The case study introduced here refers to a research dealing with the management of mineral resource extraction in Hoa Binh Province, that is a hinterland province of the Metropolitan area of Hanoi, the capital of Vietnam (Müller et al. 2016). In this context, an MFA was used to calculate the future demand for building materials by the urban metropolis and to describe the framework conditions for the design of mining in the hinterland. The case study presented is essentially based on a publication by Bimesmeier and Schiller (2017).

A bottom up MFA approach was applied. This is based on an inductive principle. Buildings and infrastructures are described with regard to their material composition. On this basis, material composition indicators (MCI) for typical buildings and infrastructure are defined (fig. 6). These are multiplied by construction activity parameters (e.g. m² living space) to obtain information on the total building material requirements of a region.

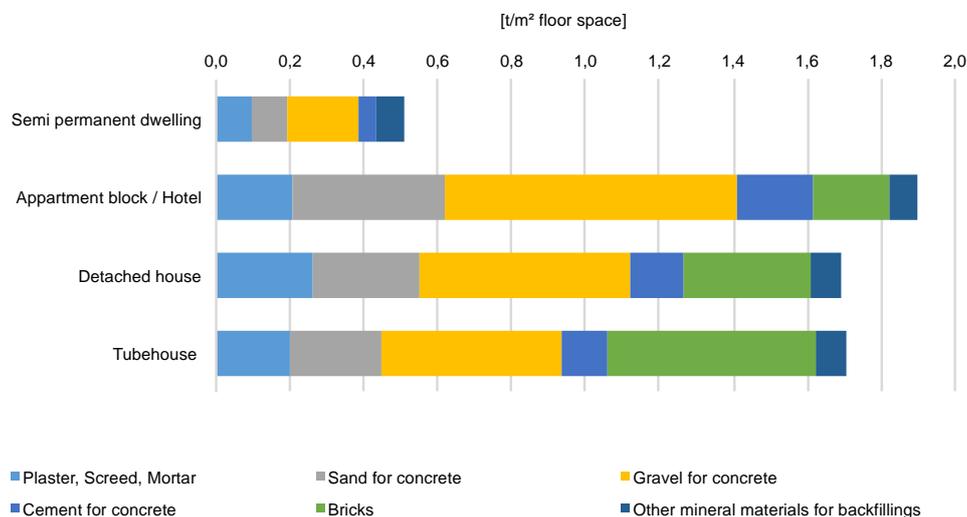

Fig. 6 Compositions of mineral building materials in typical building types in Vietnam based on metric tons per floor space (source: Bimesmeier and Schiller 2017)

Using these parameters, correspondingly also related to roads, and information on the planned development of floor space in buildings and estimates of road construction activity, the future demand for construction materials was calculated. This was done separately for Hanoi and Hoa Binh (figure 7). Assumed that each neighboring province of Hanoi and Hanoi itself covers 1/8 of its demand for mineral building, it can be estimated how much material Hoa Binh should provide annually to meet the demand (sum of black and blue columns). On the other hand, there is a supply of raw materials that is already secured by licenses.

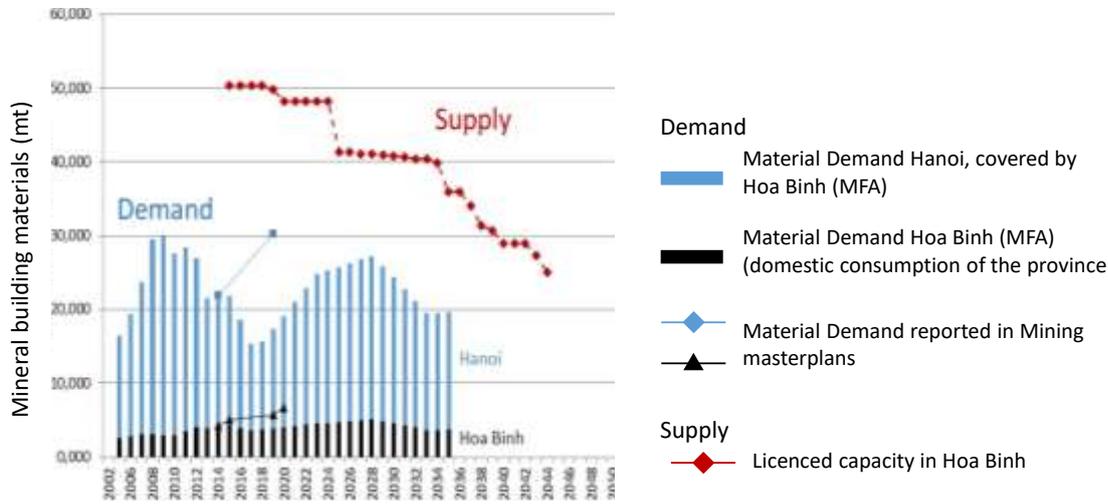

Fig. 7 Annual demand and supply of mineral building materials due to construction activities in the urbanization context (modified according Bimesmeier and Schiller 2017)

6. TOWARDS SUSTAINABLE URBAN REGIONS

The explanations in chapter 4 suggest that urbanization have a significant influence on the demand for building materials. It should be noted that it is not the increase in the rate of urbanization itself (the urbanization dynamic) that is decisive, but the degree of urbanization achieved. The hypothesis is that the largest specific consumption of building materials takes place within urban areas (not during the transformation process). Urban planning determines the urban layout as well as the urban equipment with infrastructures, and thus also the framework conditions for construction planning. Construction planning takes place within this framework. Here the construction method used in buildings and structures is determined. Depending on this, it is decided which materials are required and whether materials can be replaced by other, more efficient ones if necessary. All this has an impact on land and resource use in the hinterland. If one wants to counteract the increasing shortage of resources in the hinterland through settlement planning approaches, it is firstly necessary to know about the planning scope of action; secondly, a concept is needed with which effects on the hinterland can be represented. Due to the fact, that urban and regional planning issues are addressed, the most important indicator that is worth to be addressed is “land use”

A prominent concept addressing such “translating-issues” between resource consumption and land use figures is provided in the 90ies last century with the Ecological Footprint concept EF by Wackernagel and Rees (1996). It is an alternative idea of interpreting land as a basic resource to sustain our human needs. In the measurement of land area needed for different consumption categories, human impact can be visualised as the footprint based on the ecosystems that support us. In other words, it presents the resources removed from ecosystem to supply human needs, noting that the ecosystems are different for different areas as it depends on bio capacity of each area. However, with regard to building materials, EF is mainly focusing on energy and carbon footprint aspects associated with the manufacturing process (Bastianoni, Galli et al. 2006, Kissinger, Sussman et al. 2013, Sinha, Lennartsson et al. 2016). In addition, the built-up land footprint is calculated based on the area of land covered by built environment without mentioning the mining area for resource extraction (Global Footprint Network undated). Beyond this, however, there are certainly works that take into account land degraded by the mining process (using the example of copper mining) and land needed for waste disposal using the EF concept (Chicca, Vale et al. 2018). However, only the area directly used (extraction area) is taken into account although significantly larger areas are affected, which have to be taken into consideration (e.g. landscape consumption with a negative impact on tourism or other areal impacts). In addition to the quantitative measurement of the direct land use effect, methods must therefore be integrated that identify qualitative effects beyond these intervention areas. Possible access to this is offered by the ecosystem services approach.

Building material flows affect very different planning disciplines in urban-rural regions. This can only be managed sustainably in a holistic, comprehensive approach that overcomes urban-rural dichotomy. At first, it is of secondary importance how urban is separated from rural. Firstly, it is crucial to establish links with the areas of responsibility of the planning authorities and to work towards integrated planning approaches that are of benefit to all areas to be integrated. Thus, in terms of application oriented research, the definition of urban and rural should follow the local definitions.

In terms of basic research, the urban rural linkage approach should be used in a more generalized way as an analytical framework. The still existing lack of knowledge about correlations between urbanization and land changes in the hinterland in terms of resource consumption, in particular for building materials has to be addressed systematically. To highlight importance of the urban-rural linkages in policy papers (e.g. UN Habitat and Sustainable Development Goals (SDG)) is only the first step. The next step needed is a frame-work than an implementation-oriented support to embed urban-rural linkages in land-use and urban planning. MFA following the concept introduced in this paper has the potential to define entry points for that. These can be all the more effective and convincing if it is possible to link up with other planning discussions in the urban-rural context, such as linking infrastructure and settlement planning.

ABSTRACT

Principally, urbanisation is diffusion of the influence of urban centres to rural hinterland via peri-urban. Developing countries like India are witnessing an unparalleled movement of population and activities in the urban areas and thus, the existing cities have reached implausible dimensions of expansion. The fast growing and globalising Indian economy has produced an urban crisis marked by inadequate infrastructure and sharp socioeconomic divisions. India's urban growth is so dramatic that it unfailingly outshines every planner's vision. Under this globalization impulse, the cities are shaping new forms of urban growth. In most of the Indian cities, urban growth appears to have taken the form of urban sprawl. It appears as an unplanned and disordered pattern in the peri-urban areas, possibly emerged with the location of large infrastructure projects like information technology parks, ring-roads, airports, special economic zones, and real estate ventures. These peri-urban regions are the most vital as these acts as a litmus test of change and transition, not just locally at the interface of urban and rural, but in the shape of the whole city-region, or the 'rural-urban-region'. Among all the innumerable causes of urban sprawl, this research focuses on airports as, in India airports are massive multi-use occupiers of peri-urban land and have always been a reason for the expansion of urban areas.

Airports may be understood as a reflection of their respective cities. Due to three key developments in aviation sector – commercialization, privatization, and globalization – the economics of airports changed dramatically. Airports are actually reshaping physical, political, and societal landscapes. Today, airport is a relational socio-spatial process within the greater process of globalised urbanisation. The growth of air traffic has major implications for their immediate surroundings, as well as for the growth of the city-region. These dynamics produce externally well-connected and uneven nodes within global city-regions. As a result, the relationship between city and airport is undergoing modification, and airports have become an integral part of regional planning. Thus, airport is more than simply a large-scale piece of infrastructure on the urban periphery; and a better understanding of development and planning at the city-airport interface is needed. Given this large and increasing degree of interconnection, the challenge of planning and governing a socially and spatially cohesive yet globally accessible form of development is an important area of research. This research justifies airport-oriented development (AOD) as a potential source of adhesion and driver of growth in making more efficient urban-rural systems. It reviews the phenomenon of AOD in Indian scenario and examines the different models (Airport Corridor, Aerotropolis, Airea, Airport City, Airfront, Decoplex). It illustrates how institutional contexts, mainly intergovernmental relationships, and specific policy instruments give rise to distinct patterns of (AOD). Taking Tier-II Indian cities as test bed for reforms, the research attempts to propose innovative policies for coordinated and cooperative infrastructure moving away from the current inert and isolated decision making processes in the urban-rural dichotomy.

Keywords: Revisiting rural-urban dichotomy for integrated regional development; Transforming Metropolitan Regions: Ideas and Examples; Regional and Urban Policy and Governance

1 INTRODUCTION

With regards to urban-rural governance and planning concerning airports, its surroundings, and the greater region around, this paper aims to contribute to understand the geography of urban-rural regions by connecting regional planning and airport development to the literature on urbanisation within the context of global cities research. The study attempts to review the scope of airport-oriented development as a possible potential source of adhesion and driver of growth in making more efficient urban-rural systems. The research is divided among various sections where Section 0 discusses about issues related to urbanisation and sprawl and the linkage between sprawl and airports. Section 0 provides the relationship between airports and planning, justifies the need of airport-oriented development, and elaborates the concept in detail. Section 0 lists out the prevailing models of AOD along with their brief descriptions. A rational criticism is also provided in Section 0. The final conclusion of the study is provided in Section 0.

1.1 Urbanisation and Sprawl

Urbanisation as a phenomenon has existed since long and the rate of urbanisation is one of the highest in developing nations like India. By 2050, India will become world's most populous country and almost 50% of its population will live in cities (Brar, et al., 2014). By the year 2030, 590 million people will live in urban areas (Figure 132). Hence, there will be a huge demand for more efficient urban systems. While the Indian government is boosting for smart cities, the reality is a web of rising inequalities and powerless local authorities. The socio-spatial structure and hierarchy in the ever-expanding cities of India is growing every day. It has produced an urban crisis characterized by the deficiency of suitable infrastructure and growth management. "India's urban growth is so dramatic that it consistently outstrips even the most perspicacious planner's vision for it" (Roy, 2009).

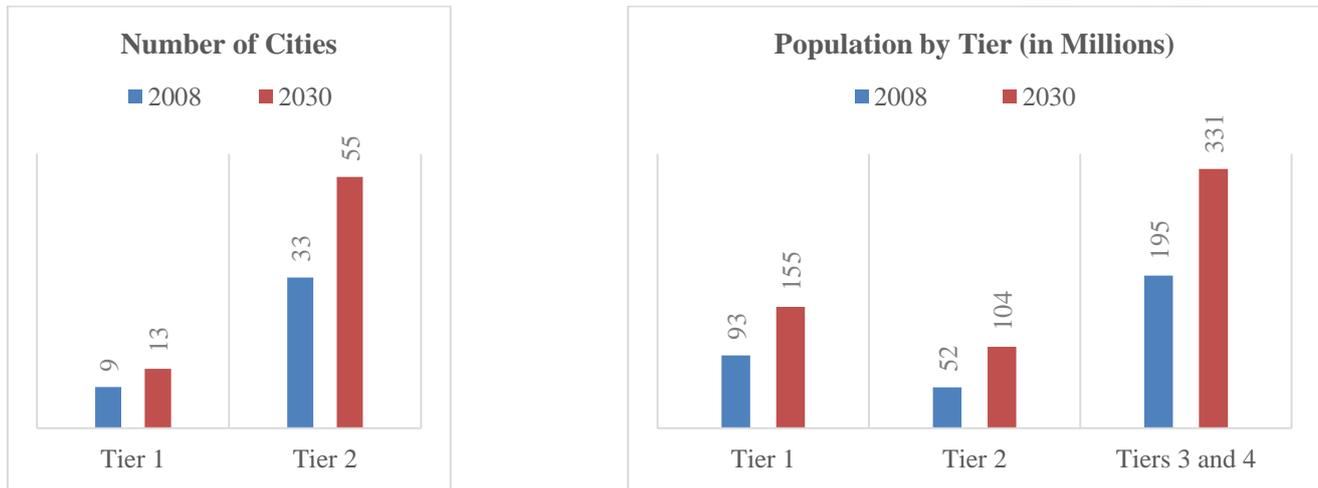

Figure 132: India's urban growth (2008 and 2030) (McKinsey Global Institute, 2010)

Urbanisation also denotes a diffusion of the influence of urban centres to rural hinterland in the form of urban sprawl. "Urban sprawl is a land use pattern with low levels of eight distinct dimensions – density, continuity, concentration, clustering, centrality, nuclearity, mixed uses, and proximity" (Glaster, et al., 2001). However, recently, it has become fashionable to compare sprawl with dynamic evolution of the synchronized spatial growth and urban areas scattering (Zeng, et al., 2015). Thus, the characterization and modelling of urban sprawl is an important activity, especially in countries like India with rapid urbanization (Habibi & Asadi, 2011).

There is also a big debate for what is formal and what is informal in India's urban planning. Roy (2009) states that "Informality does not lie beyond planning; rather it is planning that inscribes the informal by designating some activities as authorized and others as unauthorized". On the contrary, India's planning regime is itself a non-formalised unit, in a constant state of ambiguity and deregulation (Ambarwati, et al., 2014). Correspondingly, a new planning regime is in horizon in India, a shift from state-run set-up is to privately built and/ or managed infrastructure (Roy, 2009). Thus, the planning of Indian cities cannot be limited to forecasting and management of growth only. In its place, it should be the management of resources, like land, through dynamic processes of informality. Where the use, purpose, and ownership of land cannot be rigid and it is impossible to map with any set of regulations (Varghese, 2016). In this context, there is an urgent need for a more dynamic and decisive planning system to 'future-proof' Indian cities (OECD-CDRF, 2011).

Sprawl is contradictory with the characteristics and the projected idea of Indian city that stresses more on the concept of 'compact city'. But, India urban agglomerations are 'distributed' in shape. There is a diverse pool of small, medium, large, and very large cities spread all over the country. Reports from McKinsey (2010) Institute suggest that India should carry on with a distributed model of urbanisation but with intensive approaches to its different tiers of cities and foster the connectivity between these cities. Thus, narratives like 'connectivity' and 'shape' have a great role in urban development and it becomes vital to understand and enquire that which actors may employ both these narratives to help in positioning the urban areas in global economy (Coventz & Thierstein, 2014).

