban transformation, whose image reflects the new social division of space and of the industrial standardized production, resulted in a more intense land use and occupation, contributing to a scale never before reached of urbanization by the end of the 20th century, the scale of megacities and global cities.

Since then, several urban and architectural approaches have been elaborated, facing the enormous scale of the economic and social challenges and the constraints that affect millions of people who have chosen the city as preferred habitat. However, only now their methodologies have reemerged, evoking other urban approaches that must be apprehended or recovered.

How can we include in the ongoing urbanization process all the multiplicity and aggregate approaches that are forming tangible and intangible emergent territories, whose description or mapping has become a very hard task to achieve?

The new urban dynamics have force urban designers to develop new proposals for planning and management of cities, especially in the case of large metropolitan areas. Facing rapid transformations and technological challenges several visions and methodological approaches in the teaching of urbanism are currently being discussed, in reply to numerous programmatic questions and philosophical orientations. This entails the reformulation of proposals and of academic course units, implying a holistic re-reading of the themes and objects of study, and requiring new teaching logics leading to a better understanding of the cities and megacities phenomenology.

This article seeks to focus its research work on the study of the “dark matter” that upholds the body of the city, although not always visible despite being a territorial constant, looking to the analysis of possible development visions, new urban concepts and planning methodologies to better understand the on-going metamorphosis of urban forms.

FROM THE BIG CITY TO THE URBAN SPRAWL

The expansion and urban growth are not unique phenomena of the modern city. “In fact, the city and the suburb appear in a concomitant way: (...) this extension would avoid the stuffiness of agglomeration closed within the perimeter of the walls” (Munford, 1964:605). However, unlike what has happened with the classical city, the various types of expansion and growth of last century’s major cities were not previously outlined in technical terms, nor were they the result of a conceptual or geographic-specific process. Their conformation appears as the result of the “natural” evolutionary cycle of each city with its surrounding territory, without it necessarily corresponding to a previously conceived theoretical-urbanistic basis.

The city has always been a polarizing urban reality of human activity, and the 18th century industrialization was first and foremost an accelerator of urban development, which had been growing steadily since the Renaissance. With the Industrial Revolution, the city lost its umbilical relationship with history and vernacular tradition. Emancipated, it reached adulthood and started a new life, independent of its paternity. It was in a gradual manner that the industry made its way

to the city in search of capital, markets and an abundant supply of low-cost labor, resulting in the formation of the big city and more recently the metropolitan regions, the world- and global cities.

To Ludwig Hilberseimer, “industries and mechanized transportation have made possible the creation and the rapid growth of our cities. But this growth, unplanned and undirected, has resulted in sheer chaos. Each part of the city affects other parts disadvantageously. Blight and slums appear. Traffic hazards increase. City dwellers begin to desert the city for the suburbs. The very forces which created the city seem now to be destroying their creation. Meanwhile, decentralization and suburbanization, proceeding without plan or direction begin to create outside the city the same chaos and confusion” (1955:108).

This growth, commonly referred to as *urban sprawl*, is used to describe the physical expansion of urban areas. Classically, the urban sprawl is a phenomenon that originated in the United States of America at the beginning of the 20th century, which was powered by the fast access to the private car ownership and the residents preference for isolated familiar houses, built on the outskirts of American cities.

Currently, the sprawling cities correspond to the idea of an inefficient and uncontrolled urban development, without planning, characterized by a mix of land uses and an expansion pattern of low-density vast areas, mostly in rural areas, in 18th and 19th century cities’ urban fringes. According to the European Environment Agency (EEA), the urban sprawl is the leading element of urban growth and implies unequal, scattered and spread out development with a tendency for the discontinuity, and is now seen as one of the biggest challenges in contemporary urban planning.

Referring to this multiplicity of spaces, Peter Sloterdijk, proposed the concept of *Foam City*, which he described as “a topological singularity, defined by manifold places to gather crowds, local apartments complexes serving as housing capsules and, finally, as territories where have being establish the various institutions of the world of work, through which, the majority of citizens ensure the economic foundation of your existence” (2005:578-579).

This marked metropolitan dynamics subverted the urban structures and led to a definition of the concept of Metropolis that overflows the classic space frame, comprising the perimeter of everyday urban activities in large cities and in their peripheries. In this context, the word *city* acquires an ambiguous meaning: should it be used to designate the entire urban agglomeration, or only its core (Marques, 2015:11)?

GLOBAL CITY AND MEGACITY

As Saskia Sassen refers, at the end of the 20th century the geography and the composition of the world economy have changed, producing a complex duality: a spatial dispersion, while the organization of economic activity remains globally integrated.

These changes in the functioning of cities had a massive impact both in urban form as well as in social and economic world order. According to Sassen, a new kind of city emerged: the global city (term first applied by Sassen in 1991).

We must, however, differentiate the concept of *global city* from the concept of *megacity*, establishing a difference between the true role each city represents globally – Calcutta is a megacity, but not a global city, Frankfurt is a global city but is not a megacity.

A global city, beyond its physical scale, has a direct and tangible effect worldwide through socio-economic and financial factors, the ability to influence the cultural industries and the circles of technological innovation, in the emergent context of the civilizational process that is appointed as globalization. Rather, a megacity can be characterized primarily by its scale and spatial dispersion, massive concentration of inhabitants and sufficiency of services – all this without having a correspondence to an interconnectivity with the beforementioned factors, associated with the global cities’ network.

The *Globalization and World Cities Study Group and Network* (GaWC) sought to develop a system to classify and establish a hierarchy on global cities, which they designate as *world cities*, taking into consideration that these “cities are assessed in terms of their advanced producer services using the interlocking network model (...) indirect measures of flows are derived to compute a city’s network connectivity – this measures a city’s integration into the world city network”⁴⁷⁰.

Among the various patterns of classification and hierarchy levels proposed by the GaWC, we highlight the following:

- *Cosmopolitan characteristics and economy of multinational corporations – this consists in identifying the strategic domain of certain global cities on the global system through analysis and order of preference regarding locations of multinationals corporations’ headquarters and the performance of its influence in politics, business, communications, finance, education, culture and technology.*
- *The new international division of labor – centered on the power and decision-making ability of multinational companies in the context of the new international division of labor, based on location criteria of the great financial centers, headquarters of international companies and institutions, important industrial centers, transportation centers and population size.*
- *Internationalization, concentration and intensity of service production – in which the urban hierarchy results from the high concentration of command points in the world economy organization, offer of services and markets for the products, and specialized innovations produced on a global scale.*

⁴⁷⁰ See GaWC Research Bulletin 23.

- *World cities as international financial centers – which identifies the major cities and their relative position as supranational financial centers, "Capital capitals" which enhance the effect of cities' polarization.*

Through the decomposition of these factors at various levels of analysis: cultural, political, economic, and geographic, simultaneously worked from an empirical and theoretical point of view, it is possible to estimate what distinguishes a world city from a megacity. This distinction between cities is subject to a monitoring process that evaluates the progress of development and consequent implications in their re-ranking, according to the previously established criteria.

Hence it is logical to conclude that the concept of global city or world city does not derive as much from its urban or architectural morphology, but rather from economic, technological or productive factors, which condition the urban body's configuration that then becomes understood as the supporting element of a complex connectivity of financial markets, from which urban development and possibly the urban public policies depend on.

NEW URBAN CONFIGURATIONS

As a result of the beforementioned economic transformations and the increased concentration of population in large cities, there is a significant territorial transformation, now being possible to perceive the main trends that characterize, in morphological terms, the formation of new urban organisms. According to Jacqueline Garnier (1997:126), the growth of urban contemporary organisms can be identified, generally, in four main space systems: urban-agglutination, urban-agglomeration, conurbation and urban-nebula. We proceed to analyze each of these forms of territorialization.

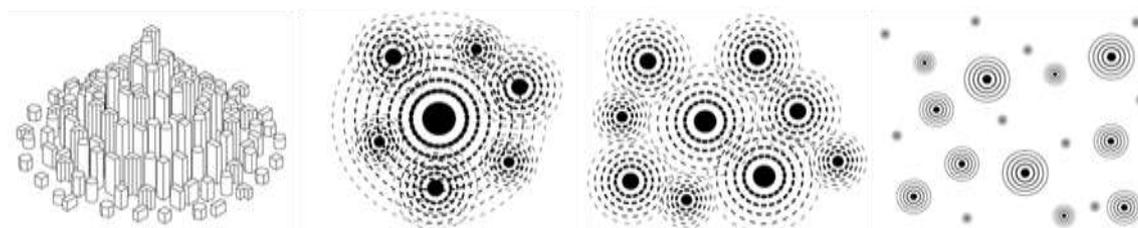

Figure 1 - Urban-agglutination, urban-agglomeration, conurbation and urban-nebula. (own source)

Urban-agglutination – In urban agglutination, also called internal filler, all the space inside the city is occupied. As much as possible is built in the same area, or the floors in urban buildings are multiplied by increasing built volume through growth in height. This urban morphology corresponds to what we can designate as *compact city*, which corresponds to the concept of *inner-city*, term used to designate the central area of metropolitan areas. Urban growth models developed by the Chicago School explain how this process can acquire different organic settings – concentric, by sectors, or multicore – the latter being the spatial model which best characterizes the current growth process of large cities, where each core becomes a sub-center of agglutination, by developing into a new urban centrality or *Central Business District*. After a first phase of urban concentration, the city tends to expand to the periphery obeying a growth process that we previously designated as *urban sprawl*.

Urban-agglomeration – The urban agglomeration is the result of the attraction that a main city exercises on surrounding areas, dormitory-cities, satellite cities and the culturally defined local centers. It is the main city that organizes the converging transport network, concentrations, etc., thus functioning as a “mother city” that “exports” to its colonies trade services, culture and the political and economic power kept from its old origin. Urban agglomerations can be of linear type, star-shaped or in network, usually depending on privileged directions for transport communications between the various sub-nucleus of the polycentric system.

Conurbation – Conurbation is a term originally introduced by Patrick Geddes to signify a new form of social grouping, born at the end of the first period of industrialization. “To focus these developments, indeed transformations, of the geographic tradition of town and country in which were brought up (...), we need some little extension of our vocabulary; ... what of ‘Conurbations?’ (...) new form of population-grouping, which is (...), developing new forms of social grouping, and of definite government and administration” (Geddes, 1949:14-15). Currently, the term conurbation applies to the spatial model that results from the parallel growth of several neighboring cities distributed in a territory where the main centers maintain a degree of independence from one another and a marked identity, even if one of them has some prominence. Examples of conurbations are the cities distributed along the East coast of the United States of America, or the Japanese Archipelago megapolis.

Urban-nebula – Urban-nebula consists of an irregular scattering of small towns, very close to each other, showing the existence of a spatially extensive and virtually homogeneous activity. In many cases these are new cities born of small industrial cores connected to service districts, or small and medium-sized cities where there has been a rapid increase in economic activity and intensive population growth, irregularly distributed by geographical areas of homogeneous nature, but not subject to the action of polarizing larger urban centers. There is, in this case, a certain independence of each urban nucleus. If this implies or can generate, on the one hand, competitive factors inducing local development, on the other hand, this structural autonomy can minimize the use of Regional synergies.

NEW SPATIAL CATEGORIES

In any of the urban settings described earlier, we can chart multiple built environment patterns, each one translating distinct social, cultural, economic and political meanings which distinguish them according to various categories of space:

urban, suburban, post-suburban, urban periphery, peri-urban and rururban. These categories can be understood as expressions of the urban sprawl territorialization, which we propose to analyze by taking into consideration its morphological topology and basic characteristics of land occupation.

Urban space – The urban space, usually associated with the concept of “city”, corresponds in general to a human settlement with a heterogeneous population, dependent on external food products but a supplier of goods and services to the surrounding area. Max Weber defined the “city” as a dense agglomeration of dwellings, a “location” and a “market place” (2014:44-45). A clear and universal definition of urban space raises numerous difficulties, resulting in each country adopting a definition for this category of space⁴⁷¹. Multiple criteria are used in order to define and characterize the urban space: administrative, quantitative (populational), minimum densities, functional performance, etc. In addition, there are important reasons of historical, cultural, and architectural nature that could justify the classification of what can be understood as urban space or city.

Suburban space – The classification of suburban space or suburb is given to the space that corresponds to the compact urban precinct that communicates directly with the traditional limits of the city, included, administratively, within the urban generation perimeter. This urban precinct is an area of residential neighborhoods, usually emerged around train stations and road transport. It is characterized by a mixed occupancy density, strong connections and dependence of the major transport axes, with very little traces of its former rural occupation.

According to Beaujeu-Garnier this new historical period of urbanization will give rise to various types of urban agglomerations. The *dormitory city* where a population lives that commutes daily to work in another city, which in general corresponds to the center-city. Another type encompasses what is traditionally called *satellite city*: small urban centers that offer employment to its population, but whose services, trade and equipment are relatively deficient, which leads people to search for complementary alternatives in the center-city nearby. A third category consists of old small towns, significantly distant from the large urban center, with well-defined local function and relatively satisfactory equipment and services (1997:130).

Post-suburban space – The establishment of the post-suburban space is not new in the development process of cities. Several examples illustrate how the relationship between center-city and its periphery is frequently transformed as a result of the deconstruction and reconstruction of the urban form and nature (Marques, 2015:14). The idea of a post-suburban space is pointed out by Garreau as a residential suburb transformed into an area of diverse activities (shopping malls, office parks, perimeter centers, multi-purpose centers, etc.) which structure new centralities in *Edge Cities* (1991).

Although the concept of post-suburban is not yet stabilized from the theoretical or technical point of view, it can be understood through the idea of *Suburbia*, defended by Bruce Bégout as an urban space that exceeds the central city and that can no longer be seen as a simple peripheral extension of the city, that straps all around and extends it (2013:13). “If the setting of the traditional City (...) corresponds to the Ptolemaic vision of a limited world, hierarchical and centralized, the suburbia acquired its mental and spatial configuration of the Copernican revolution: (...) an urban universe with no center or periphery unlimited, no hierarchy of places, an errantry space not limited for any sphere of fixed stars” (Bégout, 2013:25).

Peri-urban space – The peri-urban space (Garnier, 1997) is characterized by a great diversity of land uses, morphological and functionally organized in dependency of a central urban core and peripheral urban nucleus associated to the surrounding territorial system development. Here are located the *outer-cities* and *exurbs*, small towns or villages, far away from the center of the metropolis, but inhabited by people who work there. In the case of large South American or Asian megalopolis the peri-urban space is often termed *periphery*, an area normally associated with a “no-go area”, that is, an area suffering from severe urban fragilities which corresponds also to a “dangerous territory” for non-residents and a place of “forced” compromise of its residents with a certain marginality that manages the neighborhoods and residential areas. In a morphological perspective, the *periphery* corresponds to a type of urbanization mainly inhabited by low-income populations, characterized by informal and ephemeral or precarious buildings, occasionally stage for verticalization phenomena of its territory, designated as *hiperperiphery* (Torres and Marques, 2001) where the absence of basic infrastructure or services is evident.

Rururban space – This space category corresponds to the outer area of the peri-urban areas, which, as the term indicates, has predominantly rural features, but is subject to internal changes as a result of its proximity to spaces with urban characteristics. Its formation can result from a process of decentralization which involves the movement of people and jobs from larger cities to small villages, towns or cities located at a greater distance from the metropolitan center. As the name indicates, in the rururban area, the urban and the rural coexist; the rural area constitutes the “natural” territory, not destined for urban occupation, in which a vocation for agricultural activities, livestock-rearing, forestry or mineral-related activities is recognized, as well the space that integrates nature reserves for environment protection, or that is occupied by infrastructures that do not confer to it the status of urban land.

The boundaries between the various categories of space cannot be physically defined since each level has transition zones with mixed features. The inexorable urban sprawl ends up absorbing the smaller classic urban centers that integrate a network of nodal points of the system, or ceases to occupy agricultural spaces (small farmlands) which remain expectant of a real estate intervention or are converted into green spaces or urban parks. We can still find distributed around the

⁴⁷¹ According to the Regulatory Decree No. 15/2015 of August 19th, the Portuguese Ministry of Environment, Spatial Planning and Energy states that the urban land corresponds to what is urbanized in wholly or partly built and, as such, defined to be built in urban and territorial master plan.

great Center, several other urban polarities of variable sizes, interacting with the surrounding territories. Therefore, this classification cannot be understood as a sequence of space categories, since in practice these types of spaces are spread out unevenly and in a fragmented way throughout the city-region.

There are other categories of social, economic, cultural, ethnic, occupational and functional nature that allow us to understand the morphological stratification of the territory and the metamorphoses which occur in metropolitan areas. Nevertheless, an approach of the theme through these disciplines goes beyond our field of study, so we refer to them in order to alert the reader to other possibilities regarding territorial analysis.

FROM DISTRICTING TO ZONING

The multiple morphological settings and categories of urban spaces resulting from urban sprawl that we previously described, have given rise to a complex functional division of the land, which in turn implied the reconceptualization of theories and public policies for urbanism in order to develop appropriate tools for spatial planning and territorial management of metropolitan macro-structures.

Cities have always been divided, however, since the early 20th century a model of land division was institutionalized at international level: *zoning*.

According to David Johnson, the birth of zoning occurred in United States of America between 1911 and 1916, originating from a visit of lawyer Edward Murray Bassett to Germany in 1908: having made him particularly impressed with German method of reduction of residential density by dividing land use areas, a method that Werner Hegemann and other Germans urbanists were using for urban planning (1996:39).

In 1913, the Fifth Avenue Commission (created by George McAneny, Borough President in New York), submitted the draft of a report, mostly work of Bassett, which emphasized the regulation of buildings and the distribution of land uses, by “zoning”, as it came to be called (Johnson, 1996:39). In 1916, zoning was established as the main process of land development and control. As an urban planning model, it quickly dispersed throughout the United States (Johnson, 1996:40).

In Europe, the second CIAM⁴⁷², held in Berlin in 1931 was dedicated to “The Functional City”, whose “guidelines” would be based on those already used by Van Eesteren since 1929 at the Urban Development Section (PCS) of the Amsterdam Public Works Department, namely in 1934 in the Expansion Plan of Amsterdam.

“The Expansion Plan of Amsterdam was similar to other zoning plans implemented at the time, but it was beyond them when trying to predict and find future global developments. (...) specific housing strategies proposed in the expansion plan were left deliberately vague. (...) the plan of Van Eesteren was understood more as a ‘functional’ solution that took into account the “rational” development methods that would come to be organized by CIAM. This represents a change in the sense of a planning-oriented process that relied on comprehensive statistical data to project areas for various uses without draw any detail” (Munford, 2000:61).

In the fourth CIAM conducted in 1933, the concept of Functional City was structured on a set of postulates which gave rise to the so-called “Athens Charter”. The principles of the new urban theory did not advocate a solution of continuity, but a break with the old city, offering a modern alternative to the chaotic existing image of most major cities in the beginning of 20th century. To the CIAM, the city should be conceived as an aggregate of blocks associated with *neighborhood units*, in a group or set of groups distributed according to a functional hierarchy based on a *zoning* process.

Zoning consisted of an operation applied over the city plan with the aim of assigning to each function and each individual the proper place, based on the differentiation required between the various human activities, each one claiming its particular space in one of four dominant functions: *inhabitation units, work units, leisure units, and circulation units*.

To Peter Sloterdijk “the consistent mission to form a common element on three pillars of urban life – work, accommodation, public space, and gathering (the latter being equivalent to the leisure unit of the Athens Charter), implied that the terms ‘traffic’ and ‘communication’ became imposed on urban literature – as if we wanted to reduce the phenomenon of city to general movement and signal flows” (2005: 578-579).

According to Marcuse and von Kempfen, the land divisions by functional performance “are the result of economic, physical or organizational logic”, and “zoning [is] the accepted legal incorporation of such divisions” (2002:13). To these authors, “although functional zoning is generally defined by economic use (...)” this is not as obvious as it may seem, stressing other possibilities such as *‘performance zoning’*, which “seeks to define the permission of land uses not by its economic nature but by its environmental impact – generation of traffic, projection of shadows, blocking of air circulation, occupation of green space, etc. (2002:13).

The most important factor underlined by the functional model is the need for flexibility in the planning of new developments and to accommodate changing patterns from phase to phase. Nevertheless, this flexibility cannot be infinite and zoning does not imply the ceasing to stablish commitments as the land is consumed and its use is consolidated with buildings.

On this subject, an article entitled “Space and the City”, published in the April 2015 issue of THE ECONOMIST magazine, states that zoning codes were designed as a way of balancing the social good of a productive growing city with the private costs which growth often requires – yet, the land use regulations have evolved into something pernicious: a mechanism

⁴⁷² Congrès Internationaux d'Architecture Moderne or CIAM.

through which an artificial scarcity of land is generated, with high economic costs resulting from its weak utilization, in result of an application of zoning codes unable to balance social interest and urban growth, and of the regulation that limits the height and density of buildings, contracting supply and inflating its price.

CHANGES OF THE URBAN PARADIGM

Some new factors contribute to the change of functionalists paradigms, among which we highlight: a) the introduction of a urbanology based on a multi-disciplinary logic of the plan as instrument for territorial planning; b) the scale and increasing complexity of urban systems and infrastructures; and c) the growing need to satisfy sustainability issues through the (re) introduction of ecology concepts in the definition of the practical nature of planning. To these factors we add the problematic of exercising democracy, the right to social justice and equal opportunities that should govern the urbanization and the lives of their communities who dwell in it.

The formulation of a new planning methodology for mega-cities and metropolitan regions, results from the observation of the advantages in adopting an integrated and comprehensive planning process aimed toward strategic objectives that respond to challenges and opportunities, and the need to secure a negotiating and participative structure that provides coherence to the community project, represented by the actors and agents with impact on the articulation of both physical and social dimensions of cities.

The resort to a charter of urbanistic principles and the application of the strategic urban plan arises also as an answer to some of the shortcomings of the functionalist planning. In a simplified way, the new approach to city planning adopts two fields of study and characterization in terms of regional planning and urban planning: a) an analysis of the general trends in international, national and regional frameworks, which can influence urban development; b) an internal review of the factors that characterize the urban community, with the aim of defining the strengths and weaknesses, the potentialities and the insufficiencies relating to the themes previously listed.

Another significant change is the one that occurs with the perception of the metropolitan, as the one described by Sloterdijk to whom “the true function of metropolitan areas is clearly to ensure good neighborliness between centers and non-centers – no longer in form of a super centrality, but understood as an agglomeration of topographical forces” (2005:579).

This multi-polarity was denominated by the EDEC⁴⁷³ as *Polycentric System*, an articulation system for urban inter-centers, which corresponds to a territorial logic with the aim of achieving economies of scale in the complementarity generated between cities, and in the acquisition of critical mass and synergy effects made viable through the cooperation of cities with identical profiles and potential resources. Its focus is thus of a broader nature than the city itself, aiming to promote integrated territorial development strategies where several cities cooperate with each other, join forces to develop additional functions or in using together equipment and services.

Following the line of thought we have explored about urban paradigm changes, we highlight the principles laid down in the European Charter of Urbanism (2013), which is based on “new Athens Charter 2003”⁴⁷⁴, giving continuity to a global vision focused on the concept of *Connected City*, an urban development process anchored in the following topics:

A city for all, whose Government reaches social cohesion; The city with social participation, where urban planning should serve to strengthen the sense of belonging and identity; The healthy city, where it is possible to promote equal opportunities of access to public health facilities; The productive city, planned in order to strengthen its economic foundation, and that is able to provide local work to its citizens; The innovative city, which encourages the use of information and communication technologies; The city with accessibility and mobility, where public transport interconnection and car-free zones are created; The environment city, in which all plans and programs are based on principles of sustainable development; The city of culture, source and repository of human civilization, involving the principle of mixed uses, that introduces variety and vitality in the urban fabric.

If the Athens Charter, in 1933, presented an objective program for the city, pointing out specific guidelines for its zoning and urban design, the European Charter of Urbanism corresponds to a change of urbanistic paradigm, based on a set of principles of subjective order, reflecting the trends currently observed in contemporary society, identifying other potential urban development and the specific commitments that the planners should advocate as a response to challenges urbanization is facing.

CONCLUSIONS

The metamorphosis of urban forms are linked to technical and social revolutions and have a directly relationship with the dissolution of the city limits as a result of an unplanned *urban sprawl*, characterized by a certainly urban chaos or entropy, which has given origin to new and diverse urban configurations and categories of space that we tried to describe following a systematic approach.

The Metropolitanization phenomenon does not refer only to the growth of major cities, but also to a structural change of the urban environment, the redefinition of the hierarchy of cities, the modelling of space in consequence of complex networks of mobility, dispersion of social and economic activities, and a diffuse fragmentation of urban morphological units.

473 Esquema de Desenvolvimento territorial Comunitário (EDEC), 1999, Postdam.

474 Edited by the European Council of Social Planners.

Opposed to the conceptual model of the baroque city and to the culturalist concepts of the industrial city, Functionalism emerged as planning methodology for a city characterized by profound transformations: technological, economic and socio-demographic that alter the scale, composition, density and the interrelation of city with the territory.

Functionalism became the planning model of continuous urban expansion areas, in many cases to solve problems of unplanned growth that remains since the first industrial revolution, seeking to offer accommodation for a large number of people moving from the countryside to the cities or small towns to large ever growing metropolitan areas.

Analyzing the basic aspects of territorial organization guiding the major metropolitan areas, we can see that the networks of their polycentric urban systems rely on a functional hierarchical order and on horizontal relationships which reveal the need for an articulation inter-urban scheme, supported on the concept of growth poles.

The study of the evolutionary transformations of human settlements and of their new habitat, implies at the same time the need to review the analysis systems which allow us to obtain a synthesis of numerous variables, being simultaneously able to test the effectiveness of new urban standards developing a language that describes possible interdependencies between them, guiding their combinations and indicating how each one can be integrate into the existing built environment.

Theorists and practitioners have contributed to the reflection on the concepts identified in metropolitan areas, such as: multilevel territories, hybrid territories; urban alterity; spaces in transition, etc. – all related to social practices and cultures, actors and stakeholders of the urban space, factors that constitute a basis that allows for the characterization of the social identities of megacities in relation to other global or worldwide cities.

1115 INTERGENERATIONAL TRANSMISSION OF INDUSTRY OF EMPLOYMENT AMONG RELIGIOUS COMMUNITIES IN URBAN INDIA

Farhana Khatoon

Assistant Professor, Vivekananda College, Madhyamgram, Kolkata, Email: farhana.khushi@gmail.com

ABSTRACT

It is assumed that the educational status of father has great bearing on the educational and occupational aspiration of the sons. An individual grows in the family and in the development of individuals, family's economic condition in general and father educational and occupational achievement in particular plays a great role. Here in this paper an effort has been made to present the intergeneration shifts in industry of employment among Muslims and Hindus religious groups. Education of fathers' and his occupation reflect the family's general social standing and indicate the benefit in terms of education and occupation provided to the next generation. The data for this has been taken from two successive rounds of the National Sample Survey (NSS) i.e. 2004–2005 to 2009–2010. Only those households have been taken into consideration in which two generations are living together. The cross tabulation of sons parameters with the males head of the households parameters shows that intergenerational persistence among Muslims was very high in the case of agriculture, manufacturing and trade and hotel industry. It is seen that intergenerational persistence is very high in the case of Muslims than the Hindus religious groups. So, one can say that the influence of fathers' industrial choice on the industrial choice of sons' is greater in the case of Muslims than the Hindus. Among Muslims throughout the period intergenerational persistence is very high in the case of the manufacturing sector. This shows the effect of the historical association of Muslims in this sector and also the influence of fathers' industrial choice, on the sons' industry of employment.

Keywords: Employment, Intergeneration, Muslims, Religious Communities.

INTRODUCTIONS

Intergenerational transfer of education and employment has been analyzed by sociologist. Intergenerational effect results from both the individual parent and the individual child. As mentioned by the Visakha Verma (2000)⁴⁷⁵, *'an understanding of the pattern of intergenerational occupational mobility is essential to know related issues like (1) what factors are responsible for the existence of unequal economic opportunities; (2) the reproduction of an existing division of labour and the perpetuation of existing class inequalities'*. It is assumed that the educational status of father has great bearing on the educational and occupational aspiration of the sons. An individual grows in the family and in the development of individuals, families' economic condition in general and father educational and occupational achievement in particular plays a great role. In studying intergenerational occupational mobility one is usually concerned with the relationship between social origin and current social position. Education and occupation are the major indicators of social status. The main aim of the paper is to see how inequalities in opportunities in term of employment in today's generation reflect very unequal opportunities that individuals inherit from their parents'. Equality of opportunities plays a great role in transfer of opportunities to future generations. The central argument is that: how children's occupational attainment is related to the fathers' occupational attainment? Is it a product of intergenerational stickiness or the result of other socioeconomic constraints? Limited empirical work has been done in this area of research in India. This approach of analyzing intergenerational occupational opportunity has been followed in several papers in different countries. But none of the study analyses intergenerational mobility among religious groups.

India is a multi-religious society and the nation can only prosper when every section and community of the country can garner the fruit of development. Some sections of the society made significant progress in terms of education and occupation while others are lagging behind. Muslims the largest minority community of the country is not performing well in many of the developmental parameters in general and occupation in particular. There has been a range of work on intergenerational mobility in the U.S and other western countries. This issue has not been well documented in India. A Few notable exceptions are Rajarshi Majumder (2010), Jalan and Murgai (2010), and Hnatkovska et al (2011), all of these scholars have focused on intergenerational mobility among the Scheduled Caste. The researcher is not aware of any other study, which documents the intergenerational occupational mobility among religious groups.

METHODOLOGY AND DATABASE

Methodology is a tool through which the research agenda is arranged in a systematic way. The methodology followed in the study is as follows. The study has used the National Sample Survey Organization (NSSO) database on Employment and Unemployment (Unit Level Records) for 55th, 61st and 66th rounds, pertaining to the years 1999-2000, 2004–2005 and 2009–2010 respectively. In order to present the intergenerational shift in employment among Muslims, the samples were restricted and information was taken only for those households in which one male member and their children are residing. The Co-residence is one of the criteria for the selection of household. Family records have been superimposed on personal records so as to obtain intergenerational data on education, employment and other socioeconomic parameters. Multilevel filtration has been done to obtain a desired sample. In the first instance, only those households in which father and their son in the age group of 15–59 years residing are taken into consideration and then the religious

475G. Visakha Varma and P. Hanumantha Rayappa (2000), "Pattern of Intergenerational Mobility: A Study of Calicut City", Artha Vijnana, Vol. XLII, No. 3, pp. 286–301.

breakup of these households are taken into consideration. This excludes the large number of households in which sons aged 15–59 years are not residing with the father also excluded the household whose children are outside the household for some reasons. This has reduced the sample size to a great extent, but the sample is representative enough to make the analysis. Intergenerational transition matrix has been used for education, industry and occupation transition. Each row of the table denotes occupation of father while column indicates the same for sons’.

Work Force Participation Rates by Religious Communities

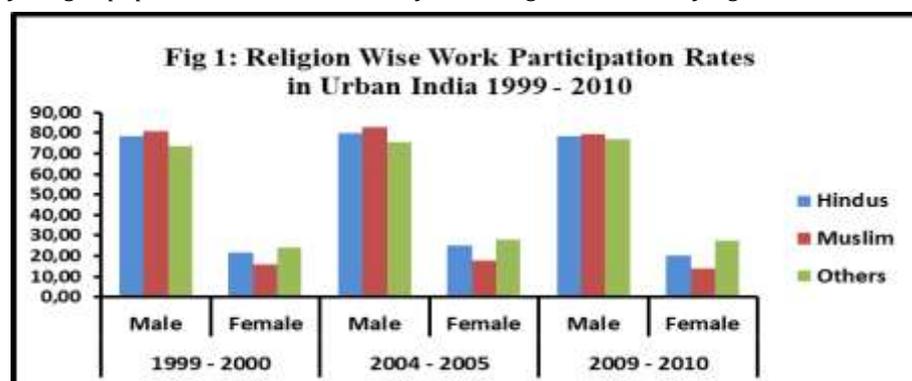

According to NSSO, “a person who is either working or seeking or available for work constituted the labour force”. Workforce participation rates or employment rates are important indicators to assess the proportion of the population actually engaged in any economic activities. Employment is critical for overall well being of the individual and their families.

Table 1 Employment Rates among Religious Communities in Urban India 1999–2010

States	1999 - 2000			2004 - 2005			2009 - 2010		
	Hindus	Muslims	Others	Hindus	Muslims	Others	Hindus	Muslims	Others
J&K	45.40	42.70	45.10	47.40	46.60	43.40	48.70	44.10	50.50
U.P	48.00	53.40	41.10	49.70	55.00	46.60	43.40	48.50	52.00
Bihar	43.80	45.20	39.30	41.80	51.10	41.90	40.90	40.90	47.60
Assam	47.30	53.50	47.90	50.00	49.10	50.20	46.10	42.60	40.10
West Bengal	49.70	53.80	47.60	52.20	55.80	49.60	51.30	54.70	32.70
Kerala	55.90	42.90	51.90	56.00	40.50	54.80	55.60	37.50	56.70
India	51.50	50.30	49.30	54.10	51.60	52.60	50.70	48.10	52.40

Source: Employment & Unemployment among Religious Groups NSS Rounds 55th, 61st & 66th

The table 1 presents the workforce participation rates of religious communities. The analysis of the table shows interesting facts. It can be observed that from 1999–2000 to 2004–2005, the workforce participation rates among Muslims have increased in majority of the selected states. It is also found that during the period 2009–2010, workforce participation rates have declined among both the Hindus and Muslims. The possible explanation might be due to the increase levels of education the workers are unwilling to participate in any kind of employment. However, errors may be on account of sampling decision. The above table shows, the Muslim population employed/worker in any gainful activity to the total Muslim population (15–59 years). Fig 1 shows that the female work participation rates are very low among both religious communities. Work participation rates among Muslims females were much lower than the Hindus and other religious communities. The possible reason for the sorry state of Muslims female work participation rates might be due to Muslims religious outlook. The other reason as mentioned in the Sachar Committee report (2006)⁴⁷⁶ ‘One of the reasons for lower participation rates of Muslim women may be higher dependency rates due to relatively higher share of the younger population in the community, resulting in women staying at home’.

Religion Wise Status of Employment of Workers

Another important issue with regards to employment is the type of employment being generated. Here an attempt has been made to explore this aspect of employment. During 1999–2000 (table 2), among Hindu workers, 38.20 per cent of male 36.90 per cent of female were self employed. The corresponding proportions for Muslim were 52.70 per cent for male and 55.40 per cent for female. The proportion of regular wage employed among Hindus was very high. The proportion of Muslims, male self employed was lower than the Hindu male. The same is true in case of female. Only 22.40 per cent of Muslims female are regular wage employees. One can also infer from the data that the proportion of casual labour was higher among female than among male workers across the religious communities.