1.2 Sprawl and Airports

The spatial pattern of the urban growth is not easy to decipher as each city-region has its own unique array and most of the urban form for Indian cities emerged unplanned. There are certain questions to be pondered upon concerning the channelization of this sprawl like where will be the future growth centres, how will be the densities distributed, which urban form is likely to optimize deployment of investment, how to best link spaces via transportation networks and hubs, etc. (Brar, et al., 2014). To answer these question, the cause of sprawl needs to be determined and among the innumerable causes of urban sprawl, the paper focuses on airport infrastructure. This is because, in India, airports have always been a major reason for the expansion of cities. They attract certain land uses to their vicinity while discourage others. Existing neighbouring land uses affects airport's ability to expand. Extending airports, building new ones, and decentralizing airports may compromise the purity and sustainability of the peri-urban region.

Planned development in and around the airport is a relatively newer perception in India. With time it is felt that the airport can no longer be isolated from its surroundings. Now airport has become more than just a hub for human movement and its immediate subsidiaries. It is actually a driver of business location, urban economic growth, and global economic integration (Conway, 1993). Walker & Baker (2010) rightly says that an airport city is the ultimate transit oriented development (TOD) strategy, and thus, airport-centric or airport-oriented development (AOD) comes into picture (Freestone & Baker, 2011). To keep up with economic growth, increasing number of passengers, and expanding cargo volumes, many airports round the globe are already extending their reach and impact beyond the traditional airport boundaries and developing significant non-aeronautical commercial facilities, services, and revenues. Similarly, Indian airports are also gradually transforming from mere air transport infrastructure to multimodal multi-functional enterprises and are generating substantial commercial development.

In nutshell, airport oriented development has two prominent effects – urban sprawl at regional level and economic development at global level (Erro! A origem da referência não foi encontrada.). Airport fuelled growth is touted as an innovative urban development solution but little concrete research has been done on the airport-oriented development for Indian cities. This is because the planning literature has not yet truly addressed the concepts and models of airport-oriented development (Freestone & Baker, 2011). This paper attempts to review the literature based on airports and urban planning and airport-oriented development models with special emphasis to Indian scenario.

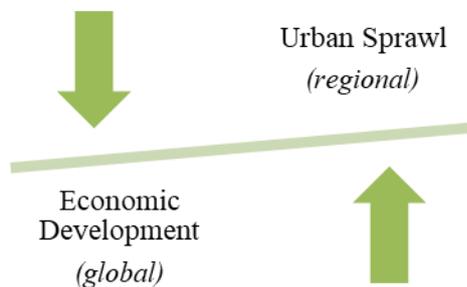

Figure 2: Prominent Impacts of AOD

2 AIRPORT-ORIENTED DEVELOPMENT

In most of the world, urban growth appears to be in the form of sprawl. The catalyst for this unplanned and disordered patterns are generally the location of large infrastructure projects such as airports, highways, industries, etc. (Lovera, 2015). Similarly, Indian megacities are also witnessing significant changes in their peri-urban regions due to the location of projects like information technology (IT) parks, ring-roads, airports, special economic zones (SEZs), and other real estate ventures (Ramachandraiah, 2014). This study specifically focusses on the role of airports and their better management.

2.1 Airports and Planning

It is strongly believed that airport-oriented development could cure the malaise of haphazard planning and boost the economy of a region. If properly designed, an airport can actually brand the city or region globally. Regional economy has always been a key factor for the growth in air service demand. And vice-versa also holds true, as air transportation itself can be a strategic cause and facilitator of a region’s economic growth. Air services have a substantial positive effect on the growth of a region and its magnitude varies by region’s size and industrial specialization (Blonigen & Cristea, 2012). India sees a great potential in aviation sector. The annual growth rate for revenue-passenger-kilometres in India is 19.2% for the year 2014-15 which is the highest in the world (IATA Economics, 2015). Some of the airports in India like New Delhi and Hyderabad airport are consecutively getting high rankings in the world in their categories. The contribution of aviation sector in Indian economy is creditable as it contributes INR 330 billion (0.5%) to the national GDP annually (Oxford Economics, 2011). Besides the direct contribution, major catalytic impacts caused by airports on its region include generation and improvement of regional economic competitiveness and augmentation of the accessibility of the region. It also has influences on the social development and has patterns of spatial effects (Halpern & Bråthen, 2011). However, a well-functioning airport and growth in passengers is one thing but the overall growth of the region is another.

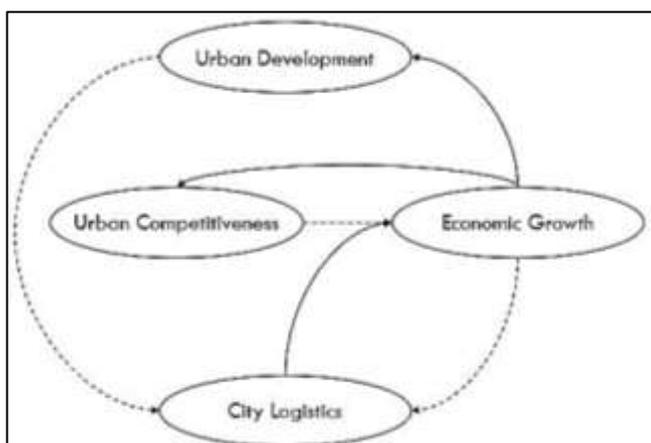

Figure 133: Relationship between City Logistics and Urban Economic Development (Boloukian & Siegmann, 2016)

The rigorous airport-oriented development is a comparatively newer spatial phenomenon around the world. Along with the growth in air traffic, the related commercial activities and the subsequent spatial development clusters around its immediate settings, and at times, in the further locations linked efficiently to the airport (Zepezauer, 2012). As a consequence, airport zones have started attracting urban central functions and have attracted investments and subject to intensified spatial development as shown in Figure 133. The relationship between airport and planning has always been argumentative because of the concentration and localisation of the negative impacts. But the wave of globalisation, non-aeronautical revenues, and deregulation of the industry has unleashed new economic potential forces (Freestone &

Baker, 2010). This has transformed the scale of planning from just the airport towards the broader region (Kasioumi, 2015).

Significant amount of research has been done till date to identify and examine the determinants of regional development but the contribution of aviation sector in it is still sparsely explored. The interaction between airport infrastructure and spatial planning remains a crucial area to explore. Spatial impacts of airports at local, corridor, and regional level and their assessment is critical (Federal Office for Spatial Development, 2003). Today's airport presents an almost insoluble planning puzzle in its nexus of benefits and costs over varied spatial scales. Particularly, the combination of locally concentrated dis-benefits and diffused regional benefits is unique to airports. Therefore, the larger airport region is "recognised as an increasingly unsettled space caught in the crossfire of different ambitions and is posing considerable challenges for regional planning governance" (Freestone & Baker, 2010). This becomes more interesting in Indian scenario where the airport design and planning is controlled by the Airports Authority of India, a public sector undertaking and owned by the union government of India. While the surroundings are managed by the local development authorities, municipalities and village *panchayats*.

2.2 Need for AOD

Airports may often be understood as a reflection of their respective cities. Indian airport industry has seen a tremendous growth in the last few years owing to three key developments in the sector – commercialisation, privatisation, and globalisation. The economics in and around airports have changed dramatically since then. The internal airport management, which was more of welfare oriented, is now focussing on operational efficiency along with significant revolution in the relationship with other airports. With the change from the point-to-point to the hub-and-spoke system, today airlines offer more connections, making flying affordable and more attractive (Zepezauer, 2012). Today, airport is more of a relational socio-spatial development within the greater course of 'globalised urbanisation' (Dey & Grappi, 2015). The growth of air traffic has major implications for their immediate surroundings, as well as for the growth of the city-region. The dynamics around airports produce externally well-connected but uneven nodes within the potential global city-regions.

As a result, simultaneously, the relationship between city and airport underwent a modification, and airports became an important factor for urban planning (Hesse & Rodrigue, 2006). An emphasis on airports has the latent power to reveal the complex and multifaceted dynamics between the urban-global contexts (McDonough, 2015). Airport is both, an object and a catalyst in the process of 'globalised urbanisation', rather than the outcome of a binary 'local' or 'global' influence (Cidell, 2004). Thus, airport is more than simply a large-scale piece of infrastructure on the urban periphery; and a better understanding of development and planning at the city-airport interface is needed. Given this large and increasing degree of interconnection, the challenge of planning and governing a socially and spatially cohesive yet globally accessible form of development is important (Wijk et al, 2014).

2.3 AOD Concept

The concept of airport-oriented development has evolved gradually but still has not found a common universal definition or specifications. A number of researches are being carried out for the enhancement of the whole notion. Kasarda (2010) refers to airport-oriented development as bringing together airport planning, urban-regional planning, and economic development in a synergistic fashion. Development of non-aviation activities and transformation of airport into places of innovation, entertainment, relaxation, and business blends the airport into the fabric of cities, and 'airports in cities' transforms into city-airports (Cyrek & Weltrowska, 2013). Certain desirable conditions allow the formation of areas like large industrial areas with a high concentration of commercial activities in the proximity of airports (Flores-Fillol & Nicolini, 2006). The planned industry around the airport can be divided into three broad layers – core, dependent, and related as in Figure 134.

AOD planning principles generate 'economies of speed' and boost aviation- facilitated trade activities by improving air connectivity (Kasarda & Appold, 2014). 'Aero-regionalism' is another related concept conceived by Addie (2014). It explores the relationship among globalization, airport industry and city-regionalism. It further relates the infrastructural and political integration of airports with the possibly varying local institutional and policy frameworks. A number of business models exists and can be examined for the airport cities for formulating regional development strategies (Appold & Kasarda, 2011). The key factors and trends for the conceptualization of AOD models may vary from region to region and can be analysed accordingly (Wang, et al., 2011). A successful airport-oriented development requires co-ordinated investments and strategies. It may have various types of governance structures namely, market-driven, hierarchy-driven, and network-driven and their hybrids too (Appold & Kasarda, 2009).

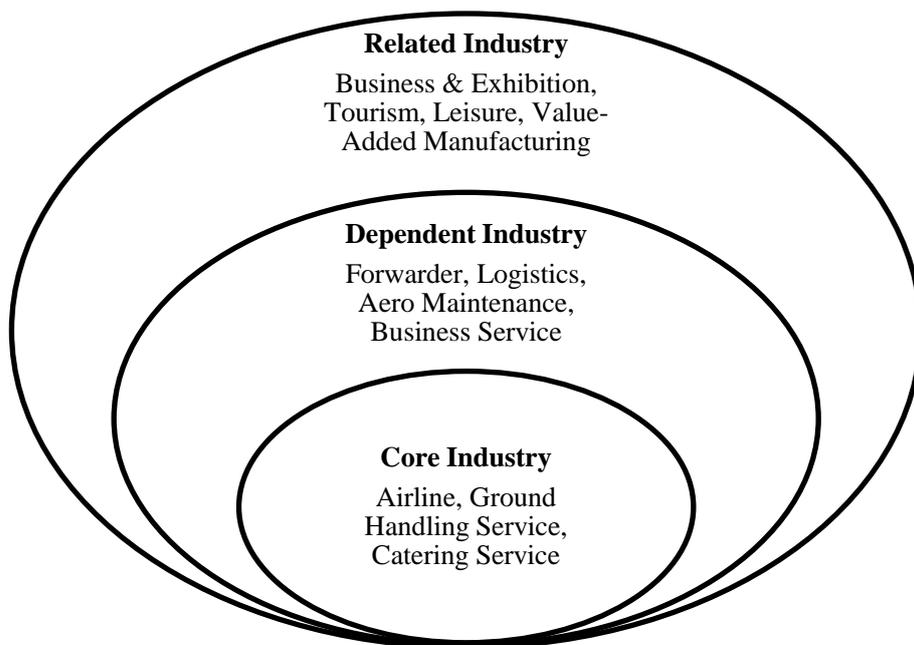

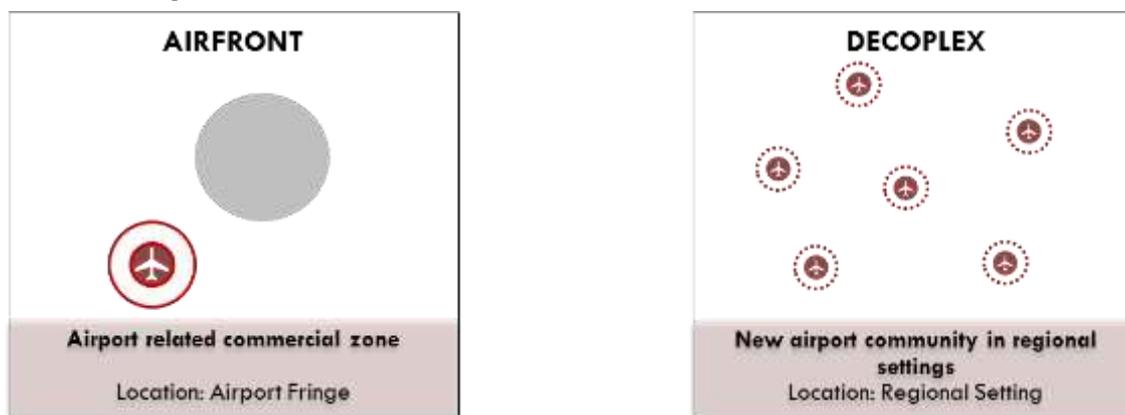

Figure 134: Spatial zoning of airport-oriented industries (Wang & Hong, 2011; Kasarda, 2010)

There are three layers of spatial impacts instigated by an airport on its region (Federal Office for Spatial Development, 2003; Stangel, 2011; Halpern & Bråthen, 2011).

1. *Local*: There is an impact at local level because of AOD as the airport needs land, leads to fragmentation of urban and natural areas, causes emissions, harms flora and fauna, and affects development of residential and recreation zones. It also catalyses growth stimulus, area redevelopment, logistics hubs expansion, and linking of service locations.
2. *Corridor*: It promotes the creation of infrastructure corridors or spatial concentration of workplaces as there may be functional fragmentation or consolidation of land-uses, such as the shift of service locations. However, the structure of centres may change (centralization or decentralization of activities).
3. *Regional*: Regional economic development may be encouraged or hindered by alteration of spatial networks, i.e. the relation between centres and rural areas, between residential and recreational areas, between the towns themselves and with neighbouring towns.

3. AOD MODELS

Several planning models are created which all highlight the airport as an economic gateway. To understand the know-how of the concept of AOD, a detailed study of different planning models and their conception is conducted and represented in Figure 135. **Erro! A origem da referência não foi encontrada.** (Freestone & Baker, 2011; Freestone & Baker, 2010; Kasioumi, 2015; Zepezauer, 2012; Stangel, 2011; Peneda, et al., 2011). Brief concepts and impacts of the six models are also presented below.