Table 2: Religion Wise Status of Employment of Workers In Urban India 2009–2010

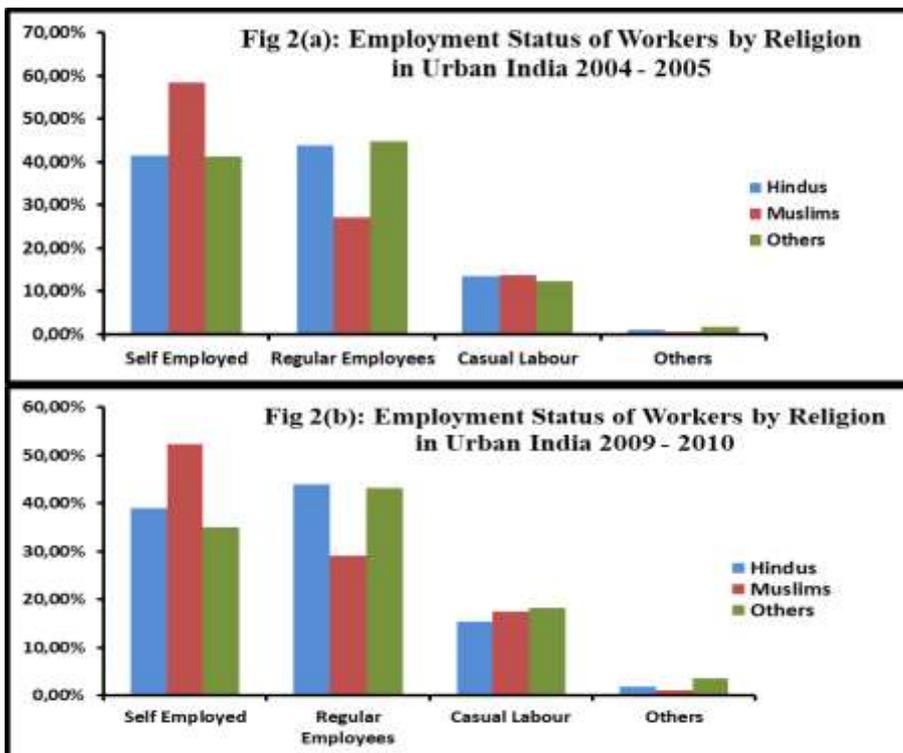

Employment Status	1999 - 2000		Muslim		Others	
	Hindus		Male	Female	Male	Female
	Male	Female	Male	Female	Male	Female
Self Employed	38.20	36.90	52.70	55.40	40.10	25.10

476Sachar Rajinder (2006), “Social, Economic and Educational Status of the Muslim Community in India”, A Report Prepared by Prime Minister’s High Level Committee.

Regular Employees	44.90	36.80	29.20	22.40	43.50	54.00
Casual Labour	14.60	23.30	16.10	19.50	12.90	16.70
Others	2.20	2.80	1.90	2.60	3.30	3.80
2004 - 2005						
Employment Status	Hindus		Muslim		Others	
	Male	Female	Male	Female	Male	Female
Self Employed	42.00	39.90	58.50	58.40	43.50	34.90
Regular Employees	44.70	41.10	27.50	25.40	43.50	48.20
Casual Labour	12.30	17.60	13.50	15.10	11.70	14.40
Others	1.10	1.30	0.50	1.00	1.40	2.60
2009 - 2010						
Employment Status	Hindus		Muslim		Others	
	Male	Female	Male	Female	Male	Female
Self Employed	39.90	35.10	52.60	50.40	36.20	31.20
Regular Employees	44.20	42.50	29.40	26.80	42.30	45.90
Casual Labour	14.10	20.60	17.00	20.50	18.00	18.70
Others	1.80	1.70	0.80	1.80	3.40	4.10

Source: Employment & Unemployment among Religious Groups NSS Rounds 55th, 61st & 66th

For urban Hindus male, the proportion of self employed declined from 42 per cent in 2004–2005 to 39.90 per cent in 2009–2010. The same trend was observed in case of urban Muslims male, which was 58.50 per cent in 2004–2005 and decreased to 52.60 per cent in 2009–2010, while the proportion of Muslim female self employed decreased from 58.40 per cent to 50.40 per cent during the same period. The further analysis highlighted a rise in the Muslim males and females share in regular wage earning and casual labour during the 2004–2005 to 2009–2010. Similar trends were also observed in the case of the Hindus. Thus, it can be concluded that self-employment grew significantly with a fall in casual employment in 2004–2005; there was a marginal rise in regular salaried employment during the same period.

In 2009–2010, the trend was different. The proportion of self employment has decreased in case of Muslim female and it is the lowest since 1999–2000. The decline of self-employment was very high for Muslim female workers. As pointed out by Sonya Rastogi (2007),⁴⁷⁷ ‘Muslims are underrepresented in both public and private sectors and are largely confined to non-farm self-employment. Muslims are also less likely to be employed in the protected sector, and are therefore in more vulnerable employment positions. It is important to note that wage employment itself does not confer economic advantages and historically, Muslim participation in self-employment has protected them somewhat from the dire poverty faced by landless agricultural laborers, but their exclusion from regular employment, reduces their avenues for upward economic mobility, particularly in the current era where the rewards to white collar work have been rising’.

Religion Wise Proportion of Workers in Different Industrial Categories

⁴⁷⁷Rastogi, Sonya (2007),” Indian Muslim Women’s Education and Employment in the Context of Modernization, Religious Discrimination and Disadvantage, And the Rise of Hindu Fundamentalism and Muslim Identity Politics”, Doctoral Thesis submitted to University of Maryland.

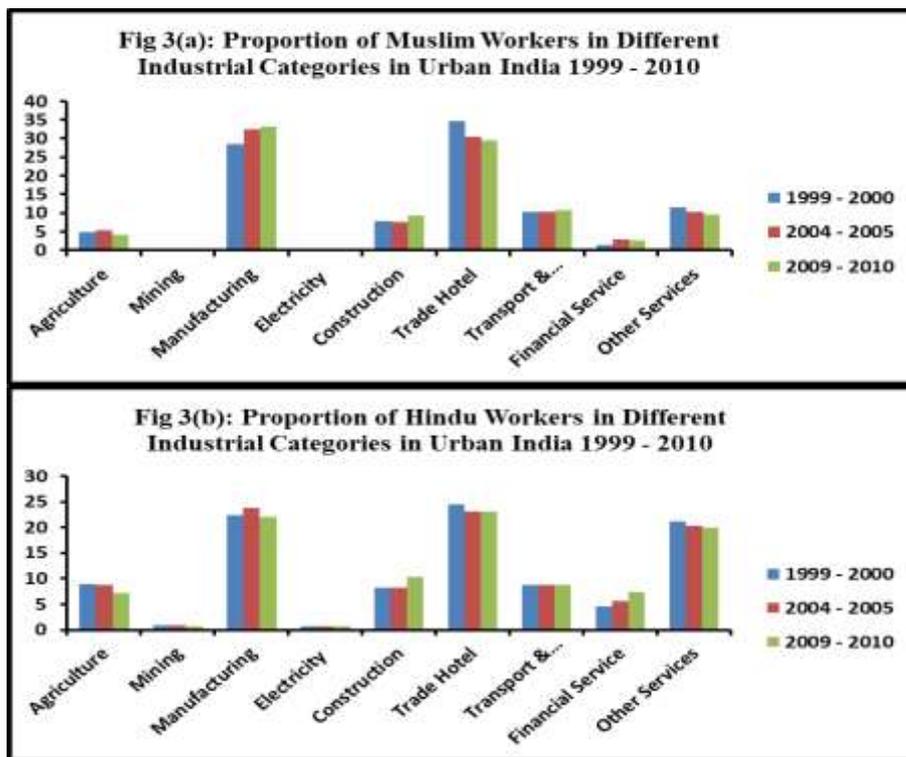

To assess the structural change in the employment pattern of usual worker the different rounds of NSSO data are compared. The table 3 shows the religion wise percentage distribution of usual status⁴⁷⁸ workers by industrial categories in urban India. It is observed from the table that employment of Muslims as well as Hindus has declined in primary sector that is agriculture and mining and quarrying activities during the period under consideration. It can be seen from the table that a sizeable proportion of Muslim workers were employed in the manufacturing sector. Muslims share in this sector was 28.50 per cent in 1999–2000 which rose to 32.50 per cent during 2004–2005 within the span of five years, this further increase to 33.20 per cent during most recent quinquennial rounds of 2009–2010. More importantly, along with a decline in the share of employment in agriculture, there has also been a decline in the share of employment in manufacturing for Hindus in urban areas during 1999–2010. It can also be inferred from the table that a greater proportion of Muslim workers are engaged in trade, hotel and restaurant, the corresponding shares of Hindus are also high in this sector.

Table 3: Religion Wise Distribution of Workers by Industrial Categories in Urban India 1999 – 2010

Industrial Categories	1999 – 2000		2004 – 2005		2009 – 2010	
	Hindus	Muslims	Hindus	Muslims	Hindus	Muslims
Agriculture, Hunting & Fishing	8.90	4.90	8.70	5.40	7.20	4.20
Mining & Quarrying	0.90	0.50	0.90	0.20	0.70	0.30
Manufacturing	22.30	28.50	23.70	32.50	22.10	33.20
Electricity, Gas & Water Supply	0.80	0.30	0.70	0.30	0.70	0.40
Construction	8.20	7.80	8.30	7.70	10.40	9.30
Trade, Hotel & Restaurant	24.50	34.70	23.10	30.40	23.00	29.60
Transport, Storage & Communication	8.70	10.30	8.80	10.30	8.70	10.90
Financial Business & Services	4.50	1.50	5.70	2.80	7.40	2.70
Community, Social & Personal Services	21.20	11.50	20.30	10.20	19.90	9.50

Source: Employment & Unemployment among Religious Groups, NSS Rounds 55th, 61st & 66th

It is observed that even in the services sector, there has been a fall or no change in the proportion of employment in the trade, hotel and restaurant and transport and communications sector with a slight increase in the finance and real estate sector. The entire decrease in proportion of employment in the agricultural as well as the manufacturing sector has been compensated by an increase in employment in the construction sector among both the religious communities in urban areas.

MANUFACTURING SECTOR RELIGION WISE ANALYSIS 1999-2010

Two Digit Level

One digit industrial classification present broad generalization and show greater proportion of Muslims are concentrated in the manufacturing sector. Manufacturing sector constitutes host of activities; here an attempt has been made to analyse within manufacturing sector Muslims are mostly employed to which type of manufacturing activity. The greater proportion of total Muslim workers is employed in the manufacturing industries. Analysis of religion wise manufacturing

⁴⁷⁸Usual status worker corresponds to usual principal status and usual subsidiary status worker together.

sector employment at a disaggregated level that is two digit industrial classifications shows that in 1999–2000, within the manufacturing sector almost 39 per cent of workers were engaged in manufacturing of tobacco product (13.70 per cent), textiles (23.10 per cent) and wearing apparel (12.70 per cent). The corresponding shares of Hindus workers were 3.40 per cent in tobacco product, 16.20 per cent in textiles and 7.20 per cent in wearing apparel. Another interesting fact which emerged from the table is that Muslims presence was remarkable in tanning and dressing of leather industry. One of the possible explanations for this is because of religious sentiment Hindus do not consider it suitable to engage themselves in this industry. In printing, chemicals and fabricated metal products, etc. Muslims workers' shares were negligible while the presence of the Hindus is remarkable. It can be inferred from this that in all those sections of manufacturing, which requires technical and managerial skill Muslims presence are conspicuous (Appendix, 1) by its low share.

During 2004–2010, the same trend has been observed. Out of the total workers engaged in manufacturing sector Muslims' shares in textile and wearing apparel has increased considerably. It was 24.20 per cent and 20.80 per cent in 2004–2005, which rose to 27.50 per cent and 23.30 per cent respectively during 2009–2010. Major concentration of Muslim workers in these industries attributed to their historical dominance in these industries. It is also found that in the food product and beverage industry, Muslim workers declined from 10.90 per cent in 1999–2000 to 5.10 per cent during 2009–2010. In all other manufacturing industry sections their shares are abysmally low.

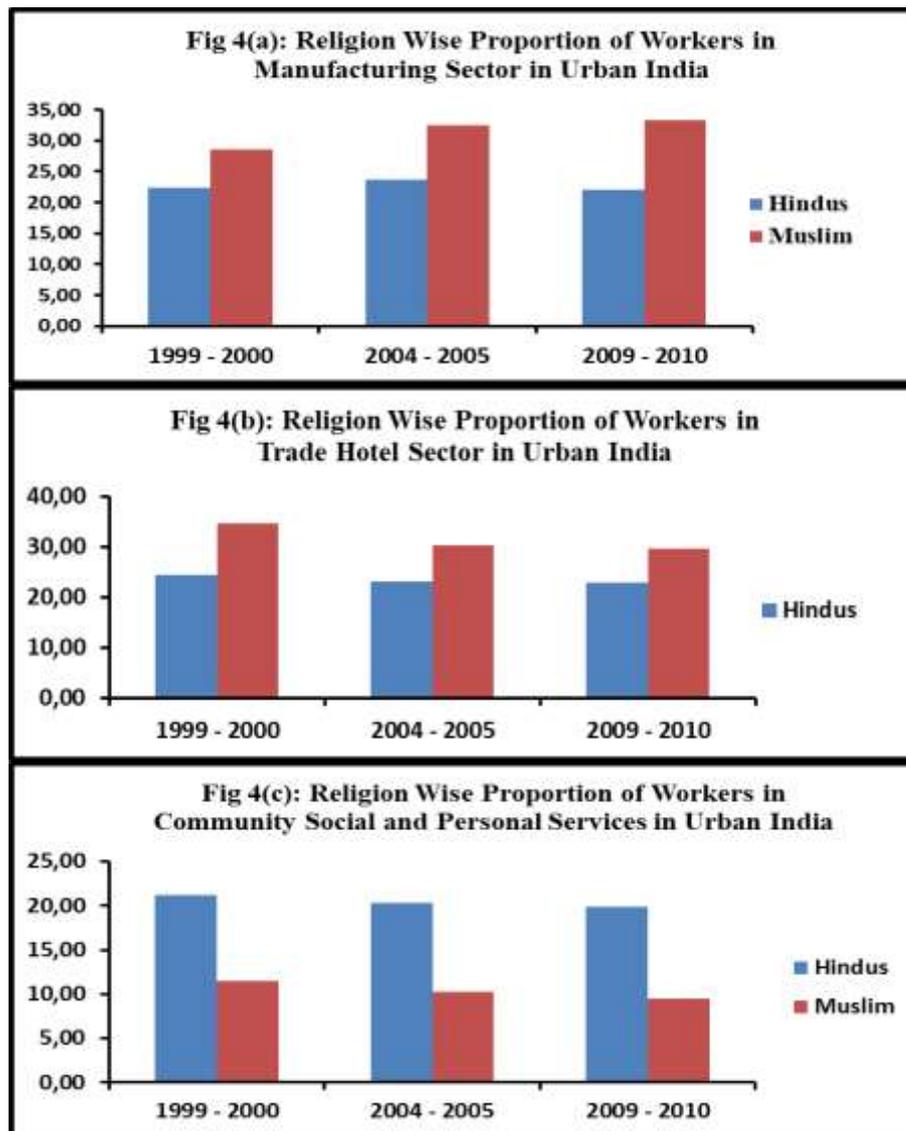

Table 4: Shares of Workers in Trade, Hotel & Restaurants & Community Services Sector in Urban India (Two Digit Level) 1999 – 2010

Trade, Hotel & Restaurant						
Trade, Hotel & Restaurant	1999 – 2010		2004 – 2005		2009 – 2010

TRADES, HOTEL AND RESTAURANT: RELIGION WISE ANALYSIS 1999 – 2010

Two Digit Level

The presence of Muslims workers' in trade, hotel and restaurant industry is remarkable. Trade, hotel and restaurant are broad industrial category. It gives the generalized picture. Further, in order to ascertain within this broad category, in which specific industry Muslims are largely employed, industrial classification at two digit levels has been analyzed. It is found that in 1999–2000, a greater proportion of Muslims workers were largely employed in retail trade industry i.e. 75.50 per cent. The corresponding shares of Hindus in this industry were 73 per cent. It is also observed that during the span of ten years, Muslims shares in retail trade industry has declined, still their presence in this industry is significantly very high as it was 69.30 per cent during 2009– 2010, greater than the Hindus (67.60 per cent).

Another important fact revealed by the table is that during the period under consideration, in all sub classification of trade, hotel and restaurant industry, there is an increase in employment among Muslim workers, the same is true with the Hindus workers also. This is mainly due to the fact that in the post liberalization period shares of service sector in the employment generation, has increased considerably and provides opportunities for both the religious communities, but within this there are inherent disparities. Thus, it can be assumed that as the majority of the Muslims are self employed, they are largely concentrated in retail trade and hotel industries.

COMMUNITY, SOCIAL AND PERSONAL SERVICES: RELIGION WISE ANALYSIS 1999–2010

Two Digit Level

Another important industrial sector, which employs sizeable proportion of Muslims workers is community social and personal services. From the table 5, it can be assessed that in 1999–2000, in the public administration & defense, social security, industrial sub classification, shares of Muslims workers were 31.10 per cent which declined to 26 per cent in the subsequent period i.e. 2009–2010. The corresponding share for Hindus was 38.50 per cent and declined to 30.40 per cent. Although there are disparities in employment among different religious communities, yet the declined in employment was observed in all religious groups. One interesting fact which emerges from the table is that in 1999–2000, Muslims workers' share in the education sector was 22.60 per cent, which further rose to 30.20 per cent during 2009–2010. The share of Hindus workers in this regard was 24.40 per cent and 29.40 per cent. Increasing shares of Muslim workers in education were due to the slight increase in education among Muslims. It can also be assumed that decreasing share of both Hindus and Muslims workers in defense and public administration sector is due to changes in the preference of youth about this sector. Moreover, the harsh work culture in the defense could be another deterrent for youth to enter into this industry.

Religion Wise Intergenerational Industry Transition Matrix: 2004–2005

Here an attempt has been made to facilitate industry choices of two groups. The purpose is to analyse the relation between fathers' industry choices to that of the sons'. In order to facilitate the presentation, an attempt has been made to aggregate the four digit industry code that individuals report into one-digit. Thus seventeen categories have been grouped into seven broad categories comprising agriculture, Manufacturing, Construction, Trade Hotel etc., Transport, Storage etc., Financial Intermediation, Community Social and Personal services. The result presented in the table 5, as with the education transition matrix, each row of the table denotes the industry of the fathers' employment while the column indicates the industry of the sons' employment. Thus going across the columns along any row *i* would indicate the probability that a household head working in the industry *i* have the sons' working in the relevant industry column. Off-diagonal elements measure the degree of intergenerational industry mobility. The same analysis has been done for both the time period of 2004–2005 and 2009–2010.

Table 5: Religion Wise Intergenerational Industry Transition Matrix in Urban India 2004–2005

All Population	Sons' Industrial Category						
	Agriculture	Manufacturing	Construction	Trade ,Hotel	Transport	Financial Intermed	Other services
Fathers' Industrial

N.A: No Population Covered under that Particular Industrial Category.

The table shows some interesting facts. Among all religious groups it is seen that if the father is employed in agriculture and allied industrial sector of the economy, there is a greater probability of sons being employed in the agriculture and allied sector. This sector has highest intergenerational persistence. Intergenerational persistence in a choice of industry is also high in the industrial category of trade hotel, manufacturing and construction while it is low in financial intermediation and transport sector. It is also seen that if the father is in financial intermediation or transport and storage sector of the economy, there is a greater shift in industrial choices of the sons of the household while in other industrial category intergenerational persistence is very high.

Similar analysis has been made to assess the situation in the religious communities of Hindus and Muslims. In the case of the Hindus too it is found that intergenerational persistence is highest in the case of agriculture and allied sector, trade and hotel, manufacturing and community social and personal services while it is low in financial intermediation and transport storage and communication industry. It can be inferred from the table that if the father is in a particular industry, there is very high probability of sons being in that particular industry.

The same analysis has been done for Muslims father son households and it is found that as in the case of Hindus the intergenerational persistence among Muslims are very high in the case of agriculture, manufacturing and trade and hotel industry. It is seen that intergenerational persistence is very high in the case of Muslims than the Hindus religious groups. So one can say that, the influence of fathers' industrial choice on the industrial choice of sons, is greater in the case of Muslims than the Hindus. From the table it can also be inferred that if the father is employed in manufacturing and trade and hotel industry, there is most likely that sons' will also be employed in that sector. If the father is in manufacturing, around 62 per cent of sons' are also in the manufacturing sector and only 38 percent are employed in other industrial category. Thus sons' choices of industry are largely influenced by the fathers' industrial category.

Table 6: Religion Wise Intergenerational Industry Transition Matrix in Urban India 2009–2010

All Population	Sons' Industrial Category						
Fathers' Industrial	Agriculture	Manufacturing	Construction	Trade Hotel	Transport	Financial Intermed	Other Service
Agriculture	84.00	2.70	1.20	3.30	3.10	0.40	5.40
Manufacturing	4.00	57.20	6.90	12.20	7.40	2.40	9.80
Construction	7.30	8.70	51.80	12.40	8.10	1.80	9.80
Trade, Hotel	4.00	8.10	5.10	64.00	7.30	2.10	9.30
Transport	5.10	11.90	9.90	13.20	41.60	2.10	16.20

N.A: No Population Covered under that Particular Industrial Category.

Religion Wise Intergenerational Industry Transition Matrix 2009–2010

The table 6 shows the interesting fact, during 2009–2010 it is seen that the intergenerational persistence is very high in agriculture industry, the same pattern has been observed in the case of Hindus and Muslims religious communities. Among all religious groups, the table shows the high intergenerational persistence in case of all industrial categories, meaning thereby if the fathers in particular industry, the probability of sons' are being employed in that industry is significantly high.

The religion wise analysis shows the same trend as is observed in the case of total population. The sons of agriculturist are largely employed in the agricultural sector. Not all the industrial category shows high intergenerational persistence as in the case of transport and financial intermediation, the intergenerational persistence is very low. This suggests that the sons' of father employed in these industrial categories moves to other industrial category not necessarily in the industry of his father.

As mentioned before the purpose of this analysis is to see whether intergenerational persistence is the main factor of Muslims being employed in certain industrial groups and not in other. This research finds that the intergenerational persistence among Muslims father son is very high as compare to other religious communities. From the table it can be seen that in 2009–2010 also, high intergenerational persistence has been found in agriculture, manufacturing, trade and hotel. It is also observed that as compared to Hindus intergenerational persistence among Muslims are low in the case of agricultural, while it is high for manufacturing trade and hotel, and transport industry. Thus, one can conclude that among Muslims throughout the period intergenerational persistence is very high in the case of the manufacturing sector. This shows the effect of the historical association of Muslims in this sector and also the influence of fathers' industrial choice, on the sons' industry of employment.

CONCLUSIONS:

To sum up the foregoing discussion it can be said that

- In 1999–2000, a greater proportion of Muslims were self employed. Their shares in regular salaried employment were lower than Hindus. During the subsequent periods, i.e. 2004–2005 and 2009–2010, though there is a rise in the Muslims male and female shares in regular wage employment, they are still lagging far behind the Hindus and other religious communities.
- Industrial category wise analysis of Muslims workers shows that a relatively greater proportion of Muslims were employed in the manufacturing sector. Muslims share in this sector was 28.50 per cent in 1999–2000 which rose to 32.50 per cent during 2004–2005 and further increased to 33.20 per cent during 2009–2010.
- It is also found that a greater proportion of Muslims engaged in trade, hotel and restaurant sector. Muslims presence in financial business and services, and community, social and personal services were lower than the Hindus. This also suggests that Muslims, mainly engage in the employment which does not demand high educational and technical expertise.
- In 1999–2000, within the manufacturing sector, a greater proportion of Muslims workers were engaged in the manufacture of textile (23.10 per cent), tobacco products (13.70 per cent) and wearing apparel (12.70 per cent). Over the period of time Muslims shares in the manufacture of tobacco products declined while their shares in textiles and wearing apparel manufacturing is still very high.

- Muslims presence was remarkable in tanning and dressing of leather manufacturing. In printing, chemicals, publishing, and fabricated metal products manufacturing their shares was negligible. Thus, it can be said that in all those sectors of manufacturing, which requires technical and managerial skills, Muslims presence is conspicuous.
- A significantly higher proportion of Muslims workers were employed in the retail trade sector within the broad industrial sector of trade hotel restaurant and community services. Thus, it can be said that the majority of Muslims are concentrated in retail and wholesale trade industry.
- A sizeable proportion of Muslims workers were employed in community, social and personal services industry sector. Within this sector comparatively higher proportion of Muslims were engaged in public administration and defense.
- In case of Hindus, it is found that intergenerational persistence is highest in the case of trade and hotel, manufacturing and community social and personal services while it is low in financial intermediation and transport storage and communication industry. It can be said that if the father is in a particular industry, there is very high probability of son being in that particular industry.
- The intergenerational persistence among Muslims are very high in the case of manufacturing and trade and hotel industry. The influence of fathers' industrial choice on the industrial choice of sons' is greater in the case of Muslims than the Hindus. If the father is employed in manufacturing and trade and hotel industry, there is most likely that sons will also be employed in these sectors. Thus son choices of industry are largely influenced by the father industrial category.
- In 2009–2010, high intergenerational persistence has been found in manufacturing, trade and hotel. As compared to Hindus intergenerational persistence among Muslims are high for manufacturing trade and hotel, and transport industry. Among Muslims throughout the period intergenerational persistence is very high in the case of the manufacturing sector.

1137 NON-WESTERN ALTERNATIVE STRATEGY FOR POPULAR PARTICIPATION IN ENVIRONMENTAL GOVERNANCE PROCESS OF BANGLADESH

A.K.M. Mahmudul Haque

Associate Professor, Department of Political Science, University of Rajshahi, Rajshahi, Bangladesh. Email: akmmahmudul@yahoo.com

ABSTRACT

In most countries, the demand for environmental conservation percolates upward, from ordinary people to decision-makers. However, in Bangladesh and other developing countries, there is often no demand from the people for environmental protection laws: rather, there may be apathy or hostility to the issue. Therefore, in many such countries, well-constructed laws are not enforced and have no effect. This article explores, first, the underlying cultural and cognitive differences which lead western and eastern people to have very different concepts of the environment and of their roles in protecting it. Then, it develops non-western alternative strategies for making a place for popular participation in environmental protection law and policy which is consistent with non-western culture and philosophy. The study is based on secondary data collected through content analysis method from relevant literatures, research journals, books, news articles, web sites and various published and unpublished materials. The outcome of the study would lead to better environmental results in reality.

Key Words: Environmental Protection, Culture in Government, Western vs. Non-western, People's Participation, Law Enforcement.

INTRODUCTION

In most countries, the demand for environmental conservation percolates upward, from ordinary people to decision-makers. The people form environmental concern groups like [Earth System Governance Project](#), [International Union for Conservation of Nature](#) (IUCN), [World Nature Organization](#) (WNO), [Centre for Science and Environment](#) (CSE), even the Green Party, put the environment in the headlines and make it impossible for the State or major opinion-makers to ignore or forget the Earth.

In America, in the 1960s, it was the 'highway revolts'⁴⁷⁹ against building of new highways that helped to produce the Environmental Protection Act 1970, creating the Environmental Protection Administration. It was ordinary people, sharing information, holding meetings and demonstrations, lobbying politicians etc. whose pressure produced green stickers⁴⁸⁰, saved the whales⁴⁸¹ and the baby fur seals⁴⁸², got genetically-modified food labelling requirements or bans⁴⁸³ and international environmental NGO Greenpeace almost started a war between France and New Zealand over nuclear fallout from bomb tests in the Pacific Ocean in 1985⁴⁸⁴.

However, in Bangladesh, environmental protection has been a "top-down" affair⁴⁸⁵. Donor countries pushed Bangladesh to act and the Government acted, mainly to keep the donations coming. Some say that the real purpose was merely to create an image of environmental protection and not to do anything for the environment. There was no groundswell of support or public demand. Environmental policy is not an issue in Bangladeshi elections, except sometimes at the local level. The majority of the people are apathetic, uninformed or even hostile to environmental protection, especially when it interferes with popular infrastructure construction⁴⁸⁶.

This article will first explore why Bangladeshis have so much less interest in protecting the environment than Europeans, Americans and Australians. Then the article will consider how an effective environmental protection policy can be constructed without such popular support as exists in other countries, in ways more consistent with Asian culture.

PART I

Environmental Policy without Environmental Consciousness: The Bengali Concept of the Environment

Bengalis have a concept of the environment much like that of other tropical, non-western people, like Africans and South Americans, who, not so long ago, lived in nature in a jungle setting⁴⁸⁷. They never looked after nature: nature looked after them. They have a great faith in the power and perfection of nature and cannot believe that anything they do could damage it.

485 Cf. Islam, N., "Protecting Bangladesh's Environment" (2000) 88 Journal of Social Studies 34, at 36 et seq. who lamented the unmet need for a broad-based social movement for the environment in Bangladesh that never existed.

486 As the author found in his study of environmental governance in Rajshahi, Bangladesh, "Environmental Governance of Urban-Local Government in Bangladesh: Policies and Practices" (PhD Dissertation, Institute of Bangladesh Studies, University of Rajshahi, 2015).

487 Cf e.g. Swan, K. and Conrad, K., "The Conflict between Chinese Cultural and Environmental Values in Wildlife Consumption" in Routledge Handbook of Environment and Society in Asia (2014) and Meinert, C., ed. Nature and Environment (2013). Indeed, Oberlin College offers a paper entitled "Nature and the Environment In East Asian Culture" <http://obiemaps.oberlin.edu/courses/nature-and-the-environment-in-east-asian-culture/> accessed 19.5.16.

Western people think of themselves as custodians of the Earth and responsible for maintaining it⁴⁸⁸. Most Bangladeshis are Muslims and the *Quran* says:⁴⁸⁹

Do you not see that Allah has made subject to you whatever is in the heavens and whatever is in the earth and amply bestowed upon you His favors, [both] apparent and unapparent?

Of course, if you believe that nature is created “subject to you”, you do not care so much about what happens to nature. You use it and enjoy, without any responsibility or care for it.

There are other cultural aspects to the difference in thinking too. Western people are teleological⁴⁹⁰: they always ask “what is the purpose?” and believe that they can change the future from action today. Asians conceive of time as the ebb and flow of the sea, believe that they cannot change anything and consider that all they can do is to adjust as everything changes around them⁴⁹¹. Of course, if you believe that you can change the future, you want to act today to save the Earth for your great grandchildren. Yet, if you believe that you can do nothing, the concept of trying to do something is quite silly.

The role of science is also an important source of the differences in thinking between Bengalis and western people about nature. Science is not a Bengali concept. Science is thoroughly western in its emphasis on the objective, on logical inference and on its attempt to understand processes and predict their outcomes⁴⁹². That is not to say that Bengalis do not study science but it is difficult for them: someone who gets “golden A+” (all subjects A+) in the Science stream in the Bangladesh Higher School Certificate is thought of as extremely intelligent, as few can do it. Indeed, a few years ago, almost all the Bangladesh Bank Governors (a highly prestigious position) were Physics graduates, not economists.

The point here is not about who gets better marks in Science but to emphasize that western people instinctively believe and trust scientists but Bengalis do not. If scientists say that the world is being destroyed by our actions, westerners feel that they must stop it urgently. Bengalis are unlikely to understand the scientists, less likely to believe them and may find their predictions of doom rather humorous. The scientists are not like them: they are different

A Different Kind of Politics

Western politics is fundamentally interest group politics⁴⁹³. Parties appeal to different interest groups by offering them the policies they want. In Government, the interest groups jostle for influence and negotiate among themselves to arrive at policy decisions. The pluralist model⁴⁹⁴ predominates and no one can make a decision by himself.

Bangladesh politics is not like that. Policies are handed down by a charismatic Party leader. When there is a coalition Government, the policies may be the result of negotiations between the Prime Minister and her coalition partners. The leader's Party members follow blindly to support the policies, with their lives if necessary and the opposition Party members oppose root and branch. There is no negotiation and interest groups do not take a leadership role to get their preferred policy adopted. Rather, the Parties try to infiltrate, intimidate and puppetise the civil society organizations to get them to support their Party's policy choices.

Therefore, there is no obvious porthole for civil society organizations to use in influencing policy decisions in the direction of protecting the environment. There has never been a Green Party in Bangladesh, although there is now one in almost every western country. The one successful civil society organization on environmental issues, BELA (Bangladesh Environmental Lawyers Association), has not really tried to use the political process to get environmentally-friendly policies. They use the courts to stop environmentally-unfriendly actions and have been very successful in getting High Court injunctions to stop various acts of central and local government.

Some Environmental Movements

Yet things might be changing. BAPA (“*Bangladesh Poribesh Andolon*” meaning “Bangladesh Environment Movement”), is a Bangladesh environmental voluntary society (which stresses that it is not an NGO and receives no contributions) that has achieved some major successes on environmental policy issues. They proceed through seminars, conferences, deputations, press conferences, publications and public rallies. On their website, they claim among their policy successes the banning of plastic bags, leaded petrol and two-stroke engine vehicles⁴⁹⁵. The views and opinions of civil society and NGOs are now given more importance by the Government⁴⁹⁶.

The formulation of NEMAP (National Environmental Management Action Plan), in 1995, was the first time that the Bangladesh Government actively involved the NGOs and civil society, in policy development. The Government

488 One of the most clear examples was the British Government's White Paper, “This Common Inheritance” in 1990, HMSO, Cmnd 1200, “We have a moral duty to look after our planet and to hand it on in good order to future generations”.

“proactively initiated a consultation process, in association with NGOs, journalists, academics, and other segments of civil society”⁴⁹⁷.

The only NGO directly related to Environmental Impact Assessments (EIA) in Bangladesh is the National EIA Association of Bangladesh (NEAB), which was formed in late 1997. It provides a platform for the EIA planners, practitioners and enforcing agencies in Bangladesh. Since its inception, NEAB has been working to create awareness of EIA in all sectors of government planning. It assists in the development and extension of EIA, prescribing a Code of Conduct for EIA professionals, building national capability and establishing a liaison between EIA practitioners and policymakers in Bangladesh. A Memorandum of Understanding was signed between the NEAB and International Union for Conservation of Nature (IUCN), Bangladesh Country Office, in 1999. Under the agreement, IUCN’s Asia Regional Environmental Assessment Program, based in Kathmandu, Nepal, and NEAB are working together to strengthen environmental assessment capacity in Bangladesh.

Bangladesh Environment Network is based in New York City and is composed of Bangladeshi emigrants. They have been mainly assisting in communication about the environment since 1998 and work mostly through BAPA.

Many national and local newspapers and periodicals have introduced *Environmental Pages* on a regular basis. Television and radio are also engaged in broadcasting environmental issues with national and global implications sometimes, especially on 5 June (Environment Day).

The civil societies and NGOs have established effective linkages with the regional and international agencies, including the UN agencies like ESCAP, UNEP, and UNDP, for implementing environmental programs. They have provided training, workshops, seminars, etc. on a collaborative basis. Some research and educational institutions provide important information and policy guidelines to the Government, civil society and NGOs on environmental issues.

PART II

A Non-Western Strategy for Environmental Protection

There are some truths which transcend culture and one of them is that the environment must be protected. People in some cultures may have less information and less concern about the environment but that does not change the fact that their environment is endangered now too. In such cases, dying may be culturally sensitive but it can never be an acceptable result: at least because what happens to one culture on this little globe affects other cultures. Slash and burn agriculture was very much a part of Indonesian culture but the release of huge amounts of greenhouse gases from burning forests punched a big hole in everyone’s ozone⁴⁹⁸, from which we have still not recovered.

So an alternative strategy must be found and that must be culturally sensitive. The alternative strategy cannot depend on the sort of popular movements that have powered the environmental movements in the west but must obtain its legitimacy from the sorts of places that non-western leadership obtains it.

Now let us revise for a moment where non-western leadership gets its legitimacy:

- **Ascribed Status** – age, gender, family background, etc
- **Wealth** – in Asia, wealthy families are liked instinctively and often without reason, sometimes because they bribe everyone generously
- **Association** - people who are associated with persons of high status and influence often obtain some vicarious power and influence from that association
- **Required Status** – as in the Bangladesh local government legislation in 2009⁴⁹⁹, when the leaders require people to participate in a process, even when they would not have dared try, participation becomes acceptable and possible

Using these basic concepts of what gives an Asian the right to participate in a process and to monitor the actions of his social superiors, we can begin to develop the idea of a participatory process of environmental protection policy⁵⁰⁰ not based on environmental consciousness. Participants should be mostly older, male⁵⁰¹ and from famous or wealthy families. They should be associated with people of high status. The legislation should require the participation of other

500 Bulkeley, H and Mol, P.J., “Participation and Environmental Governance”, *Environmental Issues* (May 2003) no. 2 (2003): 143–54 explain the development of popular participation as an essential concept of environmental governance in the west from the 1980s onward. By 2011, Wesseling, A., Paavola, J., Fritsch, O., Renn, O., “Rationales for Public Participation in Environmental Policy and Governance” (Nov. 2011) 43 (11) *Environment and Planning* 2688 were calling public participation a “mantra” of environmental governance (in the west).