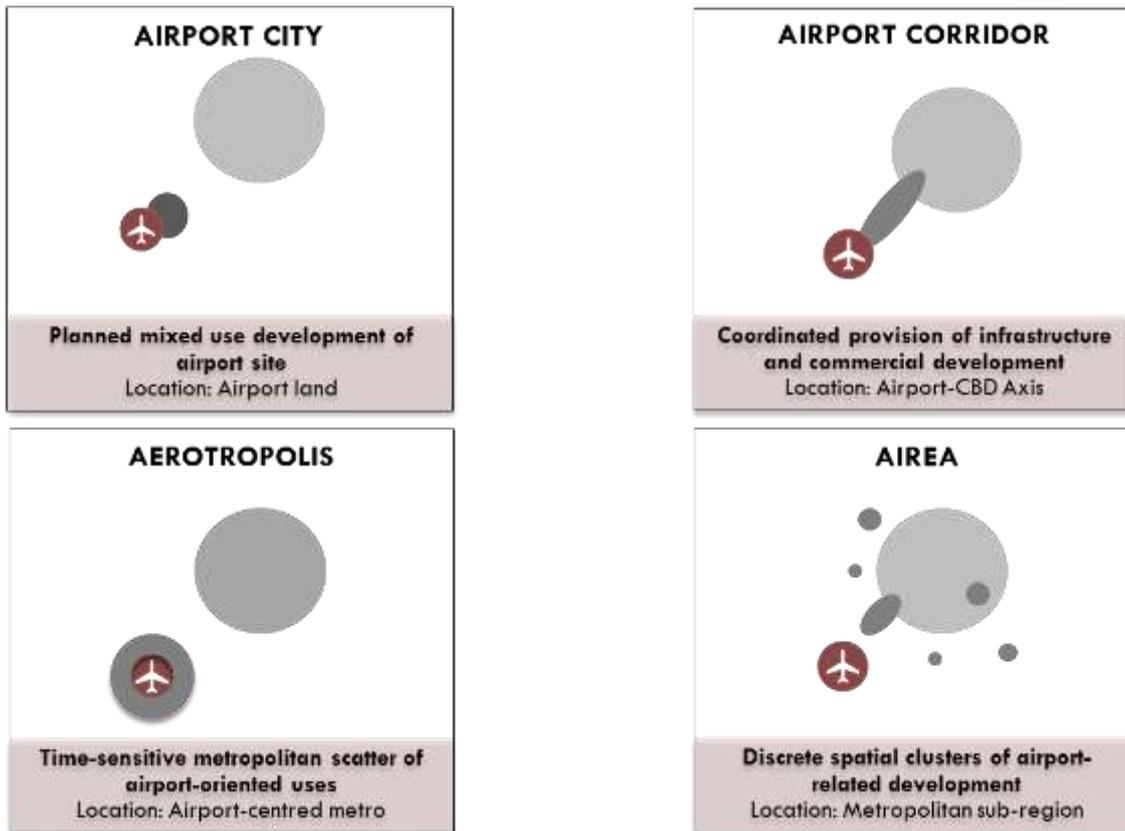

Figure 135: Planning Models of AOD (Freestone & Baker, 2011; Freestone & Baker, 2010; Kasioumi, 2015; Zepezauer, 2012; Stangel, 2011; Peneda, et al., 2011)

1. *Airfront*: It is the basic airport-related commercial zone located at the airport fringe. The key stakeholders are the local inhabitants in the form of public-private partnerships. It is generally on the scale of business district model and may be governed by special planning organisation.
2. *Decoplex*: It is conceived by the master developers in the master plans where the new airport community is scattered in the regional setting. The model takes the form of a regional industrial-leisure complex.
3. *Airport City*: Airport City refers to the planned mixed-use development of the airport site generally by the airport authorities. Such a development is seen near Delhi airport. It has a number of high density and compact mixed-use centres with non-aeronautical activities.
4. *Airport Corridor*: This is the most common type of model in major Indian cities. It occurs along the main axis that joins airport with the city core area by provision of coordinated infrastructural facilities and related commercial development of mixed densities. This may be developed by public or private developers (or both). The corridor is developed as per mutual airport and city development strategies.
5. *Aerotropolis*: It is the most elaborate form of airport-oriented model which is an airport-centred metropolis and has time-sensitive logistics, commercial, and leisure activities linked with the airport in the best possible hierarchy. Aerotropolis provides a number of competitive advantages to the urban form
6. *Airea*: Discrete spatial clusters of airport-related development in the greater metropolitan region is called Airea. The major advantage is the multiplicity of economic development and market nodes as it has polycentric urban form.

4 AOD CRITICISM

The positive impacts of airport-oriented development are innumerable, but there are major challenges involved too. Unlike transit-oriented development, the process and impacts are much complicated and intricate for airport-oriented development because air traffic as a mode can be highly disruptive. Peneda, et al. (2011) and (Kasarda, 2010) identify few critical factors for airport-oriented development – connectivity of the airport and its surroundings; economic potential of the region; availability of other related infrastructure in the region; sustainable development; commercial attitude by the airport operator; demand for air travel and much more. However, having all these in place may still not guarantee success (Figure 136).

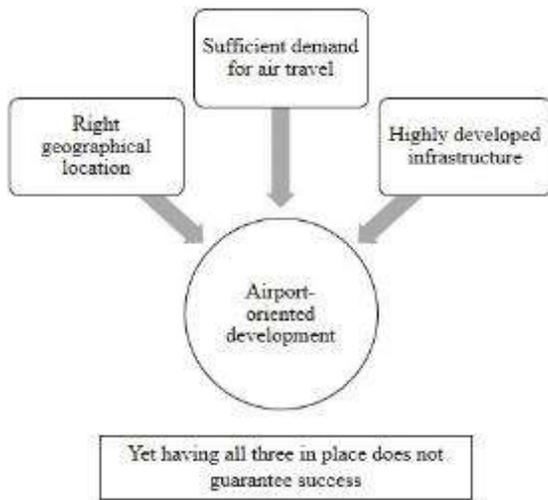

Figure 136: Issues related to airport-oriented development

Clearly, the scenario will vary depending on the airport and the region and their functions. In many cases, airport-related activities may choose the airport surrounding area because of the airport's image and its air connectivity. However, Stangel (2011) identifies that the land-price and surface connectivity are the key factors in locating certain activities in the vicinity of airport and not the air traffic. Also, it is speculated that air transport might not replace the existing components of international economic development to much extent. AOD also raises concerns regarding its long-term sustainability in terms of future energy provision, security, and upcoming export pathways (Charles, et al., 2007).

Taking the case of existing airports, a number of local and regional planning constraints exist at and around them which are incoherent with the AOD principles. In such physically constrained areas, bounded by ages of prior development, application of airport-oriented development may not be possible as variety of problems is experienced during the enlargement and development of existing airport facilities (Saldiraner, 2013). Spatial effects and developments generated by airports may not fit well with local or regional comprehensive plans and master plans in many cases. Airport-oriented development might also intensify urban sprawl, which might not be desirable in many cases. It may pose serious environmental risks too. Putting airport at the centre of thinking and 'facilities first' approach might also not work for all situations (Zhang, 2015).

Re-orientation from airport-centred to region and economy-centred and from a focus on facilities to a focus on fundamentals is required (Appold, 2013). Given the non-stop global growth in air traffic, local and regional planning authorities shall prepare better and in advance for the growth around airports. This can be done by planning efficient connections and zoning to control the haphazard and unfettered growth in favour of airport-oriented development.

5 CONCLUSION

Airport-oriented development is a recent phenomenon for developing nations like India. Given the pace of urbanisation in India and the growth in airport industry, a huge potential is seen in bringing airport planning and urban and regional planning together as discussed in Section 0. Also, the potential of each region and its airport may vary and has to be addressed accordingly. Kasarda (2010) acknowledges that "neither the presence of an airport nor planning alone makes for a successful airport-oriented development". As conveyed in Section 0, conventional and rigid planning approaches seem more and more problematical for the dynamism that airports and its region share. Fundamental principles towards planning for a more efficient urban-rural systems may be listed as follows:

- Realistic economic impacts including the effects at local, regional, and global level;
- Synergised integration of airport planning with local or regional comprehensive plans and master plans and visions of the community;
- Collective sense of responsibilities and duties among the involved stakeholders;
- Efficient governance framework to facilitate coordination and communication among all the concerned authorities;
- Concern for the immediate and long-term environment impacts at local and regional level;
- Strategies for economic development and marketing for the airport region and tools to attract and retain investment.

The paper strongly recommends the urgency to review and revise the current approaches and policies that take airport as an alien unit and always placed it out of the city-core. An innovative approach is required for bringing together airport planning and urban-regional planning in a combined synergised manner. Need of the hour is to develop more meaningful and efficient ways of reading airports and airport-oriented development. This will eventually lead to more ways of understanding contemporary urban-rural agglomeration processes and their planning and governance in the context of the global city-region. Under these conditions, airport-oriented development can surely act as a potential source of

adhesion and driver of growth in making more efficient urban-rural systems. This will lead to a development of more visually pleasing, economically proficient, and sustainable urban and rural India.

1552 THE ROLE OF URBAN PROXIMITY IN THEIR PERIPHERAL AREAS: A STUDY OF THE RURAL AREAS AND CENSUS TOWN IN WEST BENGAL, INDIA

ABSTRACT

The urban proximities means the spatial proximity of rural areas to the urban center. The major objectives of the study is showing the impact of an urban center to their peripheral areas. The spatial dimension of inequality in India has been shown through the income differential across states and gap between rural and urban area. But another dimension of inequality that intra-rural inequality has to be examined, which is an indicative of how the growth benefits have penetrated into the catchment area. It is very challenging for the residents further away from the city to take the high speed, service driven and globalization-linked economic growth. Even in the case of public policies, “villages located at greater radial distances have been under-provided with paved roads, irrigation facilities, electricity supplies, telephone links and the like”. This phenomenon supposed to deepen the “close to urban bias” trends of the developmental dynamism. As a consequence, poverty use to go down in the umbra village vis-a-vis increased within penumbra villages. In this theoretical ambience, it is interesting to study how the spatial proximity to cities and town has an impact on the housing, basic amenities and household quality of living in the peripheral rural area. The role of urban proximity have been shown in two level; firstly how the urban area affecting the peripheral rural area, on the other hand, how the statutory town affecting their peripheral census town. For showing the urban proximity, the data of distance from the nearest urban center for every village have taken from District census handbook of Census of India for 2011. Then the distance has been categorized as per the IHDS divisions. An unequal range have been taken for categorizing the distance from nearest town. Buffer around the statutory town have been taken as a tool of showing the influence of statutory town to their peripheral census town. The radius of the buffer around the statutory town have been taken as “0-15km.”, “15-20km” and “20-25km.” These findings show that the rural household in the peripheral rural areas actually receives better housing, basic amenities and household quality of living compared to the distant villages. This fact is also true for the neighbour census town of the statutory town where there is a linear declination of accessibility of household quality of living. So, it is observable that, within such long period of adopting modern development theory, trickling down is still limited only within the peripheral areas. The distant rural place from the rural areas is in the shadow of modern developmental paradigm. Though the government is responsible for minimising spatial inequality through the progressive distributional functioning of growth outcome, still it is far away from achieving that goal. So, the spatial manifestation of developmental activities and provision of basic services to the citizens showing a “close to urban bias” tendency.

ABSTRACT

In this paper, I examine what would happen if India were to be a little more liberal in its definition of urban areas, similar to that of other countries. Using Census of India 2011 at the village level, I find that if both male and female 75% main non-agricultural employment were to be considered, along with criteria relating to population and population density, India would be 33% urban. If 50% male main non-agricultural employment were considered, along with population and density, 36% of India would be urban. But if male and female 75% non-agricultural employment were to be considered as the only criterion, 78% of India would be urban. If only the population criterion were to be considered alone, 47% of India will be urban, and if the population density criterion alone were considered, 74% of India will be urban. Further, I posit a behavioral model of the characteristics that predict the level of urbanization – the population, population density and non-agricultural employment, in line with existing studies, using cross-country data from the World Bank, making an attempt to understand if the predicted levels of urbanization for countries, are different from their actual levels. For India and several other countries, I find that the predicted level of urbanization is significantly higher.

JEL Classification: R10, R58

Key words: Urbanization—definition, Urbanization—Cross-national, Urbanization—India, Urbanization—conservative, Urbanization—liberal

INTRODUCTION

Cities and towns have emerged as centres of domestic and international investments where most of the commercial activities take place globally. A large number of papers have been written on urbanization and comparing various aspects cross-nationally (Brueckner (1990); Hofmann and Wan (2013)). However, definitions of what is urban vary greatly across countries, as confirmed by Cohen (2004).

Until we make our definition comparable to that of other countries, it is extraordinarily difficult to make cross-country comparisons of urbanization and their various consequences.

We hear quite often that India is a country of villages and only 31.2% of India is urban as of Census 2011, with the remaining 69% residing in rural areas. This is largely an artifact of the definition and is relative.

The Census of India defines settlements having the following characteristics as urban areas:

- (a) a population of five thousand or more;
- (b) a minimum density of 400 persons per sq km or 1,000 people per square mile; and
- (c) at least 75% of male main work force outside agriculture.

By contrast, other countries' definition of what is urban is much more liberal –it is just based on population. Only a few countries in the world – such as Japan (which stipulates that 60 per cent or more of the population (including their dependents) have to be engaged in manufacturing, trade or other urban type of business as a criterion for urbanization), Botswana (the criterion being 75 per cent of the economic activity is non-agricultural), Malaysia (which specifies 60 per cent of their population (aged 10 years and over) engaged in non-agricultural activities to be considered urban) and Zimbabwe (the criterion being more than 50 per cent of the employed persons to be engaged in non-agricultural occupations) -- define urbanization based on the pursuit of non- agricultural employment, which is restrictive.

OBJECTIVES

In this paper, I examine what would happen if India were to be a little more liberal –in its definition of urban areas, similar to that of other countries.

Further, I posit a behavioral model of the characteristics that predict the level of urbanization – the population, population density and non-agricultural employment, in line with existing studies (Alkema et al (2013)), using cross-country data from the World Bank, making an attempt to understand if the predicted levels of urbanization for countries, are different from their actual levels.

Using Census of India 2011 at the village level, I find that if both male and female 75% main non-agricultural employment were to be considered, along with criteria (a) and (b), India would be 33% urban. If 50% male main non-agricultural employment were considered, along with (a) and (b), 36% of India would be urban. But if male and female 75% non-agricultural employment were to be considered as the only criterion, 78% of India would be urban. If only the population criterion in (a) were to be considered alone, 47% of India will be urban, and if the population density criterion alone were considered, 74% of India will be urban.

While a behavioral model of urbanization takes into account GDP, importance given to agriculture as reflected in subsidies, rural-urban income ratio, commuting costs, and so forth, in this paper, I take a deterministic approach and estimate the urbanization across countries as a function of the criteria based on which most countries typically define their urban areas. I estimate urbanization across countries as dependent upon their non-agricultural employment, population and population density.

This paper is organized as follows. First, I review relevant literature. Then, I review the definitions of urbanization across representative countries of the world. Following this, I describe the methodology of the paper and data sources. The following section presents the interesting findings of the research, describing how urban India would be, if we were to use various assumptions. This section also contains the results of the econometric regressions cross-nationally, which are used to 'predict' the level of urbanization, given common characteristics which are used as criteria almost everywhere. A final section summarizes the paper and concludes with policy implications.

EXISTING STUDIES

There are a large number of studies which study the determinants of urbanization in a cross-national context since the 1980s (Firebaugh (1979); Kasarda and Crenshaw (1991); Brueckner (1990)). Many of them study the urbanization and urban primacy in many contexts, Pandey (1977) studies this in the context of India. More recently, Sridhar (2016) studies urbanization and its drivers in the Indian context. Moomaw and Shatter (1996) study urban primacy. The thrust in many papers is that while urbanization is a natural process, urban primacy, the extent to which a country's urban resources are concentrated in one or two large cities as opposed to more evenly spread, is much more directly affected by policies and politics (see Davis and Henderson (2003) and Henderson (2003)). Here in this paper, I argue that even urbanization is determined by policies and politics.

Seto et al (2011) reported a worldwide observed increase in urban land area of 58,000 km² from 1970 to 2000, with India, China, and Africa having experienced the highest rates of urban land expansion. However they found that much of the observed variation in urban expansion was not captured by either population, GDP, or other variables in the model, which suggested that contemporary urban expansion is related to a variety of factors difficult to observe at the global level, including international capital flows, the informal economy, land use policy, and generalized transport costs.

Table 1 summarizes how urbanization is defined by various countries of the world.

Table 1: Summary of Definitions of Urbanization, Selected Countries

Country	Definition of urbanization
Australia	Urban centres with 1,000 inhabitants or more.
Botswana	Agglomerations of 5,000 inhabitants or more where 75 per cent of the economic activity is non-agricultural.
Canada	Since the 1981 census, areas with 1,000 inhabitants or more and a population density of at least 400 inhabitants per square kilometre. The definition of urban has changed slightly between 1951 and 1981.
China	For the 2000 census, the urban population was composed of population in City Districts with an average population density of at least 1,500 persons per square kilometre, other population in suburban-district units and township-level units meeting criteria such as contiguous built-up area, being the location of the local government, or being a Street or having a Resident Committee. For the 2010 census, urban population included all urban residents meeting the criterion defined by the National Bureau of Statistics of China in 2008, i.e., the criterion used in the 2000 census plus residents living in villages or towns in outer urban and suburban areas that are directly connected to municipal infrastructure, and that receive public services from urban municipalities.
Germany	Communes ('kreisfreie Staedte' and 'Kreise') with population density equal or greater than 150 inhabitants per square kilometre.
Japan	Cities defined as 'shi'. In general, 'shi' refers to a municipality that satisfies the following conditions: (1) 50,000 inhabitants or more; (2) 60 per cent or more of the houses located in the main built-up areas; (3) 60 per cent or more of the population (including their dependents) engaged in manufacturing, trade or other urban type of business.
Malaysia	Gazetted areas with their adjoining built-up areas and with a combined population of 10,000 persons or more. Built-up areas were areas contiguous to a gazetted area and had at least 60 per cent of their population (aged 10 years and over) engaged in non-agricultural activities. Areas had also modern toilet facilities in their housing units.
UK	Settlements with 10,000 inhabitants or more. For the censuses up to 1971, administrative boundaries were used.
USA	Densely settled territory that meets minimum population density requirements and with 2,500 inhabitants or more. A change in the definition for the 2000 census from place-based to density-based affects the comparability of estimates before and after this date.
Zimbabwe	Places officially designated as urban, as well as places with 2,500 inhabitants or more whose population resides in a compact settlement pattern and where more than 50 per cent of the employed persons are engaged in non-agricultural occupations.