501 It is true that there are women leaders in Asia: in Bangladesh, two women have been Prime Ministers for almost the whole time from 1990 to the present. Yet those women are only there because one is the daughter of the founder of the nation and one is the wife of a national hero who was also a very popular President: both assassinated. This is true in other nations of Asia too: Prime Minister Sirimavo Bandaranaike of Sri Lanka (daughter of a former Prime Minister); Prime Minister Aung San Suu Kyi of Myanmar (daughter of Gen Aung San, who liberated the nation from the Japanese in World War II); Prime Minister Indira Gandhi of India (cousin of Prime Minister Jawaharlal Nehru); Prime Minister Park Choong Hae of South Korea (daughter of President Park Choong Hee); Prime Minister Shinawatra of Thailand (sister of Prime Minister Thaksin Shinawatra). Yes, women can be leaders in Asia: but they need to draw their legitimacy from some popular male member of their family who was a politician or national hero. Similarly, women can be a part of local environmental councils but preferably the daughter or sister or wife of the popular local male MP or male local council Chairman.

persons who do not meet these requirements, to give them their missing status. Inclusion of other persons without the required social status and without legislative mandates might cause the members to lack popular support and respect, so that they are ignored or laughed at in practice.

The picture emerging seems to be one of a kind of Environmental Congress: a group of wealthy, high-status people who are required to act on environmental issues. We can imagine the kinds of issues they would be suitable to act on, not being technical experts:

- auditing expenditures on environmental protection
- hearing complaints against the enforcement or non-enforcement of environmental policy
- developing new ideas for environmental policies
- setting out goals and objectives for environmental policies
- setting up meetings for community participation in developing environmental policies

Such a local Environmental Congress could inject communities with some interest and information about the environment. They could start discussions on needs and priorities. They could hold officials responsible (depending on the powers given to them in the legislation establishing them) or at least ask them questions about what they are doing and why. They could make plans and lay out goals and objectives for improving the environment in their local areas.

Obviously the establishment of such Environmental Congresses would have to be a “top-down” action. No one is rushing to create them. It is their creation in legislation that would give them the legitimacy they need to accomplish their goals. The legislation should set out areas of their authority and give a mandate to investigate official actions, make plans, organize popular meetings, audit expenditures, adjudicate complaints and to submit policy proposals directly to the Minister.

Britain started to involve individuals in environmental policy but this was participation in implementation, not in policy development⁵⁰². Mainly, these were campaigns to educate the public and ask them to carry out policy decisions like making their homes more energy efficient or reduce carbon emissions⁵⁰³.

CONCLUSION

While some environmental organizations have been created “from the bottom up” in recent years, there has not been a fundamental change in the ways most Bangladeshis think about the environment. There is still no widespread demand for environmental protection.

This situation could continue indefinitely: however, there are real consequences to doing so. In the west, strong civil society movements for environmental protection keep pressure on the State, to show action and results. When this is absent, things can tend to settle into a “no noise” situation, where nothing is done and no one complains about it. In politics, “the squeaky wheels get the grease”.

There have been many reports that the environmental laws and policies in Bangladesh and other developing countries are mainly for show and do not lead to any results⁵⁰⁴. This is the direct result of the absence of political and public pressure in favor of these issues.

This is not only a phenomenon of Bangladesh. This is a common reaction of ordinary people to environmental protection in many parts of the developing world. At one level, hungry people care about roads more than trees: yet it runs deeper. As discussed at the beginning of this article, the concept of the role of people in the environment is fundamentally, philosophically and culturally different in non-western societies. What has happened in Bangladesh (or, more accurately, the fact that little has happened) was therefore totally predictable and understandable. Leaving aside the broader issues about non-western societies trying to copy western law to become “modern”, let us just say that the environment is not the right place to do that.

In Brazil, Jose Puppim de Oliveira found that government agencies often fail to implement environmental protection policies mainly because they lack political support, have insufficient resources, have underdeveloped institutional capacity, and tend to overlook the importance of cooperation at the local level⁵⁰⁵. The story sounds the same as Bangladesh. Gamman found a similar picture in his study of the West Indian islands, St Lucia, Barbados and St Kitts. He ascribed this to four major elements: national politics, behavior in the donor agency, the culture of decision making, and economic necessity. So he was one of the first to recognize the role of political culture in the failure of environmental protection in developing countries⁵⁰⁶.

506 Gamman, J., Environmental Policy Implementation in Developing Countries (1990).

Bell and Russell start their article by saying⁵⁰⁷:

Most developing countries have long since established laws and formal governmental structures to address their serious environmental problems, but few have been successful in alleviating those problems.

Now we are arguing that we need to look more deeply, to culture, to understand why. That article said that the problem was caused by international finance organizations pushing market-based solutions on people who lacked the infrastructure and what we might call the “market-based culture” to carry them out. Yet it is so pervasive a problem that we believe it runs deeper than that.

If we care about the environment, then we need to care about what happens to it in the developing world, where many of the problems are. So far, there has been a lot of action in the western countries and not that much real change outside them. If this goes on, the environment will not be improved.

This article has put the argument that there is a fundamental difference in world view between the western and non-western countries about the environment. When we accept and understand it, we can understand why the global summits failed and why environmental protection, western-style, is not working in the non-western countries. So we need to start thinking about ways in which we can be more effective in protecting the environment in the non-western world. This article has put forward one idea for trying to do that: the centrally-sanctioned, locally-based “Environmental Congress”. It is certainly not the only possible way. Yet let us begin to think in such a culturally-sensitive way of new alternatives to get better results in protecting the environment in non-western countries.

1180 CITIZENRY AND IRRIGATION MANAGEMENT: A CASE STUDY OF TWO WATERSHEDS OF WEST BENGAL

ABSTRACT

The 73rd Constitutional Amendment Act,1992 introduced the concept of participatory governance in India. Since then participation has been an attribute, common to all avenues of the government. The importance of irrigation for an agricultural economy like that of India called for participation in the decision making and implementation of schemes in the irrigation sector as well. It called for Participatory Irrigation Management (PIM) which refers to the involvement of the irrigation users- the farmers, in the management of the irrigation system-at all levels and in all aspects of management. It called for Participatory Irrigation Management (PIM) which refers to the involvement of the irrigation users- the farmers, in the management of the irrigation system-at all levels and in all aspects of management. PIM is closely linked to Irrigation Management Transfer (IMT), which is the transfer of management responsibilities from the government agencies to the stakeholders or private sector entities. This was attained by organising the farmers and stakeholders into various groups which came to be known as “water users groups”. PIM has a number of advantages over the traditional irrigation management that includes better cost recovery, equitable distribution of water among farmers, reduced tail end deprivation, need based utilisation, ecological benefits, strengthening of the managerial capacities of the beneficiaries etc. A number of projects have been in operation across India which provides for the formation of such user groups. In this paper the Pradhan Mantri Krishi Sichai Yojana (PMKSY)-the erstwhile Integrated Watershed Management Programme (IWMP), has been studied to understand the status of PIM. For the purpose, PMKSY programme (IWMP7/ Batch III) in the South 24 Parganas and (IWMP 1/ BATCH III) in the Bardhaman (west) districts of West Bengal have been considered. The study has been made since the inception of the project in 2011-12 till the current year 2016-17. The agro- ecological condition of the South 24 Parganas district is well suited to the cultivation of horticultural crops. This is hindered by the unavailability of sweet water in the region and the prevalence of conventional farming techniques among the farmers. Bardhaman faces the shortage of cultivable land. The study here reveals how the organisation of local masses into various user groups, under the assistance of the watershed committees and the government departments, benefitted the regions. The study of two districts from two diverse agro-climatic regions show how the local needs vary climatically, thus necessitating the proper comprehension of local needs. Thus the study at the micro level, reveals how potential based planning can be enabled using the local expertise and involvement of the “folk”. It calls for a better understanding of the positive effects of grassroot level planning that includes the citizenry at levels of planning, its implementation and proper execution. : Participatory Approach, Grassroot Level Planning, Citizenry, Participatory Irrigation Management, PMKSY.

1204 THE STATE DETERMINED GROWTH CENTER AND VACUUM IN REGIONAL DEVELOPMENT: A STUDY OF OF ULUBERIA INDUSTRIAL GROWTH CENTER, HOWRAH, WEST BENGAL, INDIA

ABSTRACT

Growth Center Strategy is a very familiar approach in regional planning. Growth centres are considered as potential for optimum utilization of existing resource basewith least environmental degradation for a sustainable development of a defined region. It is the task of regional planner to identify and plan growth centers after detailstudy of socio economic and historical background of a region. But it is often found that the state itself labels some sites as growth center that sometimes lack detail study of the socio economic structure and historical background of the region. This paper envisages the impact of such state determined Growth Center in regional development with a case study of Uluberia in Howrah District, West Bengal. Uluberia GC was planned during 90's along with other 7 growth centers in a Plan named "Vision 2025" by Kolkata Metropolitan development Authority to fulfill multifaceted objectives i.e. reductionof congestion problem of Kolkata metropolitan area, industrial resurgence, overall regional economic growth through local employment generation. The basicpremise behind such planning was that the location lies outside the embargo of the metropolitan area, and if proper infrastructural support could be channelized in effective manner it would result into overall regional development without increasing pressure in Kolkata Metro city. For this purpose i) the industrial units have been classified in terms of size, pollution categories, types of products, employment generation capacity etc. ii) The pattern of functional linkage of this growth center also been identified by the manufactured product supplyand labour supply areas. iii) The study also attempted to determine the success of the studied centre for fulfillment of its planned objective. It is found that the area is functionally linked with different parts of the country (West Bengal, Mumbai, Gujarat, Madhya Pradesh, Uttar Pradesh etc.) as well as abroad (China, Middle East countries, USA etc) through collection of raw material and delivery of finished product. The Uluberia GC employs approximately 2500 persons but more than 50% of labour are coming from other than Howrah region (Midnapore, South 24 Parganas, Hooghly, Kolkata). On the other hand, 30% of industries closed permanently and some of them are facing industrial sickness due to strong competition, adverse effects of demonetization, increased transport cost. It is realized that the 'growth center' lacks thequalities of a true growth Center as they are. The growth center planning for Uluberia does not taken into consideration the availability of local resource and local linkages and acts as a segregated industrial area. This planned growth center plays the role of isolated industrial pocket. It neither fulfils the goal of its planning i.e. to reduce the burden of Kolkata nor does it succeed to exert growth for its immediate region. It calls for preparation of a proper regional plan through reducing the specific growth generating factors for the area. Key words: Growth Center, Functional Linkage, Regional Planning.

SS13.2. Citizenry and Regional Planning

1254 ROLE OF THE COMMUNITY RESIDING IN NEW TOWN IN THE PLANNING AND DEVELOPMENTAL PROCESSES TAKING PLACE IN THE TOWNSHIP

Kahini Ojha, Aritra Chakraborty

1 INTRODUCTION

A city or town is made of the people, by the people and for the people. In fact, it can be said that the inhabitants of a city or town are the ones who give life to the urban space, making it a living entity with a distinct cultural landscape. Hence, the government and people in authority should place the citizens as the first priority before formulating any developmental policies. It is essential for any inclusive city to have citizens who are aware, better informed and is capable of thinking ethically and sustainably before conducting their daily activities. In this regard, Singapore sets an excellent example of how sincere efforts made by the government in giving immense significance to the quality of life and making its citizens the first priority, acted as a catalyst for Singapore to become an inclusive and 'Intelligent Island' with high human development index (Mahizhnan 1999).

The urban population of India is growing at a faster rate than its total population. This is especially true in case of the Indian metropolitan cities. In fact, the India: Urban Poverty Report of 2009 estimated that by 2030, 41% of India's population would reside in urban areas. It is paradoxical that to deal with the socio-economic problem of the immense pressure created on the urban areas, India has adopted the approach of creating new satellite towns near the metropolises to decongest them, instead of adopting measures to regenerate the existing socio-economic conditions of the cities. This approach of India has been termed as the "bypass" approach by Bhattacharya and Sanyal (2011) who are of the opinion that this would just solve the problem temporarily.

Park, Burgess and McKenzie (1984) were of the opinion that a city 'is something more than a congeries of individual men and social conveniences.' Thus, a city can be defined as:

a state of mind, a body of customs and traditions, and of the organized attitudes and sentiments that inhere in these customs and are transmitted with this tradition. The city is not, in other words, merely a physical mechanism and an artificial construction. It is involved in the vital processes of the people who compose it; it is a product of nature, and particularly of human nature (Park, Burgess and McKenzie 1984, p.1).

In this age of globalization, the urban elite want to be a part of the global cities for the attainment of which the large cities are going through the phase of gentrification. Since the 1900s, the concepts of urban metabolism, smart cities, sustainable cities and green cities have been popularized by renowned global institutions and scholars; citing their significance in tackling with the perils of the rapid pace of urbanization. Thus, the policy makers have key role to play in improving the quality of life of the people living in cities and to make the cities liveable. Lindfield and Steinberg (2012) were of the opinion that a city could be considered to be a green city only when measures were 'undertaken in a comprehensive, planned manner that not only positively impacts the city in question but also contributes to environmental sustainability at the global level.' Thus, the whole idea behind the creation of green cities is to make these cities liveable.

Green cities are becoming an integral part of urban planning in the contemporary times. 'The green city is an ideal of universal appeal that transcends temporal, special and cultural divides' (Hestmark, cited in Jim 2004). It can be assumed that a city with high quality of green spaces could be considered as an example of effective planning and management which is suitable for establishing a healthy environment for humans and flora and fauna in general (Adams and Leedy, Johnston, Godefroid, cited in Jim 2004). Thus, green cities can be defined 'as those that are environmentally friendly' (UNEP 2011). Some cities are also called green because of their highly ambitious green policies which aim towards better environmental performance.

New Town is a satellite town of Kolkata, located in the district of North 24 Parganas of West Bengal, India. It is a fast growing planned township which is situated in the eastern part of the Kolkata Metropolitan Region. New Town had nailed it into the smart city status in the second round of the Smart City Mission of India. Since, the Government of West Bengal was against imposing water tax and was sceptical about the outcome of pumping in Rs.500 crores from the corporate sector to match the grants given by the Central Government of India, the former decided to spurn the smart city offer (*The Telegraph Metro* 18 August 2016, p.15). Thus, keeping in mind the long term development of the region, in 2016, the Government of West Bengal decided to develop New Town into a green city instead of a smart city.

The authorities in charge of New Town have adopted a set of progressive policies which are easily available and accessible to the public in the official website of New Town Kolkata Development Authority (NKDA) to make them operative in a transparent manner. However, it is most important for the inhabitants of the township to be aware of these policies, especially the ones related to the Green City Mission to successfully and effectively transform New Town into a green city. Thus, this is a unique feature of New Town, where the Government is trying to incorporate its citizens in the planning process by initiating e-governance and other awareness programs to ensure an inclusive and holistic development of the township.

2 MATERIALS AND METHODS

A mixed approach comprising of both qualitative and quantitative techniques have been used to prepare this report. The various sources of the secondary data collected were the daily newspaper *The Telegraph* (especially its Friday edition *salt lake*), journals, blogs, the information provided in the official websites of NKDA and Housing Infrastructure

Development Corporation Limited (HIDCO) and by interviewing a few government officials of NKDA and Bidhannagar Municipal Corporation (BMC). Primary data was collected by interviewing randomly selected one hundred and seventy residents of Action Area - I of New Town (which is the most populous and developed part of the township) with the help of a detailed questionnaire.

Simple, cartographic techniques had been used to analyse the data obtained. Likert Scale was used to analyse the questions where the respondents had been asked to rate the amenities that the township provides them. There were also a few open ended questions in the questionnaire schedule which were meant to study the perception of the people about their township. Such perception based questions were analysed by using the software NVivo 7 and online word cloud creating software.

3 THEORY

New Town which was carved out of the larger area of Rajarhat in the later years of its developmental process was erstwhile a fertile piece of agricultural land. The land use pattern of New Town has gone through a drastic change over the years from being a prosperous piece of agricultural land to completely being converted into a township with no agricultural land in it. It is a well planned modern township with an approximate population of 70,000 to 90,000 people residing in it and an approximate population of 30,000 to 60,000 people commuting to and from it for work (NKDA 2017). After Sector V of Salt Lake, New Town forms the second IT hub of the Kolkata Metropolitan Region. New Town is enabled with 10.5 km of Wi-Fi Zone connecting the Major Arterial Road stretching from the Airport to Sector V of Salt Lake. It is India's first Wi-Fi road connectivity and this stretch has already been declared as a green corridor (Chakraborty 2014).

The State Urban Development Department has planned New Town's Green City Mission by taking suggestions from the Indian Green Building Council, Indian Institute of Technology Kharagpur, Kolkata Municipal Corporation and the Confederation of Real Estate Developers' Association of India. By adopting the "green" policies, New Town has taken a leap towards achieving its development in a sustainable manner. Since, New Town is still at an early stage of development, it is remarkable to see the progressive transformation that is taking place in the township to make it an environmental friendly and inclusive town.

One hundred and seventy people residing in Action Area - I of New Town were surveyed about the extent to which they as citizens were aware of the Green City Mission, the developmental works taking place in their township, the amenities that they are entitled to in their neighbourhood and the facilities that their residential complexes provide them. Action Area - I was selected as the study area since it is the most inhabited and developed part of New Town.

3.1 Emergence of New Town as a place of residence

New Town as a township is approximately a decade and a half old. The sudden growth of real estate after liberalisation witnessed innumerable stakeholders building modern residential complexes in New Town. Though many residents said that they had bought their land many years back, they had shifted recently after the construction work had completed. There were also a few people who bought apartments in New Town as assets since the price of land of New Town has been ever increasing since its inception. Such people visit their apartments once in a while as they mostly live in their house which is in the proper city of Kolkata.

Among the people surveyed, most of them claimed that they were residing in New Town for less than five years. Many among such people were students and employees studying in schools or colleges, or working in the offices of Sector V, New Town, Salt Lake and Kolkata. Thus, these people who recently moved into the township were mostly people who hailed from places outside the Kolkata Metropolitan Region and came to New Town for the livelihood opportunities available in this growing township. It is to be noted that a significant percentage of people came from other districts of West Bengal and even outside West Bengal who live in New Town in rented apartments. This shows how the livelihood opportunities of New Town has acted as a pull factor in attracting people from far and wide places to come and reside in New Town.

People who were residing for more than five years were all permanent residents. An important fact that can be inferred from this is that though New Town had started experiencing in flow of residents from more than ten years ago, it witnessed maximum in flow of residents in the last five years. This also reflects upon the fact that there has been rapid pace of urbanization and development of New Town in the last five years.

Some of the people said that they had shifted to New Town as they had bought their own home. Thus, it was a shift from rented apartment to own apartment. These people lived in different parts of Kolkata and chose New Town as their permanent place of residence because it is a well planned city in their opinion. Many retired people exclaimed that they shifted to New Town to move away from the congested city life of Kolkata. There were happy with the open space available in the township. Few among these people were old couples who lived by themselves as their children do not live in the same city. Thus, they chose to move out from the hustle bustle of congested city life and live within a peaceful environment.

3.2 Background of the residents

New Town from its very conception had been built for the urban elite. Most of the people surveyed had responded by saying that their family income (per annum) ranges between Rs.6,00,000 to Rs.9,00,000, followed by people with family income above Rs.9,00,000 per annum. Only 28% of the people said that their family income (per annum) ranges between

Rs.3,00,000 to Rs.6,00,000 and a mere 5% of the people said that their family income (per annum) was less than Rs.3,00,000.

Thus, it can be inferred that New Town comprises of people belonging to the upper class and upper middle class. These are the people who have chosen New Town as their place of residence to avail the modern amenities and experience world class infrastructure. New Town is being planned following modern city planning guidelines and this is what is attracting people to shift to New Town. With the skyrocketing price of land of New Town, it has become one of the posh localities of the Kolkata Metropolitan Region.

From the survey it has been seen that while proper Kolkata still dominates the place of work or the location of the school or college of most of the respondents, it is closely followed by Sector V. After Sector V, it is Salt Lake and then New Town which forms the destination of the place of work or college of these respondents. Most of the people surveyed were either students or people belonging to the service sector. It is to be noted that New Town is barely more than a decade old. So, going by the age of the Kolkata and Salt Lake versus the age of New Town, it can be said that New Town has made remarkable growth in providing livelihood opportunities not only to its own residents, but also to the residents of the Greater Kolkata. In fact, the central business district of New Town which is still under the planning and development process claims to be the next commercial hub of the Kolkata Metropolitan Region.

The survey result reflects upon the fact that New Town has emerged as a township where people who migrated to Kolkata for educational and employment purposes, have made their temporary homes. Due to its proximity to Sector V of Salt Lake which is the IT hub of Kolkata Metropolitan Region and which also houses a number of commercial and educational institutions, these migrants have chosen New Town as their place of residence. It was also found out that people chose New Town as their place of residence because of its comparatively cheaper rent than Salt Lake.

4 RESULTS AND DISCUSSION

4.1 Awareness of the citizens about New Town being transformed into a green city

New Town is under the massive ambitious mission of getting transformed into a green city. However, it is most important for the inhabitants of the township to be aware of this Green City Mission to successfully and effectively transform New Town into a green city.

From the survey undertaken, it has been revealed that more than 50% of the people are aware of the basic concept behind a green city and the fact that New Town is being transformed into a green city. This is an important point to be noted since it is this basic awareness of the citizens about their township that is praiseworthy. Those few people who said that they were not aware of New Town being transformed into a green city were the people who were not from the Kolkata Metropolitan Region and had shifted to New Town recently.

Newspaper formed the source of information about the Green City Mission of New Town to 68% of the residents, while 14% of the people came to know about the Green City Mission from the hoardings that were displayed in the township. This reflects upon the pivotal role of media in spreading awareness among the people about the Green City Mission of New Town. Spread of word from acquaintances about New Town being transformed into a green city formed the source of information to 17% of the residents; and from this it can be said that the people were genuinely enthusiastic towards the initiation of this green city project. However, only 1% of the people came to know about the Green City Mission from government websites like the official website of NKDA and WBHIDCO. The fact that the government had put up notices in its website, shows the interest of the government to involve the citizens of New Town in the planning process. This was an important initiative taken up by the government to create an inclusive society but unfortunately very few people had availed this medium to obtain their knowledge.

It was good to see that majority of the people were enthusiastic about this mission and looked forward to the changes that were taking place in the township to make it a green city as 55% of the residents said that they keep a follow-up of the news updates on the Green City Mission of New Town, while 45% of the people said that they do not bother themselves with it. Among the people who kept a follow-up of the happenings of their township, 88% of the people banked on the newspaper to acquire information, while the remaining 12% people got the information from their acquaintances.

Whether the residents were criticizing some of the policies or were in praises for the policies initiated by the government to transform New Town into a green city will be discussed in the later part of this article; but the fact that they were getting themselves involved in the discussion is what needs to be appreciated. Their eagerness, their opinions, their acute sense of belongingness and some of their possessiveness towards their township is what reflects upon the love and the healthy relationship that the residents share with their place of residence.

4.2 Role of the government in spreading awareness among the citizens about the Green City Mission

One of the most important aspects behind creating a green city is to make its citizens aware of the concept behind a green city. From the survey conducted it was revealed that 35% of the people confirmed about the awareness programmes that were being held by the government where the opinions of the residents were asked for to make New Town a more citizen-friendly township. The residents who said that there were awareness programmes held and their opinions were asked for, mentioned the various ways in which the government had made them aware and had asked for their opinion. The different ways in which the government had approached the citizens were:-

- Letters were sent to some of the respondents. In the letters, the government had made them aware of the Green City Mission and had asked for their opinion regarding what are the changes they would want to see in the township.
- While inaugurating one of the parks in New Town, the people present in the inaugural ceremony were made aware of the Green City Mission of New Town and an interactive session was held where the opinions of the residents were being asked for regarding the changes they wanted to see in the township.
- Some of the residents had submitted the changes they wanted to see in the township to the 'Durga Puja Committee' of their residential complex and their letters were sent to NKDA.
- Some of the residents said that they had received text messages in their phone where they were made aware of the Green City Mission and their opinions for asked for regarding the changes they wanted to see. However, one of the respondents said that only those people who had registered themselves as residents of New Town in the official website of NKDA were the ones who got text messages from the government.
- During a medical camp that was held in one of the parks in New Town, the people present over there were asked to fill up forms stating the changes they wanted to see in New Town.

Some of the respondents said that though they were not present in the awareness programmes, they had heard about it from their acquaintances.

4.3 Extent to which the residents were aware of the facilities provided to them by their residential buildings

Green buildings form an integral part of any city that claims itself to be a green city. This aspect of the green city especially needs to be taken care of because of the rapid pace of urbanization taking place in the township.

Most of the respondents lived in residential buildings with 5 to 15 floors, followed by buildings with up to five floors and then buildings with more than fifteen floors. The floor of a building is indicative of the height of the building and this is why this was an important question that had to be asked to the respondents. It has been mandated by the authorities that buildings above the height of 15 metres should install solar panels and in the next section of this article, it would be seen that all the respondents who said that their residential buildings have solar panels installed it, live in buildings which have more than fifteen floors. Also the more the number of floors, it can be expected that the more will be the number of modern amenities available to the residents of such buildings. This is because such buildings are constructed by large real estate companies whose target group comprise of the urban elite who do not want to compromise on neither luxury nor amenities.

A large number of people said that they do not have any idea about whether their building is green certified, or have solar panels or water harvesting/recycling system but another significant percent of respondents said that their buildings do not have any of the three mentioned aspects that a building present in a green city should have. Among the three mentioned criteria, solar panels being installed dominated the rest, followed by the building being green certified and then having water harvesting/recycling systems. Most of the respondents who said that their buildings fulfil all the three aspects mentioned above, or at least two among the three aspects, belonged to high rise buildings having more than fifteen floors. It is to be noted that the concept behind transforming New Town into a green city was initiated in the year 2016, and the respondents who had been surveyed lived in residential buildings that were constructed way before that. Thus, it can be said, in due course of time more buildings are expected to come up that would abide by the green building norms.

4.4 Role of the residents and the extent to which they are aware of the amenities present in the township

It is important for any settlement to have residents who are aware of their surroundings and the amenities that they are entitled to. The same principle applies to New Town and it is more important for its residents to be aware citizens because an important aspect of green city is having citizens who are aware and are eager to actively participate in the functioning of the city in their own small ways to create an environmentally friendly urban space.

Having access to WiFi is an important aspect of any modern city that plans to function through e-governance. This is because if free WiFi is provided it would encourage the residents to actively be a part of the e-governance. New Town has taken up e-governance seriously and has also set up the Bishwa Bangla network for providing free WiFi to the people present in New Town. However, this WiFi is available only through the 10.5 kilometre stretch of Major Arterial Road stretching from Sector V of Salt Lake to Airport. Thus, the WiFi connectivity works well only in and around the area of the Major Arterial Road, while the places away from it either do not have access to it or face the problem of poor network.

Among the people surveyed, most of them said that they have access to the free WiFi provided by the government, while another group of people said that they do not have access to the WiFi as their residential area is out of coverage of the network. Some people also said that though they have access to the free WiFi, the network is poor and cannot be used effectively. One of the respondents said that the government is planning to set up another WiFi tower near her house which would provide free WiFi to the people who are living away from the Major Arterial Road.

Unfortunately most of the people surveyed were not aware of the online system of lodging complaint in the official website of NKDA. This is an important part of e-governance where people can fill up a citizen grievance form available in

the official website of NKDA and lodge a complaint without going through the hustle of physically visiting the NKDA office. It is a privilege that the citizens of New Town are entitled to but due to the unawareness of the citizens, this facility has not been utilized in its full potential. When the respondents who were aware of the system of lodging online complaints were asked if the system is effective and responsive, all of them unanimously said that they have no idea as they had never lodged a complaint. This reflects upon another issue that people are satisfied with the basic facilities like supply of water and electricity in their home. Till a few years back New Town was in the news for the high iron content in the water that it supplied to its residents. However, after the recent establishment of the water treatment plant near Nazrul Tirtha, this problem has been solved.

On being asked whether the respondents segregate wastes into biodegradable and non-biodegradable wastes, other than a few people, the majority said that they do segregate wastes before disposing them. It was good to see that most of the people abided by this waste management norm set by the government. In fact, when the respondents were asked whether there are sufficient wastebins in the township, they all unanimously answered by saying that there are sufficient wastebins in the township. A striking fact about New Town is its picture perfect cleanliness.

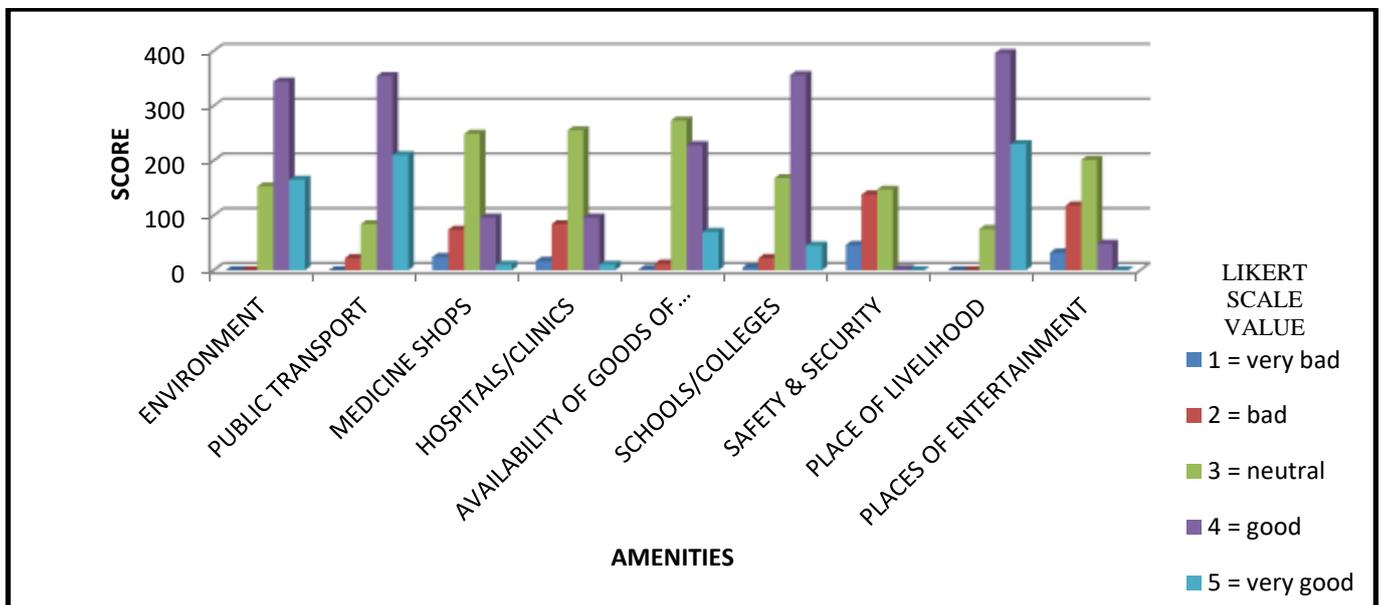

One of the key and basic aspects of the Green City Mission of New Town is to increase the green cover of the township. But from the data collected, it was revealed that the indiscriminate felling of trees to make way for construction work and further urbanization is still continuing. The respondents who are residing in New Town for a long time said that over the years the greeneries of New Town has been declining. Quite a few respondents said that leaving aside the part of land occupied by Eco Park, large extents of the township are devoid of sufficient greeneries. On the other hand, people who had shifted to New Town recently or had shifted to New Town from congested places were of the opinion that New Town has sufficient greeneries/water bodies/parks.

The survey conducted revealed that some of the major concern of the respondents were regarding the increasing air and noise pollution arising from the construction sites and lack of sufficient public washrooms in the township. Few respondents also complained regarding lack of usable pavements because of the hawkers encroaching the pavements. But there were also many respondents who were satisfied with the available pavement space and were not disappointed with the hawkers as they were themselves loyal customers of the hawkers.

ATMs and banks form an integral part of our daily lives. Thus, proximity of residences to ATMs and banks have become an important aspect to judge the quality of infrastructure available in a town or city. When the residents were asked how far is the nearest ATM or bank from their place of residence, all the one hundred and seventy respondents answered by saying that they are located approximately within 1 kilometre of radius from the place of their residence. This remarkable feature shows the demand for such infrastructures in the township. Presence of such financial institutions nearby also reflects upon the fact that New Town is indeed a posh locality which has more ATMs or banks present than the number of medicine shops!

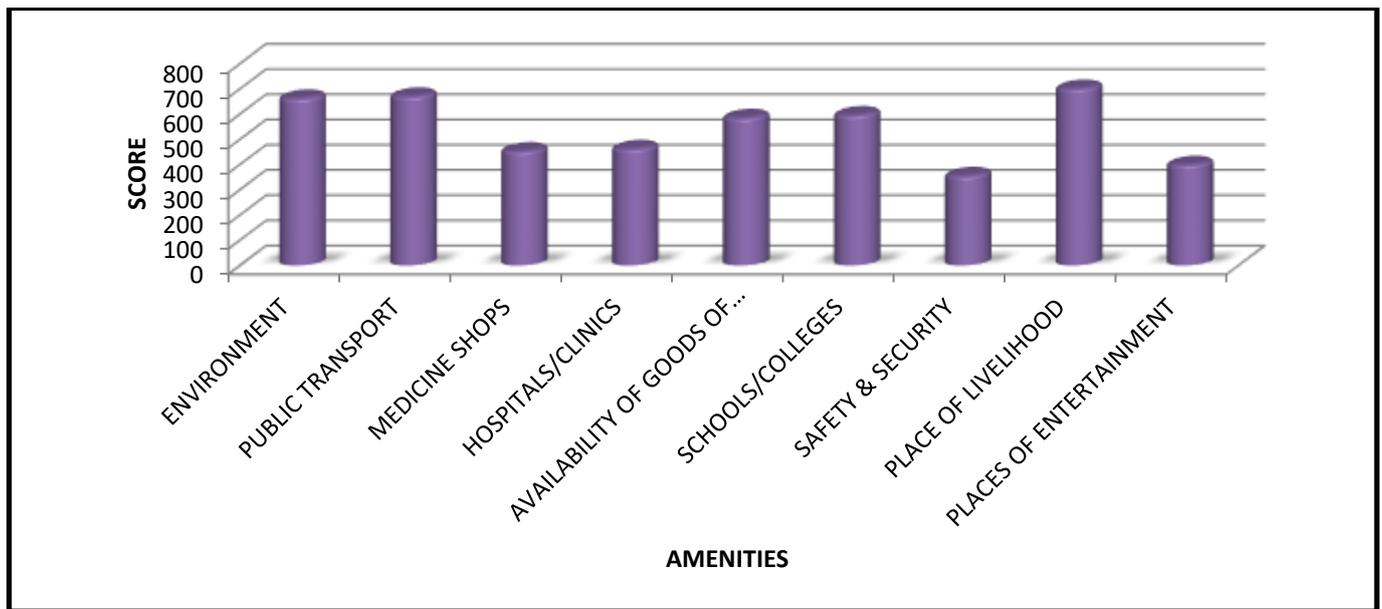

4.5 Resident’s perception of New Town

The perception of the residents on the town where they reside is of great importance. The most important part of the primary survey was to study the residents’ perception of New Town. For studying this, Likert Scale was used to rank the amenities available. The other opinion based open ended questions asked were - what in their opinion is the best part of living in New Town, the major drawbacks of New Town and what are the changes they want to see in New Town. From the answers received for these three questions, word frequency query was run in NVivo and then word frequency clouds were prepared to analyse the data. Going by the rule of word frequency cloud, the more the number of times a word has been mentioned in the data collected, the bigger would be the size of the word in the word frequency cloud created, hence, reflecting upon the importance of that word.