Source: World Urbanization Prospects (2014)

DISCUSSION OF URBANIZATION DEFINITIONS ACROSS COUNTRIES

As may be seen in Table 1, most advanced countries including the USA, UK, Canada, Australia, and Germany define their urban areas based on population or population density only. Asian countries including Japan, Malaysia, and African

countries such as Zimbabwe define urban based on non-agricultural pursuits. Even in these countries, the proportion of population in non-agricultural pursuits varies from 50%-60%.

India and China are two very comparable countries in terms of their trajectory of growth and the importance of urbanization post-reforms, which is 1978 for China and 1991 for India. Given the comparisons, a comparison of China's definition of urbanization is in order. As Brezzi et al (2012) point out, the current standards for designating cities and towns in China include total population, population density, economic scale, fiscal income, and infrastructure. According to these standards, a county can be designated a **county level city** if it is in line with the following requirements: *i)* when the population density is over 400 persons per km², the number in non-agricultural employment is more than 80 000, and the percentage in total employment is more than 30%; *ii)* when the population density is between 100 and 400 persons per km², the number of non-agricultural employment is more than 120 000 and the percentage in total employment is more than 25%. When a city at county level needs to upgrade itself into a **city at prefecture level**, it has to meet the following requirements: its total non-agricultural population needs to be more than 150 000 while the non-agricultural population in the resident place of government must be no less than 120 000, and the percentage of the tertiary industry in total GDP needs to be no less than 30%.

Hence, as we see, China defines its urban areas a lot more liberally than India or the advanced countries. It is important to understand the way in which urbanization is defined, given it has ramifications for the scale of economic growth, given few countries of the world have reached a per capita income of \$10,000 without reaching 60% urbanization, as Annez and Buckley (2009) point out.

METHODOLOGY

This paper is primarily based on rich and extensive secondary data available from the Census of India at the village level. There are two different data sets from the Census –the Primary Census Abstract -- the B tables (which report data on workers by industrial category) at the village level for all Indian states) and the Village directory, which were used to compute possible urbanization percentages, based on the current definition, with variations in the proportion of non-agricultural employment, and various combinations of population and population density, given the international evidence discussed.

We had discussions with the Karnataka Census directorate as to how one could merge the Census PCA and the village directories, since the village directory contained data on the geographical area of the place, and the PCA contains data on the population and agricultural employment by category, such that we could compute non-agricultural employment. As per suggestion from the Census, the village codes were matched across these two files. Once this was done for every state, then we had the population, population density (which was computed by dividing the population by the geographical area) and non-agricultural employment for every village, of which there are 6,40,947, in all the states of the country. Assuming that the urban areas were rightly designated, I confined my analysis to only the villages.

While the Census defines urban areas, based on a combination of population, density and non-agricultural employment, I considered various scenarios examining various assumptions regarding population engaged in non-agricultural pursuits and also considering what would happen if just one of the criteria were to be used for defining urban. Then, I relaxed the criteria/assumptions in various combinations, which can be used to define a place as urban, and examined the effect of definition on the extent of urbanization in various scenarios as described below.

- a. Scenario 1: First I applied the standard Census definition of urban to villages, assuming they do not satisfy the criteria (which is why they are classified as rural), along with population and population density criteria specified;
- b. Scenario 2: Instead of confining one to just male non-agricultural employment, I included **both male and female full time non-agricultural employment in the 75%**, along with population and population density criteria specified;
- c. Scenario 3: Another scenario in which I included both **male and female both full and part time non-agricultural employment in the 75%**, along with population and population density criteria specified;
- d. Scenario 4: **Only male part time and full time non-agricultural employment in 75%**, along with population and population density criteria specified;
- e. Scenario 5: Here I considered the criterion of **male full time employment in non-agricultural occupations and assumed this to be 50%** for a place to be considered urban, along with population and population density criteria specified (the same as the current Census definition, except that the 75% is replaced with 50%);
- f. Scenario 6: Here I considered the criterion of **male full and part time employment in non-agricultural occupations and assumed this to be 50%** for a place to be considered urban, along with population and population density criteria specified;
- g. Scenario 7: Next I considered the criterion of **male and female full time employment in non-agricultural occupations and assumed this to be 50%** for a place to be considered urban, along with population and population density criteria specified;
- h. Scenario 8: Next I considered the criterion of **male and female full and part time employment in non-agricultural occupations and assumed this to be 50%** for a place to be considered urban, along with population and population density criteria specified;

- i. Scenario 9: Here I considered the criterion of **male full time employment in non-agricultural occupations and assumed this to be 60%** for a place to be considered urban, along with population and population density criteria specified (the same as the current Census definition, except that the 75% is replaced with 60%);
- j. Scenario 10: Here I considered the criterion of **male full and part time employment in non-agricultural occupations and assumed this to be 60%** for a place to be considered urban, along with population and population density criteria specified;
- k. Scenario 11: Next I considered the criterion of **male and female full time employment in non-agricultural occupations and assumed this to be 60%** for a place to be considered urban, along with population and population density criteria specified;
- l. Scenario 12: Next I considered the criterion of **male and female full and part time employment in non-agricultural occupations and assumed this to be 60%** for a place to be considered urban, along with population and population density criteria specified;
- m. Scenario 13: Here I considered **only male plus female main non-agricultural employment of 75%** to be the sole criterion, and dropped the population and population density criteria;
- n. Scenario 14: Here I considered **only population of greater than or equal to 5000** as the sole criterion, and dropped the non-agricultural employment and population density criteria;
- o. Scenario 15: Here I considered **only population density of greater than or equal to 400 persons per sq km** as the sole criterion, and dropped the non-agricultural employment and population criteria;

As discussed, while (a) is being used by the census of India with a cut-off of 75%, several of the scenarios are much more liberal definitions of when a place should be considered urban. Indeed it should be mentioned that some scenarios which take into account women may be more restrictive than the current definition being used.

Once the above was done, I estimated the deterministic model of urbanization in which the proportion urban is dependent on criteria used by India.

The model used was

$$\text{Urbanization} = \alpha_0 + \alpha_1 \text{ population} + \alpha_2 \text{ population density} + \alpha_3 \text{ Non-agricultural employment} + e \tag{1}$$

This was done using a cross-country data set from the World Development Indicators (WDI) Online for 2016, where data were available for 186 countries.

The next section presents the findings from this research.

Findings: How urban would India be?

Using the procedure explained, we arrived at estimates of how urban India would be under each of the 15 assumptions highlighted in scenarios (a)-(o). Table 2 summarizes this for all India.

Table 2: Alternative Assumptions and India’s Urbanization

Assumption	India’s urbanization rate
Scenario 1 (the current census definition)	33%
Scenario 2	33%
Scenario 3	33%
Scenario 4	33%
Scenario 5	36%
Scenario 6	37%
Scenario 7	36%
Scenario 8	36%
Scenario 9	35%
Scenario 10	35%
Scenario 11	35%
Scenario 12	34%
Scenario 13	78%
Scenario 14	47%
Scenario 15	74%

Source: Census of India PCA, Village Directory and Author’s computations

Econometric Regressions

Equation (1) was estimated econometrically for the cross-country data set to understand which criteria predict urbanization best. First, Table 3 presents summary statistics for the cross-country data set.

Table 3: Descriptive Statistics, Cross-Country Sample

	N	Minimum	Maximum	Mean	Std. Deviation
Urban	214	8	100	59.83	24.225
Total Population	216	11,097	1,378,665,000	34,300,000	134,800,000
Population Density	215	0	20,204	443.72	2028.966

% Employment in Services	186	6	88	55.07	18.874
% Employment in Industry	186	2	54	19.09	8.643
% Non-agricultural employment	186	9	100	74.16	23.589
Valid N (listwise)	185				

On average, the countries in the data set are nearly 60% urban. Countries such as Singapore, the special administrative region of Macao and Hong Kong in China, Gibraltar, and Bermuda, among other countries, are 100% urban. At the other end of the spectrum, Caribbean countries such as Trinidad and Tobago are only 8% urban. In terms of population, China is the most populous, and the least populous country is Tuvalu in the Pacific.

The average population density (persons per sq km of land area) is greater than the 400 persons specified by India. Nonetheless, the country with the maximum population density is the Macao SAR in China, with the least one being Greenland, which doesn't even have 1 person per sq km of its land area.

On average, nearly three fourths of the 185 countries' population is in non-agricultural employment, of which more than half is in services, and about a fifth is in industry, on average. The country with all its employment in non-agricultural pursuits is Guam, and the country with the least proportion in non-agricultural employment is Burundi in the African sub-continent.

Table 4 summarizes the cross-country regression for the model indicated in equation (1). The table shows that clearly population density and non-agricultural employment have a positive and significant impact on urbanization, which is natural to expect. What is new about this result?

Table 4: Cross-Country Regression of Urbanization

Parameter	Coefficients	t
(Constant)	7.48	1.86
Total Population	0.00	-0.28
Population Density	0.00	2.08
Non-agricultural Employment	0.68	13.26
R-squared	0.52	
Model F value	64.23	
Number of observations	185	

We predicted the level of urbanization based on the above model, which we call as restrictive. Whenever the predicted level of urbanization for a country is higher than the actual level, we define the country as being restrictive in its definition. We find that of the countries for which we had all data, about 44% countries had restrictive definitions in the sense that their predicted level of urbanization was greater than the actual level of their reported urbanization. The country which is the most restrictive is Trinidad and Tobago in the West Indies, whose actual urbanization is only 8%, but the predicted urbanization for this country is 75%! The reverse is also true, there are many countries whose actual level of urbanization is much higher than their predicted level of urbanization. The most prominent among these are the Virgin Islands, whose actual urbanization is about 95%, but their predicted urbanization is only 69%. Table A1 in the appendix to this paper contains the actual and predicted urbanization levels for all the countries.

As demonstrated in the first part of this paper, India certainly belongs to the restrictive category, since its actual urbanization is 33%, but predicted urbanization is 43%. Clearly, as Sridhar (2011) indicates, there are several factors which could lead a country to making its definition more restrictive. India has been perceived to be a country of villages for a long time, hence policies have proliferated with regard to appeasing the rural voters, villages and farmers. There are a large number of programs which address their infrastructure and service needs such as Bharat Nirman (in irrigation, rural electrification and rural telecommunication connectivity), Pradhan Mantri Gram Sadak Yojana (for rural roads), rural housing (Indira Awas Yojana), water supply (the Rajiv Gandhi National Drinking Water Mission) and sanitation programs (the Swacchh Bharat Mission). Besides there is also the flagship Mahatma Gandhi National Rural Employment Guarantee scheme (MGNREGS).

If we take urban areas, there are also a large number of programs that address their infrastructure needs. First, apart from the smart cities mission for the chosen 100 cities, there is the Urban Infrastructure Development Scheme for Small and Medium Towns (UIDSSMT). The objectives of the UIDSSMT are to improve infrastructural facilities and help create durable public assets and quality oriented services in cities & towns, and to enhance public-private-partnership in infrastructural development. The components for assistance under the UIDSSMT include all urban infrastructure development projects such as water supply, roads, parking space, drainage, solid waste management, sewerage, urban renewal, preservation of water bodies and prevention of soil erosion.

Further, at the beginning of the decade in 2000-01, the Government added a new clause in the Income Tax Act of 1961, exempting interest income from bonds issued by local authorities. Funds raised from tax free municipal bonds are to be used only for capital investments in urban infrastructure for providing potable water supply, sewerage or sanitation, drainage, solid waste management, roads, bridges and flyovers; and urban transport (if this is a municipal function under the respective state legislation). Thus far, very few smaller cities (such as Nagpur and Vishakapatnam) have been able to utilize this.

Besides, regional centres for urban and environmental studies (RCUES) have been established with the purpose of meeting the training and research needs in the urban sectors in various states. These centres assist the state governments in disseminating information about the various policies and programs in the field of urban governance and also undertake

research activities and organize training courses, seminars, workshops and conference, on topics relating to local self government, urban development, urban management, water supply & sanitation, property tax, municipal audit and accounting, public housing, low cost sanitation and urban poverty alleviation programs.

It should be clear that the objectives of all programs, whether rural or urban, are to improve the infrastructure and service provision in those areas so that they can contribute to the country's overall productivity in a better way and to improve the lives of the residents in those areas. In this, there is no question that the urban areas are ahead of the rural areas, hence the rural areas of the country stand to benefit with better public services (despite the plethora of rural and urban programs) if they were to be reclassified as urban, since there are a large number of benefits associated with being eventually urban.

Table A1: Actual and Predicted Levels of Urbanization

Country	Pred. urbn	Actual urbn	Pred-Actual	Restrictive defn

1698 URBAN AND RURAL: INTERROGATING THE BINARIES - WATERSCAPE OF UDAIPUR, RAJASTHAN, INDIA

ABSTRACT

In studying urban and rural spaces there is a known and familiar narrative which dominates the development discourse where the dichotomy between them becomes glaring. The binaries are created by juxtaposing one against the other, the core versus the periphery. But the question arises that are these binaries the only way to examine the rural and urban and the flows as well linkages between them? Can we problematize this dichotomous understanding and re-examine the underlying assumptions? This paper attempts to answer these questions by examining the case of Udaipur in western India where water transfer schemes are operating to quench the thirst of expanding urban space. The tentacles to fetch water have stretched beyond the city boundaries to explore and meet the urban demands. This paper illustrates that these diversion schemes present a complex relationship between the rural, urban and peri-urban where these spaces are not discrete but have overlapping boundaries, not merely geographical but also in terms of equity and access. Instead of looking at these two spaces as distinct we focus on the interlinkages, connections, and relationships between them. In doing so, the question arises - what is gained? Yes, it does gain when we adjust the lens to examine such terrains. In doing so we encounter this newly produced socio spatiality through the lens of water transfer - a waterscape - socio natural assemblage. The ever- evolving interactions, and linkages between the urban, peri urban and rural become crucial as they open the possibilities where instead of seeing them as discrete spaces they can be seen as a continuum of flows and transformations. Usually most of the studies explore either of them, overlooking the potential in such implicit and explicit relationships as well as ruptures which evolve due to such configurations connecting the two spaces. Spatial configurations of the urban and rural boundaries collapse as the area witnesses transformed socionatural relationships which evolve due to such dependence, exchange and flows in a newly configured waterscape. This paper argues that conventional spatial categories and units extensively used for planning processes are fragmentary in especially in case of hydraulic flows and infrastructure like water transfer schemes which divert flows of water remaking the entire landscape and thus producing a new spatiality. In fact the rural, urban and peri- urban are reconfigured (in a waterscape) through resources such as water connecting these spaces /zones/ corridors which are continuously transforming - it is not stagnant - making it dynamic. The movement of resources (read here as water) in these spaces are rapid making them porous and fluid as compared to other spatial configurations which are already established and fragmentary. Hence in these new configurations and reconfigurations of a waterscape lies the possibilities of change and regional integration.

1025 DETERMINANTS OF RURAL TO URBAN MIGRATION IN LARGE AGGLOMERATIONS IN INDIA: AN EMPIRICAL ANALYSIS

Sabyasachi Tripathi

Assistant Professor, Department of Economics, Lovely Professional University, Email; sabya.tripathi@gmail.com; Phagwara, Punjab 144411.

ABSTRACT

The paper investigates the relevant determinants of rural to urban migration in large agglomerations in India. The OLS regression results based on data from 51 cities, show that city-wise employment and unemployment situation (measured by male self employed, not in labour force male, male casual labourer) have a negative impact on city level rural to urban migration. The level of poverty (measured by poverty head count ratio) and inequality level of a city also has a negative impact. However, infrastructure condition (availability of total number of electricity connection) of a city has a positive impact on city-wise rural to urban migration. Economic conditions also matters higher level of rural to urban migration. Finally, it suggests that cities need to equip themselves with better infrastructural facilities along with higher job opportunities to encourage urbanization through rural-urban migration for higher and sustainable economic growth in India.

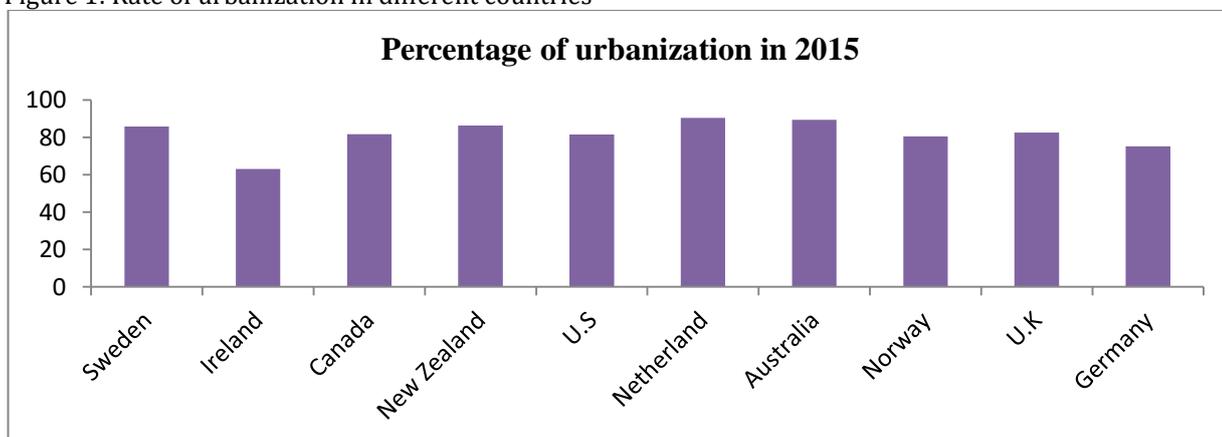

Key Words: Urbanization, rural to urban migration, urban economic growth, India.

JEL Classification: R12, O10, O15

I. INTRODUCTION

In the wake of the rapid urbanization in recent years, Indian economy is witnessing a transformation from an agro-based rural economy to an urbanized modern economy. After independence, urbanization rate has increased continuously; in urban population in India was 28.53 percent in 2001 which increased to 31.16 per cent in 2011. The growth of urbanization has led to higher economic growth (Tripathi, 2013; Tripathi and Mahey, forthcoming) i.e., urbanization is the engine of economic growth in India. Currently 31.16% urban population is contributing about 63% of India’s GDP (GOI, 2011). However, the percentage of population residing in urban areas in developed countries is far greater than in India. As shown in Figure 1, per the data given by World Urbanization Prospects (WUP) (UN, 2014) 85.8 % (or 75.3 % or 63% or 81% or 90.5 % or 89.4 % or 80.5 % or 82.6 %) urban population live in Sweden (or Germany or Ireland or Canada or New Zealand or U.S.A. or Netherlands or Australia or Norway or U.K.) as of 2015. This clearly indicates that India's urbanization rate is lower than in the developed countries.⁵¹³ It is also predicted that India’s future development process ought to be lead by high urbanization rate.

Figure 1: Rate of urbanization in different countries

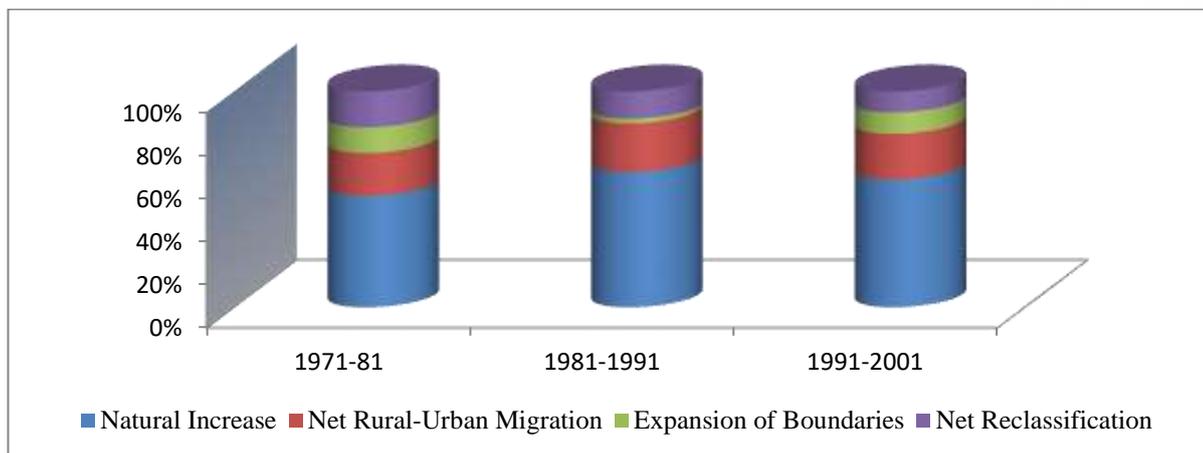

Source: WUP (2014)

The urban growth occurs due to the natural growth of population, expansion of city boundaries, net rural to urban migration, and reclassification of rural areas into urban. Figure 2 shows that net migration from rural to urban areas contributed to about 21 per cent to the increase in urban population in the 1990s, a little smaller than its contribution of 22.6 per cent in the 1980s. Natural increase has been by far the largest source of increase in urban population (62.7 per cent in the 1980s and 59.2 per cent in the 1990s).

Figure 2: Sources of Increase in Urban Population

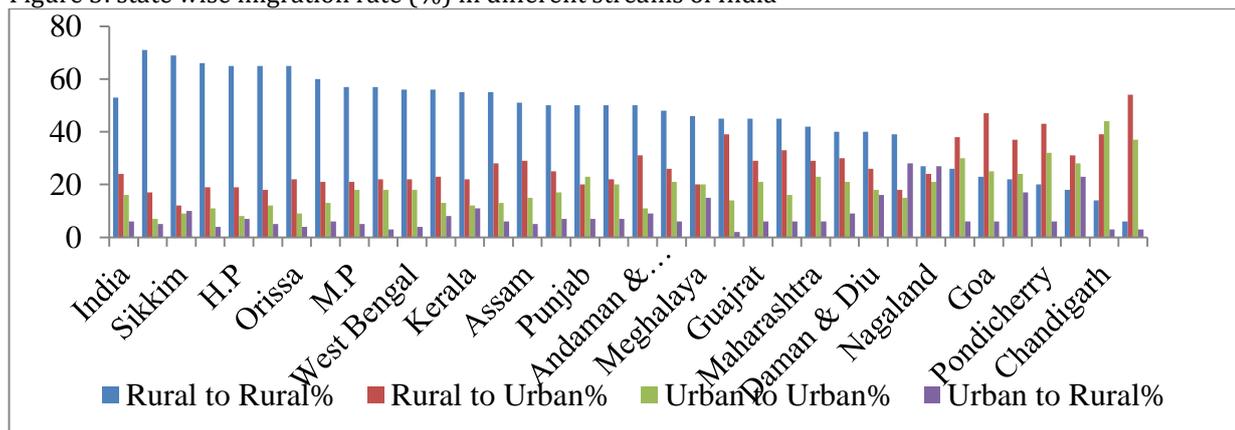

⁵¹³ Though different countries follow different definitions to measure urbanization still we can say India’s urbanization rate is much lower than other developed countries.

Source: GOI (2011)

Migration is the transfer of population from one area to another. Labour migration from agricultural sector to non-agriculture sector in 2007-08 was 66% in which 63% of migrants were men in India. The migration of male population is greater than female. Migration leads to higher growth in urban population, but the migration rate has been very low in India. To increase the growth rate of urbanization, it is essential to promote rural to urban migration. Migration depends upon many factors like job opportunities in urban areas, urban poverty, and higher urban wage rate. Thus, migration positively impacts, the growth of economy, albeit indirectly. Rural to urban migration leads to the growth of economy through the growth of urbanization. Migration could be voluntary or coercive. Voluntary migration occurs due to the promise of job opportunities, education, better medical care, securing family links, industrial job, higher income etc. in the host city. On the other hand, forced migration occurs due to drought, political war, poor medical care, loss of wealth, forced labour, etc.

Figure 3: state wise migration rate (%) in different streams of India

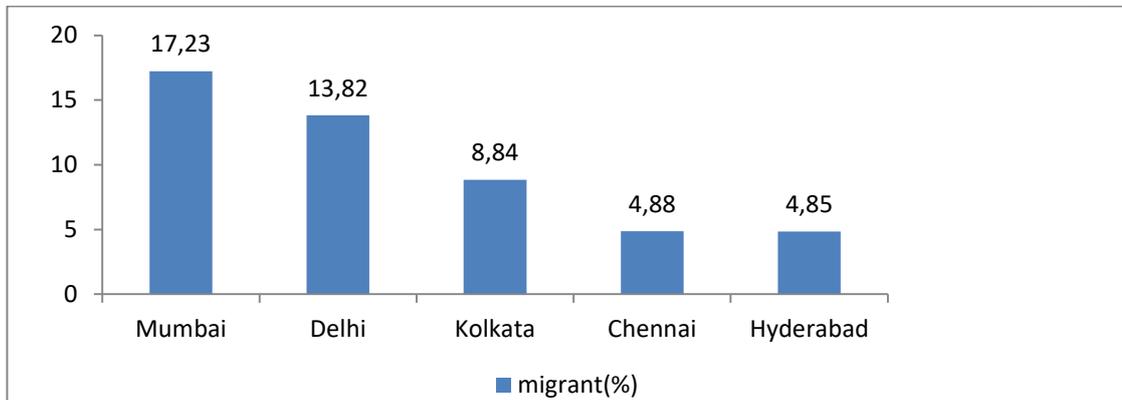

Source of data: NSSO 64th round National Sample Survey of India

The 64th round of Indian National Sample Survey Office (NSSO) on “Employment & Unemployment and Migration Particulars” during July 7 to June 8 2007-08, covered a sample of 1,25,578 households and 5,72,254 persons. The survey, taking into account the entire mobility including within - and between states, estimates the mobility of the Indian population as about 30 percent. However, within this 30% the share of migrants within the state was 85% and across state, 15%. In other words, migration was by and large rural to rural. Figure 3 provides figure of state-wise migration between rural to rural, rural to urban, urban to urban, and urban to rural. As can be seen from the table, in internal migration, the maximum percentage of migration was rural to rural. Rural to urban migration was the highest in Delhi at 54%. In the rural to urban migration stream, Sikkim had the lowest percentage value of 12%. The percentage of urban to urban migration was quite in Chandigarh at 44%. The percentage value of urban to urban migration was quite for Manipur also. The figure shows that the percentage of rural to urban migration is less than that of rural to rural migration in India. On the other hand, developed or economically advanced Indian states have a higher level of rural to urban migration rate than the less developed states. It becomes clear from the above analysis that in order to have higher development, rural-urban migration needs to be promoted.

Given the present focus on smart cities/million plus cities, it is necessary to consider India-specific data on migration, particularly rural-urban migration arrive at any meaningful conclusion. The diagram below (Figure 4) shows the trends of migration in top five million plus cities on the basis of census of India in 2001 on a time-scale of ten years and more than 10 years. Mumbai reported 17.32% its population as migrants, which is quite higher than in other million plus cities. The second-ranking city, Delhi, reported 13.82% as its migration of population.

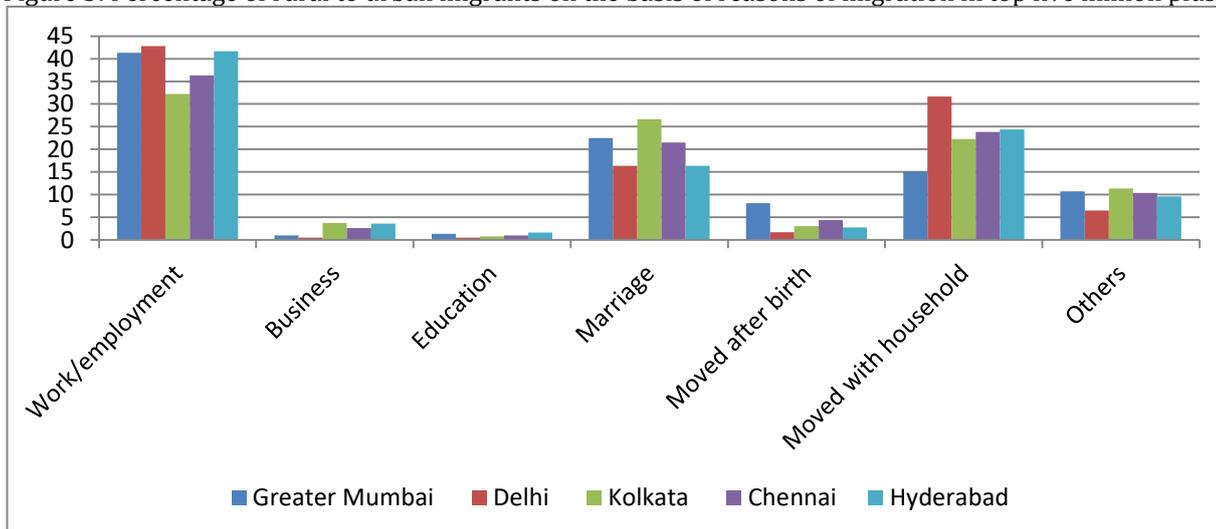

Figure 4: Percentage of rural to urban migration in top five (as per population size) million plus cities

Source: Census of India 2001

The Census data also provides enough clues about the reasons for rural to urban migration in these cities. Figure 5 shows the percentage of rural to urban migrants on the basis of reasons of migration in top five million plus cities with the time duration of ten years and more than ten years. The figure indicates that the main reasons behind the migration of population are work and employment. A large part of migrants move from backward to modern areas due to lure of job opportunities. It is observed that the largest rural-urban migration was to Mumbai (28,47,510 persons), of which 41% people cited work and employment as reasons for migration; 22% people migrated due to marriage in which the percentage of women was higher than that of men. Migration to Delhi, Chennai and Hyderabad also show the same pattern; higher rural to urban migration was dominated by work and employment reasons in these cities. Marriage and consequent relocation of households is also cited as causes for rural to urban migration.

Figure 5: Percentage of rural to urban migrants on the basis of reasons of migration in top five million plus cities

Source: Census of India (2001)

Recently, government of India has launched several policies and programmes to promote urbanisation-led development in India as urban areas have traditionally contributed higher level of GDP than rural areas. Among the various policies, 100 Smart Cities Programme, AMRUT (Atal Mission for Rejuvenation and Urban Transformation), JNNURM (Jawaharlal Nehru National Urban Renewal Mission), UIDSSMT (Urban Infrastructure Development Scheme for Small and Medium Towns), NERUDP (North Eastern Region Urban Development Programme), NUIS (National Urban Information System), Capacity Building for Urban Local Bodies, Lump Sum Provision Scheme for the benefit of North East Region (NER) including Sikkim, Brihan Mumbai Storm Water Drainage (BRIMSTOWAD) project at Mumbai, PPP (Public Private Partnership), Clean India Mission are the major programme and policies introduced by governments in recent years to promote urbanization in India.

The above discussion clearly indicates that India is experiencing a higher level of urbanization and its contribution to national income is also high. This in turn indicates that Indian economy is going through a transformation from an agricultural based rural economy to an industry and service lead urban economy. In fact, recent years government has initiated and implemented various urban related policies and programs to promote urbanization in India. However, the country needs still better policies in the days to come to promote planned urbanization in India and to absorb the maximum economic potential that urban areas can provide for sustainable economic growth in India. Given the importance of knowing the factors which contribute to rural to urban migration in India, it is imperative to systematically study the determinants of rural to urban migration in India. It is only fair to that rural to urban migration will lead to future rapid urbanization in India which in turn will lead to higher and sustainable economic growth. It is hoped that the findings of this paper will help policy makers to formulate effective policies in India to promote urbanization through rural to urban migration. It is also surmised from a review of existing studies on this topic is that this is first study in India which considers city specific factors to identify the reasons behind city level rural to urban migration.

In this study, urban agglomeration is defined as a geographic concentration of urban population and related economic activities. This implies that urban agglomeration includes, but is not equal to, urbanization. Here, cities with 750,000 or more inhabitants as of 2015 are defined as large urban agglomerations. There are several reasons behind the selection of such large agglomerations as the units of analysis. First, World Urbanization Prospects provide updated data for the cities with 750,000 or more inhabitants for the years 1950 to 2025 with five year intervals, whereas Indian census data only provides data up to the 2001 census (as latest 2011 census data is yet to be published) with a 10 year interval. Second, because of the unavailability of city specific data for a large number of variables used in this study (e.g. city income data), city district (where the sample city is located) is used as a proxy of a city. Larger cities are a good proxy for a city district as they cover a larger portion of a district than the smaller cities. Third, as India's urbanization (i.e. share of urban population) is mainly centred around Class I cities, these cities by definition belong to Class I cities. On the other hand, urban economic growth is defined by growth rate of city domestic income (i.e. non - primary district domestic product [DDP])

II. BRIEF REVIEW OF LITERATURES

To understand the movement of people occurring within the country, it is important to study the migration pattern initially. Arzaghi and Rupasingha (2013) argued that the migration of rural to urban occurs due to diversification. The migrants get opportunities to migrate due to correlation of income between origin and destination as measure of diversification, as in the case of United States. Iversen (2006) argues that the rural to urban migration is a dynamic migration model. The reasons of migration are social network, multipliers, spillovers, and caste affinities and the job opportunities in urban areas. According to McCatty (2004) who examined the need of rural to urban migration in developing countries, migration takes place in these countries due to both the push-pull migration forces these forces are of two types -- voluntary forces and involuntary forces. Voluntary forces are job opportunities; education, medical facilities, high per capita income, transport facilities, high living standard etc., and the involuntary forces are political disputes, strike, fighting with neighbors, lack of transport facility, illiteracy, natural disaster, bullying etc.