(Source: Primary Survey)

Fig. 1: Study of the respondents' perception on the amenities available in New Town, using Likert Scale

(Source: Primary Survey)

Fig. 2: Total score of each of the amenities calculated from the Likert Scale values

In Fig. 1, the score has been calculated by multiplying the number of respondents who had chosen a particular Likert Scale value with the value of the Likert Scale chosen by the respondents. While Fig.1 shows the individual Likert Scale score of each of the amenities, Fig. 2 shows the total score of each of the amenities.

From Fig. 1 and 2 it is clear that according to the respondents, New Town serves as an excellent place of livelihood while safety and security of the township is very poor. The reason behind the high score of place of livelihood is the presence of innumerable commercial institutions in New Town and its close proximity to Sector V of Salt Lake which is the IT hub of the entire Kolkata Metropolitan Region. On the other hand because New Town is still under the process of development and is dotted by large vacant plots of land with construction work going on, it serves as the hide-out of the anti-socials and the criminals at night, which is why it makes the township an unsafe place, especially at night.

Environment and public transport also scored high and individually had high Likert Scale values. As far as the environment is concerned, people gave high Likert Scale ranking for the clean and peaceful environment, while some respondents gave low Likert Scale ranking because of the pollution caused by the construction sites, presence of hawkers and safety and security issues. Public transport received high Likert Scale ranking by the people who reside near the Major Arterial Road, while those who reside in the interior parts, gave comparatively lower ranking. However, the overall score of environment and public transport are high.

Availability of goods of daily need and presence of schools/colleges have also scored moderately well. Those who had given low ranking to availability of goods of daily need, stated that the township is devoid of sufficient mechanical repairing shops, standard shops selling groceries (not hawkers or malls) and petrol pumps. Some of the respondents had given low ranking to the availability of schools/colleges in the township stating that there is a lack of good primary schools/colleges teaching non-technical subjects. On the other hand, schools/colleges received high ranking by those who stated that even though there are not many educational institutes within New Town, but plenty of them, especially colleges are present in Sector V which is in close proximity to the township.

The scores of hospital, medicine shops and clinics, and places of entertainment are on the lower side of the score card. Respondents who had given low ranking to hospital said that there should be more government hospitals and multi-purpose hospitals established in the township. Many of the respondents complained that medicine shops are found in clusters in the township and are not ubiquitously distributed; while there is a severe lack of doctor's chambers and clinics in the township. Mixed reviews were derived from respondents ranking places of entertainment as the middle aged and the old people were fairly satisfied with the places of entertainment available; while the youth gave low ranking to the availability of places of entertainment. This is because the youth complained of lack of standard restaurant chains, lounges and nightclubs in the township.

Thus, by using Likert Scale, we have been able to derive at a wide range of opinions on the amenities available and not sufficiently available in New Town. It was a useful technique to assess the areas of strength and weakness of New Town.

Word frequency query was used in NVivo 7 to check the number of times a particular word has been used. It is an obvious fact that the more number of times a particular word is used, that word would be of greater relevance. Word frequency query is an important technique that can be used to NVivo to effectively analyse qualitative data.

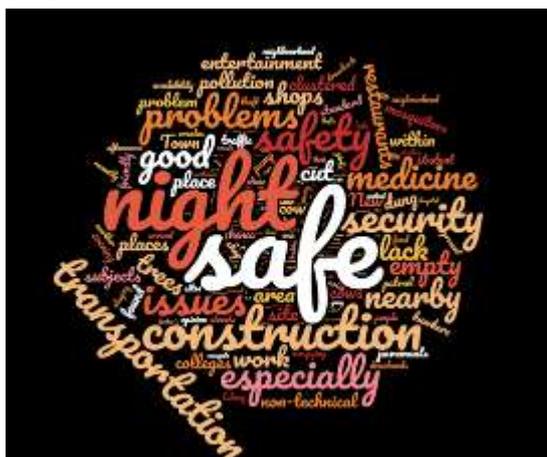

(Source: Primary Survey)

Fig. 3: Word frequency cloud on residents' opinion on the best part of residing in New Town

Fig. 3 gives a glimpse of the word frequency query that was being run in NVivo 7 using words which were drawn from the comments made by the respondents to the question on what according to them is the best part of living in New Town. From the figure it can be seen that words like 'clean', 'peaceful', 'city planned', 'nice environment', 'congested' (implying less congested), 'greens', 'modes' of 'transportation' and 'e governance' have been most frequently used words.

Thus, it can be inferred that according to the respondents, the cleanliness of the well planned township, the peaceful environment, less congested space, greeneries and different modes of transportation available are the various advantages of living in New Town. The combination of these various factors acts like the pull factor attracting more people to come and reside in New Town.

(Source: Primary Survey)

Fig. 4: Word frequency cloud on residents' opinion on the worst part of residing in New Town

From Figure 4 we can at a glance see the most frequently used words by the respondents when they were asked what according to them is the worst part of residing in New Town. From the figure it can be clearly seen that words like 'safe', 'safety', 'night', 'construction', 'security', 'transportation', 'medicine', 'empty', 'trees', 'restaurants', 'entertainment', 'mosquitoes', 'college', 'hawkers', 'petrol pump', and 'drunkards' are some of the most frequently used words.

Thus, it can be inferred that safety and security, especially at night is a matter of major concern of most of the respondents. Some of the respondents also complained of drunkards being seen in the empty streets at night. People were also disappointed with the pollution caused from the construction sites and the indiscriminate felling of trees to make way for the construction work. Lack of sufficient modes of transportation at night, prevalence if too many mosquitoes, lack of sufficient number of petrol pumps in the vicinity, lack of non-technical colleges and lack of restaurants and places of entertainment in the township are some of the major drawbacks of residing in New Town.

(Source: Primary Survey)

Fig. 5: Word frequency cloud on residents' opinion on the changes they wanted to see in New Town

Figure 5 shows the result of the word frequency query that was run in NVivo 7 using words drawn from the response made by the respondents when they were asked about what are the changes that they would like to see in New Town. From the figures it can be clearly seen that words like 'security', 'entertainment', 'safety', 'police', 'transport', 'patrolling', 'medicine', 'construction', restaurants', 'trees', 'petrol pump' and 'lounges' were some of the most frequently used words.

However, this question had drawn different opinions from people belonging to different age groups, except the common issue of safety and security which everyone irrespective of their age group were concerned about and wanted the authorities to take initiative to make New Town a safer township to reside in. Some of the respondents had also suggested that there should be police patrolling at night to increase the safety and security of the township.

It was noticed that respondents belonging to the younger age group wanted more places of entertainment like good restaurant chains and lounges to open up in the township. On the other hand, most of the elderly respondents wanted more medicine shops and clinics to open up in New Town.

Most of the respondents said that they were waiting for all the construction work to get over as soon as possible because the construction sites were causing pollution. Some of the respondents also said that they were eagerly waiting for the construction of the East-West Metro Rail service to get over soon so that they can travel in metro. Some of the respondents also said there needs to be more petrol pumps established in the township.

Many among the respondents said that they would like to see more trees being planted in the township as a whole and not only in Eco Park. Some of them said that because New Town is gearing up to become a green city, the authorities should pay special attention to increasing the green space of the township ubiquitously and not only focus upon Eco Park.

5 CONCLUSION

It can be said that a trend of the government has been observed where huge investments are being made behind developing the infrastructure and beautification of the township; while there are major setbacks noticed in providing the citizens of New Town with some of the basic amenities like a safe environment and ubiquitous distribution of medical facilities and green space. For a holistic development of the township, the authorities should first focus on providing the basic amenities like safe and secured environment, provision for more ubiquitously distributed medical facilities and at last but not the least prevent further felling of trees in New Town. Other investments should be made after these basic amenities are being made available to all the citizens of the township.

Some of the important observations made and recommendations suggested are:-

- The authorities have made sincere efforts to spread awareness about the Green City Mission among the residents of the township. However, a gap has been observed between the efforts made by the authorities and the residents, as all the residents are not aware of the awareness programmes that were held in the township. Majority of such people comprise of the working people.

Thus, such methods of spreading awareness should have been applied where all the residents would have been aware of the happenings in the township. Like for example, hoardings should have been put up by the traffic signals, in the bus terminus and outside major places of public attraction like Eco Park, City Centre 2, Axis Mall, Nazrul Tirtha, Rabindra Tirtha, Mother's Wax Museum etc. to make the people aware of the government's ambition of turning New Town into a green city and the other developmental works that are taking place.

It would have been even better if the authorities would have asked the residents to fill up online forms about what are the changes they wanted to see in the township. This could have been done through sending push messages to the residents in their mobile phones with the link of filling up the online form. In this way, it would have been an inexpensive means of reaching out to the mass and creation of a more inclusive society.

- Though the authorities of New Town have made provisions for e-governance, unfortunately very few residents are aware of it. The same applies to some of the other amenities like new public washrooms that have been

constructed; or norms such as segregation of wastes into biodegradable and non bio-degradable wastes before discarding them, are certain facts of which many of the citizens of New Town are unaware of.

To ensure that all the residents of the township are aware of the norms that they are supposed to follow and are also able to enjoy the amenities that they are entitled to, the authorities in charge of New Town should periodically send circulars to the secretary of each of the residential complexes, who would be in charge of putting up the circulars in the common notice board of each of the residential complex so that all the people of the respective residential complex can have a glance through it. Hence, it would be the responsibility of both the policy makers and the community residing in New Town to maintain a two-way communication for ensuring holistic development of the township. The residents should also be made aware of the provision of e-governance and encouraged to periodically check the official website of NKDA and WBHIDCO to get updates about what is happening in New Town.

- The condition of public transportation in the interior parts of the township is very poor and residents availing public transport have to solely depend on the availability of totos (e-rickshaws) or bank on booking app cabs. Provision should be made to extend public transportation routes to places in New Town that are away from the Major Arterial Road and connect the interior parts of the township.

Another problem related to transportation is lack of availability of public transport from late evening onwards. Once the peak hour is over, the availability of public transport reduces or one has to wait for a long time to avail public transportation facilities.

- Most of the residents complained about New Town being unsafe at night and sometimes even in the afternoon. This is because of the empty plots of land and large number of construction sites which at times turn out to be the hide-outs of the anti social people. Theft is also common in the township as many of the apartments lay vacant either because its inhabitants are out for work for long durations or its inhabitants live in proper Kolkata and have bought these apartments as assets. Some of the residents also complained of incidents of snatching of valuables, even in broad daylight.

Thus, policies should be formulated to increase safety and security of the people of New Town. One of the methods through which this can be done is through police patrolling in the township at night. CCTVs can also be installed at regular intervals in the interior parts of the township, as this is where most of the crimes take place.

- New Town lacks sufficient availability of machine repairing shops, service centres, clinics and doctors' chambers, petrol pumps and local shops where goods of daily need would be available (not malls or hawkers). Though plots of land have been allocated to educational institutes in the township, they are yet not functional as they are under construction. Thus, these basic facilities should be increased and made available to the residents as soon as possible.
- One of the major and basic facility that New Town lacks is that there is not a single active fire station in the entire township. According to one of the articles written in the Friday special edition of *The Telegraph salt lake*, though the foundation stone for a fire station had been laid behind Axis Mall of New Town four years back, construction work has still not begun. One of the representatives from the state fire and emergency services was quoted saying in the same article that construction work could not begin as they were yet to receive funds for the construction from the Public Works Department.

Thus, it is highly recommended that all the internal disputes should be solved and construction of the fire station should begin at the earliest. Since, New Town comprises of high rising buildings, there should be provisions in the fire station to tackle with any fire mishap in the higher floors of the buildings.

Thus, it can be concluded by saying that the residents of any settlement form the foundation on which the entire civilization rests. The diligence of the government and the enthusiasm and cooperation of the citizens are all that are required to create an inclusive society. A society can grow up to be a healthy one only when it houses healthy and aware residents.

1278 CITIZENRY AND GOVERNANCE: A GENDERED PERSPECTIVE IN KOLKATA MUNICIPAL CORPORATION AREA

ABSTRACT

In India, the world’s largest and one of the oldest democracy, a three-tier electoral system is in operation- constituting of Members of Parliament, Members of Assembly and Members of Urban Local Body or Panchayat depending on the level of urbanisation. Long back Plato initiated the debate that whether in a democracy there should be a direct rule of ‘demos’ i.e. the masses or of the ‘notables’ i.e. the representatives and was in favour of latter. Later philosophers like Thomas Paine, James Mill also spoke in favour of representatives or ‘down-scaling’ of governance with division of power. In modern democratic setup, it is through the elected representatives at all levels the citizenry seek to articulate their urges, expectations and grievances. In a real democracy, equal rights of men and women are imperative both in terms of electorates and representatives. But the representation of women in the seats of power has been abysmally low all through, for which 33 percent reservation in the lowest tier has been constitutionally approved. In the megacity of Kolkata, which is said to be the intellectual capital of the country, the situation is no different. The endeavour of the paper is to find out the role of the elected women representatives in serving the citizens by utilising the local area development (LAD) funds allocated to them like Member of Parliament Local Area Development Scheme (MPLADS), Bidhayak Elakas Unnayan Prakalpa (BEUP), Councillor’s Fund; highlighting the effectiveness of the projects in bridging critical infrastructural gaps; analyzing the sector-wise fund utilisation, project maintenance and management, viability of the projects ; bringing out the actual position of the women representatives in the political structure and society in general highlighting their achievements and struggles; and portraying the role of the women electorates- their psyche, needs, aspirations. The discussion involves quantitative and qualitative analysis about the involvement of citizenry in local area development projects and local governance, sectoral involvement of funds, temporal progress of schemes, level of fund utilization, degree of infrastructural development carried out by women representatives along with the perception study of the women electorate about their elected counterparts to get a fair bit of idea about the true position of the women at all strata in political sphere.

1296 ASSESSING THE DIFFERENTIAL IMPACT OF MICROCREDIT PROGRAMMES UNDER SELF HELP GROUP MODEL (SHG) AND NON-BANKING FINANCE COMPANY MODEL (NBFC)

ABSTRACT

Various traditional and innovative approaches have been adopted by micro financial institutions (MFIs) for increasing the credit flow to the poor vulnerable people of unorganized sector in India. It helps them to improve their socio-economic status through utilization of the credit. In this study SHG model under National Rural Livelihood Mission (NRLM) and NGO based Non-Banking Finance Company (NBFC) Model: not for profit and for profit patterns have been considered with the aims to assess the differential impact of microcredit programme for the betterment of the beneficiaries. For this purpose, five point Likert-Scale questions have been asked to measure the effectiveness of both of the programme in the following variables i) income, ii) productivity level and skill, iii) poverty status, iv) food security, v) child education, vi) health, vii) asset building, viii) living status, ix) repayment. It is considered that borrowers who had scored more than 60% in the above mentioned variables have improved their livelihood. In this study 5 selected explanatory independent variables are i) time with the institution, ii) mode of credit utilization, iii) household types by income source, iv) loan sufficiency, v) involvement with other credit organization. To understand the effects of the independent variables on beneficiaries' improvement researcher have carried out a bivariate (chi-square) as well as a multivariate analysis (logistic regression). Chi-square test and Odd ratios (ORs) derived from the logistic regression analysis reveal that most of the variables are statistically significant in relation to improvement of the beneficiaries. In case of SHG the base rate for improved beneficiaries is 46.9% and 53.1% for not improved category. As compared to borrowers who did not improve, borrowers who improved it is more likely to cultivators (OR 1.23) and non-agricultural workers (OR 2.08) as main source of income in respect to reference category with several income source, to utilize the credit in fully productive activities (OR 14.70), partial productive activities (6.36) than non-productive activities. Borrowers categories with involvement with SHG for 1 to 4 years and 5 to 8 years are less likely to improve their livelihood (OR .06 and .35) than the reference for 9 or more years. So far the "improved beneficiaries" of NGO is concerned the study shows different result where base rate of improved beneficiaries is 67.9% and 32.1% for not improved beneficiaries. Compared to borrowers who did not improve, borrowers who improved it is more likely to agricultural labor (OR 2.85) household as main source of income, to use the credit in fully productive activities (OR 5.25) and to have involvement with other credit organization (OR 4.23). Identically the time association with NGO has no significant role in improvement of beneficiaries. It is found that predictor variables interact differentially with improvement of beneficiaries in case of the models of microcredit delivery under consideration. It is due to the structural and functional differences of these models. Key Words: SHG, NGO, microcredit, NRLM, NBFC, improved, effectiveness, binary logistic regression, OR.

ABSTRACT

The purpose of this study is to be clarified that constructing gaming simulation model based on information scenario from questionnaire survey in L’Aquila. This gaming simulation model is expected that it can be reproduced real situation and real DIM in the time of disaster in L’Aquila, Italy. However, it couldn’t do gaming simulation to test subjects, the result of gaming simulation will be provided not only players can understand actual situation of disaster time, but also it can be measured what kind of DIM mostly reduced, what kind of DIM is affected victim’s QOL and Sense of Place factors.

Keywords: QOL, Sense of Place, Disaster Information Mismatch (DIM), Gaming Simulation

1 RESEARCH BACKGROUND AND OBJECTIVES

The international disasters database (EM-DAT: Centre for Research on the Epidemiology of Disasters) reported number of disasters was less than 50 events in 20th century but increasing exponentially toward the end of 20th century, now reported natural disasters over 10 times from 20th century in 21st century in its “World trend of natural disasters 1900 – 2010”. In case of historic cities, it is really weak of city’s vulnerability. It means that it is easier to being destroyed itself when earthquake happened. At the same time, it also has vulnerability for resident’s safety after an earthquake. In this sense, it should be safe for resident’s living environment in times which is all disaster phase. In this sense, it takes consideration to make evacuation plan with participatory process for resident’s safety to understand their own town’s risks before occurring big earthquake [2]. However, it must be considered policy and plan based risk after occurring natural disaster. One of them is an Information sharing system among victims and information sender such as national relations, public sector, NPO (NGO), some volunteers and so on. But nowadays, information sharing after the natural disaster is not working well, because of emergency time. People have to survive from natural disaster, but all of things is information such as where should we evacuate immediately after earthquake, when will public sector provide food and water living in evacuation shelter and so on. In our survey, a lot of disaster information mismatch among residents need and sender’s supply is occurred in L’Aquila, Italy. At the same time, if disaster information mismatch is happed, victim’s feeling become feeling of uneasy. However, what kind of information mismatch and which disaster phase affected to residents feelings. The purpose of this study that is constructing gaming simulation model based on information scenario from questionnaire survey, case study in L’Aquila Italy.

2 RELATED WORKS

2.1 Disaster Information Mismatch among victim’s needs and information senders

This section review about disaster information mismatch among victim’s needs and information senders in historical area. Disaster information mismatch is some phenomena that has a gap between victims needs and information senders supply. This phenomena is happened around the world in a time of disaster. For instance, in case of Ayutthaya flood in 2011, it was occurred by heavy rain as two time the previous year. It was damaged the whole of Thailand including capital of Ayutthaya from August to December 2011(The death: 813, the missing: 3(The department of the interior, Thailand)). In this time, it was shared huge disaster information by public information, mass media, inter- organizational relations, however it was mentioned[3]: how much necessary information was given victims from huge disaster information, was it include really necessary information.

As shown Fig. 1, in the field of tourism, people with more sever access needs require additional and more specialized information. However, the supply of this information becomes more scarce for those with higher accessibility requirements. So the gap between demand and supply of accessibility increase, with a greater effect on those who need information[4]. In this sense, this situation is same as a time of disaster. There are variety of people such as baby, young, adults, aged people in disaster area. Thus, it has multiple specialized information needs in each disaster phase: temporary evacuation, temporary shelter, temporary house phase). It must be filled in those kinds of gap between demand and supply. This is information issue for victims. In this study, those kinds of phenomena as information problems and information mismatch among demand and supply is called “Disaster Information Mismatch(DIM).

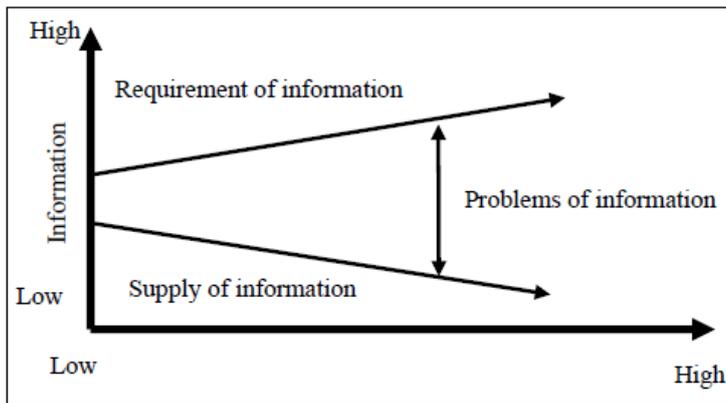

Fig 1. Information Issue for disabled travelers[4]

2.2 Victim's consideration QOL in a time of disaster

This section reviews two categories of previous study on the subject Quality of Life: research on components of Quality of life, and research on necessary condition in disaster prevention to be regional inheritance in the field of psychological aspect.

Demura et al[5], constructed QOL components model based on previous study[5]. QOL which means subjective satisfaction is composed by condition of individuals (physical aspect, psychological aspect, social aspect and so on) and condition of environment. When it is focused on psychological aspect, it is composed by feelings of uneasy, pain of body and so on. In consideration of victim's QOL in a time of disaster, victim's QOL is more decreasing than normal life, because of changing life environment by disaster (it is increasing the feeling of uneasy). At the same time, historical city has much vulnerability. It means that historical city has historical building which is easy to broken by natural disaster. So victims must evacuate the other place for a long time in a disaster time. Thus, psychological aspect of QOL is most consideration things.

On the other hands, research on necessary condition in disaster prevention to be regional inheritance in the field of psychological aspect, Kanegae et al[6], mentioned that not only national relations and public sector must need "Disaster Preparedness" but also it most necessary of suitable and immediate "Disaster Response" by residents(victims) to be sustainable inheritance and to be decreased the damage by natural disaster. Shirotsuki et al[7], elaborates on the importance of resident's participatory process after natural disaster to reserve and restore historical city, cultural heritage. Participating those kinds of activity is depended on emotional bonding as thoughts, feelings, beliefs to specific place and community. Thus, it has usefulness to be clarified that effect of resident's participatory intention by resident's emotional bonding to be regional inheritance in policy science aspects. In this sense, it must be consider emotional bondings (Sense of Place[8]) in a time of disaster as same as QOL.

3 RESEARCH DESIGN

3.1 Case Study in L'Aquila Italy

L'Aquila, Italy is one of the municipality, provincial capital and prefecture capital located in center of Italy with a population of 67,000. It was occurred big earthquake(M 6.3) in 4th April, 2009. It is easier to generate earthquake because of collision among Eurasia Plate and African Plate. It is damaged not only 309 deaths, but also many historical buildings such as church of Anime Sante, provincial buildings and so on were collapse. As case of Italy in historical area, it has "Authenticity" to restore historical areas. Thus, it takes long time to restore whole of the historical city. It means that victims must evacuate other place for more long time than usual city. In actual condition, nowadays more than 10,000 people live in temporary houses (L'Aquila Municipality)(Name: C.A.S.E and M.A.P.), but it has been 10 years since L'Aquila Earthquake happed. In case of L'Aquila Earthquake, all of things after disaster is coped by public sector (DCP: Department of Civil Protection).

3.2 Recovery process after an earthquake in L'Aquila Italy

This section describes the process of recovering after a disaster in L'Aquila Italy. Vivacqua et al.,(2012) mentioned Risk Management process after a disaster were divided into "Mitigation", "Preparedness", "Response", "recovery". But recovery process is longer than other disaster phase in historic city because it takes long time to reconstruct their buildings that it has long history and it is difficult to repair them in sight of authenticity. Thus in this study, it is divided Response and Recovery into temporary evacuation, evacuation to shelter and move to temporary shelter (Fig 2).

In L'Aquila, it established more than 100 laws such as "the PS" and "the PdR" that is one of most influential. It has started to build in C.A.S.E and M.A.P as temporary housing in 19 areas, L'Aquila. (Fig 3). After reconstructing victim's houses, they came back home. But it remains more than 10,000 people stay in these temporary houses.

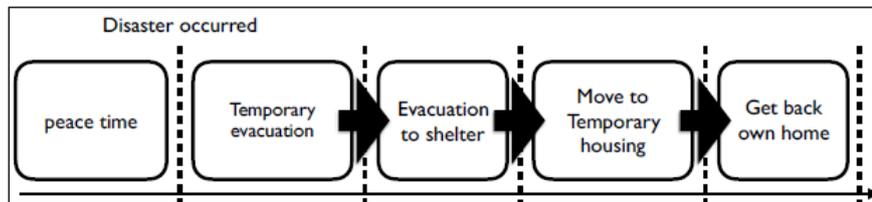

Fig 2. Process of Disaster Phase

Fig 3. Temporary housing in L'Aquila(Left: C.A.S.E, Right: M.A.P.)

3.3 Abstract for questionnaire survey

This section describes the abstract for questionnaire survey in L'Aquila for constructing gaming simulation model with DIM scenario. Table 1 is displaying the questionnaire contents distributed to victims living in L'Aquila had experienced L'Aquila earthquake in 2009.

Table 1. Questionnaire Survey

Questionnaire survey 1	
Date	From 2 nd to 26 th February
Scope of the survey	Victims living in L'Aquila(including students)
Number	27 samples
Contents	<ul style="list-style-type: none"> ● Actual DIM happened in L'Aquila Earthquake in 2009 ● Sense of Place factors ● Intention of moving other place without L'Aquila after the earthquake in 2009.

4 CONSTRUCTING DIM SCENARIO BASED ON QUESTIONNAIRE SURVEY

In this section, it describes constructing DIM scenario based on conclusion of questionnaire survey. First of all, phenomena of DIM are happened in various time after big earthquake. So it divided disaster 4 phases[9]: from happened earthquake to move temporary evacuation phase, living in temporary shelter phase, living in temporary houses phase, restore phase. Restore phase is that victims can live in house without temporary houses. Second of all, it is describes making scenario. In scenarios, it is set in situation that big earthquake is happened as same as L'Aquila Earthquake in 28th February 2018, it is very cold day. In case of L'Aquila Earthquake, all of things after disaster is coped by public sector (DCP: Department of Civil Protection). So it is estimated that DIM is happened by communication of DCP members and victims Moreover, in this study, it is measured resident's QOL by occurring DIM, so each scenario has not occurring DIM case and occurring DIM case in 4 disaster phase to show to test subject.

4.1 Scenario in earthquake happened to moving evacuation space

In this section, it is considered that is constructed DIM scenario in a time of earthquake happened to moving evacuation space. As a result of questionnaire survey, most often answer is "I don't know where is the evacuation place, and which root is safety" in from happened earthquake to move temporary evacuation phase. Thus, DIM of from happened earthquake to move temporary evacuation phase is that case of not understanding temporary evacuation place and safety root, and case of understanding.

4.2 Scenario in arriving and staying in Temporary Shelter

From this section, it is made DIM scenarios in a time of arriving and staying in Temporary Shelter. In the result of questionnaire survey, two most often disaster information needs are "Confirmation of family's safety" and "actual condition of their house and entry to City Center". But DPC member didn't share such a kind of information. In this case, it is made two scenarios. One of case, when big earthquake happened, victims must take care of their family's safety. So one of the DIM situation of temporary shelter phase is that victims want to know family's safety, and person ask DCP member to know family's safety, but they don't know how to do. Other scenario is about actual condition of their house and date of entry city center. Before L'Aquila Earthquake, almost people live in around "City Center". They have a life in City Center from a birth. But there are so many historical buildings in City Center. In L'Aquila Earthquake, everyone cannot enter to City Center because almost building was collapsed and it was so dangerous. So, victims wanted to know actual condition of damage of house and when it is possible to enter to City Center. In second DIM case, it is set scenario that victims want to know actual situation of house and when it is possible to enter to City Center, so person ask DCP staff about it, but they answer is "we don't know in detail".

4.3 Scenario in moving temporary Shelter

Last scenario is that application of living temporary shelter in the time of moving from temporary shelter. Italy constructed temporary houses after L’Aquila Earthquake (Name: Progetto C.A.S.E and M.A.P). Many victims moved to temporary houses. But respondents of this questionnaire survey worried about how to apply to live in temporary house. So last DIM scenario is that victims want to know how to apply to live in temporary house, person ask them about it, but their answer is “we are not sure now”

5 GAMING SIMULATION MODEL WITH DIM SCENARIO AND ITS EVALUATING METHOD

In this section, it describes constructed gaming simulation model with DIM scenario and its evaluating method. Before its explanation, it is explained the validity of using gaming simulation model in this study. In this study, it will be clarified effects of victim’s QOL and emotional bondings to place by DIM. However, it is impossible to reproduce actual situation in the time of disaster in a virtual space. One of capable methods is gaming simulation. In a gaming simulation model, it includes 4 parts: “Briefing”, “Making a Role”, “GAME”, and “Debriefing” sections. From now on, it will be describing each part in bellow.

5.1 Briefing

In this section, it presents “briefing” in this gaming simulation model. In Briefing section, facilitator will explain rule of the game, introduction of L’Aquila, Italy (In case which there are some person have never been to L’Aquila.), and introduction of L’Aquila Earthquake. Moreover, facilitator also will take test subject who never been to L’Aquila to City Center (Mostly Main Street), L’Aquila to see real situation of under reconstructing in virtual space using Google Street Map (Fig 4). In this sense, test subject can have image and feeling in L’Aquila.

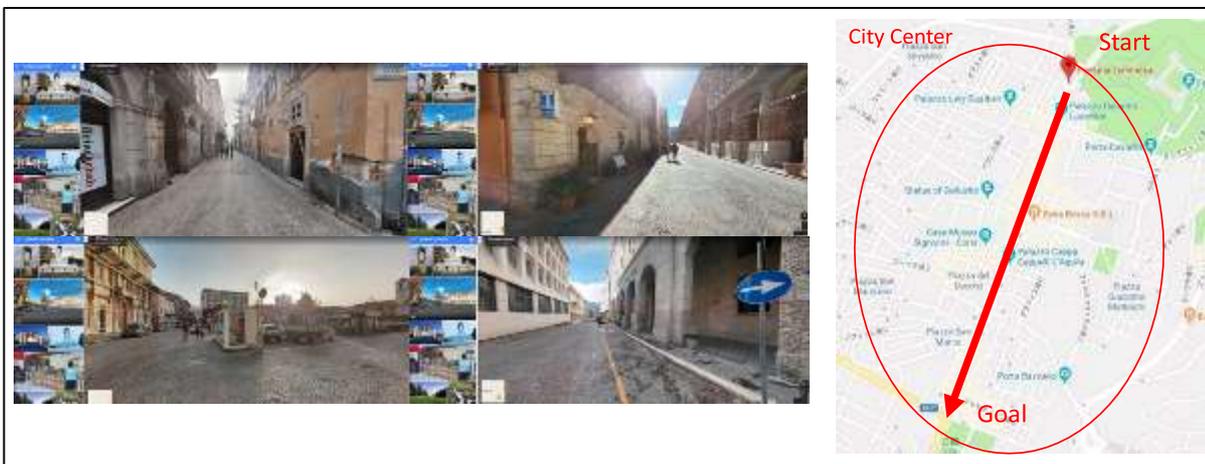

Fig 4. Google Street Map(Left) and the way of waking in virtual space(Right)

5.2 Making a Role

In next this section, it presents “making a role” in this gaming simulation model. In this gaming model, earthquake will happen in L’Aquila, so test subject has a role as L’Aquila’s resident. In this gaming model, it will be set role in bellow (Fig 5). The reason(Fig 6) why role in this game “have strong attachment to L’Aquila is more than 74% respondents answered “strong agree” and “ Agree a little” to question: I feel relaxed when I’m at my Place(L’Aquila) before the L’Aquila Earthquake.

[Role in this gaming]

- You are resident living in L’Aquila for almost 25 years. When you are child, you often go out City Center with your friends after school.
- You have a strong attachment to L’Aquila and you can feel relax in being in L’Aquila.

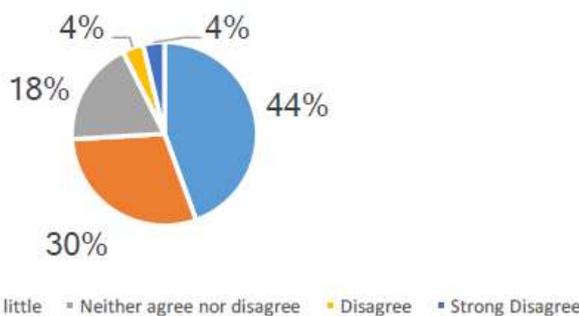

Fig 6. Result of questionnaire survey about place attachment factor

5.3 GAME with DIM scenarios

From this section, it describes GAME with DIM scenarios. As it is constructed DIM scenarios based on result of questionnaire survey divided by 3 disaster phases, it shows both of DIM and No DIM scenarios to test subjects in order of disaster phases. For instance, in the time of “from happened earthquake to move to evacuation space”, as shown in Fig 7, facilitator shows one of the scenarios (DIM or No DIM) randomly, after showing scenario, test subject answers some questions. Next, facilitator shows other scenarios (if he shows DIM scenario in the time of “from happened earthquake to move to evacuation space”, after that, he shows No DIM scenario in the time of “from happened earthquake to move to evacuation space”), after showing scenario, test subjects answer some questions once again. Then, it will be moved to next disaster phase. So, test subjects can experience one term of disaster in virtual space. After showing all of scenario, it will be finished this gaming.

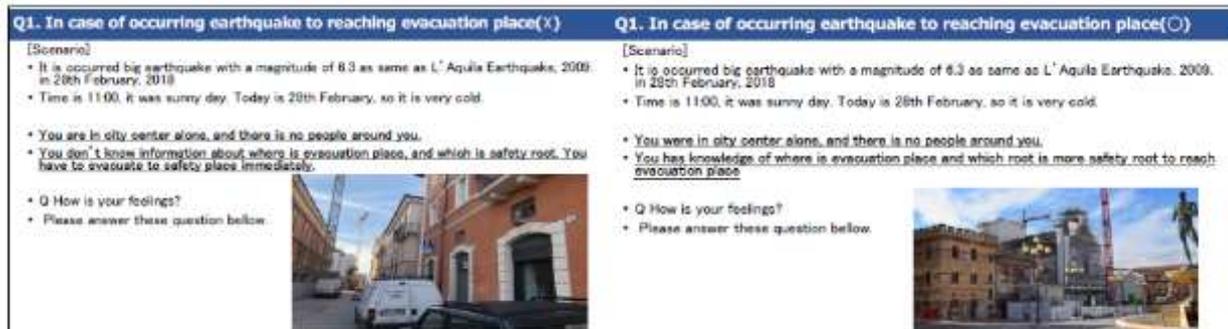

Fig 7. Example of DIM scenario (left: happened DIM, right: No DIM)

5.4 Debriefing

In this section, it describes “Debriefing” in this gaming. First of all, the word of debriefing means the process of most important point after gaming simulation. It means that the experience of gaming simulation is not just experienced, it is most important process of debriefing for players to attach more deep understandings, insights, and willingness to learn [10]. Thus, in debriefing in this gaming, facilitator explains why these scenarios was made by, what based was these scenarios made by, and so on. By doing so, player of this gaming can understand actual situation of time of disaster and DIM happened.

5.5 Evaluating victim’s QOL with Sense of Place factors

As shown Table.2, it is abstract of survey. In questionnaire survey, it is compose by feelings of satisfaction(Q1) and uneasy(Q5), Sense of Place[8](Q3,4,5) factors and intention of moving to other place without L’Aquila(Q6) based on related works. In feelings of satisfaction and uneasy section, responses were scored on seven-point scale from 1” satisfied” to 7” unsatisfied. At first, respondents feeling is 4” Now your feelings” If respondents don’t change their mind by showing scenario, respondents have to check 4” Now your feelings” In Sense of Place factors section, Sense of Place is comprehensive components: composed by Place Attachment, Place Identity, Place Dependence. In analysis, response were scored on seven-point scale from 1” Most agree” to 7” Most disagree. But now, it didn’t do gaming simulation, and cannot verified its validity.

Table 2. Questionnaire Survey

Questionnaire survey	
Contents	Feeling of satisfaction(Q1), Feeling of uneasy(Q5), intention of moving other place without L’Aquila(Q6), Place Identity(Q2), Place Attachment(Q3), Place Independence(Q4)[8]

6 CONCLUSION AND FUTURE DESIGN

In this study, it is constructed gaming simulation model with DIM scenarios can measure not only victim’s QOL but also victim’s emotional bondings to place using by Sense of Place factors. This gaming simulation model is expected that it can be reproduced real situation and real DIM in the time of disaster in L’Aquila, Italy. However, it couldn’t do gaming simulation to test subjects, the result of gaming simulation will be provided not only players can understand actual situation of disaster time, but also it can be measured what kind of DIM mostly reduced, what kind of DIM is affected victim’s QOL and Sense of Place factors.

ACKNOWLEDGEMENTS

We are grateful to their all cooperation, especially, special thanks for Dr. Federico D’Ascanio (Post- Doctoral fellowship, DICEAA, University of L’Aquila), Ms. Machiko NAGASAWA, and Mr. Paolo Busilacchi to coordinate our questionnaire survey. This work was supported by Graduate School in Ritusmeikan University “International Joint Research Scholarship”.

1367 ROLE OF LOCAL SELF- GOVERNMENT IN WATER RESOURCE MANAGEMENT OF RURAL WEST BENGAL- A CASE STUDY FROM SUNDARBANS

ABSTRACT

Following the 11th schedule of Indian Constitution (article 243G (b) Local Self Government is conferred with the “Power, Authority and Responsibilities to prepare plan and implementation of schemes for economic development – such as Minor Irrigation, Water Management”. Prevailing Mahatma Gandhi National Rural Employment Guarantee schemes (MGNREGS) in India enable the rural lsg to carry out the schemes on Manag like-1) Water harvesting – works like ponds, tanks, small dam, stop dam, etc. (section 4.(i).2) – working manual of MGNREGA), 2) irrigation canal including micro and minor irrigation works – construction, de-silting, lining, renovation and correction (section 4. iii). This paper aims to analyse the role of rural Local- Self- Government (Gram Panchayat) in harvesting of rainwater through MGNREGA programme in Sundarbans area of West Bengal. Sundarbans is mostly saline affected mono cropped area but there is enough monsoon rainfall that could be conserved there. There is an urgent need to de-silting, re-excavate of existing minor canals and excavation of ponds, tanks for harvesting of excess monsoonal rain water. The methods of the study consists of i) measurement of depth and volume of existing canals as well abundant river cut-off (100%), ponds (60%), ii) Preparation of the Rainfall Budget, iii) watershed delineation and determination of outlet point with the help of Arc GIS, IV) Determination of potential irrigation water with the help of IRC:SP:13-2004, v) volume of irrigation water created by the Local Self Government through MGNREGS and determination of wasted monsoonal rainfall. It is observed from the survey that only two canals are re-excavated out of 12 natural canals and 576 ponds are excavated through this programme in last 10 years. The total volume of all water bodies is 5.1 million cubic meters which have capacity to preserve 32% of excess rainfall. That could cover 2.09 sq km (13.79%) of the canal catchment area. The volume of excess rainfall is 15 million cubic meter of it, at least 55% rainfall could be conserved even after loss of rainwater through Infiltration, Base Flow, and Potential Evapotranspiration. But in reality only 32% of excess rainfall is reserved in the existing irrigation structures. The total volume that is created by the Gram Panchayat (G.P) through the MGNREGS is 1 million cubic meter in 2007- 2017. It is observed that maximum emphasize is given for the excavation of Non- farm pond (80%) than canal excavation work. Hence the initiative that has been taken by the G.P for irrigation development through MGNREGS programme is not properly implemented. Again negligence of irrigation causes peoples’ dissatisfaction with agricultural income. It again acts as push factor for out migration of agricultural labour. To break this vicious cycle, emphasize should be given on the re- excavation of canal and abundant river cut-off. It calls for preparation of the regional plan in holistic way. : LSG, MGNREGA, Rain Water Harvesting, Sundarbans

1424 ASSESSING THE ROLE OF BRICK INDUSTRY ON CHANGING RIVER MORPHOLOGY IN THE LOWER GANGA DELTA AREA OF WEST BENGAL, INDIA AND ITS REGIONAL IMPACT

ABSTRACT

Brick is an essential material for urban development. The main raw materials for the industry are soil and coal. In Ganga Delta area of West Bengal, there are 772 brick fields along the river Ganga, Nowi, Sunti, Nonagong, Haroagong-Kultigong, Ichhamati which produce 25.5 million bricks per brick field per year on in an average. It needs 2484.9 m³ of soil which is mostly extracted from the said rivers. This study focuses on how the river morphology is affected by the brick fields in lower Ganga Delta in West Bengal. For that, cross profile, volume of cross sectional area, tide monitoring, quantity of suspended sediment at different position on the sampled rivers are determined. As well as 60 brick fields have been surveyed to collect information on demand of raw materials as well delivery of bricks by quantity and location, and These rivers have a self-destructive nature of tide. The observed duration of tide inflow is about 5 hours and outflow duration is 7 hours approx. So, silt is deposited in a rate of 0.48 gram/liter. If it is collected by the brick industry scientifically, it can help the rivers to maintain their flow. But the river silt usually extracted without any consideration of silt accretion points. Even the river bank(levee) is often scabbled. This is to minimise the transport cost. Besides construction of spur of broken bricks and, silt pond on the river accelerate the silt deposition. The immediate effect of these changes are river bank erosion and intrusion of brackish water into the agricultural field, it again reduces the soil fertility. The profile of the river becomes asymmetric near the brick fields. Till 2016, 90% of the brick fields had no certificate of pollution control,Besides violating the State Land Reforms Act 1955 (sec-4), brick companies convert agricultural land into brick field and big ponds for collection of loamy soil, needed to produce high quality bricks. The newly emerging urban nodes like Kolkata New Town, Barasat, Sonarpur, Baruipur are the recipient centres of the produced bricks. Rapid urbanization around the metropolis in absence of long term comprehensive planning is not only creating the drainage problems but also is hampering the regional system. : brick field, cross profile, silt pond, sinuosity, suspended sediment, , tide monitoring, metropolis, regional system,

1505 SURVEY FOR CONSCIOUSNESS ABOUT CAREER CHOICE OF LOCAL RESIDENTS - CASE STUDY IN BALI, INDONESIA

ABSTRACT

Recent years, there is a subject about economic development for tourism industry and concentration of labor populations in international tourism destination in developing country. For this subject, in this study, we intend to survey the current situation of the choice of local people's occupation, and we conducted a consciousness survey to know 'the idea of work values for future career choice' in local residents. This research contains two studies background. The first point is the viewpoint of student's consciousness of career choice and the second point is the viewpoint of labor in resort areas in developing countries. The former is based on previous research on occupation selection. The latter is based on the status of employment at Bali island in Indonesia. We will show this study with these two viewpoints as the main theme. In this study, a questionnaire survey was conducted. This questionnaire is classified in 5 contents (1. Face Sheet, 2. the idea of work values, 3. about working in the tourism industry, 4. about working in agriculture, 5. about the tourism industry mixing the agriculture) and has 59 questions in total. The style of all questions except for the question of Face Sheet is answered by likert scale of eight levels. This survey is targeted at University Students and high school students.

1664 REGIONAL PATTERN OF RELIGIOUS COMMUNITY-WISE CHILD NUTRITION: A CASE STUDY OF NORTH 24 PARGANAS, WEST BENGAL

ABSTRACT

Background: Child nutrition is a major national health issue worldwide because it’s mostly represent national as well as community-wise state of health and economic development. Traditionally, a person’s nutrition level has been defined at a personal level as well as at a societal level and should integrate other factors into a health assessment, including evaluations of diet, physical activity, family history, and other appropriate health screenings. The present study is designed to determine and analyse the regional pattern and socio-economic factors associated with nutritional status of children in different communities. This study is aimed to compare age and gender-specific height, weight and Body Mass Index (BMI) percentiles and nutritional status among primary school-aged children using different anthropometric measurement. Objectives: To investigate the nutrition status using anthropometric measures among the primary school children in rural areas and to find out different socio- cultural and economic factors that influence the nutritional status of this population. Methods: A cross-sectional study is performed among school going children in nine rural blocks out of total 22 blocks of North 24 parganas. Socio-economic and demographic characteristics are documented and anthropometric measurements are performed to calculate Nutritional Status. Major calculated indices are BMI-for-age, weight and height-for-age. The data is entered and analysed using SPSS (IBM SPSS Statistics 23). Results: An intensive health and nutrition study is conducted on 200 children (aged 1–12 years) in nine blocks of north 24 parganas in West Bengal and nutritional status calculated in three forms such as underweight, stunting and wasting. Under nutrition is found to be more common in primary school children in minority communities. Basically, female children are significantly more prone to under nutrition. Though low monthly family income, large family size, Food habit and access to better sanitation are found to have influence on nutritional status yet maternal education and employment ratio are more significantly associated with under nutrition among school children. Conclusions: Child malnutrition is a major national health issue in different Regional-communal sectors of west Bengal. This study not only related to untoward health issues but to social issues as well. Health education programmes among the population studied could be effective for solving the problem.

1543 SOCIO-POLITICAL INDENTITY CONSTRUCTION OF INDEGENOUS COMMUNITY IN BANGLADESH

ABSTRACT

Identity is a subset category in which membership is determined by attributes associated with descent, language, religion, culture, history, ethnicity, citizenship. There has been an increasing convergence and divergence on the categorization of indigenous identities in Bangladesh. This paper examines how various brands of identity politics have served to create the basis of social exclusion, resulting in different forms of identities i.e. indigenous, tribes, races, ethnic sects, minority, aboriginal, upajati, jhumiya, pahari, adibashi etc. This paper has been prepared based on the secondary data, which has been collected from reviews of books and articles, development reports, government documents and electronic resources. Indigenous people have been at the fore-front of various struggles against feudal and colonial forms of oppression and exploitation. The British reign extracted their regional wealth and segregated them from the rest of Bengal, followed by the Pakistan government behaved in the same manner. By denying the existence of ethnic, the state of Bangladesh declared the people of Bangladesh are to be known as Bangali/Bangladeshi, while they prefer the term indigenous or Adibashi. This identity dilemma is a threat for this community and has resulted in perceptions of marginalization and social exclusion. In many respects, the security and integrity of all indigenous is seem to be threatened, and they are targeted not only of land-grabbing, but also of human rights violations including arbitrary arrest, rape, killing and religious persecution. They are also marginalized and deprived of economic benefits, social power and privileges. Following the marginalization, this community has been experiencing tremendous pressure to sacrifice their traditions, languages, and cultures, which in turn gives rise to anxieties and irritation. Now it is the time of affirmative action and implementing international norms, constitutional recognition as indigenous people is a must to end the discrimination and repression against them.

1587 THE ROLE OF COMPLEMENTARY CURRENCIES IN TERRITORIAL DEVELOPMENT

Eszter Szemerédi

PhD student, Széchenyi István University, Doctoral School of Regional Sciences and Business Administration, szemeredi.eszter@sze.hu

INTRODUCTION

As theme of the 12th RSAI World Congress is *Spatial Systems: Social Integration, Regional Development and Sustainability* in this paper I argue, that complementary currencies (CCs) are effective bottom-up tools that can play an important role in territorial development. Complementary currency is a popular research topic, but its literature is still scarce compared to research on territorial development.

The questions this paper deals with: (1) Can a development model, that - rejecting traditional methods of development researches - does not focus on assets, but rather on extending capabilities and on the ability of a local community have more significant economic and social consequences than the traditional models? (2) How can a local community implement such a monetary innovation and what are the impacts of such innovations? To answer these questions a systematic approach is necessary, thus the paper attempts to synthesize existing typologies, and build a new systematic classification.

For this the chosen framework approach is Amartya Sen's Capability Approach to local development. Based on this typological framework the paper attempts to build a practical model of implementing a complementary currency.

The first section discusses the terms and concepts related to complementary currencies, with special emphasis on the Capability Approach (CA) to local development. The second section determines the place of complementary currency in the theory of Capability Approach. The third section discusses previous attempts to classify CCs, the fourth proposes a typology. The last section presents the conclusion.

LOCAL DEVELOPMENT AND CAPABILITY APPROACH

The term local development is used in a variety of ways by practitioners, policy makers and academics depending on which social or economic phenomenon they focus on. Under development one understands interventions made to improve a situation. The scale of improvement when using the term local development includes "the territory with diversified land area, characterized by economic, social, cultural and political homogeneity and a common, broadly understood identity" (Sekula, 2002:59).

An important, though obvious, observation is that there are also different opinions regarding the objective of local development. Some researchers place the emphasis on economic development; others combine economic and non-economic factors (Wilson, 1995, cites Mezei, 2006). Bennett and Krebs (1991) or Faragó (1991) consider job creation as the primary goal of local development (Mezei, 2006). According to Puljiz (2004) the main objective of local economic development is enterprise development, which then entails the growth of employment and the improvement of the quality of life (Mezei, 2006). According to Jouen (2011) "local development means territorial, integrated strategies which mobilize many local actors in the form of a partnership. Its short-term aim is to improve the local living and working conditions, and its long-term ambition is structural change" (Jouen, 2011:2).

Definitions focus on well-being and quality of life, but it is not clear what is understood under well-being. Most of the terms focus on instruments, means of welfare eg. improving competitiveness and innovativeness, and based on the dominant traditions of welfare economics automatically assume a link between these and quality of life (Gébert, Bajmóczy, 2014).

At the core of capability approach is the expansion of freedoms. Well-being is evaluated through the notions of functioning and capabilities. Functioning means a set of activities/role/characters that can be practiced/done/played by or are attributed to a person. Capability means the level of freedom a person has to choose from the available functionings. It means all available alternative ways of life that a person can pursue; that is, the ability of a person to show what he can or could do (Gébert et al., 2016:26). The notion of deprivation is closely linked to this, as it means that a person does not possess enough resources and conversion factors to enhance his freedoms.

The standard version of Amartya Sen's approach focuses on individuals (Rauschmayer et al., 2017), but through the implementation of a complementary currency not just individual freedoms but the collective capability set of participants changes too. Much of the interest in CA literature lies on how social interaction is relevant to a person's capability development. Sen and Evans agree that collective capabilities derive from social interaction. The term „socially dependent individual capabilities" used by Sen expresses that social structures, such as a community currency group influence individuals. Evans states that "individual capabilities depend on collective capabilities" (Evans, 2002:56). Sen also sees people's commitment to the group as important and necessary for its existence, and uses the term „individually dependent collective capabilities" (Davis, 2015:9).

Davis (2015) applies Granovetter's (1985) social embeddedness framework to individual and collective capabilities, and distinguishes three different kinds of social groups. These are market activity, public deliberation, and community participation. Davis (2015) states that in the case of community participation social groups depend almost entirely on individuals' commitment to them and on strong identification with their overall goals and the role opportunities they create for members. That is, their collective capabilities are highly individually dependent. At the same time, individuals

and their individual capabilities are particularly “socially dependent” in being especially tied to their roles and relationships in such groups.

The purpose of local development is to “extend the capabilities, that is, to provide as many valuable opportunities as possible for the members of a local community” (Gébert et al., 2016:26). According to Faragó (1994) “internal structural changes are occurring, the corollary of which is the increase in opportunities for local individuals and the local society, there are more options to choose from and the same possibility becomes available for more sections of society” (cited by Farkas, 2002: 45).

“The capability approach views human beings as active agents, directing their own lives” (Alkire, 2008:7). “They can’t be regarded as passive recipients of development” (Gébert et al., 2016: 26). The main aim of the development process is to expand “the range of valuable states/activities that the members of a local community can actually do or achieve” (Gébert et al., 2016: 30). Capability approach states, that “having the resources and means alone does not ensure that people achieve the desired state of being” (Gébert et al., 2016: 33). G. Fekete (2005) stresses the need to “motivate and prepare actors for how to use these tools and how they can responsibly take part in a process leading to improvement” (G. Fekete, 2005: 46). Gébert et al. (2016) emphasize the combined use of expertise and local knowledge in development.

As the Capability Approach regards people as active actors, this framework is in harmony with the endogenous model of local development, which presumes that the key to a territory’s sustainable development lies in its own resources, that the force of development is the local community.

Lowe (2000) identified the sources, which were used as theoretical base for the concept of endogenous local development. The main driving force was the notion of self-reliant localities that could control their own development. In response to the intensifying processes of globalization many communities started to look for alternative, local solutions and implementing alternative currency systems is one of them.

COMPLEMENTARY CURRENCY IN THE CAPABILITY APPROACH

When describing currency systems, which operate alongside the national currency the terms complementary currency or community currency are the most widely used. Existing literature offers a variety of different interpretations of what distinguishes complementary currencies from national currency (Schroeder et. al, 2011). “According to Kichiji and Nishibe (2008) the four characteristics of complementary currencies are: (1) they circulate in relatively small geographical areas, (2) they are non-governmentally issued, (3) they are non-convertible, or have restricted convertibility, (4) they have zero or negative interest-bearing” (Schroeder et al., 2011:33).

They exist in many forms depending on their function and geographic delimitations (Preissing, 2009). Whilst local currencies serve a specific area e.g. a town, a city or a neighborhood, regional currencies are used in a wider geographical area. This paper does not examine the so called technical cash equivalents.

Complementary currencies are used around the world, attempting to provide answers to central questions of territorial development. The aims of CCs “include the creation or strengthening of a locally rooted resilient economy, giving value to skills and things not valued by the standard market, and creating social ties in neighborhoods” (Rauschmayer et. al, 2017). The following 1. Table shows its benefits and the capabilities a CC could expand.

60Table 1: Benefits of CCs and the related capabilities

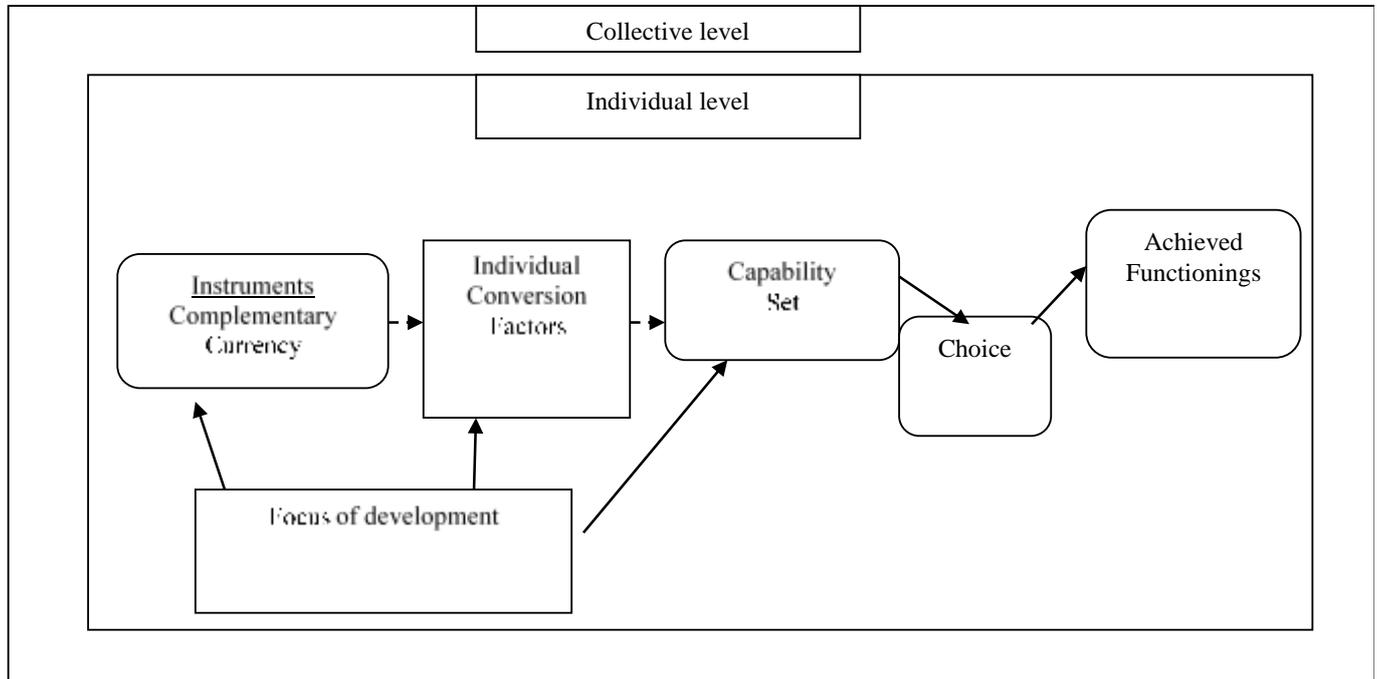

Area	Benefit	Capabilities/Functionings
Economic	Increased importance of undervalued activities	Self-sustainment, income generation, autonomy, learning new skills
	Increased alternative opportunities to fulfill basic or higher needs	Self-sustainment, obtain needed services or products
	Increased purchasing power	Access to more, higher level services, self-sustainment
	Increased access to the local market	Access to a more varied diet, self-sustainment
	Increased employment opportunities	Income generation
	Fostering self-reliance and individual self-esteem	Self-confidence, feeling useful
	Increased volume of currency in the local area	Autonomy, independence from government, large corporations
	Increased support for small enterprises	Autonomy, self-sustainment
Social-Political	Increased strengthening of social relationships	Social interaction, opportunity to participate, learning new skills
	Increased activity of local citizens	Express and act on personal values, experience new activities
	Disencouragement of the exclusion of disadvantaged people	Opportunity to participate, integration of disadvantaged people
	Increased awareness of alternative ecological values	Opportunity to learn, to participate
	Increased altruistic behavior of citizens	Feeling useful, contribute to the quality of life in the region

Source: own construction, based on Complementary Currency Resource Center, Retrieved April 27, 2018 from <http://complementarycurrency.org/helpdesk/benefits.html>

The traditional development approach considers the complementary currency as the main output of the process. The implementation of a complementary currency is the development program itself and is detached from the input-output interface of the Capability Approach. While in the Capability Approach the monetary innovation is a component of the development process. It is one of the ingredients or inputs for achieving the goal of development: a wider set of capabilities. In Capability Approach the development process does not end with the implementation of a complementary currency.

Since Capability Approach considers income as a capability, as a means of achieving the desired state of being, the end result of a development process is the achieved functioning. The following 1. graph shows complementary currency embedded into the model of Capability Approach.

Graph 1: The place of complementary currency in the Capability Approach

Zagata (2004) states, that “the establishment of complementary currency in a locality is per se unique”. The result depends on factors such as the needs of the community, on the ways of carrying out transactions, on the forms of exchange etc. In consequences of the diversity of complementary currencies and the wide range of designs and goals there have been many approaches, frameworks and models attempting to classify CCs, but there is no commonly accepted typology.

The major problem that arises is that CC schemes due to their diversity and dynamics escape from any rigid classification. In addition different objectives may lead to different categorizations (Blanc, 2011). The next section provides an overview of the existing typologies using Capability Approach attempts to classify CCs, through placing the focus on the involvement of a local community, the commitment of its participants and the set of capabilities they aim to widen.

EXISTING TYPOLOGIES

In English literature there are only a few classification systems on the subject and these are mostly proceeding from the traditional understanding of money, which is unable to capture the special features of complementary currency initiatives (Martignoni, 2012). To build a relevant system one must first review the theoretical and methodological contributions to the topic. According to Blanc (2011) the difficulty lies in creating a system that is flexible enough to let space for innovation. Building a new one should not have the aim of replacing existing typologies.

Kennedy and Lietaer (2004) tried to create a typology of CCs according to their purposes, but eventually discussed the way they are issued, their function and the way their costs are covered.

Blanc (2002) mentioned four rationales for monetary localism which frequently combine each other. The first is related to income collection mostly through seigniorage. The second is a change in the nature or conception of exchange and its context. A third is, to protect the local economic space against external monetary disruptions like a recession and/or inflation and finally, to increase local economic development (Blanc, 2006).

Blanc (2011) also proposed that one should not focus on items but rather on projects. In his article he introduces a distinction between three sorts of projects. There are territorial projects centered on a geopolitical space, community projects and economic projects centred on production and market exchange activities. He also emphasizes the importance of the project’s background. Implementers could be non-profit organizations, informal groupings, governments or firms. Schemes implemented by firms and national currencies are removed from his analysis. He sets ideal-types of currency schemes based on the space considered, on the purpose and guiding principle. He also proposes a second level of classification, distinguishing four generations that overlap and are progressively transformed.

Jerome Blanc and Marie Fare (2013) also presented a paper that concentrates on the role played by local governments and administrations in the development and differentiation of CCs. They explain the role of governments in the emergence of four generations. They also discuss the problems local governments have to overcome, and traps to avoid if they commit themselves to implement such schemes. The presented generations help to understand the relationship between complementary currencies and local governments. In the first generation of CCs e.g. LETS model the local administration does not play a role, they are not part of implementation process. Second generation schemes e.g. time banks have been used as tools to strengthen social ties at the community level. The third generation CCs e.g. Ithaca Hour seek advanced partnerships with local governments and authorities, also with local banking institutions. The fourth generation has a central role for local governments.

Marie Fare et al. (2015) also examined the impacts of complementary currencies in terms of sustainable territorial development. They identify three potentials in relation to sustainable development: the territorialization of economic, social and political activities, the revitalization and stimulation of exchanges and modifying practices, values and social representations.

The Talent Switzerland association classifies currencies by purpose and by sector (Dold, 2010). A spectrum between market/competition and relationships, gift economy is presented. Sectoral money that can be used for limited economic activities is also distinguished e.g. Fureai-Kippu for care in old age, or educational vouchers in Brazil.

As a conclusion they can either be very similar in their nature or very different, it depends on the circumstances in which they are implemented. A typology should not be built in order to classify the researcher's observations, and initiatives should not be forced into an existing framework.

BUILDING A TYPOLOGY

Blanc (2011) argues that the right way of building a typology is making first its purpose clear. This paper concentrates on how community and complementary currency schemes can support territorial development. In order to build a typology the paper focuses on projects and not on items e.g. the different bases for currency. The general philosophy, the guiding values serve as a major orientation point for the system. This section first reviews the objectives of CCs, from which a classification matrix is derived.

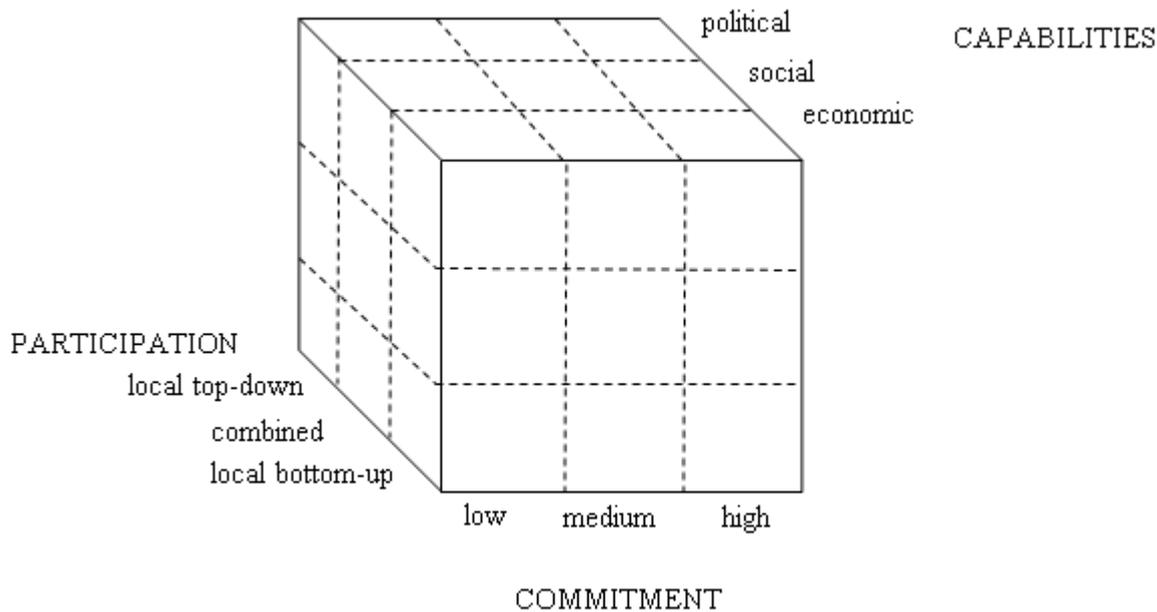

Most complementary currency systems seek to boost local economies and promote social integration by exchanging local services and production (Fare, Ahmed, 2017). Their aim is to redesign local social, economical and environmental relations. Studies analyzed and questioned their ability to achieve this. Leyshon et al. (2003) and North (1998) proposed an evaluation of their potential in terms of local economic development (job creation, self-employment, access to free credit) and social well-being or social inclusion (promotion of social bonds, social and human capital held by persons in a situation of exclusion, fairness, self-confidence, quality of life).

Recent reflections about intentional objectives name CCs as tools for "scale changes in sustainable local development through a collaborative and cooperative vector, innovative wealth valuation and the preservation of social protective systems" (Place, Bindewald, 2015:155). Dittmer divides CCs by their meso and macro objectives such as community-building, incentivizing eco-localization (Dittmer, 2013). Place and Bindewald also mention the typology made by Monnaie en Débat in 2011, which similarly focuses on meso and macro level objectives.

These authors - and others who followed - relied on different methodologies in assessing the impact of CCS, most of them differentiating between social, economical and environmental and political goals.

Under this respect this section proposes a typology, which would help to understand the interrelationships between goals, participation, commitment and freedoms. These separate but interrelated dimensions, each of which has at least three components can be visually linked together into a cube. This framework can be used to analyze the ways in which they contribute to local development according to the Capability Approach. The presented framework, the CC cube is shown on the 2. Graph below.

Graph 2 : The dimensions of the Complementary Currency Cube

Source: own construction

Each side of the cube is a dimension, but the blocks within the cube can be rotated and any side of the cube can be used as a starting point of the analysis. In this section we first begin with the dimension participation. It is seen as the opportunity for participation in the development and implementation process. The dynamic one must explore is how the complementary currency is created, what terms.

As any local development process, the development of a complementary currency can be a bottom-up/grassroots initiative or a local top-down initiative. Local top-down means that the starting point is the decision made by the local government. Supporters of this method state that any other way the local community would not be exposed to a monetary innovation like the complementary currency. The mixed method means that experts design the complementary currency, but integrate the local community in the process through knowledge-sharing. This way the complementary currency, its form will be designed according to the functioning the local people want to achieve.

The level of commitment is strongly related to how, and what terms is the currency created and to the freedoms the participants want to achieve. Depending on the formality or informality of the complementary currency individuals' commitment ranges across the full spectrum of commitment from very high to very low levels. Grassroots initiatives' existence depends almost entirely on the commitment of participants and their identification of its goals. The groups' collective capabilities, their opportunity to achieve the desired state of being are highly individually dependent. At the same time participants' individual capabilities are highly socially dependent in the way that the achievement of economic, social or political freedoms is closely tied to their participation in the group, to their roles and relationships in the group. Complementary currencies that are implemented through a top-down development process may not need such a high level of commitment. Because of the formal framework the organizations' collective capabilities are not as individually dependent. The formal operational system may make the wider use of a complementary currency possible, but the participants' commitment depends on the value (under value here we understand the freedoms they can achieve) they derive from these possibilities.

The development of a complementary currency and the commitment of its participants also depends on the freedoms its participants want to achieve. The motivation to participate may differ based on the functioning they want to obtain. Klandermans argues that movement participants are motivated by three fundamental reasons: "people may want to change their circumstances, they may want to act as members of their group, or they may want to give meaning to their world and express their views" (Klandermans, 2004:361).

Those who want to expand their economic freedom, those who join because of economic self-interest may have a higher level of commitment, because the functioning related to basic needs such as being well-nourished can only be achieved through their role in the group. Those joining out of economic necessity are more reliant on the use of a complementary and do engage in more transactions.

Those who join out of social reasons, to fulfill higher needs, such as the state of being a useful member of the local community may be more willing to give time and money to the organization of a complementary currency. The research on participation in community currency systems carried out by Ed Collom (2011) has results that prove the congruence between the motivations and individuals' involvement in a complementary currency system. The research also proves the members of the analyzed time bank joined to act on their values and to better the society.

A complementary currency may provide an opportunity to expand their political freedoms. As it is an alternative movement participants may join it to create an alternative wealth valuation system, an alternative market opposed to

the traditional economy. The extent to which they can express their alternative views defines the level of commitment they show. The interrelations between the dimensions are shown on the 2. Table below.

Table 2: Interrelations between the dimension of the CC cube

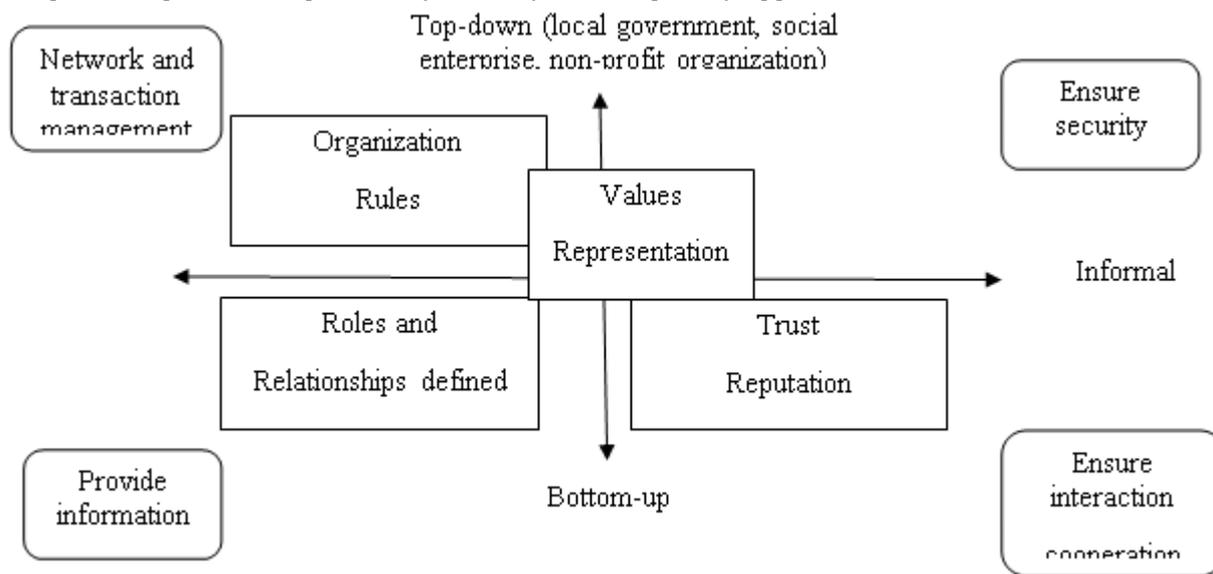

Commitment	low $\xrightarrow{\hspace{10em}}$ high	Capabilities
Participants capabilities	Socially dependent $\xrightarrow{\hspace{10em}}$	economic social political
Complementary currency scheme collective capabilities	Individually dependent $\xrightarrow{\hspace{10em}}$	
Participation	local top-down combined local bottom-up	

Source: own construction

This classification attempt appears to be flexible enough, and lets the possibility of combinations be analyzed. It could be a planning instrument, because implementers can plan its technical design, its circulation principle etc. according to the capabilities intended to be extended, to the participation and to the commitment needed. In order to develop and keep a CC operating in the long term implementers have to know if a CC has to be built around a democratic participation principle organized around non-profit organizations, if it needs a “technically demanding and expensive system” (Blanc-Fare, 2013: 70) or if it could work in a self-organizing way.