In the context of India, Mitra and Murayama (2009) found that intra state migration is much higher in magnitude than inter-state migration rate in India. Male and female migration rates are closely inter connected irrespective of whether they migrate from rural areas within the states and outside the states. The social and cultural diversity in India stands as a major hindrance to population mobility. Bhagat (2014) argued that migrants with low education and skills, given with the seasonal and temporary nature of their employment, are more vulnerable and subject to various kinds of exclusions in urban areas. Migration is treated more as an issue of governance rather than one of development in developing countries like India. Akram (2015) analyzed the push factors of rural to urban labour migration in India. His empirical analysis shows that increase in per capita Net State Domestic Product tends to decrease the number of out-migrants from the rural areas of that state whereas increase in the proportion of population living below poverty line, higher proportion of Scheduled Castes in the population and illiteracy rate in the rural area of the state, etc. tend to decrease rural to urban labour migration from that state to other states. Agasty and Patra (2013) who examined the determinants of rural to urban migration in the Indian states of Orissa states that there are two types of variables that influence the migration rural to urban: micro variables and macro variables. These are the two variables that influence people to move from one place to another. Micro variables are individual variables and macro variables refer to the factors that influence the whole population of a particular place or area to move.

However, there only a few studies that have tried to investigate the economic factors that contributes to rural to urban migration in India. Therefore, it is hoped that the present study will be useful not only to measure the effect of migration on urbanization but also its effect on economic growth and development.

III EMPIRICAL FRAMEWORK AND RESULTS OF THE ESTIMATION OF DETERMINANTS

To empirically investigate the determinants of rural to urban migration in large agglomeration in India, the following OLS regression model is used for estimation.

$$\text{Migrant} = \alpha_0 + \sum_{i=1}^9 \alpha_i X_i + \epsilon \dots \dots \dots (1)$$

Here, the dependent variable 'Migrant' in equation 1 has two different forms; first it is measured by percentage of rural to urban migration in large agglomeration in India and secondly, it is measured in terms of the total number of rural to urban migrants. The X_is are independent variables i.e. city wise total self employed male, city-wise self employed female, level of inequality, railway station- distance from the city, total number of electricity connections, not in male labour force, city-wise total number of universities, casual worker male, city output, city-wise poverty headcount ratio, city-wise poverty gap ratio, city-wise total no. of medical facilities, city wise average rain fall, city-wise total receipts and city-wise total number of colleges.

Appendix table AI lists out the all the cities which are considered for the study. Summarized in Appendix table AII are the descriptions, measurements, and data sources of all of the variables used in estimation of OLS regression of Equation 1. Table 1 explains the means, standard deviations, minimum, maximum, and coefficient of variation (CV) values for the variables used for the regression analysis. Most importantly, the CV aims to describe the dispersion of the variables in a way that does not depend on the variable's measurement unit. The higher values of CV for railway station distance from the city in and total number of electricity connections indicate a greater dispersion in these variables. On the other hand, city output, city wise average rain fall and city wise total number of self employed male show a lower dispersion in these variables. On the other hand, Table 2 presents the row correlation coefficients.

Table 1: Description of data used in the regression equation

Variables	Mean	Std. Dev.	Min.	Max.	C.V.
Percentage of rural to urban migration in 2001 (prum)	18.6	12.2	2.7	47.4	65.7
Total number of rural to urban migrants (trum) (in thousands)	383.1	794.9	25.7	4651.5	0.21
City wise total Self employed male in 2004-05 (selfm)	328.4	94.6	188.8	615.8	28.8
City-wise self employed female in 2004-05 (selff)	91.0	71.8	7.4	348.2	79.0
Level of inequality in 2004-05 (Gini)	0.3	0.1	0.1	0.6	28.7
Railway Station distance from the city in 2001 (raildist)	0.4	1.4	0.0	8.0	383.6
Total no. of electricity connection in 2001 (elect) (in thousands)	461.4	1222.2	0.0	8560.3	0.26
Not in male labour force in 2004-05 (nlfm)	215.1	64.2	72.3	439.2	29.8
City-wise total number of universities in 2001 (univ)	1.1	1.2	0.0	5.0	105.0
Casual worker male in 2004-05 (casualm)	104.3	60.4	9.3	300.9	57.9
City output in 2001 (ddp)	16597.8	7614.6	797.2	38412.6	45.9
City-wise poverty headcount ration in 2004-05 (fgt0)	12.2	12.5	0.2	57.8	102.4
City-wise poverty headcount ration in 2004-05 (fgt1)	2.3	3.1	0.0	16.1	132.7
City-wise total no. of medical facilities in 2001 (medi)	187.4	213.8	2.0	781.0	114.1
City wise average rain fall in 2001 (rain)	1075.3	570.2	266.0	3053.0	53.0
City-wise total receipt through taxes and revenue derived from municipal properties (trmp) (in lakh) in 2001	14.9	53.2	0.0	380	0.004
City-wise total no. of colleges (ctc) in 2001	41.5	49.0	1.0	195.0	118.2

Note: Figures in parentheses represent robust standard errors. ***, **, and * indicate statistical significance at the 1%, 5%, and 10% level, respectively. Source: Estimated using equation 1.

Table 3 presents the estimated regression results from Equation (1). Regression 1 reports the full model where all the independent variables for OLS estimation are considered. On the other hand, regression models 2-4 represent the parsimonious model by excluding the explanatory variables that did not show statistically significant results or match with the expected sign conditions. Regression models 1-5 consider the robust standard errors (to control for heteroskedasticity). The significant values of F statistics for Regressions 1-4 indicate that the overall model is statistically significant. The higher values of R² indicate that Regression 1 explains a good percentage of total variation in the dependent variable. The study has also calculated the adjusted R², as it adjusts for the number of explanatory terms in a model, i.e., it incorporates the model's degrees of freedom. The multicollinearity problem does not seem to be troublesome, as the mean VIF values do not exceed 10 for Regression model 1-5.

Regression 1 shows that city-wise total self employed male has a negative impact on the percentage of rural to urban migration. In particular, a 100 percent increase of city-wise total self employed males decreases rural to urban migration by 8 percentage points. However, percentage of city-wise total self employed female has a positive impact on the percentage of rural to urban migration. This indicates that cities having higher percentage self employed female attract higher rural to urban migration whereas cities having higher percentage self employed male discourage to urban migration. This is may be case that if women have the chance to make them self employed in the city; more rural women from rural households will migrate to urban areas to earn more provided that their male partners also find jobs in the same city. The possible increases in income of the households make rural to urban migration easier and also attractive. On the other hand, city-wise availability of higher number of electricity connections has a positive impact on rural to urban migration. The estimated result show that a 10 percent increase of total number of electricity connection in the host city increases rural to urban migration by about 65 percent. It is important to indicate here that availability of electricity connections stand as a proxy of availability of infrastructure facility. The result indicates that infrastructure facility has a positive impact on rural to urban migration. Finally, regression 1 shows that city wise per capita income also has a negative impact on percentage of rural to urban migration. This means that if a city has higher per capita income (i.e., richer city), it discourages rural to urban migration. It therefore indicates that a richer city may be more expensive for a person to migrate from rural to urban areas. City-wise total number of colleges also has a negative impact on percentage of rural to urban migration. This indicates that the educational facilities do not attract higher percentage of rural to urban migration. The other independent variables i.e., city-wise level of inequality, road distance from a city to nearest railway station, poverty ratios, medical facilities, number of universities, average rain fall, and total receipt through taxes and revenue derived from municipal properties do not show any statistically significant effect on the percentage of rural to urban migration.

Regression 2 shows very important results; it shows that level of inequality in a city has a negative impact on the percentage of rural to urban migration. On the other hand, road distance from the nearest railway station to a city exerts a positive impact. In particular, a one percent increase in level of inequality (or road distance from nearest railway station to a city) decreases (or increases) 32 (or 2) percentage of the rural to urban migration. The result indicates that if a city has higher level of inequality, it discourages rural to urban migration. On the other hand, if a city has higher road distance from the nearest railway station, naturally indicates the lower economic potential and therefore it encourages rural to urban migration. This means that cities having lower economic potential attract higher rural to urban migration. Similarly, cities having lower percentage (number) of the higher number of persons those are not in labour force attract

lower percentage of rural to urban migrations. This shows that employment potential in the host city is one of the main factors behind rural to urban migration. People moves from rural areas with the expectation of getting absorbed in the urban areas. City wise total number of self employed male or females, and total number of electricity connections of the host city has a similar impact on percentage of rural to urban migration as explained in regression 1. However, city-wise total number of universities, number of male casual worker, poverty head count ratio, medical facilities, and average rain fall again do not show any statistically significant effect on percentage of rural to urban migration. Most importantly, city wise per capita income lost its significant level in regression 2 compared to regression 1.

Regression 3 shows that city-wise total number of male casual worker has a negative impact on rural to urban migration. A 100 percent increase in total number of casual workers decreases rural to urban migration by about 5 percent. This clearly indicates that cities need to provide formal regular jobs than making the migrants casual workers to attract higher level of rural to urban migration. City-wise total number of self employed males or females, level of inequality, road distance from nearest railway station to a city, availability of electricity connections and number of persons not in labour force show a similar impact on percentage of rural to urban migration. However, city-wise poverty situation does not have any significant impact on rural to urban migration.

Regression 4 shows that city-wise higher poverty ratio (measured by poverty head count) has a negative impact on city-wise rural to urban migration. A 10 percent increase in poverty head count ratio decreases city-wise rural to urban migration by about 5.5 percent. This indicates that poorer cities discourage rural to urban migration. On the other hand, city-wise higher total receipt received through taxes and revenue derived from municipal properties, also have a positive impact on rural to urban migration. This indicates that strong economic conditions encourage higher rural to urban migration. The availability of electricity connection in a city shows a positive impact on rural to urban migration as explained in regression 3. However, city wise total number of universities and squared poverty gap ratio again do not show any statistically significant affect on city-wise rural to urban migration.

Finally regression 5 considers the total numbers of rural to urban migrants as the dependent variables. The estimated results show that city-wise total number of self employed males has a negative impact, and city-wise total number of self employed female has a positive impact on city-wise rural to urban migration. These results are identical to the results obtained in regression models 1-3. However, other independent variables do not show any statistically significant effect on city-wise rural to urban migration. It also indicates that the data considered in this study does not fit properly when the total number of rural to urban migrants is considered as a dependent variable.

IV CONCLUSION AND POLICY IMPLICATION

This paper tries to investigate the determinants of rural to urban migration in large cities of India based on 2001 data. For this analysis, data from various sources such as Census of India and unit/individual level data of National Sample Survey data on employment and unemployment and consumption expenditure data have been used for analysis. Due to lack of city-wise data district level data is used by considering urban sample located in that particular district as a proxy of the city. OLS regression method is used to analysis data in this study. City wise rural to urban migration rate and total number of rural to urban migrants are considered as dependent variables.

The descriptive analysis shows that India's urbanization rate is much lower than other developed countries. Natural increase in population is one of the main sources of increase in urban population in India. The net rural to urban migration from 1991 to 2001 is about 21 percent. Economically developed states have been witnessing higher rural to urban migration than economically underdeveloped states. Among the large cities, Mumbai has recorded the highest (i.e., 17.32%) rural to urban migration rate in the time span of ten years and more, among all other large agglomerations. City-wise analysis shows that reasons for rural to urban migration are predominantly work/employment and marriage.

The OLS regression results show that city-wise total number of male self-employed, level of city level inequality, males not in labour force, male casual labour, city-wise per capita income, city level poverty measured by poverty head count ratio, and city wise total number of colleges have a negative effect on city-wise percentage of rural to urban migration. On the other hand, city wise total number of self employed female, road distance to nearest railway station from a city, total of number of electricity connections and city-wise total receipts through taxes and revenue derived from municipal properties have a positive impact on city-wise rural to urban migration. On the other hand, city-wise total number of self employed male has a negative and city wise total number of self employed female has a positive impact on city-wise total number of rural to urban migrants. This results indicate that city level employment situations, city level inequality level, city level poverty and infrastructure facilities play an important role in rural to urban migration.

It is quite obvious that the country needs more rural to urban migration for economic development in India. In rural areas, more population depend upon agriculture, and the higher dependence on agriculture leads to disguised unemployment in rural area. If the disguised unemployed population is relocated in urban areas, then the supply of labour and demand of consumer goods in urban areas will increase. This will in turn lead to more production, higher level of economic activity and also higher per capita income. The level of job opportunities in the cities will also increase in this process. And this increase will promote investment which will in turn lead to further economic growth. So, the economic growth in India can be catalyzed through the growth of urbanization resulting from rural to urban migration.

In this perspective we suggest the following policies; first, we need to increase the job opportunities in the urban area for higher rural to urban migration. Second, level of urban poverty and urban inequality has to control for this purpose. Third, basic urban infrastructure facilities such as road, electricity, education etc has to increase not only to make

investment friendly but also to promote rural to urban migration. Finally, living cost such as urban housing prices has to control for making Indian cities migrant friendly for higher and sustainable economic growth.

APPENDIX

Table A1. Names of Cities Used in Regression Analysis

Agra (Agra), Aligarh (Aligarh), Allahabad (Allahabad), Amritsar (Amritsar), Asansol (Bardhaman), Aurangabad (Aurangabad), Bangalore (Bangalore Urban), Bareilly (Bareilly), Bhiwandi (Thane), Bhopal (Bhopal), Bhubaneswar (Khordha), Chennai (Chennai), Coimbatore (Coimbatore), Delhi@, Dhanbad (Dhanbad), Durg-Bhilainagar (Durg), Guwahati (Kamrup), Gwalior (Gwalior), Hubli-Dharwad (Dharwad), Hyderabad (Hyderabad), Indore (Indore), Jabalpur (Jabalpur), Jaipur (Jaipur), Jalandhar (Jalandhar), Jamshedpur (Purbi- Singhbhum), Jodhpur (Jodhpur), Kanpur (Kanpur Nagar), Kochi (Eranakulam), Kolkata (Kolkata), Kota (Kota), Kozhikode (Kozhikode), Lucknow (Lucknow), Ludhiana (Ludhiana), Madurai (Madurai), Meerut (Meerut), Moradabad (Moradabad), Mumbai (Mumbai), Mysore (Mysore), Nagpur (Nagpur), Nashik (Nashik), Patna (Patna), Pune (Pune), Raipur (Raipur), Ranchi (Ranchi), Salem (Salem), Solapur (Solapur), Thiruvananthapuram (Thiruvananthapuram), Tiruchirappalli (Tiruchirappalli), Varanasi (Varanasi), Vijayawada (Krishna), Visakhapatnam (Visakhapatnam).
--

Note: City district (where the sample city is located) is used as a proxy of a city to measure all the variables (except population data) used in estimation of OLS regression of Equation

1 by considering urban sample persons (if data available for rural and urban separately) of that district. Name in parentheses indicates the name of the district in which the city is located. @ Delhi are considered as a whole proxy of a city district.

Appendix A2: Variable sources and definitions

Work-force participation rate (WPR) (As given in NSSO: The number of persons employed in *usual status* (ps+ss) per 1000 persons is referred to as work force participation rate (WFPR) or worker population ratio (WPR) in *usual status* (ps+ss). **Usual principal activity status:** The usual activity status relates to the activity status of a person during the reference period of 365 days preceding the date of survey. **Usual subsidiary economic activity status:** A person whose usual principal status was determined on the basis of the major time criterion could have pursued some economic activity for a shorter time throughout the reference year of 365 days preceding the date of survey or for a minor period, which is not less than 30 days, during the reference year. **Usual activity status considering principal and subsidiary status taken together:** The usual status, determined on the basis of the usual principal activity and usual subsidiary economic activity of a person taken together, is considered as the usual activity status of the person and is written as usual status (ps+ss). According to the usual status (ps+ss), workers are those who perform some work activity either in the principal status or in the subsidiary status. Thus, a person who is not a worker in the usual principal status is considered as worker according to the usual status (ps+ss), if the person pursues some subsidiary economic activity for 30 days or more during 365 days preceding the date of survey.

City output: Per capita non-primary District Domestic Product (DDP) over the period 2000-01 to 2004-05 at 1999-2000 constant prices is taken as a measure of urban economic growth. Source: Directorate of Economics and Statistics (DES), various State Governments, GoI.