If its an informal, grass-root initiative the scheme’s collective capabilities are individually dependent. Participants need to build trust and reputation, the leaders of the scheme need to ensure the interaction and cooperation between the participants. If the scheme’s implementation is coordinated by experts, by the local government or by a non-profit organization with the involvement of the local community the implementers must ensure the representation of the citizen’s opinion. Participants only show commitment if it is provided and the value they derive from it is higher than their distrust against something new. If the norms are laid down, participants feel that their security is ensured. If it’s a bottom-up initiative formalized, the participants’ roles and relationships must be clearly defined; information must be provided about their roles and transactions, in short their network must have a formal framework. In top-down coordinated schemes great emphasis needs to be put on a sophisticated system of support, on network management to ensure the local community’s trust and commitment, to eliminate conversion factors that may appear. The 3. graph below illustrates the planning route they could take.

Graph 3: The place of complementary currency in the Capability Approach

Source: own construction

There are some limitations that have to be taken into account when using this framework. There is no single strategy or starting point, as CCs, their extent, their forms and overall their projects evolve rapidly, new combinations of existing schemes or basic items are spreading. One must understand the interrelations of the dimensions, how they are changing and has to build multiple strategies, based on the given starting point of analysis. One must keep in mind that it is not a checklist, it is an analytical framework which can be used to analyze how implementers of a complementary currency can support a change in the local community. It can be used by actors of change to reflect on how their work could contribute to local development, how they can change the individual and collective capabilities of local citizens.

CLASSIFICATION OF HUNGARIAN COMPLEMENTARY CURRENCIES BASED ON THE CC CUBE

In this section the paper attempts to classify Hungarian complementary currencies based on the above developed typology. From the operating complementary currency schemes I selected those with the most differences from each

other, to encompass the whole spectrum. To understand how CC schemes work in Hungary one must look at the first experiments in this area. "The confrontation of the theoretical presumptions and practical effects is quiet difficult under the conditions of the European post-communist countries" (Zagata, 2004: 482).

The traditional rural communities' element was the so called Kaláka, which is the form of mutual neighbor's help. The relative closeness of the communities and the lack of resources have given rise to this kind of circle of mutual help (Zagata, 2004). Also during wartime alternative currencies, emergency currencies were used to counter the negative effects that came from the lack of money.

The first still existing LETS scheme, the Talentum was established in Budapest in 1996. It was inspired by the LETS initiative in Austria. Talentum has around 150-200 members, who have meetings every second months. Most of the deals are made during these meetings or at club meetings. In the following years several similar initiatives have emerged, with mixed results e.g. the Zöld Forint Kör (Green Forint Circle) at Gödöllő, a city close to Budapest, as well as LETS in Szolnok, Miskolc (Óra Kör), Tiszaluc and Győr (North, 2004). It appeared that these schemes attracted mainly young people, but the older generation refused to join. Some believed that the complementary currency system tried to bring back the traditional elements of rural communities, which could not work "in the specific conditions of Hungary as a post-communist country" (Zagata, 2004: 483). Some of the early initiatives like Talentum are still operating, but most of them ceased to exist.

The second wave of CC schemes appeared with the Kékfrank in Sopron, in 2010. Shortly after the Balatoni Korona and Bocskai Korona were also introduced. Some other schemes discussed are the Alsómocsoládi Rigac, and the so called Kör initiatives (Jacsó, 2013). Following the discussion of these schemes I attempt to analyze them based on the presented framework.

SOPRONI KÉKFRANK

Kékfrank was created by a patriotic community, who wanted to reorganize the once organic social and economic relations. The inventor Tamás Perkovátz introduced some other vouchers in Sopron before creating the Kékfrank. The complementary currency was built on an existing community of patriots, who used Perkovátz's purchase vouchers (Perkovátz, 2010).

For the creation of Kékfrank a new European form of enterprise served as background. The European Cooperative Society is an entity that opens the door for cross-border cooperation. The "HA-MI Összefogunk/If-We Unite Limited Liability European Cooperative Society" was founded by 123 members, both entrepreneurs and individuals. Its strategic partners are the Rajka and Region Credit Union, Chamber of Commerce and Industry, Industry Corporation of Sopron and Its Environs, the CIG Pannónia Insurance Company and the University of the West Hungary Faculty of Economics (Szalay, 2011). Everyone can become a member through purchasing a minimum of 1 share. The complementary currency can be converted into the national currency.

Interesting fact that although the project fulfills multiplex goals, has the revitalizing of local economy as its purpose, the local government does not play any kind of role in its operation. Although the local government has a passive role, its attitude is not dismissive. It does not try to make decisions that are not favorable to them, but does not make any decisions to help them either. As it is a bottom-up initiative its existence depends on the use of the complementary currency, on the number of transactions carried out. Most of the members are local enterprises, whose dependence on the currency is not very high, as the income generated from it is only around 5% of their total income.

BALATONI KORONA

The complementary currency debuted in 2012, and is a result of a complex partnership between the local governments of Veszprém, Várpalota, Balatonfüred, Balatonalmádi, Litér, Nemesvámos and Tihany, the Kinizsi Bank and three other business partners.

In this case the local governments acted as initiators. They provided an appropriate legal framework, technical and financial support, and integrated it into specific public policies. The Balatoni Korona Ltd. founded by members of the partnership issued its currency in March of 2012.

Its main objective was to revitalize the economy of the region and to contribute to social cohesion through re-forming social ties (Sárdi et al., 2013). It meets various objectives and is used as a potential public policy tool by local governments. The "local governments are the largest issuers as they provide some other allowances, fees and premiums in Korona. The total amount of such payments is about 12-13 Million Forint, from which 9 Million is related to Nemesvámos, and Várpalota" (Sárdi et al., 2013:13).

General opinions about the system are positive, but the scheme is not without difficulties. The major problem lies in the permanent financial limitations, the erosion of social networks, and the lack of trust in each other. Generally members' commitment is quite low, and just in the case of Kékfrank their capabilities can not truly be expanded because of the currency's limitations.

BOCSKAI KORONA

The complementary currency was first introduced in 2012. Preparations began in the summer of 2011, when the local government of Hajdúnánás founded a holding company, the Hajdúnánási Holding Zrt. to ensure the scheme's financial

and institutional background. An interesting fact that at first it was intended to be used only locally, and just later on spread to the surrounding municipalities (Sárdi et al., 2013).

It is a project aiming to affect economic relations in a “geopolitically-defined space” (Blanc, 2011: 6). Local government uses it to achieve certain ends, namely the revitalization of local economic exchanges. The scheme focuses on the daily consumer behavior of local population, so its aim is to strengthen the relations between local businesses, and the local individuals. Its objective is to keep their purchasing power inside the municipality. “To keep it local means that first they even rejected the request to expand it to Debrecen” (Sárdi et al., 2013:14).

The acceptance of the Korona is very high. Participants’ capabilities are highly dependent on the use of the Korona. As it is a local top-down initiative the collective capabilities are not so highly individually dependent than in the case of Kékfrank.

ALSÓMOC SOLÁDI RIGAC

The Rigac is based on similar considerations as the Bocskai Korona. Its foremost purpose is to combat poverty and exclusion, to promote local consumption and to provide resources for the community. It is implemented only in Alsómocsolád; the local government is responsible for its issuance.

Among the discussed CC schemes it is the one most widely used as means of payment. Local governments provide allowances, fees and premiums in Rigac. Local government collects local taxes in the local currency, and companies tied to the local government also pay part of their employees’ salary in Rigac.

Inhabitants use around 90% of the local currency through the local governments system, because it also became possible to pay in Rigac for public services such as transport, home social care, culture etc (OFA Nonprofit Kft., 2015).

It is highly favored among local citizens, their commitment to the use of Rigac is very high, as their individual capabilities are highly socially dependent. The local community also took part in its planning and implementation.

TOKAJI DUKÁT

The latest in the line is the complementary currency of Tokaj wine region. It was born in March 2016 as a result of 27 municipalities’ partnership in the region. The idea of making a complementary currency to make the regions’ economy prosper again dates back to 2013. The local governments created the Dukát based on the example of Bocskai Korona (Parádi-Dolgos, 2016).

Its main goal is to strengthen the economic and social ties between the municipalities, and is designed to act as a tourist attraction. It is used to promote consumption of local or organic produce. As in the case of Bocskai Korona discounts are provided when purchasing local products (Parádi-Dolgos, 2016). Because of its relative newness there is little information available on the complementary currency.

The brief overview of the major CC schemes in Hungary illustrates how they are used in territorial development, how they are created, with what kind of goals. The 3. Table below summarizes the information about CC schemes in Hungary.

Table 3: Classification of Hungarian CC schemes

Issuer	Kékfrank Ha-Mi Összefogunk European Limited Liability Cooperative	Balatoni Korona Balatoni Korona Zrt.	Bocskai Korona Hajdúnánási Holding Zrt.	Alsómocsoládi Rigac Local government of Alsómocsolád	Tokaji Dukát Holding of 27 local governments in Tokaj wine region
Origin	founded in Sopron May 2010	founded in March 2012, cooperation between 7 local governments	founded in July in Hajdúnánás	founded in May 2013 in Alsómocsolád	founded in March 2016, cooperation of 27 municipalities
Scope	Sopron and its region, cross- border	7 municipalities around the lake Balaton	Hajdúnánás	Alsómocsolád	Tokaj wine region
Purpose	revitalizing local economy, strengthening cross-border cooperation and social ties	strengthening regional economy, and revitalizing social exchanges	strengthening local economy, protecting local businesses, stimulating local exchanges	strengthening local economy, revitalizing community ties	strengthening community ties, protecting regional economy

CONCLUSION

This paper attempts to provide an analytical tool in order to make sense of the many forms, and contexts CCs appear. The author believes that this typology opens new perspectives to analyze complementary currencies, because it is based on the basis of individual and collective capabilities of local citizens. However the paper would not be complete without answering the question we identified in the introduction. The question is if it could have more impact than traditional development models? In order to answer this question we have to go back to the Capability Approach of local development. Applying this approach we move away from the classical view, which looks at a complementary currency as the end result of a development process. In Capability Approach complementary currency is regarded as an instrument to reach the desired state of being, so it is only the first step in the development process. This approach does not assume automatically a link between the implementation of a CC and well-being of the citizens, so it leaves more room for future adjustments based on the freedoms they wish to expand.

How applicable this framework is in practice, remains to be seen. The above shown Hungarian schemes can be the subject of further analyses based on the framework, and could illustrate the key factors, which lead to a successful change. It can be claimed that the success of a CC integrated into a local development project depends on the relationship between relevant actors, on the commitment its participants. The terms and the technical design should be established and managed to maximize the participation and commitment of its members.

ABSTRACT

One of the issues that are analysed in labour markets are the changes that occur in the patterns of workers' commutes as a result of changes in socioeconomic conditions. In this way, part of the literature finds certain degree of stability in labour commuting, while some authors argue that commuting is affected by workers' socioeconomic conditions. Thus, the present paper tries to find out, from the estimation of workers' commuting functions, what are the commuting determinants incorporating four types of variables, the characteristics of (i) the workers, (ii) the jobs (or hiring firms), and (iii) the municipalities where the workers reside and where firms are located. These functions are estimated based on the labour commuting microdata obtained from the Population Census of Spain for years 2001 and 2011, periods with clear socioeconomic changes, especially in terms of labour markets. Commuting functions are estimated by means of ordered probit functions. The results offer mixed evidence in relation to the initial antagonistic hypotheses, finding statistically significant changes in the sensitivity of commuting to working conditions between the indicated years, but that do not compensate for the important changes that have occurred in the labor markets.

Keywords: Workers' commutes, labour matching, socioeconomic conditions, microdata.

1 INTRODUCTION.

The economic literature includes a wide variety of empirical articles that, through the use of different statistical methodologies, raise an interesting debate regarding the stability over time of the duration of commutes, especially to the workplace. Thus, some papers (Reschovsky, 2004; McCuckin and Srinivasan, 2003; Kirby and Le Sage, 2009, among others) measure the increase in travel time to the workplace, associated to demographic changes and the increases in the size of cities and congestion. In particular, the most notorious change occurs, above all, in the percentage of workers who travel longer distances.

On the contrary, and despite these changes, Burchfield et al. (2006), Gordon, Ricardson and Jun (1991), Kim (2008), Sarzynsky et al. (2006) and Anas (2014), among many others, state that, once the levels of congestion are controlled by, the duration of commutes to workplace remains practically stable despite the increase in the size of cities, either because workers change their residences, or because there are other type of responses from workers, companies and public administrations oriented to keep these commutes times stable over time, i.e. construction of new infrastructures, changes in means of transport, alteration in the location of companies, selection mechanism of workers in firms' neighbourhood, modifications of schedules, etc.

In general, many of these studies ignore the effects that these factors may have on the labor market, specifically the existence of geographic segmentation. In fact, Thomas (1998) and Kunz (2011) argue that although there is a certain relationship between the duration of commutes and unemployment rates, it is not important enough to eliminate their differences in relatively close neighbourhoods.

As a result, there are still certain doubts, as it might seem a priori, about the radical influence that certain factors, such as the geographical configuration of the economic activity, the urban structure, as well as the socioeconomic determinants, may have over the configuration of commuting to workplace.

Spain, in particular, is a good case study of this phenomenon for at least three reasons. First, it is a country that is always pointed out for having problems of rigidity (including geographical rigidity) in the labour market (Sala and Trivin, 2014). In the second place, its economic conditions have drastically changed as a consequence of the great recession. Finally, it has abundant, detailed and similar information in two crucial moments of time, 2001 and 2011, that correspond to the moment before and during the economic crisis with a macroeconomic situation, and especially the one referred to the labour market, clearly different.

Thus, while Spain in 2001 was enjoying from economic expansion, the situation in 2011 was completely opposed, being beaten by both the internal economic crisis and the international one. As an example, of this drastic change suffered by the Spanish economy, it should be noted that the unemployment rate went from 10.5% in 2001 to double in 2011, reaching 21.4%. The economic changes in Spain have been so important that one could think that the analysed economy ten years apart correspond to totally different countries. In this changing context, it would be possible to give an answer to the question posed here, whether commuting patterns to workplace change or not over time, due to occurred socioeconomic and demographic changes.

The following section presents a review of the literature to contextualize the state of the art and the theoretical arguments pointed out, as well as the identification of the available empirical evidence. Next, the empirical model used to estimate the commuting functions to the workplace is presented. The fourth section describes the microdata employed from the Population Census of Spain for years 2001 and 2011 elaborated by the National Institute of Statistics (INE). The fifth section analyses obtained results. The paper ends with the usual conclusions and final considerations.

2. LITERATURE REVIEW.

There is previous empirical evidence that shows that the time that workers use to get to their jobs depends on different factors. These factors could be classified into three differentiated groups. On the one hand there would be the characteristics of the worker and the family environment (gender, living as a couple, children, age, nationality, education, means of transport, property of the home, etc.), on the other hand the characteristics of the job (size of the company, type of contract, qualification required, sector, etc.) and lastly the characteristics associated with the place of residence of the worker and the location of the firm (size, unemployment rate, infrastructure, etc.).

Within the characteristics of workers, one of the most analysed in this literature has been the gender. Thus, the results obtained conclude that there is clear evidence that it is women who spend less time in getting to their jobs (Lee and McDonald 2003; Fan, 2015; Neto, 2015, among others). MacDonald (1999) points out that this circumstance may be due to the fact that women usually perform more domestic tasks than men and assume a greater degree of responsibility in the care of the family and, therefore, tend to look for jobs closer to home (Chapple, 2001). In addition, the existence of a wage gap against women has also been evidenced, so this could be a cause of their lower willingness to move. Another characteristic of the workers, related to the previous one, is their family context. Thus, workers with small children make shorter trips to the workplace, especially in the case of women (Lee and McDonald 2003; Crane, 2007, among others). In addition, living as a couple also implies a reduction in the time taken to get to the job (Elliott and Joyce, 2004 and Fan, 2017). Another recurring characteristic of the worker in this literature is his nationality (or ethnic group), positively affecting the time of commutes when he or she is a foreigner or belongs to a minority ethnic group. The age of the worker has a negative effect on the time of commutes to the workplace (Green et al., 1986 and Matas et al., 2010). In turn, the level of studies of the worker also influences the time spent in reaching the workplace. Skilled workers show longer commuting times resulting from both higher salaries and more complex matching processes (Wang, 2003). The means of transport to reach the workplace is also important, this aspect is first subject to the distance to workplace (for example, if the distance is short, it is possible to go by foot), secondly to the existence of an adequate network of public transport, and the possession or not of a vehicle (Palma and Roachat, 2000).

With regard to the characteristics of the job, the variable working hours constitutes an important determinant. Workers with a full-time contract, are willing to travel longer (Giuliano, 1998; Lee and McDonald, 2003). The size of the firm, the sector in which operates, and the type of occupation are also frequently analysed (Lee and McDonald, 2003).

Finally, there are not many papers that analyse the characteristics associated with the place of residence of the workers and the location of the firms. Thus, the size of the cities could increase the time of commutes to workplace, although their urban structure seems even more relevant. In this sense, as cities become larger, the services offered by new infrastructures improve and, hence, commuting times are also reduced. With regard to the unemployment rate, there are few papers that have analysed the effect it has on the time of commuting to workplace. It is true that it would be expected that as the rate of unemployment in a city gets larger, commuting times could be expected to increase. However, some studies indicate that the existence of subsidies to unemployment, the ownership of housing, neighbourhoods where ethnical minorities are concentrated or with strong social conflict, can make commuting to this phenomenon indifferent.

3 THE EMPIRICAL MODEL.

The estimation of the commuting function to the workplace takes the form of expression (1).

$$y^* = x'\beta + \varepsilon \quad (1)$$

Where y^* is a latent variable and, therefore, not observable, that represents the time of commutes to work. x is the vector of characteristics that determine y^* . Although y^* is not observed, we have information about the time segment where the commute takes place, in this case 7 different time classes ($t < 10$; $10 \leq t < 20$; $20 \leq t < 30$; $30 \leq t < 45$; $45 \leq t < 60$; $60 \leq t < 90$ y $t \geq 90$) which are codified as follows $y \in \{0,1,2,3,4,5,6\}$. The independent variables are the determinants of these commutes, which are grouped into four different categories, (i) characteristics of the workers (age, sex, nationality, educational level, type of commuting, housing tenure regime, family structure), (ii) the characteristics of the job (activity sector, level of studies required, size of the company, working hours), and of (iii) the residence and (iv) work locations (size of the municipality, which captures the possible problems of congestion, unemployment rate, province, which controls for the urban structure and the provision of transport infrastructure).

Consequently, the estimation of this commuting function is carried out by means of an ordered probit model. The dependent variable, y , records the different times of travel to the workplace in minutes.

The regression model takes the form of expression (2).

$$y = 0 \text{ si } y^* \leq \mu_1$$

$$y = 1 \text{ si } \mu_1 < y^* \leq \mu_2$$

$$y = 2 \text{ si } \mu_2 < y^* \leq \mu_3$$

$$y = 3 \text{ si } \mu_3 < y^* \leq \mu_4 \quad (2)$$

$$y = 4 \text{ si } \mu_4 < y^* \leq \mu_5$$

$$y = 5 \text{ si } \mu_5 < y^* \leq \mu_6$$

$$y = 6 \text{ si } y^* > \mu_6$$

The estimation of the above model gives the values for both, the different intercepts β_i as well as the parameter estimates of vector β . The error term follows a normal distribution $\epsilon \sim N(0,1)$.

4 DATA.

We use data on daily mobility to estimate commuting functions to workplace. In this type of statistical databases, information is collected, in the form of microdata, including commuting times, the mode of transport and the characteristics of both the individual, his or her job, and their respective locations. In the case of Spain, the microdata samples of INE Population Census⁵⁰⁸ are appropriate, and hence, we use them for years 2001 and 2011. In both years, individuals who are not working and those who work either at home, or in several municipalities or abroad, have been excluded, since they do not offer commuting to workplace times. In addition, we have omitted people who reside or work outside of mainland Spain and people who take more than 90 minutes to arrive to their workplaces⁵⁰⁹. The final size of the samples used for the estimation of commuting functions, are of 656,748 individuals for the year 2001, and of 1,071,000 individuals for 2011.

Information on daily commutes to workplace is one of the variables available in the microdata of the Census. This is offered as a discrete variable in seven different time classes, less than 10 minutes, between 10 and 20 minutes, between 20 and 30 minutes, between 30 and 45 minutes, between 45 and 60 minutes, between 60 and 90 minutes and longer than 90 minutes. Table 1 shows the distribution of workers' commutes for each time class. More than a quarter of daily commutes to workplace occur in less than 10 minutes. It should be noted that this proportion has been reduced by just over 1% between 2001 and 2011. In addition, approximately 61% of commutes took less than 20 minutes in 2001, a value that is also reduced to 57.5% in 2011. On the contrary, 8.8% of the individuals were classified in 2001 along the two upper time interval classes, implying commuting times between 45 to 90 minutes. This proportion is increased to 9.6% in year 2011. It can be observed that commuting times to workplace have been slightly increased in 2011 compared to 2001. Thus, taking the upper value of each time interval class, while in 2001 the average time to arrive to the workplace was about 20' 36", this time has increased by just over one minute in 2011.

Table 1. Commuting to workplace. Summary statistics and the distribution by time interval classes

	2001	2011	Dif. 2011-2001
Observations	661,731	1,080,527

> 90	0.75	0.88	0.13

Source: INE and own elaboration.

* Statistics have been calculated omitting commuting longer than 90 minutes.

Regarding the determinants of commuting, homogeneous characteristics have been taken into account. a) **characteristics of the worker** such as *sex*, *age* (four age groups: 15-24 years, 25-39 years, 40-54 years and 55 years or older), *level of studies* (measured by the number of schooling years, 6 years for primary school, 12 for secondary education and vocational training, 17 for University studies), *means of travel* (private using motor vehicles, public, by foot, and other means), *nationality* (Spanish and other), *housing tenure system* (own, rented, assigned free or at a low price, and other). b) **characteristics of the job** such as the *size of the firm* (approximated by the distribution of the following size classes, less than 10 workers, between 10 and 49 workers, between 50 and 199 workers, and more than 200 workers) in each municipality and sector according to the sample of firms used from SABI database (System of

⁵⁰⁸ For the 2001 Census, the microdata offered by the INE correspond to a representative sample of 5%. In 2011, a census was not carried out, but only a representative sample of 10% of the population was surveyed. This sample is precisely the one used here.

⁵⁰⁹ Individuals of the last time class considered in the census, with more than 90 minutes of commuting time, have not been taken into account, because they have no upper limit and hence impede the calculation of descriptive statistics. These cases only represent 0.75% of the individuals surveyed in year 2001 and 0.88% in year 2011.

Analysis of Iberian Balance Sheets), the *level of qualification required by the job* (corresponding to the mode of the three schooling basic levels registered for each occupation in the National Classification of Occupations, two digits CNO-94), the *type of employment*, either full or part-time employment, and the sector of economic activity of the firm. c) **characteristics of the municipalities where the company is located and the worker resides** such as the *size of the municipality* (the census have nine different size classes⁵¹⁰ that have been grouped into three categories: less than 20,000 inhabitants, between 20,000 and 250,000, and more than 250,000 inhabitants), the *province of the municipalities* where the worker inhabits and the *location of the company* (computed as indicator variables) and the *rates of unemployment of the municipality of residence and location of the company*.

Table 2 shows the descriptive statistics of commuting times for years 2001 and 2011 as a function of the variables just described. It can be highlighted, that workers who are between 25 and 40 years old, foreigners (presenting scores far apart from national workers), and skilled workers show longer commuting times to their workplace. With regard to sex, commuting times of women and men do not show very significant differences. Regarding the means of transport used to get to the workplace, workers who take the public transport are those who spend longer times, while workers who decide to commute by foot have the shortest commuting times. In addition, the individuals living in rented houses are those who spend more time in getting to their jobs, while lower commuting times are associated to those workers who have the house assigned free, usually by the company itself. As it would be expected, individuals living as a couple show lower commuting times.

This same Table also registers some important changes in commuting times between the two years of study for some of the considered characteristics. Thus, it can be observed that although the difference in time, between Spanish workers and foreigners, remains very large, it has been reduced by approximately one minute since Spanish workers have seen their commuting times increased. It is also worth mentioning that workers with higher qualifications have also increased

⁵¹⁰ Less than 2,000 inhabitants, between 2,000 and 5,000 inhabitants, between 5,000 and 10,000 inhabitants, between 10,000 and 20,000 inhabitants, between 20,000 and 50,000 inhabitants, between 50,000 and 100,000 inhabitants, between 100,000 and 250,000 inhabitants, between 250,000 and 500,000 inhabitants and more than 500,000 inhabitants.

their commuting times to a higher extent. On the other hand, the differences have been reduced considerably for the different means of transport used. While in public transport commuting times have been reduced, commuting by foot has increased. Finally, the descriptive analysis is surprising given that the relationship between workers' commuting times and the unemployment rates follow an inverted U shape in 2001, this shape being reverted in 2011, which could be interpreted as a consequence of geographic rigidity in the Spanish labour market.

5 RESULTS.

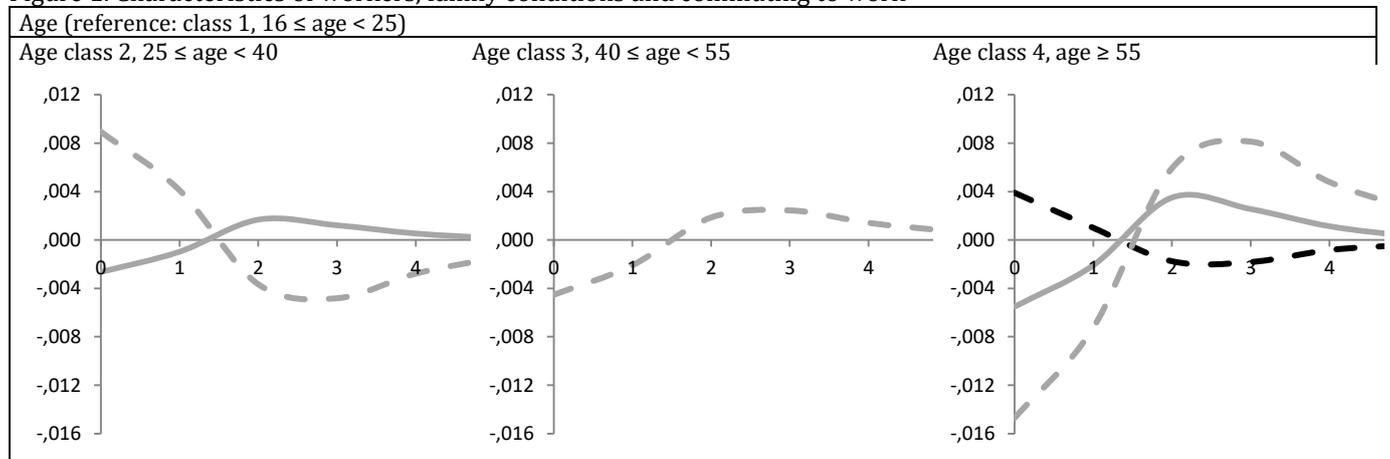

Once commuting functions are estimated by means of a multivariate ordered probit model for years 2001 and 2011, separately, we compute the relative probabilities for each characteristic and the different values that the dependent variable can take (1 to 6) in relation to each characteristic. The reference characteristics are, (i) in relation to the municipalities of residence and firm location, the first size class (up to 20,000 inhabitants), (ii) with respect to workers' characteristics, women, young workers (under 25 years old), Spanish nationality, using a privately owned car, living in an owned house and living as a couple, and (iii) in relation to the characteristics of the job, micro firms (less than 10 workers) and part-time employment. Both the years of education and the unemployment rate are included as continuous variables. The marginal effects of the regressors (except for sector and provincial indicators) on the probability of workers' commutes along each of the considered time interval classes are represented graphically.

When these variables are dichotomous, the marginal effect measures the loss or increase in the probability of commuting associated with the presence of the characteristic identified by the variable, conditioned to the fact that the rest of the regressors are evaluated in their mean values. When an independent variable has been coded as a set of dichotomous variables in different groups, one of them is eliminated in order to avoid perfect multicollinearity, and the marginal effects register the impact on the probability of commuting associated with the observation switching from presenting the characteristic identified by the omitted group to having the characteristic of the group for which the marginal effect is calculated⁵¹¹. In the case of continuous variables, the marginal effects measure the increase in the probability of commuting derived from a unit increase in the value of the corresponding regressor.

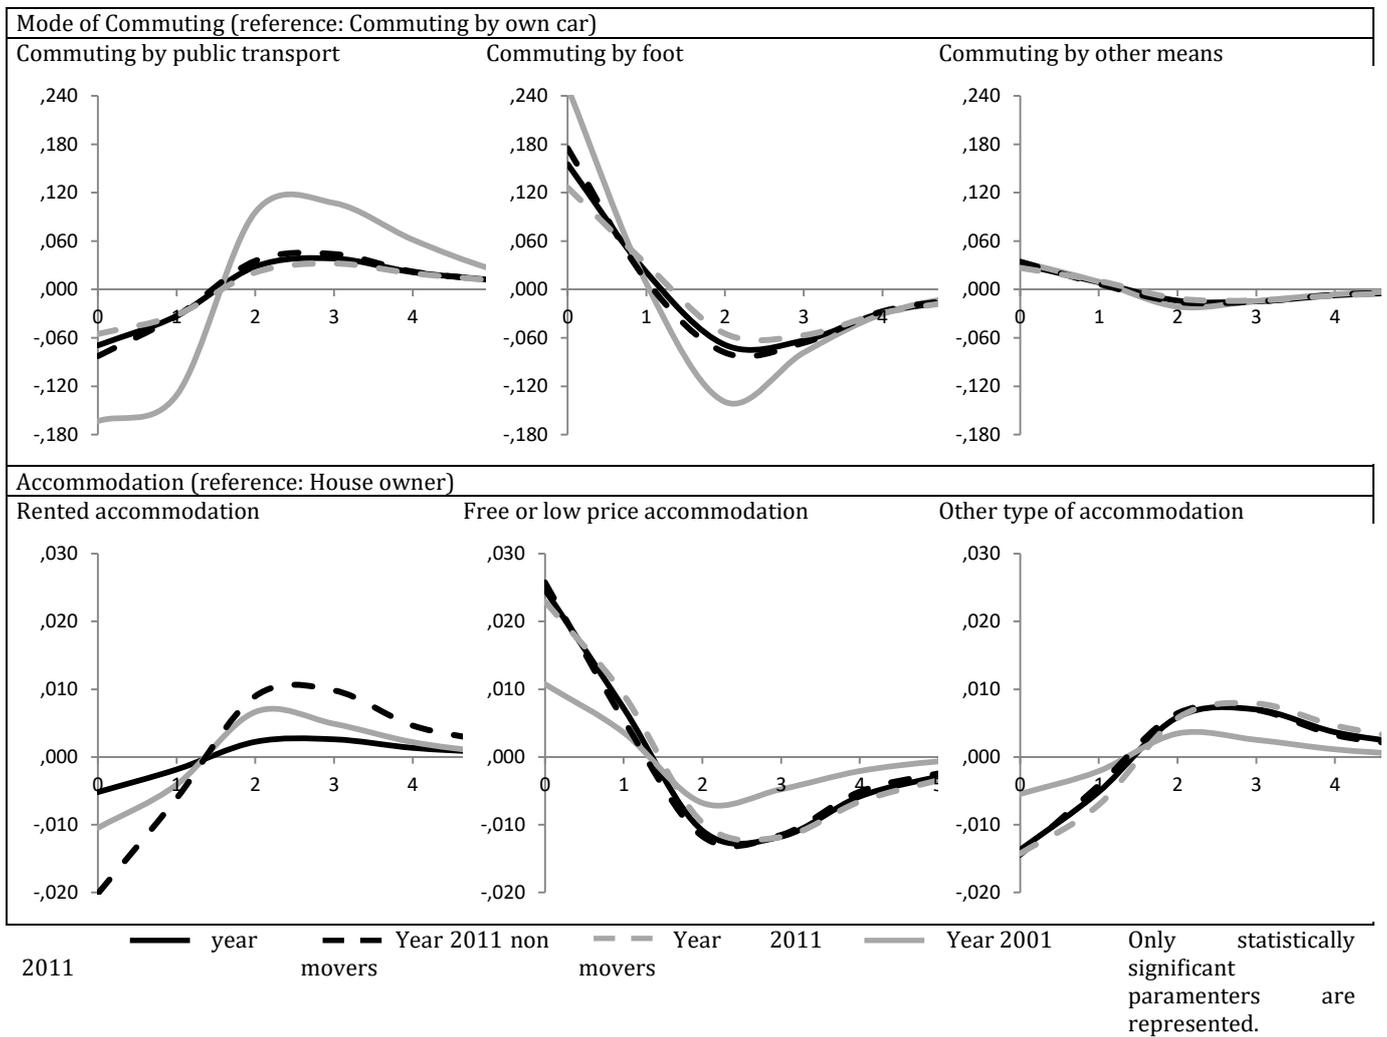

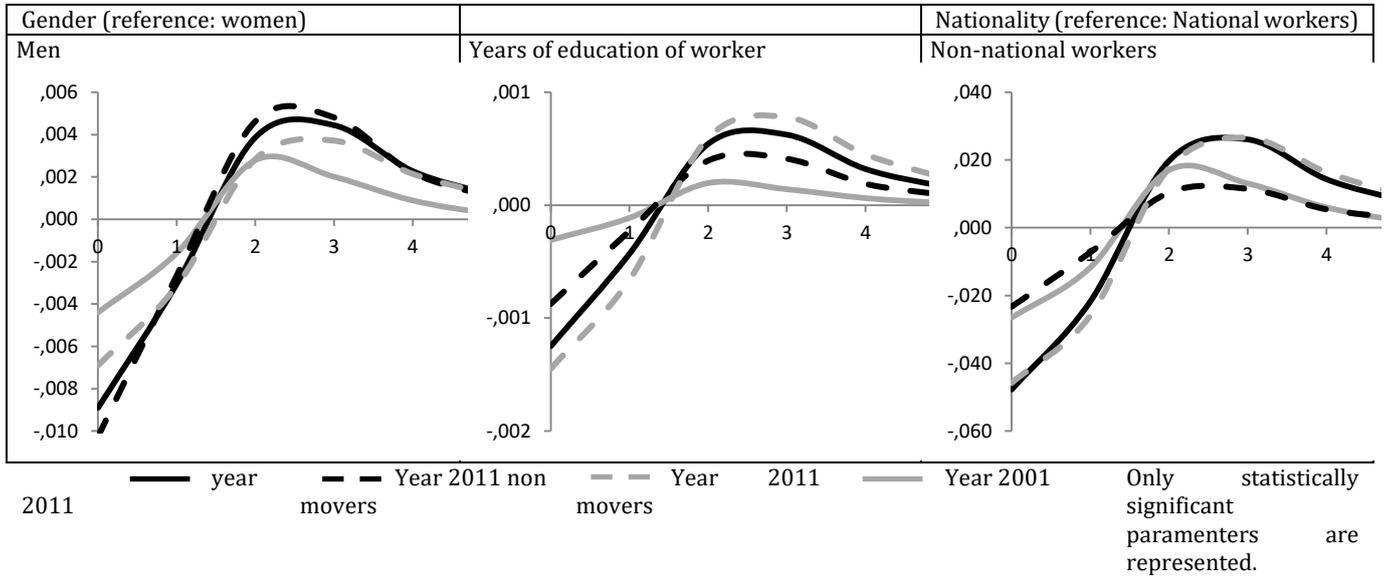

Figures 1 to 3 illustrate the marginal probabilities estimated for each characteristic at the different values that the dependent variable can take, conditioned to the fact that remaining regressors are evaluated at their corresponding mean values. Consequently, a convex (concave) probability curve from above for a given value of a characteristic will indicate that shorter commuting times are less (more) probable than longer ones. Likewise, that given characteristic shows longer (shorter) commuting times that the value set as the reference. Therefore, an increase in the curve convexity (concavity) between the two periods analysed will imply an increase of the difference with respect to the reference value. The analysis is symmetric for decreases in the degree of convexity or concavity. By construction, the area below the probability curve and the x-axis should be equal to the area above the probability curve and the x-axis. Finally, the estimation for year 2011, takes into account changes in workers' residence location along considered time horizon, estimating commuting functions for those workers changing location (movers) and those who remain located in the same address (non-movers). The distinction is made in order to evaluate the extent to which workers' choice of residence depends on job location, and if residence changes take place in order to minimise commuting times.