City inequality level: Gini coefficient of the large city districts by considering urban sample persons of that district. Source: Unit level data of NSS 2011-12 on consumer expenditure.

Rain fall: City wise average rainfall.

Medical facilities (Numbers): City- wise Total Number of Hospital + Number of Dispensary + Number of Health Centre + Number of Family Welfare Centre + Number of TB Clinics + Number of Nursing Home + Number of Other Medical Institutions.

Total university (Numbers): City-wise total number of universities.

Electrification (Number of Connections): City- wise Total number of connection by Domestic + Industrial + Commercial + Road Lighting (Points) + Others

Railway Station distance: Railway Station Road Distance (in kms)

1134 DETERMINATES OF GROWTH IN NON-MUNICIPAL PERI-URBAN AREAS OF DELHI

ABSTRACT

The interactions between urban, peri-urban and rural spaces have increased in the last decades with rising commuting, employment interactions, infrastructure provision etc. These new realities encourage to move beyond the simple classification of the urban-rural dichotomy, which is no longer adequate for analyzing the role of settlement and demographic processes. The peri-urban areas will be the dominant urban form and a challenge for spatial planning in the 21st Century in the global North as well in the global South. Most of the projected development will take place in this zone, leading to land fragmentation, loss of habitats and amenity values. In India, most of urban growth takes place outside municipal boundaries, and given the projected unprecedented growth of Indian metropolises, peri-urban areas are crucial for leveraging Indian urbanization. They require policy attention for the following reasons: first, large industries and special economic zones, which are unable to find land within the municipal boundaries due to land scarcity or high prices get land lots from the state government in the urban periphery. Second, rural unskilled migrants are settling in the peripheries of metropolises and large cities without basic services and in unplanned manner. Third, Indian regions will undergo the cycle of urbanization where cities are the engines of economic growth, thus to achieve development this growth needs to be planned and provided with basic infrastructure required to attract economic opportunities. Fourth, the unprecedented increase in census towns in close proximity to large metropolises is unplanned and makes transformation of rural to urban hard to manage. With the above background, this paper attempts to elucidate the factors that trigger growth in the peri-urban areas in order to advocate policy reforms to better plan and manage these areas for unleashing the potential of Indian urbanization. We use recent Census of India enumeration on socio-economic and demographic status as well as GIS data on settlement boundaries, and employ a combination of primary methods (interviews) and secondary methods (multi-variable OLS regressions and geographically weighted regressions). The objective is achieved with the help of following research questions: What are the determinants of peri-urban (area outside the municipal boundary) growth in Delhi? Do the factors of growth change or differ for census towns and villages or are these universal for the whole of peri-urban area? What are the location peculiarities or what differences can be ascertained between the location of census towns and villages? What are the areas that foresee growth and decline in the next decade?

1136 SPATIAL PLANNING BEYOND BOUNDARIES

Felix Knopf

Advisor at Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) GmbH, 3rd Floor, B5/2, Safdarjung Enclave, New Delhi 110029, India

ABSTRACT

Spatial Planning in India is still mostly limited to the urban agglomerations. With a strong urban growth a new type of urbanism arises, that seems to be neither rural nor urban. This so-called “Peri-Urban” growth encompasses a large amount of valuable land, and if not regulated, causes high costs for the construction of public (technical) infrastructure and leads to conflicts with other land uses such as agriculture or with environmentally protected areas. Consistent and systematic spatial planning at the level of the region can be an important contribution to plan the rural-urban linkage and to prevent negative consequences of the aforementioned current spatial developments. In this regard, the Land Use Planning and Management Project, jointly implemented by the Indian Ministry of Rural Development and the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) GmbH, wants to revive Spatial Regional Planning as provisioned in the Constitution of India.

1 INTRODUCTION

The relationship between rural and urban areas is changing and the rural-urban divide is fading, with increasing flows of people, goods and services between the two and the emergence of new migratory and livelihood patterns. This is driven in parts by high urbanization rates in many developing countries, and particularly by urban growth in the continuum of rural areas with villages, towns and cities of fewer than 500,000 inhabitants. Boundaries between rural and urban areas are becoming less distinct, and urban and rural characteristics and activities can lead to diverging territorial needs and divides between governance functionalities.

Realising the full potential of these blurred boundaries is a challenge for policy-makers and planners. Spatial planning and integrated land use management can be used as mechanisms to foster rural-urban interlinkages and promote integrated development. Overcoming the rigid rural-urban dichotomy is also a precondition for the achievement of many of the Sustainable Development Goals (SDGs) and is firmly integrated into the New Urban Agenda.

The Indian Government has recognised the importance of addressing rural-urban interlinkages by launching the National Rurban Mission in 2016. The Rurban Mission is based on the premise that comprehensive development cannot take place unless even the remotest places are developed as growth centres. Nevertheless, spatial planning in India is still mostly limited to the urban agglomerations, despite rapid urbanization and peri-urban growth. Consistent and systematic spatial planning at the regional level is therefore an important contribution to address the increasing spatial complexities of the rural-urban linkage and unlocking the development potentials of urbanization for rural areas.

Under the Indo-German Corporation, the Ministry of Rural Development with its Department of Land Resources and the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) are jointly implementing the Land Use Planning and Management Project in India. The project focuses on spatial planning at the regional scale and at the District level. The objective of the project is to improve the system of land use planning in India in order to enable and ensure that Indian state planning institutions apply policies and instruments of integrated spatial and land use planning.

“There is a need for an integrated spatial and territorial planning that keeps the urban and rural areas at the regional level in focus. India's urban-rural regions are shaped by extreme disparities in development and are deprived of adequate basic services and housing. This underlines the need for a strong urban economy that supports the regional balance of the city and the country. Such a paradigm shift requires a systematic and consistent planning approach on all scales”.

2 RURAL AND URBAN LIFE IN INDIA TODAY

Urbanization is linked to economic growth and regional development. However, development in India is concentrated in certain large cities; the rural hinterlands are deprived of growth, resulting in spatial disparities across the country.⁵¹⁴ Despite the known fact that there is substantial migration from rural to urban areas in India, still almost 68% of India lives in rural areas, according to Census of India 2011. Keeping these facts in mind, a reality check of Mahatma Gandhi's “India lives in villages” seems reasonable.

The urbanization in India has reached from 10.8% in 1901 Census to 31.16% in 2011 census. As per the Census 2011, there are 7,935 towns in the country. There are 468 towns with population greater than lakh out of which 53 has a population of one million or above each. These Million Plus cities are the major urban centres in the country.

As per the Census of India 2011, the definition of urban area is as follows:

- Statutory Towns: All places with a municipality, corporation, cantonment board or notified town area committee, etc.
- Census Towns: All other places which satisfy the following criteria:
 - o a minimum population of 5,000

⁵¹⁴ Jain, M. and Pallagst, K. 2015. Land Use Beyond Control. *disP – The Planning Review*, 51:3, 29-43.

- at least 75 per cent of the male main working population engaged in non-agricultural pursuits
- density of population of at least 400 persons per sq. km.

Statutory Towns are notified under law by the concerned State Government and have local bodies like municipal corporations, municipalities, municipal committees, etc., irrespective of their demographic characteristics. Census Towns were identified on the basis of Census 2001 data.

A big percentage of urban growth has the form of patches around the city-centres that are often disconnected from each other. Although these patches have urban characteristics as per the census, they are not statutory urban areas and thus lack institutional structures and capacities to tackle challenges in regard to infrastructure planning and service provision.

As a result, high rise buildings and residential complexes with high densities occur in rural areas - often without including basic infrastructure like roads, electricity, freshwater or sewage in planning. Cities and villages suffer from this development, as it becomes increasingly difficult to determine where cities end and where the landscape and the village start. Census towns growing in the not notified urban areas around cities are only governed by rural local bodies which lack funds and empowerment to cater to urban service delivery standards and planning regulations. Although the quality of life goes urban, development goes haphazard and unregulated, exceeding land resources and demand for infrastructure.

This has implication on the prime resource of rural India, which is agricultural land. The per capita availability of agricultural land has declined from 0.5 hectares in 1951 to 0.15 hectares in 2011. With increase in population and possibility of shrinking land mass due to increased coastal erosion and floods due to climate change, the per capita availability of land is expected to reduce further to 0.2 ha in 2035⁵¹⁵. According to the Land Use Statistics (2012-13), issued by the Ministry of Agriculture & Farmers Welfare (MoA&FW), there has been a gradual increase in the area of land under non-agricultural uses. During the period 2001-02 to 2012-13, the area under non-agricultural uses has increased by 2.6 million hectares (11 per cent).

The agricultural sector has shown less than 2 percent per annum growth during the past decade. The share of agriculture and allied sectors in GDP has come down sharply from 52% in 1951-52 to 13.9% in 2011-12, whereas share in workforce remained high at 54.6%, declining to only 39.6% during the same period. Such disconnection between employment growth and GDP growth is due to lack of non-farm employment opportunities. In such a precarious situation, there is concomitant need for shifting population from agriculture to other sectors.

The McKinsey Global Institute Report on India's Urban Awakening: Building inclusive cities, sustaining economic growth (April 2010) highlights prospects of urbanization that India can look forward to in the year 2030, in terms that India's GDP will multiply five times, there will be "270 million people net increase in working age population... 70 percent of net new employment will be generated in cities". It is estimated that the current contribution of Urban India to the GDP is about 63%, which will further increase with growing urbanization.

The challenge/ solution is therefore not to stop urbanization from happening, but to regulate the phenomenon through effective planning tools like spatial regional planning, that go beyond urban boundaries and serves to reap benefits of urbanization now and in future.

3 THE NEED FOR A REGIONAL PLANNING SCALE

As described in the previous chapter, a big part of the growth is happening in a form that is described in India as "The Urban Sprawl", "The Peri-Urban", or "The Rurban". These spaces are multi-faceted as every area has a different story to say about their growth factors. Yet, the growth of these areas can be understood in three distinctly visible categories:

1. Around/ close to metropolis or large cities
2. Along National or State Highways or Railways and
3. Old cantonments or at strategic trade locations used in historic times.

Most of these areas do not have an applicable spatial plan to strategically control and steer development.

It is estimated that of the 7935 urban settlements of India, only 1233 urban settlements have approved master plans and preparation of 653 master plans is in process a total of 24% urban settlements⁵¹⁶. The application of master plans generally has a good effect on the construction, investment decisions, availability of basic infrastructure for the citizens and finds the right balance between economic aspects (agriculture, mining, industries and commerce etc.), social aspects (urban as well as rural settlements, equity of distribution etc.) as well as the environmental aspects (natural resource management, disaster prevention and mitigation, forest, climate change etc.).

Most of the rural areas in India do not benefit from a consistent spatial planning, which is the responsibility of the state governments, and affects roughly 70 per cent of the Indian population. Planning authorities are limited to urban areas, neglecting the current challenges of unauthorised development at the periphery. A common response to the expanding urban boundaries is the creation of new entities, such as Metropolitan Development Authorities (e.g. the Mumbai Metropolitan Region or Chennai Metropolitan Region). In addition, bigger scale visionary planning of corridors, transit

⁵¹⁵ State of Indian Agriculture 2015-16, Ministry of Agriculture and Farmers Welfare, Government of India

⁵¹⁶ TCPO, MoUD "GIS-base Master Plan Formulation", available from <http://tcpomud.gov.in/Divisions/URIS/Brief Note on GIS based Master Plan.pdf>

axis or big industrial regions across the country are being planned for at national level. The biggest gaps in spatial planning in India therefore exist in those areas that are not covered by either Master Plans or special plans at national level. Sectoral spatial and land use plans are also prepared for eco-sensitive zones, and economic and investment zones. Generally prepared and guided by sectoral / line departments, most of these plans are sporadic and in pockets, lack efficiency, integration and interaction with each other leading to constraints in successful implementation.

The government of India envisions that all States and Union Territories of India should possess and use a fully functional and standardised Integrated Land Use Planning and Management System, which promotes adoption of comprehensive and inclusive land utilisation strategies involving all stakeholders leading to strengthened decision making for sustainable utilisation of land resources.

Under the Constitution, not only provision for Economic and Social Planning (Entry 20 List III, VII schedule); but provision for District level and Metropolitan planning (74th Amendment, Art 243ZD for spatial planning for district and Art 243ZE for co-ordinated spatial planning for Metropolitan area) already exist.

A regional planning approach in India can help to facilitate a system of spatial planning in urban and rural areas and areas which lie somewhere in between, the so called peri-urban. Spatial district plans define the land use and provide a planning base of the whole area on a higher level, regardless of whether it is called urban or rural. In that way, it overcomes the urban-rural dichotomy by choosing a scale of 1:50,000 or above. Although the aforementioned Metropolitan Development Authorities already work at this regional scale, this level and scale of work is still new and uncommon for India, especially when it comes to rural areas.

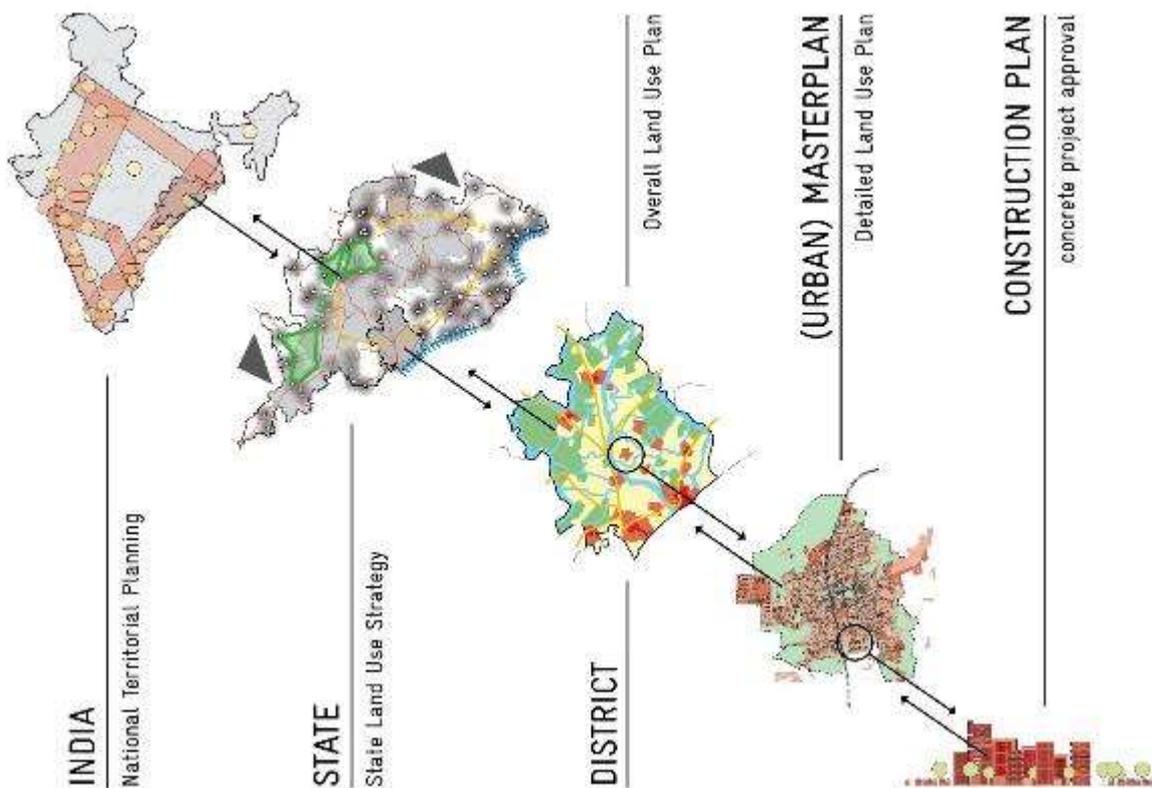

Figure 137: Levels and scales of spatial planning

In the case of Tamil Nadu, the state has only 5% of the area (excluding Chennai Metropolitan Development Area, CMDA) as planned area with master plans of two types: single urban local body or a cluster of ULBs with adjoining rural areas within a “local planning area”. Currently planning in Tamil Nadu is done in 3 levels: the visionary plans (Vision Plan 2023) with economic investments specified for various projects (corridors etc.) with no spatial maps in scale; the master plan in 1:10,000 scale (as well as lower scale like 1:4000 in places required) and Detailed Development Plans in 1:4000 scale (or lower scale 1:1000 as per need). Urban master plans in Tamil Nadu are prepared by the Local Planning Authorities (LPA), which come under the Directorate of Town and Country Planning (DTCP), for areas called as local planning areas.