In relation to the characteristics of the workers (Figure 1), a notorious change in relation to age between 2001 and 2011 is observed. In the first period, the relationship seems to be positive with age, except in the 40 to 55 age class, a result that in principle is not consistent with previous evidence, but that surely responds to the combination of factors accounted by remaining variables. In year 2011 this observed relationship disappears and age no longer has a statistically significant effect. Interestingly, when the individuals of this second year are disaggregated into movers and non-movers, the former group shows a positive relationship with age, which could respond to a process of greater sub-urbanisation in the older group.

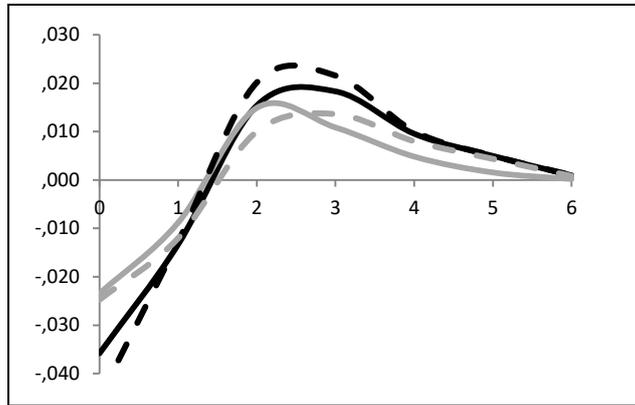

Figure 1. Characteristics of workers, family conditions and commuting to work

⁵¹¹ For example, in the case of age, four age groups are constructed and hence four dichotomous variables (less than 25 years old, between 25 and 40 years old, between 40 and 55 years old and over 55 years old). In this case, to avoid perfect multicollinearity, the first of the age groups is omitted, so the rest of the results must be interpreted with respect to it.

Type of family (reference: living as a couple)
Not living as a couple

year 2011 non movers ——— Year 2011 movers ——— Year 2011 ——— Year 2001 Only statistically significant parameters are represented.

Men show longer commuting times, a difference that increases over time, especially for non-movers. On the other hand, more skilled-workers also have longer commuting times, which, as in the case of men, increase over time, in this case as a consequence of the movers. The explanation behind this phenomenon is probably due to the fact that the population with higher education levels is precisely the one below 40 years old, which has changed residence from the family address to their own place along the considered intercensal period, by acquiring a residence in the peripheries of large cities, where housing prices have increased less than in the city centre along the years of the housing bubble.

Foreign workers also offer the same profile. Longer commuting times for year 2011 and especially in the case of movers, which perhaps identifies those workers who arrived after 2001 or those who are willing to move to improve their working conditions and acquired housing in the cheapest areas, while non-movers are identifying most integrated immigrants or those who came in along the nineties and settled in central areas in some depressed districts.

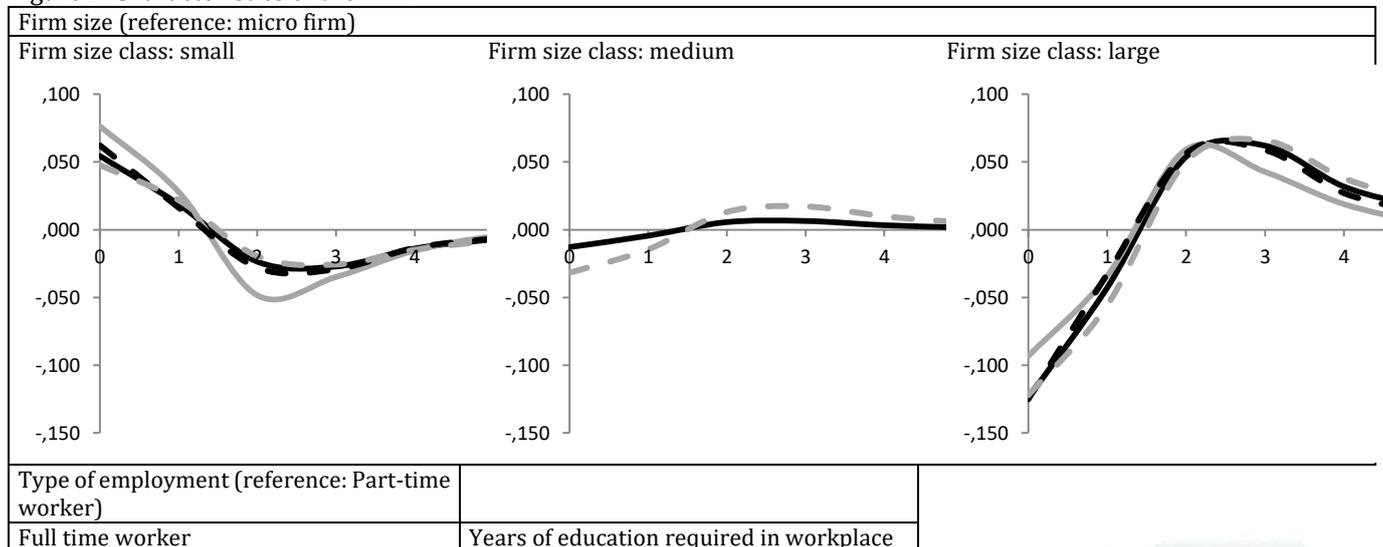

Precisely, people who live in rented houses show longer commuting times compared to those who own their houses, although a downward trend is observed mainly caused by movers.

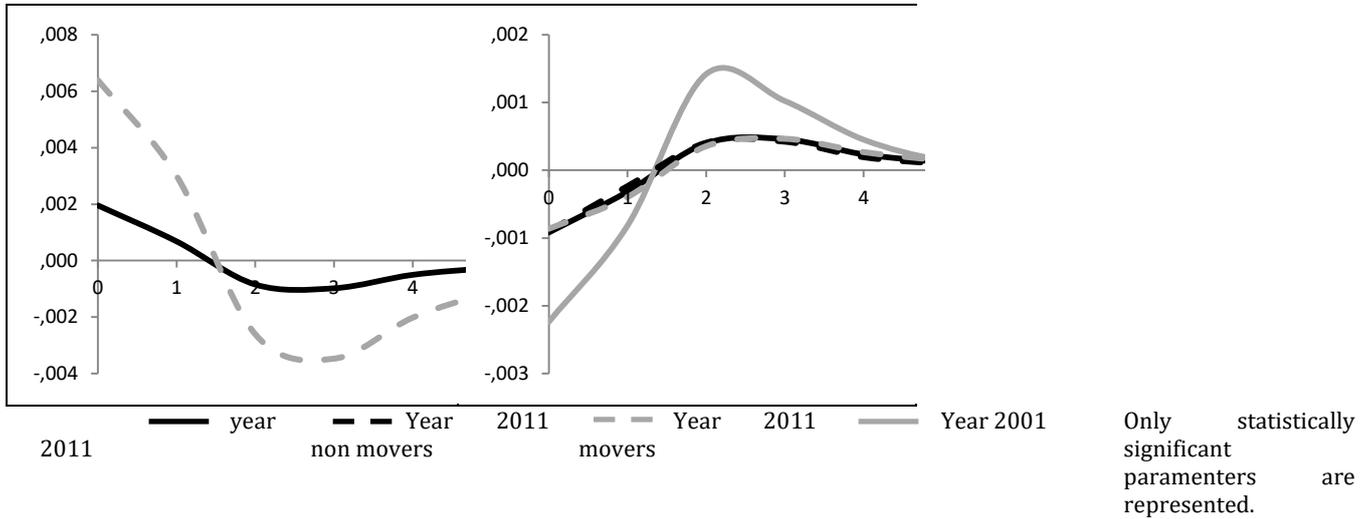

Family life is associated to shorter commuting times in relation to those who do not live with a partner and this difference increases especially through non-movers.

The chosen mode of transport also determines significant differences in the duration of commutes. Thus, the use of public transport increases the duration of commutes compared to the use of private vehicles, although a downward trend is observed in this mentioned difference. Just the opposite occurs with commuting by foot, that are related to shorter commuting times, and show an increasing trend over time.

Regarding the characteristics of the firm and the job (Figure 2), firm's size seems to show a positive effect on the duration of commutes, although some inconsistency in the medium-sized firms is observed. What does seem to be fulfilled is that the differences with respect to micro firms increase over time. Having full-time employment, as opposed to a part-time one, has no statistically significant effect in 2001, and turns to have a statistically negative effect over the duration of commutes in year 2011, possibly as a consequence of the fact that full-time employment is indicating more years of work experience and better working conditions. In fact, the change over time is observed for full-time movers. On the other hand, higher qualification levels imply longer commuting times, although this effect is moderating over time.

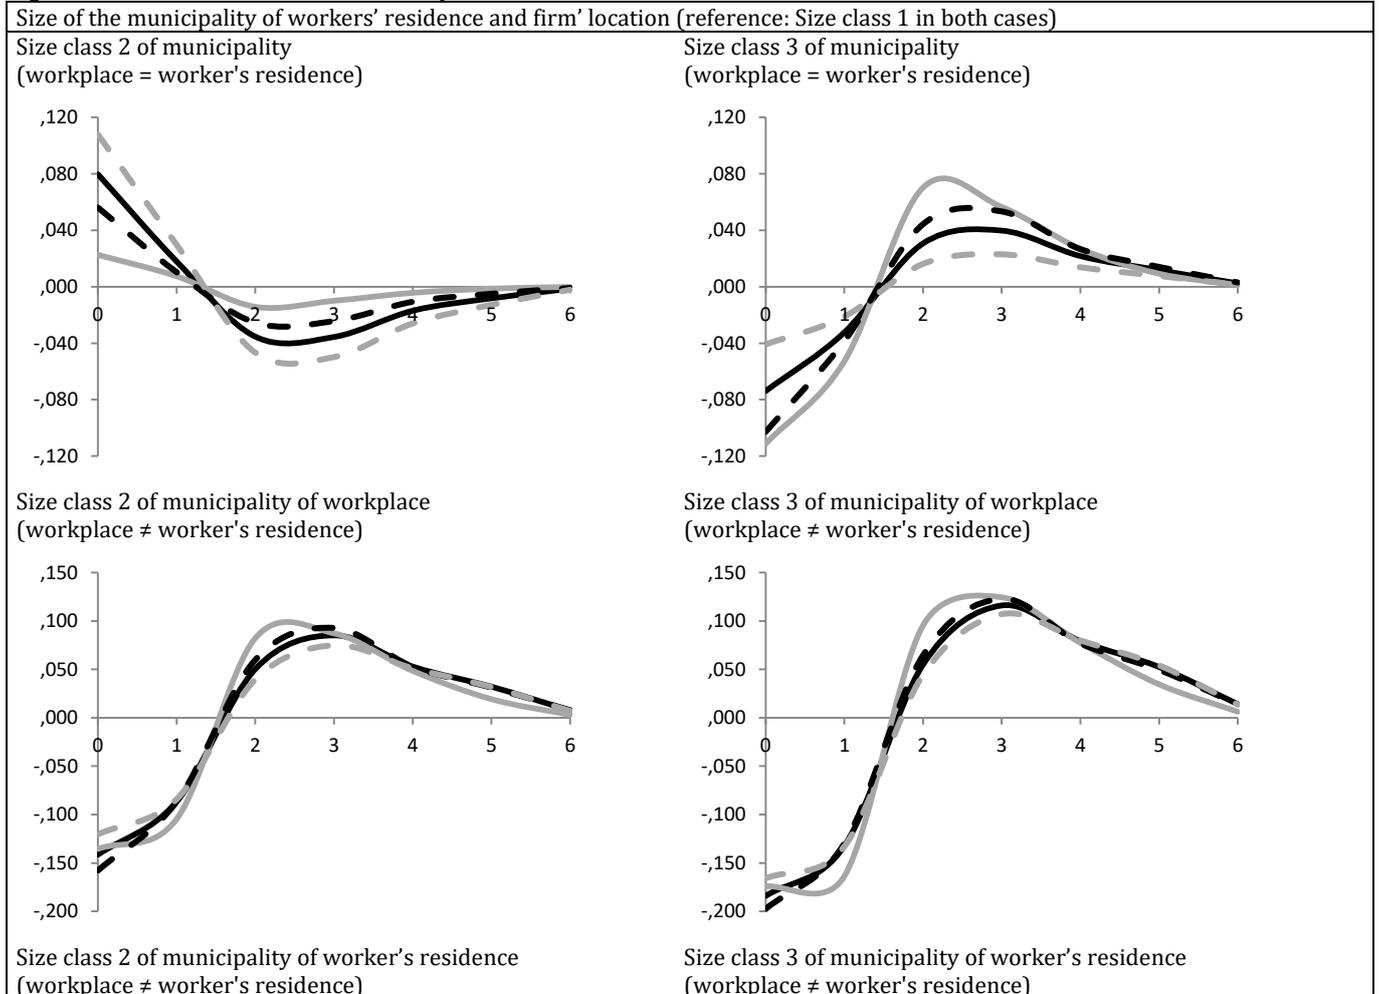

Figure 2. Characteristics of the firm

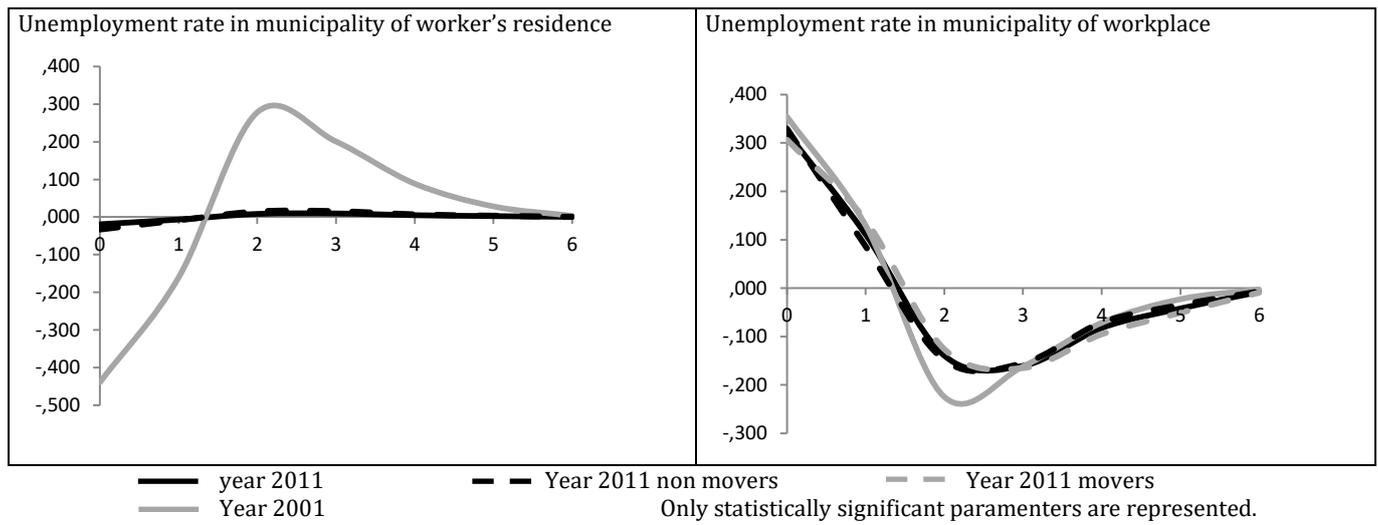

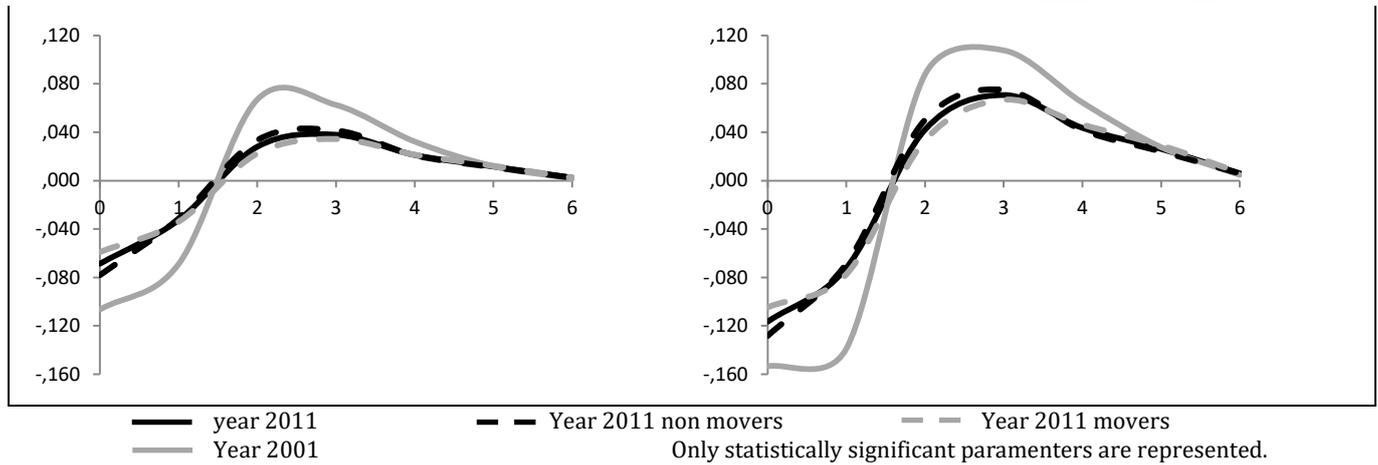

Finally, Figure 3 identifies some interesting effects regarding the characteristics of the municipalities where the worker resides and the firm is located. When residence and work takes place in the same municipality, while in the medium-sized municipalities the commuting times are shorter than in the small ones, in the large ones commuting times are longer. The effect observed on the medium municipalities is possibly due to the use of other modes of transport compared to the small ones that reduce commuting time. On the contrary, in the large municipalities commutes are of longer duration. In both cases the differences decrease over time with respect to the small ones.

Figure 3. Characteristics of the municipalities of workers' residence and firms' location

When the municipalities of work and residence are different, the effect in both cases is the same, commutes increase with size, although there seems to be a certain fall in this difference over time, possibly as a consequence of infrastructure development and efficiency improvement along the considered time horizon in the transport network between neighbouring municipalities.

The unemployment rate has a different effect depending on the municipality in which it occurs. It has a positive effect over commuting duration when corresponds to the municipality of workers' residence, favouring longer commutes of its inhabitants. Conversely, the unemployment rate of the municipality where the firm is located has a negative effect on commuting times and thus discouraging the search for workers across large areas. There is nonetheless an interesting change in the intensity between the two years analysed. Thus, in 2001 the positive effect observed for the unemployment rate of the municipality of residence of the workers was of greater intensity than the negative effect of the unemployment rate of the municipality where the firm was located, so that, in case of coinciding both municipalities, the net effect was positive. On the contrary, in 2011, the unemployment rate of the municipality of residence still shows a statistically significant positive effect but much smaller than in 2001, and the negative effect that the unemployment rate of the municipality of firm location has over commuting times is also reduced, therefore, in case of coincidence of both municipalities a negative net effect is observed.

This observed change is particularly interesting, especially in the case of the municipality of residence, which leaves almost no effect of the rate of unemployment over the duration of commutes. Possibly, this result, that provides evidence of the change in the sensitivity of commuting to changes in the socioeconomic conditions, has to be explained in terms of the important and systematic increase of unemployment in Spain between 2001 and 2011. The notorious geographical and functional rigidities of the labour market may have impeded further adjustments that could have occurred by moving to neighbouring areas.

6 CONCLUSIONS

This paper analyses the determinants of the duration of workers' commutes to their workplaces in Spain for the years 2001 and 2011. Thus the analysis is carried out in two periods under different socioeconomic scenarios, serving to evaluate the extent to which commuting functions are stable over time or, as argued by some previous evidence, these functions should only be used statically, given that changes in socioeconomic conditions, captured by relevant commuting determinants, imply changes in the values of estimated sensitivities.

Obtained results for the Spanish case appear to be in favour of the second hypothesis, as the duration of general commutes have not been modified drastically, but the changes in the socioeconomic conditions have altered the values

of estimated parameters. On average, the final impact seems to remain unaltered, as slight changes in the duration of commutes are often compensated by the changes in parameter values.

In this sense, the most important observed alteration is in the sensitivity of commuting to the rate of unemployment, especially the one occurring in the municipality where the worker resides. If the change in the value of this parameter between the estimations for years 2001 and 2011 would not have taken place, the duration of commutes would have changed very significantly.

Remaining results show greater propensity to longer commutes in the case of men, workers with higher educational levels, foreign workers, workers living in a rented house as compared to those owning the house or living as a couple, as well as those who use public transport as compared to those using a private car.

Those workers having worse working conditions and, in general terms, those who live in larger cities, commit longer commutes, except those who live and work in medium-sized cities, whose commutes durations are slightly shorter than in the case of workers living in small cities.

Finally, in order to account for the possibility of simultaneity between the decision of choosing the location of workplace and that of residence, commuting functions in year 2011 are estimated separately for the sample of individuals who have changed their municipality of residence along the intercensal period and the sample of workers who have not done so. The results seem to show a partial confirmation of this hypothesis, since in many cases it seems that the decision to locate their residence has been subordinated to the housing market bubble, at least until 2008, which has conditioned the indicated joint decision.

1509 URBAN FURNITURE CHROMATIC PLANNING AS AN INCLUSIVE FACTOR FOR URBAN SPACES

Margarida Gamito, Joana Sousa

CIAUD –Research Centre in Architecture, Urban Planning and Design, Lisbon School of Architecture, University of Lisbon; Portuguese Colour Association, Lisbon, Portugal

ABSTRACT

This paper aims to demonstrate how a coherent chromatic plan applied to urban furniture may contribute to improve the space within cities, as the different city's areas become different one from each other and, simultaneously, the urban furniture elements are converted into ergonomic factors, standing out from their background and contributing to improve the population inclusivity. In order to achieve this purpose, and because the existent methodologies weren't adequate to reach the aimed objectives, it was decided to develop a new methodology that would allow the determination of colour plans, with a higher scientific approach, as a strategy for the enlargement of urban chromatic plans perspective. The research focus has been the city of Lisbon, where the new methodology was applied to three of its neighbourhoods, which constituted the case studies, and the research and its results were tested and validated by three focus groups that included people with different ages and genders, Municipality authorities and Colour Experts.

Keywords: Urban spaces, Urban furniture, Inclusivity, Orientation and Identification, Chromatic planning

Figure 1: Colour in Urban furniture make it stand out from the environment (Source:authors)

INTRODUCTION

This paper presents the research and the case studies for a new urban furniture chromatic planning methodology, with the purpose of originating a system that would ameliorate urban furniture use, improving the visibility and legibility of its elements, transforming them in identification factors for the different city neighbourhoods, and contributing to a better orientation within the cities. This methodology is intended to be applied solely to urban furniture, which will become an ergonomic and inclusive factor, and not interfering with the city architecture or other elements of city signage, which are encoded by road legislation.

Contemporary cities, in their development, originated the necessity for complex traffic and network signage systems, that in addition to the abundance of multicoloured publicity contributes to a general confusion that causes difficulties to visitors and inhabitants orientation. Consequently, orientation within the cities can be a problem of difficult resolution, mainly on those with an architecture lacking differentiation and that don't have obvious reference points that could establish a base for wayfinding/wayshowing maps. Even tourist maps, that differentiate the cities zones through colours, don't have any correspondence in physical space, i.e., the concern to match these colours with a real use on its urban space does not exist. From this premise arose the necessity to identify the various city zones by means of specific colours that could differentiate them, considering that colour would be the most efficient mean to achieve this aim.

On this purpose Minah [1] states: "As a pedestrian, colours are experienced in a continually changing visual field. Planners have succeeded in achieving visual order in cities by implementing repetitive architectural typologies, zoning to form hierarchy in patterns of blocks and public spaces, and similar building heights". Craig Berger [2] also stresses that cities adapted themselves to tourism and convention centres, originating the necessity for urban orientation systems. These systems that gather tourism centres, maps, symbols and graphic indications, are intended to turn navigation within the city easier to their visitors and inhabitants.

The usual signage and directional systems, responsible for giving guidance to city dwellers, are designed for being perceived at a distant and fast vision of people driving motorcars on roads and highways. Within the cities, these signage systems are not appropriate to be seen by pedestrians or fulfil the needs of the entire population, because they tend to merge with the building colours and loose visibility. So, to solve this problem, it became necessary to design comprehensive directional systems that could help guiding people and, simultaneously, grant a better identification with the city.

Consequently, starting from these premises, the aim of this research grew into the creation of a chromatic plan system that would ally the city orientation to the identification of its different zones and would promote the inclusivity of its inhabitants. This chromatic plan should be applied to all the city quarters, without interfering with their architecture but giving to each zone its own identity.

URBAN FURNITURE

The denomination – urban furniture – covers all the elements, placed on the public space, with the aim to offer support and orientation to the cities occupants. These elements constitute a wide range that includes, among others, benches, litter bins, street lamps, bus stops, kiosks, cabinets, telephone booths, drinking fountains, bollards, signs, etc.

The urban furniture choice it is not a simple aesthetic condition, it must accomplish several functional requirements in order to fulfil the population needs, facilitating their lives and contributing to their comfort. So, as Águas [3] states, to assure its functionality, urban furniture must protect the health and well-being of the city inhabitants; facilitate the accessibility and use to people with visual or motor difficulties; reinforce the local identity, representing a formal family that is coherent and values the surroundings. However, while recognizing its necessity, the urban furniture functional possibilities have not been used to their complete extent, and the choice of its colour or form only rarely obeys to a logic thought.

As a mean to show the way, colour has been punctually employed successfully in interior and exterior spaces and, therefore, we could assume that a sensible and general application to urban furniture may be a way to the successful resolution of the orientation problem within the city. In fact, urban furniture systems usually present a shyness on colour application, with a dominant concern about environment integration, that makes its elements less visible and unable to accomplish their functional efficiency. This lack of visibility contributes for the exclusion of the visual impaired users, which constitute a wide percentage of the urban population

Being colour the objects characteristic which the eye first perceives, even before form or texture, we have found that colour is an efficient way to increase the visibility and legibility of urban furniture and signage systems. Therefore, an appropriate colour application improves considerably its visibility and, when the urban furniture chromatism is the same for a city area, it may be converted in an effective signage and identification component that will contribute for a better orientation within the city.

URBAN POPULATION AND INCLUSIVITY

“Inclusive Design is a way of designing products and environments so that they are usable and appealing to everyone regardless of age, ability or circumstance by working with users to remove barriers in the social, technical, political and economic processes underpinning building and design” [4].

The objective of inclusive or good design, as it is referred in Brown *et al.* [5], must be to erase, as much as possible, the differences between disabled and undised people, and contribute to the amelioration of everyone’s quality of life, that may be considered as an “interaction between the individual and the environment”, and “can be described in terms of personal control that can be exerted by the individual over the environment”. Even considering the impossibility to contemplate all the needs of people with high level of disabilities, adaptive environments should be designed in order to contemplate all people’s needs, being them with or without disabilities, and to ensure that a higher percentage of the population can enjoy all the environment facilities.

Despite these statements, the inclusive and ergonomic design, in their recent development issues, are primarily focused on people with motor limitations and tend to not include visual disabled people. Therefore, to have better visibility conditions, under an inclusive design perspective, all urban furniture elements must present a good chromatic and luminosity contrast, because urban population includes an extensive variety of people, with different visual acuities and limitations and, also a high proportion of elderly people. Effectively, as people grow older, they start to have vision limitations, because their ability to see small details decreases and eyes have a crescent difficulty of adaptation to sudden changes of light or a quick refocusing.

The estimation of Portuguese population, published by the *Instituto Nacional de Estatística* (Statistics National Institute) in December, 2016 (INE 2016) (Table1) [6], shows that Portuguese people live longer and, consequently, the ensemble of the population tends to age. So, their requirements must be taken in account because, despite their limitations, elderly and visual disabled people must be able to get out and about locally in order to age well and live independently.

Table 1. 2017 Instituto Nacional de Estatística estimates for the Portuguese population (INE 2017)

2015	
Existing population – 10 341 330	Women – 5 439 821 Men – 4 901 509
Births decrease – 8,3%	
Deaths decrease – 10,5%	
Life expectancy (2003/2005) – 77,7 years	Women – 80,93 years Men – 74,43 years
Life expectancy (2013/2015) – 80,41 years	Women – 83,23 years Men – 77,36 years
2003/2005 – 2013/2015	
People older than 65 years – increased	
People younger than 15 years – decreased	

Aging index: Older people / Younger people = 106,6-138,7 / 100

Previsions for 2060

Aging index: Older people / Younger people = 307 / 100

Also, in accord with the prescriptions of the Royal National Institute for the Blind (RNIB), UK, pedestrian paths must be easily identifiable and differentiate themselves from the adjacent walls. Likewise, every present object must detach itself from the background, in order to be recognized as an obstruction. Every urban furniture element – fences, bollards, lamp posts, litter bins, benches, etc. – must present a strong chromatic and light contrast with the environment, so that they can stand out and be more easily recognized, among other, by visual disabled people [7].

Effectively, the desire to get out does not diminish with old age and older people can continue practicing a large variety of outdoors activities whenever the environment allows it. On contrary, when it isn't easy or enjoyable to get outdoors, their quality of life will diminish as well as their physical health. Older and visual disabled people move about more frequently on foot and it presents big difficulties on poor design environments. Accessible open spaces, with good paths, safe crossings, plentiful seats, and visible signing will improve older people's perception of supportiveness and safety [8].

METHODOLOGY FOR URBAN FURNITURE CHROMATIC PLANS

The concern to establish a coherent urban image through colour studies and chromatic plans is relatively recent, despite some pioneer cases, and led to the conception of chromatic planning methodologies, gathering the necessary steps for the selection of a colour palette that would constitute the urban image. However, these plans are mainly intended for Architecture and do not take into account the presence of urban furniture, nor the importance that these elements can have in the orientation within the city

During the research it became clear that the existent methodologies weren't adequate to reach the aimed objectives of this study, and that we should develop a new methodology. This new methodology became the main focus of this research.

The research focus has been the city of Lisbon, where the new methodology was applied to three of its neighbourhoods – *Baixa*, *Campo de Ourique* and *Parque das Nações* – which constituted the case studies. Each one of these neighbourhoods is identifiable of a specific zone of Lisbon and, belonging or not to different architectural epochs, has characteristics and a history that singularize it. The first, *Baixa*, is the heart of Lisbon and was a candidate for world heritage (2004); the second, *Campo de Ourique*, is traditional and, both, commercial and residential; and the latter, *Parque das Nações*, is a recent urban zone, still under development.

Figure 2: Example of a sample area. (Source: authors)

On these city zones were applied an extensive direct observation, with the use of mechanical devices, including photographic mapping of both urban furniture and signage, in order to evaluate their visibility and legibility, as well as their colour applications. Also, in order to facilitate the study, samples routes were defined for each urban area, including the main streets and places and, also, some secondary ones, with the intention of encompassing the most representative zones, those with specific characteristics.

Along the chosen areas, an exhaustive record of all the environmental colours was made, including material samples not only from the buildings, but also from pavements, vegetation and any additional elements present with a relative permanence in the urban environment – *the non-permanent colours* – that should be taken into account for the spatial chromatic readings. All of them were then classified using the Natural Colour System (NCS), that was chosen because it allows the easy identification of every colour, even when they are located out of reach, and without needing additional equipment. Besides the NCS classification, whenever it was possible, the colourimeter was used for a more accurate measurement of colours.

All these recorded colours were completed with the background dominant colours, and with photographs of the environment elements and panoramic views from the different blocks using urban plans, architectural elevations and sections of the selected paths as well, which acted as elements of the environment colour components. The angle of the streets was also evaluated in order to determine the percentage of sky colour present in each street, because this colour interferes on the urban area colour and, therefore, must be included in the colour palette.

Figure 3: Percentage of sky, visible in different streets (Source: authors)

It must be underlined that the recorded colours were perceived colours, not always coincident with the inherent colours (the colours belonging to pigments and materials) and that the perceived colours may, also, be a partitive synthesis, particularly in the case of vegetation and tiles coated walls.

Also, when recording the environmental colours, we must take in account all the perceptive factors related with colour interactions, as well as the geographic and atmospheric conditions and the chromatic variations along the different climatic seasons. With this purpose, the palette was tested along the seasons' changes to judge the chromatic alterations aroused from the different colours of the vegetation as well as day light variations and sky colours according to weather changes to evaluate the chromatic plan pertinence.

All these colours were recorded on forms and maps, previously designed and tested, in order to create a data base that will allow the identification of the town dominant colours.

In order to guarantee the scientific rigor on each quarter chromatic plan determination, we considered the dominant colours, proportionally represented, choosing colours to the urban furniture which should establish an adequate chromatic and luminosity contrast with the dominant colours and, also, respect the traditions, culture, identity and history of the quarter. These contrasts must be observed under the possible local illumination variations, in order to be sure that they accomplish efficiently their functions.

These dominant colours, and the contribute of the local history and culture, led to the establishment of a very comprehensive urban furniture chromatic plan, based on scientific rigor.

This plan, which shall be different for every settlement, must stand out from the environment, contributing for a better legibility and identification of these elements and, in the same way, become a city's area identification element which may be used in different supports and facilitate the orientation and wayfinding within the city.

Figure 4. Examples of a possible colour plan for Lisbon three different quarters. (Source: authors)

CONCLUSIONS

As it was stated, with this project we aim to define and underline the importance of colour application to urban furniture, taking in consideration that a pertinent chromatic plan can contribute to improve the space within cities, as the different city's areas become different one from each other. Simultaneously, the urban furniture elements utilization will be improved, as they become more visible, and they are converted into ergonomic factors, standing out from their background and contributing to improve the population inclusivity.

This project empirical phase was focused in some case studies, where we implemented the use of colour plans to urban furniture as a strategy to achieve a better and inclusive design project, ameliorating this equipment visibility and use, contributing to city quarters identification and users' orientation.

For the validation of this new methodology, three sessions were organized with differentiated focus groups: the first group brought together ten people of different ages and genres, representing all users of urban furniture; the second group had nine people over sixty-five years of age, since it was in this age group that the majority of users with locomotion

or vision difficulties were found, and who would most benefit from the inclusion factor that is intended to be achieved in this group investigation; the third group, also composed of nine people, grouped specialists with work developed in the reflection on colour or who usually have in their charge decisions about urbanization that may include the installation of urban furniture.

The group of experts included five architects, two of whom worked in the town planning area of the Lisbon City Hall. The remaining participants of this group were four designers, all of them familiar, and working usually, with the problematic of colour, in its different aspects.

The validation process consisted in the presentation of a slide presentation, where the different steps of the research were reported, the need for the new methodology and its development, and the chromatic options applied to each of the studied districts were justified. Next, an example film of the chromatic applications was presented to the urban furniture, from the different districts studied and from the consequent modifications therein.

A questionnaire of six questions on the main issues addressed in this research was also distributed to each participant. The response to this questionnaire allowed the manifestation of personal opinions that were later discussed orally. Their feedback and contribution was incorporated in the colour plans model, as a recognition of the importance of taking in account urban furniture chromatic programs in urban colour plans, as a way of inclusive design implementation and city zones differentiation.

We expect that this methodology, which establishes the importance of a pertinent and structured colour application to urban furniture, will contribute to the enlargement of the urban chromatic plans perspective, allowing them to become more holistic and comprehensive.

ACKNOWLEDGEMENTS

The present study was developed with the support of CIAUD – Research Centre in Architecture, Urbanism and Design, Lisbon School of Architecture, University of Lisbon, and FCT – Fundação para a Ciência e Tecnologia.

SS14.1. Revisiting rural-urban dichotomy for integrated regional development

1299 THE DEFINITIONAL AND ADMINISTRATIVE SHORTCOMINGS IN INDIA'S URBAN SPHERE: SOME ISSUES OF DIFFERENTIAL URBAN GOVERNANCE

Aritra Chakraborty

Assistant Professor, Department of Geography, Presidency University, Kolkata, email: myself.aritra@gmail.com

INTRODUCTION

India being a less developed country is predominantly rural. Its urban milieu has started to grow in a much feeble pace. As far as 2011 census is concerned, only 31.16 percent of Indians live in cities. This in absolute term is quite large and surpasses entire population of United States. In this scenario, the issues of urbanization need a deeper understanding. The country itself has no strict procedure for designating urban status to the city regions, and it is open to interpretation, which often leads to ambiguity. The paper tries to address these grey areas which are a cause of concern. Census data has been extensively used to demarcate these gaps and small primary survey has been done to understand the nature of the deep structure of the failure in governance. The nature of popular resentment in this process of politicization has been captured to some extent. The paper examines the need of redefinition and adoption of universal criteria in the context of the meaning of urban in the country. Therefore the principal objective of the paper is to pin point the shortcomings of the definition of urban in India. The categorization of the Census Towns and their varying nature of rural as well as urban governance from state to state have also been delved. Similarly studies were done to unearth the politics which acts behind the scene as a deep structure in these phenomena. The paper also suggests some of the alternative strategies pertaining to these issues of urban governance. This has become supreme important after the 74th 'Constitutional Amendment' in India and by inserting the 12th Schedule in the constitution ((D.D.Basu, 1960). This paper examines various alternative methods and suggests a newer dimension for analysis of this present problem. In the present milieu, the country's future lies in its urban areas. Thus in nutshell there has to have a uniform code of definition of the urban in the country. The gaps are enormous and could well trigger major mass revolt in the future when the question of municipal governance would emerge as a pivotal issue in whole of the nation. The paper addresses few of these issues of shortcomings and tries to present an alternative way to address each of these issues.

Keywords: census towns, urban definition, municipal governance

MUNICIPAL DEFINITION IN INDIA

In the country there are various sets of urban nomenclature. Indian towns are classified into two broad categories. A) Statutory Towns and B) Census Towns (Census of India, 2012). In case of statutory towns, the designation of a region being urban comes directly from the state government itself. It means that if a state government wants to make a rural area into an urban one, then simply with a government statute it can do so. Therefore any region can become urban as being designated by a competent authority. However the problem of the statutory towns is that it is of various types. These are being elaborated as follows:

- 1] Cantonment Boards: Mainly these are urban areas used for the defence purpose, mainly governed by the armed forces. Their laws and regulations are not similar to other municipal bodies, because in cantonment boards, the interference of the state is limited and elected members have restricted power which they are supposed to share with the defence personnel.
- 2] City Municipal Council/ Municipal Board/ Municipality/ Municipal Committee: These are the bulk of the urban areas of the country. These municipalities can be very small or very large in size class.
- 3] Municipal Corporation: These are the largest towns and cities of the country. All of these corporations ideally should have population more than one lack. Cities like New Delhi, Kolkata and Greater Mumbai fall in this category.
- 4] Notified Area/ Nagar Panchayat/ Township/Small Town Committee/New Towns/Industrial Townships/ Outgrowths: These are the smallest of the urban areas. Some of them are being designated as the future growth centres like notified areas, while others are at the fringe of rural and urban. Many such towns are directly governed by state governments or their various agencies and not through local level governance as is done for the municipalities or corporations.

On the other hand census towns are such towns which are not being designated by state governments as towns, but Indian census demarcate some of the rural areas as towns which satisfy certain clauses which are as follows: a]The population of such regions should be more than five thousand. b] At least seventy five percent of the main working population should be engaged in non agricultural activity. c] The region should be having a population density of more than 400 people per square kilometre. These towns are not being considered as urban by the government.

URBAN GOVERNANCE IN INDIA

India's urban governance achieved a new dimension when the 74th constitutional amendment was passed in the country. It gave local self governance to urban areas. Various new powers and functions were assigned to these local bodies like preparation of plans, implementations of schemes, urban planning and regulation, land use, roads, water supply, public health, slum, urban forestry and managing the waste materials (Kashyap, 1994). The 12th Schedule of Indian constitution has elaborated all the powers, functions and duties of such urban areas which are being differentiated from their rural counterparts (K.C.Sivaramakrishnan, 2000). Moreover these urban areas are subjected to separate electoral process at each five years interval managed by a state election commission and constitution of a separate state finance commission for managing their finances. Though these powers and functions are not universal for all these towns, especially the

powers enjoyed by the corporations have a bigger ambit than those of the small municipalities, and notified areas often are directly governed by the state government itself. Cantonment Boards functioning are completely different altogether. Census Towns are since considered to be rural areas; therefore they are not at all enjoying these urban privileges. It is under this differentiated power ambit, the main focus sets up in the definitional aspects of the urban areas in India. A closer look into this aspect would reveal that there are large discrepancies in delineating urban areas from a definitional point of view.

DEFINITIONAL AMBIGUITIES IN URBAN AREAS

As mentioned earlier that urban definition of various forms varies considerably from one state to another. In Indian context, defining urban area has become hegemony in itself. There is no hard and fast pan Indian norm of delineating urban civic body in different states of the country. The distinction between small and large civic bodies in context to governance is pretty vague. Different state government uses different parameters of denoting urban municipal status which are considered to be the 'Statutory Towns'. In this respect, politics play a major role in every level. Size of municipalities, notified areas, corporations and other entities are not at all clear. The situation becomes more complex by adding the notion of 'Census Towns' which are characteristically urban but in governance, still remain rural. All these just and not so just categorisation has added tremendous level of complexity as far as governance is concerned. All of these processes for categorization, delineation and giving municipal status are all depiction of power relation in India. In some states, rural areas are pretty larger and characteristically more urbane than so called municipalities in other states. All these issues are being juxtaposed to create a mesh of difficulties in governability and reflect discontent in popular aspirations.

Indian cities are classified as cities of various size classes. Class I towns are those which do have population more than 1 lac, class II ranges between fifty thousand up to one lac, class III between twenty thousand to fifty thousand, class IV between ten and twenty thousand, class V between five and ten thousand while class VI towns as areas below five thousand of population. It is thus evident that class VI towns can only be statutory towns and not the census towns. Through minute analysis of census data of 2011 reveals that there are large discrepancies in every size class of the cities with reference to their population in general. Municipal Corporations, which are supposed to be the largest urban areas and self sufficient to a greater extent as far as finances are concerned, has no definite population class. Though there are more than four hundred and fifty class I towns in India, only in twenty two of them, municipal corporation status was established. This would not have posed any problem, because corporation status may be given to a city which was big enough, meaning bigger than the biggest of towns, as well as self sufficient in finances. But giving corporation status is completely arbitrary in nature and based upon political situation. There are many towns in Chhattisgarh like Ambikapur, Raigarh and Rajnandgaon, as well as Gangtok in Sikkim, Panjim in Goa, Chandernagore in West Bengal and Shimla in Himachal Pradesh who have population less than two lac, enjoy the status of Municipal Corporation. On the other hand Jamshedpur in Jharkhand as well as Rajpur-Sonarpur and South Dum Dum both in West Bengal, though have population more than four lac, but still considered being only municipalities.

Class I towns, which are supposed to be the largest city class group, also does have thirty two towns which are neither Municipal Corporation nor not even municipalities. Among them twelve are either cantonment boards, town panchayat, Industrial Township or notified areas, which are essentially small towns or military establishment as far as their common definitional consensus is attached. Still at least twelve of them are as large as class I towns. The remaining twenty such towns are not statutory towns at all. All of these towns (mostly in the National Capital Region of Delhi like Karnal Nagar or Nangloi Jat) are all census towns. It means that as far as municipal affairs are concerned, these towns are actually rural or large villages in government statute. Similarly in Class II towns also there are twelve designated small towns (town panchayat, notified areas etc. or cantonment boards); or even further a large section of total forty nine census towns (Table 1). The case of census towns is really peculiar. There are one hundred and eleven class VI towns which have urban governance (mostly in Himachal Pradesh) by establishing any of the municipal forms. In general these are essentially rural areas, but still enjoy town status because of government's statutes (Table 2). On the other hand there are large census towns without municipal status. The best example being Noida in the outskirts of Delhi which has a population over six lac but as far as 2011 census is concerned, it was still a census town.

Another problem of definition arises when the central town is smaller but its suburbs and outgrowth becomes larger. At each census these outgrowth becomes more populated. This is true for the majority of the large cities in the country, but in most of those cases the central town is also large enough. For example in the case of Kolkata urban agglomeration, though there are thirty eight municipal bodies, but the largest one is the Kolkata Municipal Corporation itself. But the problem is mainly in the state of Kerala, where it is extremely difficult to differentiate towns from the villages. One town ends and another large village start without having any characteristic differences except the administrative boundary. Most of the Kerala towns are therefore large urban agglomerations with the central city remaining to be small. For example, Mallapuram Urban Agglomeration has a population over sixteen lacks but its principal city Malappuram is barely a class I town. Both Ponnani and Manjeri are pretty large than the Mallapuram town with respect to the population. Same is true for Kannur urban agglomeration. In fact many other Kerala urban agglomerations are very large like that in Kochi, Thiruvananthapuram, Kozhikode and Trissur where there are large suburbs which can easily be incorporated into central city, and large census towns are also present there. All these issues have complicated the urban scenario of the country. Therefore the definitional aspect of the Indian towns needs a total rephrasing for better governance.

DABGRAM AND BALLY: CASES OF LARGE CENSUS TOWNS

Number of census towns in between 2001 and 2011 has almost tripled and India's thirty percent urban growth occurred in these census towns in the last decade. Central Government has asked the states to raise their status to statutory towns because otherwise they are still considered to be rural areas in government records (K.C.Pradhan, 2013). Schemes like Atal Mission for Rejuvenation and Urban Transformation are encouraging such move. Still many such large census towns do exist in the country. In the state of West Bengal there are two Census Towns that have population over one lac each. One is Bally in Howrah District in the suburb of Kolkata and another is Dabgram in Jalpaiguri district in the outskirts of Siliguri Town in North Bengal. It is astonishing fact that a considerable section of the population (nearly about one third in each of these cases) in these two towns do not want to achieve municipal status. They still want to remain in the panchayat areas because once they become municipalities; they would have to shell out more tax in home mutation as well as have to pay more money for their house and property; which they are currently paying. Though they want the municipal services of roads and drainage, but still people do not want to get upgraded to the municipal status. Since vote bank politics is involved, thus government of the state does not want to change the status quo so abruptly. In case of Bally, the adjoining area was a separate Bally municipality, which has been amalgamated into Howrah Municipal Corporation and the planning as well as development in that area is pretty remarkable. People of the non municipal Bally region aspire to achieve that level of development for their region, but still they are not prepared to spend any extra money. They want these affairs by remaining in the panchayat areas itself. This is truer for the low income population, who constitute the majority section of people. A case for discussion is the garbage disposal. Since in that region, there are no municipal services, therefore garbage disposal gets a severe jolt. Poor people are not being affected by this environmental pollution because they are used to live with these issues, and they dispose heaps of garbage and live in those unhealthy surroundings. They are much more concerned about giving any little extra money for development purpose. However most of the people in those two towns want municipal services for their development and governance. Politics plays a bigger role in this context. Previous Left Front Government was sceptic to any change that was going to affect their vote bank in poor quarters, which were their solid vote banks. Similarly present Trinamool government is also playing a wait and watch game because these poor people are the one who are pivotal important in time of elections. In these cases, Government itself has to play an active role involving the local population. Neighbouring Dankuni has become a municipal town by such intervention. Otherwise these areas will continue to remain rural in government records and thus there will be discrepancies in governance.

CONCLUSION

In conclusion it can be said that there are discrepancies in the urban definition in the country. Thus for better governance reframing the urban issue is required. There should be universal laws applicable throughout the nation for designation of towns and cities. Following scheme can be applied:

1. After each census the status of the towns should be reconsidered. Their ward boundaries should be changed after perfect delimitation. Any outgrowth that has happened should be incorporated into the existing towns. All State Capitals as well as Class I Towns should get Corporation status. This also being reviewed after each census. They should be given more financial power so that they could become viable on their own without much depending on the state government.
2. Census Towns should be made statutory after each census. Either they should be incorporated into any existing towns, or they should be converted into separate municipal classes. These new towns also should get administrative and financial support from the government for their initial functioning.
3. Cantonment Boards should remain unchanged because they are important for defence purpose, but all the small towns of class III, IV and V should come under the category of Nagar or Town Panchayat, Notified Areas or Small Town Committees where direct control of the state government should be high enough for their future development. The category of Industrial Township also may come under this class.
4. All class II towns should get municipal status. They should remain considerably independent from state government's intervention. However their status also should be regulated after each census.
5. Class VI towns should not be considered as urban (except Cantonment Boards). Their urban status should be removed and they should be incorporated into Panchayat areas. Their main characteristics are much more similar to the rural areas, and not to the large cities of the country.

In the coming decades, India will become more and more urban in nature. Thus the pace of converting census towns as statutory towns should be done at a faster rate. Government has taken proper steps in this direction, but much more is still yet to be done in this regard.

1335 DICHOTOMY IN PLANNING APPROACHES FOR RURAL AND URBAN AREAS: A CRITICAL REVIEW

ABSTRACT

Recent discussions on growth trajectory of India are dominated by a narrative of increasing urbanization accounting for 31 percent of population in 2011; eventhough majority of the population and growth is concentrated in rural areas. Significant share of the urban growth is taking place in the periphery of large cities, commonly referred as peri-urban or outgrowth areas. Also, Census 2011 has witnessed a quantum jump in the number of ‘Census Towns’, which has more than doubled. Though a large number of such Census Towns are near big urban areas, there is a sizeable number located away from the influence of any city. This clearly shows that multiple forces are responsible for transforming these settlements. Current research has shown that the development of these areas is generally unplanned and haphazard. In order to facilitate planned growth and development of these settlements an overarching institutional framework and support legislations are extremely important. Extensive institutional mechanism already exists for planning and management of both urban and rural areas. However there are differences in terms of their powers and functions. Similarly, elaborate spatialplanning exercises are undertaken for urban areas, which are absent in case of rural areas. These inequalities in terms of planning exercise is because the existing legislations consider urban and rural as separate categories, and does not see them as units requiring planner’s attention. This paper is based on a review of institutional framework and planning legislations of four States (Gujarat, Rajasthan, West Bengal and Madhya Pradesh). Detailed comparative analysis of these two aspects was carried out in regards to both rural as well as urban areas. Planning documents of these States were also studied to understand the scope and contents of the plan. Analysis reveals that the current stringent dualistic approach in regards to planning practices is not relevant in current growth and development pattern of India. The paper argues that there is a need to adopt an integrated approach and overall planning framework. The units (urban and rural areas) need to be analyzed in reference to their larger context, which should be the basis to determine the planning approach.

1352 A HARD AND LONG ROAD TOWARDS URBAN-RURAL COOPERATION - INTER-MUNICIPAL LAND USE MANAGEMENT IN THE LEIPZIG-HALLE REGION (GERMANY)

ABSTRACT

In many urban-regional agglomerations in Germany land for larger commercial and industrial areas is short. The Leipzig-Halle region has been successful during the last 15 years in attracting large investments in the automotive, logistics and chemical sector. Meanwhile land for larger commercial and industrial areas in both cities is short, which might be a significant disadvantage for competitiveness in the future. At the same time many smaller municipalities are facing long-term vacancies among there fully developed commercial and industrial areas, which obviously – due to location, size or infrastructural development – do not meet the demand. These vacancies go along with severe fiscal constraints among these municipalities due to the absence of tax revenues and costs for maintaining infrastructure in these areas. An inter-municipal cooperation process has been initiated more than five years ago in order to 1) rise awareness for these issues, 2) clarify need and demand for commercial and industrial land, and 3) seek for inter-municipal options to develop new, commercial and industrial areas – and to redevelop long-term vacant areas into open space or agricultural land. This process has emerged as lengthy and difficult. Some of the smaller municipalities do not share the problem of the lack of commercial and industrial land. Others fear declining tax revenue or a political debate on the loss of jobs and declining competitiveness. Existing models such as an inter-municipal pool of commercial and industrial areas have proved not applicable so far due to lacking trust between municipalities. The paper will give insights into the genesis, successes and setbacks, and communication aspects of this urban-rural cooperation process towards integrated regional development.

1524 BRIDGING URBAN RURAL DICHOTOMY FOLLOWING BUILDING MATERIAL FLOWS OF URBANIZATION

Georg Schiller, Tamara Bimesmeier, Han Thuc Tran

ABSTRACT

Urbanization and land use change are two global, closely related processes. However, their analytical framework as well as the available literature were largely developed separately so far. While land use change directly triggered by urbanization is fully realized, indirect, remote land use implications are mostly disregarded. Concepts such as urban-rural-linkages point to the diverse and close links between city and distant places due to linkages and flows of people, goods and services. Building materials contribute most to the anthropogenic material flow in terms of quantity. These are predominantly bulk non-metallic minerals like sand and stones, which are usually characterized by high transport costs and thus short transport distances. These material flows are closely linked to urbanization processes – and they manifest physical links between the urban built environment and the environment outside the cities, where mining dumping activities cause land use changes. The paper will discuss elements of a conceptual approach of a regional material flow analysis used to analyze the exchange of building material flows between urban and rural areas. It will be considered, how to distinguish between urban and rural. Third correlations between urbanization parameters and the extraction and use of building minerals will be presented in order to justify the importance of the building material flow topic within the urbanization debate. Using the example of the case study of the Hanoi metropolitan region, material flow exchanges between urban and rural areas will be presented. Doing this we will not only concretize an excerpt of urban-rural linkages, but also show examples associated references to areas of spatial planning. In the concluding chapter we summarize essential aspects, arguments and conceptual elements with which the urban - rural dichotomy can be bridged towards an integrated regional understanding of planning

Keywords: Material Flow Analysis, Urbanization, Urban Rural Linkages, Integrated Planning, Land use planning, Urban planning

1. INTRODUCTION

Urbanization and land use change are two closely intertwined processes with far-reaching consequences. However, the analytical framework for these phenomena and processes as well as the available literature have been largely developed separately (Seto et al. 2012). While land use change directly triggered by urbanization is fully realized, indirect, remote land use implications are mostly disregarded. Concepts such as "Urban-Rural-Linkages" (UN Habitat III, 2015), Urban Land Teleconnections (Güneralp et al. 2013) or the urban hinterland concept (Billen et al. 2012) rightly point to the diverse and close links between the city and the city distant places due to flows and connections of people, goods and services (fig.1).

According to the SDG 11a "positive economic, social and environmental links between urban [...] and rural areas [should be supported] by strengthening national and regional development" (unhabitat.org). With regard to physical flows, attention has focused on food energy issues so far (Fritsche et al. 2015). However, significant mass flows are non-metallic minerals (COM 2018) and 1/3 of the total Domestic Material Consumption (DMC) consists of bulk non-metallic building materials like stones, sand and soil (fig. 2). Generally these materials are traded within regional markets (low economic values in terms of weight and the high costs of transportation; Pacheco-Torgal 2014). This results in close physical urban and rural hinterland linkages.

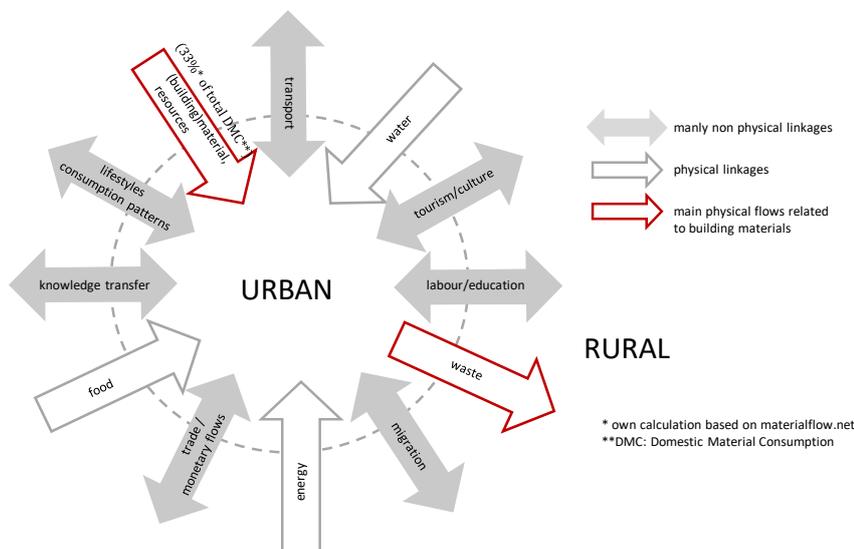

Fig. 1: Exchange relations of urban-land metabolism (altered image according to Repp et al. 2012)

UN-policy papers (e.g. UN Habitat and SDG) have addressed this issue globally and so in national policies e.g. of Vietnam (Urban Green Growth strategy, New Planning Law). The planning law is aiming to integrate Environmental Protection,

Construction Planning and Urban Planning in order to achieve national socio-economic development goals. At the city level, the main focus is on urban green growth strategies. The National Strategy for Green Growth and Action Plan for Urban Green Growth by 2030 provide indexes to define activities also towards urban green growth, but without considering of resource efficiency or building material consumption issues. The most serious gap, however, is the existing lack of implementation-oriented framework to embed urban-rural linkages in planning and thus to foster measures towards a greener urbanization.

The paper will discuss elements of a conceptual approach of a regional material flow analysis used to analyze the exchange of building material flows between urban and rural areas. It will be considered, how to distinguish between urban and rural. Third correlations between urbanization parameters and the extraction and use of building minerals will be presented in order to justify the importance of the building material flow topic within the urbanization debate. Using the example of the case study of the Hanoi metropolitan region, material flow exchanges between urban and rural areas will be presented. Doing this we will not only concretize an excerpt of urban-rural linkages, but also show examples associated references to areas of spatial planning. In the concluding chapter we summarize essential aspects, arguments and conceptual elements with which the urban - rural dichotomy can be bridged towards an integrated regional understanding of planning.

2 CONCEPTUAL APPROACH OF A REGIONAL MATERIAL FLOW ANALYSIS

There is a lot of existing knowledge on concepts suitable to analyze such physical flows induced by built environment (like buildings and infrastructure) using MFA (see e.g. Augiseau et al. 2016, Kennedy 2016, Schiller et al. 2017a), but urban-rural linkages aspects are only poor addressed so far. Exceptions are e.g. Binstock & Carter-Witney (2011) and Wernstedt 2000 who address the impact of urban growth on more distant land use conflicts following a regional concept. However, here too, only direct conflicts of use between settlement areas and extraction areas are considered. Schiller (2015), on the other hand, presents an approach that takes into account the indirect effects of construction on land use in the surrounding area. He takes into account the entire value chain of building materials, from the extraction of raw materials, their processing into building materials, their use in the construction of buildings and infrastructure to their disposal in landfills. This is where the concept outlined in figure 2 comes in.

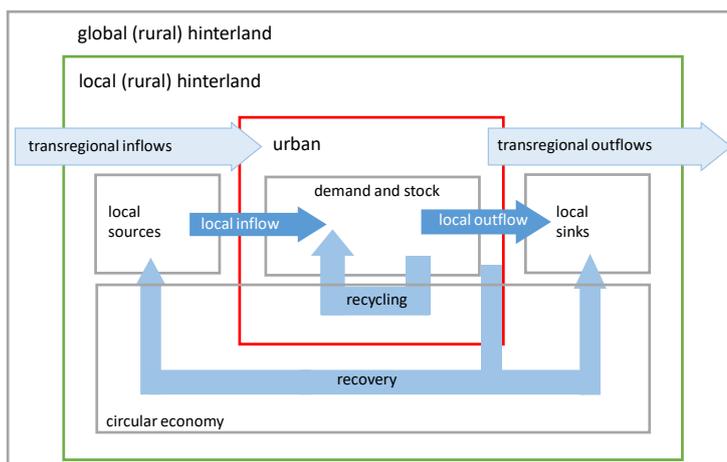

Fig. 2: concept of a regional MFA for analyzing bulk mineral building materials (own image)

According to Cramer (2017) “urban” is considered to be a material stock and a trigger for building material flows. At least in Germany, the majority of these stocks and flows are bulk non-metallic mineral building materials (Schiller et al. 2017a). It can be assumed, that this is true for urban structures worldwide. These materials are mainly taken from the region – the local (rural) hinterland. (local inflows), where also dumping sites are located (local outflows). Some of the outflows will be recovered and used for other technical purposes outside the built environment (e.g. recultivation of post mining areas or for the construction of necessary technical structures on landfills). The recycling flow describes materials that are circulated within the built environment. Recycling, recovery and disposal are key elements of circular economy. The “global (rural) hinterland” describes areas from which non-regionally traded material flows originate⁵¹² or are disposed.

3 HOW TO DEFINE URBAN AND RURAL?

Emerging and developing countries in particular are experiencing a huge surge in urbanisation (WBGU 2016). Definitions of urbanisation refer mainly to the transformation process of the rural population towards urban standards, which can be seen as an increase in the urban population, the spread of urban infrastructural development and changes in lifestyles of the rural population (Gu et al. 2012). This transformation is frequently fostered by urbanization strategies and approaches of “urban upgrading”.

⁵¹² e.g. in the case of resource scarcity - Singapore imports large quantities of sand, for example

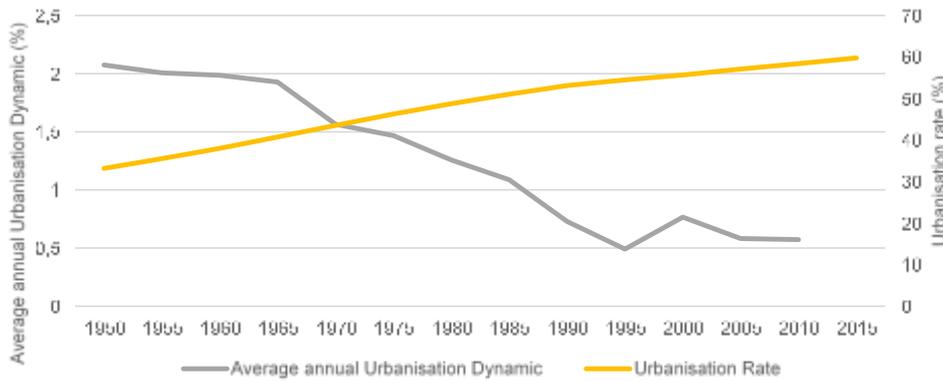

Fig. 3 Urbanization rate and dynamic from 1950 to 2015 – worldwide (own image using data from UN 2015a)

Although urbanisation is a multi-layered phenomenon of transformation, it is statistically recorded with the help of simple indicators defining “urban” and “rural” and expressed as “urbanization rate” or “urbanisation dynamic” (annual change in urbanisation rate) (fig. 3).

Akkoyunlu (2013) notes that most of the world’s nations use four different approaches when defining “urban centres”. The first option provides for a threshold value for the population according to which it is decided whether an area is urban or not. In the second option, other threshold values are additionally taken into account. The most common are those of population density and the proportion of the population employed in agriculture. The third definition refers to the administrative or political status of a municipality, through which conclusions can be drawn about urbanity. In detail, definitions of urban are quite inhomogeneous and hardly to be compared internationally (fig. 4).

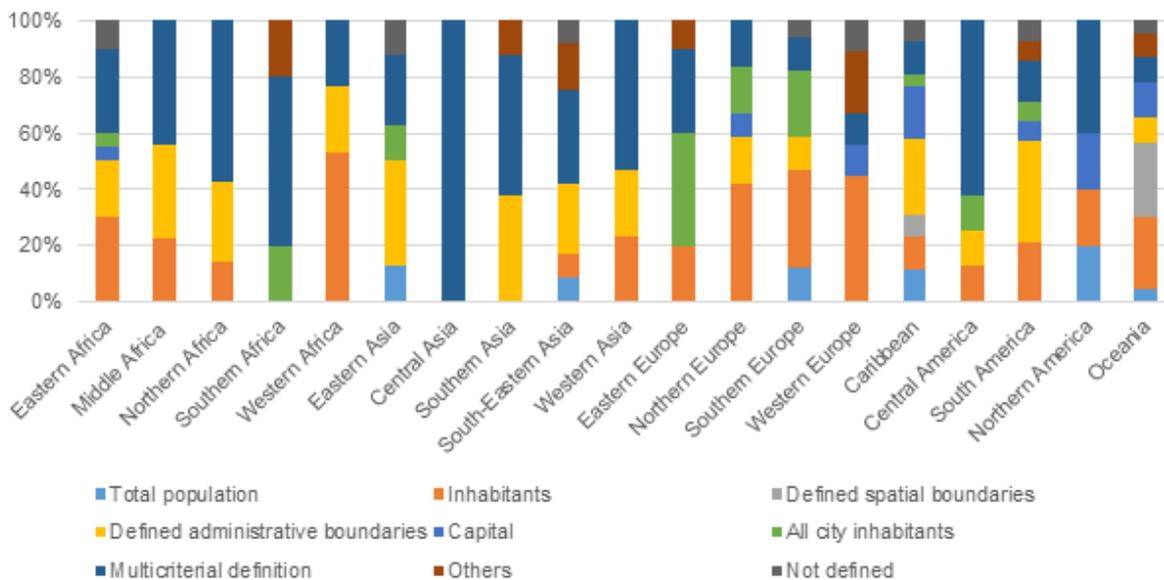

Fig. 4 Indicators for the definition of “urban” according to earth regions (own image using data from UN 2015b)

In addition to the difficulty of finding suitable indicators for the definition of “urban”, there is a problem of finding adequate spatial boundaries in order to record urbanity statistically. The authors of the World Urbanization Prospect (UN 2015b) point out that the setting of spatial city boundaries often cannot cope with population growth and note that there are basically three different approaches, which can be described as “City proper”, “Metropolitan Area”, “Urban Agglomeration” approach. In high dynamic urban regions a differentiation by administrative boundaries (“City Proper”) is problematic, since the entire urban area often extends too quickly to the surrounding area of the city. Whereas, in the “Urban Agglomeration” approach the inhabitants of the core city, suburbs and continuously populated commuter areas are counted as urban. In this way, large urban agglomerations often comprise several cities that are administratively separate but functionally interconnected. In the “Metropolitan Area” approach, the boundaries are defined according to the degree of economic and social integration of neighbouring areas. In addition to the city itself, a metropolitan region includes both the surrounding area with urban density and some additional low-density areas adjacent to and connected to the city (e.g. by frequent transport, road connections or commuting).

In the ESPON Report (2005), the authors come to the radical conclusion that the distinction between urban and rural is increasingly dependent on people's perceptions and cannot be covered by indicators that are defined from outside.

Research projects on material flow analyses in the field of urban metabolism usually consider when defining the city (and therewith urban by implication). The main focus of this research is on the built environment. Distinctions between urban and rural areas are made in particular with regard to the differentiation of building structures. In this respect, administrative definitions on the one hand and structural building features on the other are the main distinguishing features here (e.g. Curriea et al. 2017, Tanikawa et al. 2015, Condeixa et al. 2017). Schiller et al. (2017c) considered regional types in order to distinguish between urban and rural settings. The types where used to describe different

development dynamics of built environment and therewith to investigate recycling loops within these regions taking into account the potential demand and supply of secondary materials. The demarcation of the region types was based on settlement structural features, e.g. settlement density, as well as on features reflecting the population dynamics. However, links between the region type categories were not examined.

4. URBANIZATION AND BUILDING MATERIALS

The link between urbanization and the demand for building materials is repeatedly pointed out (e.g. Cramer 2017, Fritsche et al. 2015), but never quantified in a general, but has never been explicit quantified. The central question is which parameters should be used to measure urbanization. Urbanization is usually expressed in terms of the rate of urbanization. Capital 3 also presents urbanization dynamics as a further parameter. Figure 5 shows the relationship between extraction of construction minerals and the dynamics of urbanization (5a) or the annual rate of urbanization (5b), taken all countries worldwide into account marked by positive urbanization rates (taken from UN 2015b). The countries considered were combined into groups with clustered values for urbanization dynamics and urbanization rates. Within the groups, average values were calculated for the extracted quantities of tree minerals from all assigned country values, using data from Dittrich (2014).

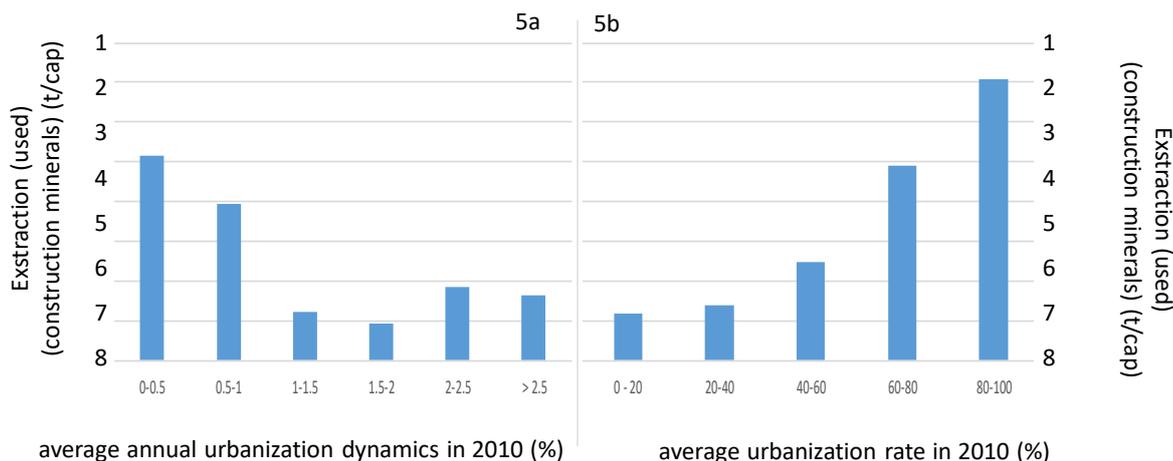

Fig. 5 Extracted and used construction minerals and urbanization (own image using data from UN 2015b and Dittrich 2014)

The figures show that there is a connection between urbanisation and the consumption of building materials. Contrary to expectations, it is not the dynamic of urbanization that correlates positively, but the rate of urbanization.

5. URBAN RURAL LINKAGES URBANIZATION CAUSED BY BUILDING MATERIAL FLOWS – A CASE STUDY