The major lacks in the planning process are the missing participative approach and demand assessment as a result of which the plans take very long for approval as there are objections from public and requests for reclassification. Similar issues exist in the Planning arena of Odisha where planning is made by consultants selected by the Department of Town Planning (DTP) or the Development Authorities. The process of each consultant largely varies and hence it is difficult to document one single process of planning in the state. Also, scope of public participation is limited to the flag end of the planning process, which does not leave any space for incorporating their demands in the plan. Their participation is limited to only raising objections and giving suggestions.

In both of the states, the town planning authorities have the mandate of spatial planning. However, the execution of this mandate in reality is restricted, as approval processes for building permits consume most of the available resources.

Thus, planning in many cases is left to external consultants. Another observation is that building in the rural periphery outside the jurisdiction of a building authority became more attractive for constructors and developers in terms on financial and time benefits. This highlights the need for an extension of planning beyond urban boundaries and look into the per-urban areas from a planning perspective.

4 THE LAND USE PLANNING AND MANAGEMENT PROJECT OF GIZ

“There is a need for an integrated spatial and territorial planning that keeps the urban and rural areas at the regional level in focus. India’s urban-rural regions are shaped by extreme disparities in development and are deprived of adequate basic services and housing. This underlines the need for a strong urban economy that supports the regional balance of the city and the country. Such a paradigm shift requires a systematic and consistent planning approach on all scales”.⁵¹⁷

Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ) GmbH is providing technical cooperation to the Department of Land Resources, Ministry of Rural Development, Government of India, for promoting Integrated Land Use Planning and Management in India at state level. As part of the agreement GIZ has agreed to support two states (Odisha and Tamil Nadu) with technical assistance towards formulation of state land use policies, development of spatial planning instruments/tools/framework and guiding documents, Human Capacity Development (HCD), organizational and institutional development. GIZ would also demonstrate application of the land use policies and guidelines by providing technical assistance in preparing a district level spatial land use plan in each state and vertically integrating it to a larger regional spatial land use plan for Tamil Nadu and a smaller town / rural area spatial land use plan for Odisha.

The objectives of this collaboration is to strengthening overall culture of a democratic and integrative spatial and land use planning at all levels by enhancing the capacities of State planning institutions in applying standard land use planning and management instruments in selected areas within the two pilot states by utilising the technical assistance as provided by GIZ.

Land Use Planning and Management project is working along with two pilot states, Tamil Nadu and Odisha. Key partners in the states are state government departments which are administrating and developing land and which have the mandate and capacity to introduce a spatial planning instrument at regional scale. In Odisha, the Revenue and Disaster Management Department is mainly concerned with land property rights and has a high stake in land development. While the mandate of the Housing and Urban Development (H&UD) Department is limited to urban areas, it has the vastest experience, competence and capacity for spatial planning. Under the H&UD Department, the Directorate of Town Planning (DTP) is the nodal agency for all urban planning related activities in the state and is majorly entrusted with the preparation of urban master plans.

In Tamil Nadu, a similar structure is followed: Here, the H&UD Department is the Authority for the Directorate of Town and Country Planning (DTCP). As the name says, the mandate is not limited to urban areas only, but covers the full territory of the state. The Planning, Development and Special Initiatives Department in Tamil Nadu is responsible for the preparation of the Five Year and Annuals Plans. State Planning Commission (SPC) is a sub-department and administrates all sectoral strategies for the state. While Department heads (Secretaries) are steering the project at management level, SPC and DTCP are the main partners for technical implementation.

In the focus of this project is a spatial planning approach on regional scale at the level of the District which is the administrative subdivision of a state and headed by a District Collector. While many Districts have planning cells which prepare development plans, district plans in most of the cases are not spatial. The budgetary planning approach does not cater to the need of regulating and steer developments spatially.

4.1 Land Use Policies

In general terms, land use policy primarily uses spatial and land use plans as well as environmental and building code regulations to affect land use. These instruments function by restricting usage of land, but cannot influence how individuals and businesses would like to use land. In most cases, they do not offer efficient, community and market driven land use patterns to emerge. At the same time many other policies and schemes which are not directly related to land use planning systems, create incentives to use land in certain specific ways. However, it is not necessary that such policies correspond to the objectives of land use planning systems. In many cases, the planning systems simply fail to achieve their objectives due to overwhelming pressures from contradicting land developments.

Thus, state land use policies in India must become a spatial governance tool that balances considerations to all sectors at all levels of governance. It is therefore targeted to develop the policies in a cross-departmental working mode, including all sectors of the state government with implications on land. Working groups are steered by external policy and planning experts to moderate the process and streamline the outcomes to a comprehensive policy document. This document aims to

- link tax policy incentives to land use policies,
- link state level fiscal systems, schemes, projects that directly impact efficiency of land use policies,
- integrate demographic and economic trends with due consideration to the fact that all settlements are interdependent,

⁵¹⁷ LUPM. 2017. "Spatial Planning beyond boundaries". Documentation: Dialogue on a Regional Planning approach at the District level. GIZ, New Delhi

- integrate all sectors and levels of government so as to promote convergence and overcome sectoral silo,
- strengthen the concept of regional considerations in planning approaches
- and to create sustainable coordination mechanisms .

4.2 Norms: Pioneers for India

Norms are Spatial Planning instruments for Regional Plan means a collection methods and approaches in the form of standards and guidelines used by the public and private sector to influence the distribution of people and activities in spaces of a region for sustainable development. It also encompasses coordination of practices and policies (SoPs, inter-sectoral coordination mechanism) affecting spatial organization (the sectoral departments, spatial planning departments). These instruments help stimulation and steering of regional development.

While already existing guidelines have a strong focus on planning in urban areas, guidelines for planning on the regional level needs more elaborate and state specific customization. One of the existing guidelines for urban and regional development are the 'Urban and Regional Development Plan Formulation and Implementation' (URDPFI) guidelines. The URDPFI guidelines specifies the scope, purpose and contents of each plan. It also provides a compilation of all types of spatial planning practices across different sectors in the country. It provides formulae for population projection and parameters for delineation of region. Currently both the states of Odisha and Tamil Nadu follow URDPFI guidelines for master planning. Receptivity and willingness for an extended set of norms is prevalent in the states. Together with key stakeholders, the preparation of a manual for district planning is underway to introduce this new set of norms.

4.3 Human Capacity Development: Planners for India

Growing urban India and a constantly growing number of urban, infrastructure and construction projects means a challenge to the public administrative workforce in the field of spatial planning in India. India needs a big amount of well trained (spatial) planners. The Town and Country Planning Organisation of the Government of India / Ministry of Urban Development estimates in its latest URDPFI (Urban and Regional Development Plans Formulation and Implementation) Guidelines from January 2015 a total requirement of "85.000 - 90.000 additional planners in the country at various levels of planning framework, which roughly works out to 1 Planner per 14,000 population."

The academic system for spatial planning produces planners mostly for the private sector. Planners in Government institutions are mostly trained by practice and can apply existing planning instruments and laws. A detailed Capacity Assessment within the two states has shown, that, when it comes to innovation and appropriation of reforms and new planning approaches, government planning institutions lack of properly trained planners. The assessment has also revealed that in both of the states there is currently no regular training offered for spatial planning officials in the state government. Rapid urbanization and industrial growth require increased control of land development and enhanced balancing of sectoral interests. Spatial planning beyond boundaries of urban jurisdictions and beyond boundaries of sectoral departments must respond to the new challenges.

With respond to the increasing demand of planners in the state, the Government of Tamil Nadu is about to introduce a common cadre of Town Planners. But there is a need of increasing the capacities not only in quantitative terms, but also in qualitative terms. Hence, a training on spatial planning will be designed and conducted under the project. A state training institute (Tamil Nadu Institute of Urban Studies) is charged with introducing this training to the annual training curricula. Similar in Odisha, where not only planners of the Directorate of Town Planning, but also district planners and revenue officers are part of the target group for training on spatial planning.

The Training on Spatial Planning is part of a wider Capacity Development Strategy as part of the Indo-German cooperation. As spatial planning is both a cross-sectoral and a multi-level domain, as many levels and sectors within in the government structure must be addressed. The strategy targets three groups:

1. Decision makers: These are secretaries from relevant departments which are crucial for decisions with spatial implications. Topics are awareness for the need regional planning and development and models for necessary cross-sectoral cooperation to balance opposing interests.
2. Planners: The above mentioned training on preparation of spatial plans at city and regional level for technical staff in the State Government.
3. Local representatives: Spatial planning finds its physical manifestation always at the local level in terms of built environment, infrastructure, environmental zones, etc. Local authorities from villages are to be trained on "spatialize" village development plans and map existing resources and future needs of the local community.

4.4 Demonstration Areas

Four demonstration areas were selected to showcase how policies and norms can be applied and to generate a real case example for the application of coordination mechanisms and newly acquired capacities through training. In Odisha, a regional scale at the district level is prepared in Ganjam District. Within this district, a land use plan for Greater Hinjilicut Municipality nearby the main city Berhampur will showcase the interlinkages between the plans on regional and local level. In Tamil Nadu, Coimbatore District has been selected as demonstration area. As part of the regional strategy of the state, a regional plan of four districts will showcase how a land use plan for such an extensive area can look like and what kind of abstraction is required at this level.

Figure 138: Demonstration Areas in Odisha

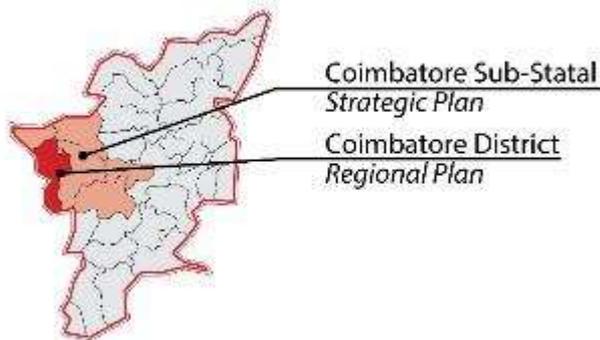

Figure 139: Demonstration Areas in Tamil Nadu

5 WAY FORWARD AND CONCLUSION

The introduction of a regional level of spatial planning requires a solid governance structure with clear responsibilities and capacities to fulfil the tasks. Both of the pilot states are working on the identification of the best suitable working model. Ownership and political will for improving the regional scale of planning are the most important factors for a sustainable impact.

Based on the learnings from the demonstration areas, the Government of Odisha could identify four feasible working models for a governance structure of district spatial planning.

1. District Planning and Monitoring Units (DPMU) are responsible for each of the 30 districts in the state and come under the Planning and Convergence Department (PCD). DPMUs prepare budgetary district plans for each district. Due to lack of capacity, there are no spatial components in these plans. The mandatory inclusion of spatial component (as per provisions of 74th CAA, GoI) in existing district plans can only be achieved when spatial planning capacities within DPMUs are built. DPMUs have the constitutional mandate and institutional statute to prepare and implement district spatial plans/regional plans. This model suggests an overarching spatial planning cell within the PCD for the entire state of Odisha capacitated with planners and experts.
2. The Directorate of Town Planning (DTP) is the main government agency for spatial planning in the state for areas outside the jurisdiction of development authorities. DTP is responsible for masterplans for the majority of cities and towns in the state, for building approvals and preparation of local area plans. It experienced and well versed with spatial planning. Looking at these already existing capacities, district/regional spatial planning may be mandated as an additional statute for DTP by expanding it to Directorate of Town and Country Planning (DTCP).
3. A combination of model 1 and 2, which would encompass budgetary support from PCD and technical support from DTP would meet all requirements. The component of spatial planning under district plans can be mandated under DTP while non-spatial component under district plans stays with DPMUs. The integration of both plan components have to be ensured through regular interactions between DPMU and DTP and would require a specific deliberation on responsibilities and coordination.
4. The last option is a rather visionary idea to create a Directorate of Rural and Country Planning within the Panchayati Raj Department (PRD). This would include the introduction of formal planning mechanisms within the PRD. Under this model, there shall be two separate wings of spatial planning in the state, one under DTP for urban spatial planning, and the other within PRD for rural and country planning. The district and local level representations of the Directorate within PRD shall be through PRI organisations (Zilla Parishad, Panchayat Samiti and Village Panchayats) that shall be capacitated with planners and experts. For such a model, there has to be evolved district level institutions which shall integrate rural and urban spatial plans for preparing integrated district spatial plans. Probable organizations can be DPMU or District Rural Development Authority.

Preconditions in the State of Tamil Nadu are different from those in Odisha. Here, the respective Directorate of Town and Country Planning (DTCP) has already the mandate for spatial planning for the entire state except for the area of Chennai Metropolitan Development Area (CMDA). Also, the Town and Country Planning Act provides the requirement of preparation of regional plans in the state. The Government has recently taken steps to reformulate the regions by clustering districts into six regions. DTCP is about to start a process of regional plan preparation through external consultants. In this context, two other provisions of the Town and Country Planning Act are to be pursued: The creation of the Town and Country Planning Board and the Regional Planning Authority.

The act foresees the Town and Country Planning Board as a steering committee “to guide, direct and assist the planning authorities, advise the Government in matters relating to planning and the development and use of rural and urban land in the State and to perform such other functions as the Government may, from time to time, assign to it”⁵¹⁸. The members comprise representatives of a series of departments, authorities and associations. The constitution of the board requires coordination and political will, as of now, it is still pending. The process of working groups for drafting the land use policy (refer chapter 4.1) is a first attempt to bring these stakeholder together and test coordination mechanisms to overcome contradicting interests of land developments. The process of drafting the policy entails the chance to open a window of opportunity for the constitution of the Town and Country Planning Board.

The same act also provides the introduction of Regional Planning Authorities. The plan preparation of selected demonstration areas (refer chapter 4.4) whether an additional authority is actually needed or other agencies can take up the preparation and implementation of the regional plan.

In general, an integrated spatial planning approach helps to make decisions with spatial implications more effective. A larger scale of spatial planning than the incumbent city scale is needed in order to meet the current challenges of haphazard development at the urban fringes. Urban and rural tends to grow together, thus, a regional level of spatial which covers both would respond to this trend. A regional planning approach at the district level can contribute towards equitable rural transformation by providing policy-makers with information to help them identify and prioritise necessary sectoral interventions. For this purpose, both planning departments as well as sectoral departments must be involved in the process of policy formulation, development of guidelines and capacity development measures. Making use of cross-sectoral synergies is a first step to address the rural-urban continuum in the governance of spatial planning.

ABSTRACT

This paper analyzes the effect that the Arab Spring has had on tourism. For this purpose, a number of countries have been selected from among the affected and potential beneficiaries (Tunisia, Egypt, Thailand and Spain) and the gain or loss of tourists has been quantified through the use of the Synthetic Control Method. Our results suggest that the two affected countries have suffered large losses in the number of tourists while Thailand has increased the number of tourists in Thailand as a result of this conflict. In contrast, in Spain no significant effect is observed.

1 INTRODUCTION

Tourism activity, like the rest of economic sectors, can be affected by political and social instability. The impact degree is greater when the social conflict is transformed into public disorders and, in extreme cases, into terrorist acts or even into armed conflicts. Of course, it becomes maximum when tourism -for which it itself can assume contact with other cultures, economic support of the regimes, or symptom of openness- becomes the ultimate goal of this confrontation or terrorist acts .

In this sense, the social conflict that originates in Tunisia at the end of 2010 and that extends into the Arab world throughout the following year, has its prolongation in armed conflicts or terrorist acts especially intense in 2015. This situation , therefore, it is a good scenario for the study of the impact that both types of events have on tourism activity and its capacity for response and recovery.

In contrast to other papers that only analyze this phenomenon from the perspective of the countries affected by this situation of political instability and conflict, here we will also try to assess the extent to which potential winners of the conflict can be detected, through a process of deviation of tourist flows to other countries.

To do this, the following section provides a brief chronology of the Arab Spring and the events of instability and subsequent conflicts. Next, we review the literature on the impact of political instability on economic activity and, specifically, on tourism. In the following section, the synthetic control method is presented, as an adequate instrument capable of evaluating the impact of instability on tourism activity and which consists in the construction of a counterfactual of the tourist flow, so that the impact is measured as difference between the real data and the constructed counterfactual. Perhaps one of the main weaknesses of this procedure is that the construction of the counterfactual must be carried out through a linear combination of the tourist flows of other economies that have not been affected by this effect, neither positively nor negatively.

To carry out this selection of countries, a process is implemented in three stages: a) identification of the countries affected by the Arab Spring; b) identification of the countries that sent their tourists to those affected and that substantially modify their bilateral flows with them; c) identification of the receiving countries (substitutes) of the affected countries through the analysis of the change of destinations of the countries identified in stage b). Once these countries have been identified, it is possible to carry out the synthetic control method that is applied to the two most affected countries: Tunisia and Egypt; and two of the possible beneficiaries: Spain and Thailand. The paper concludes with the usual conclusions and final considerations.

2 THE ARAB SPRING AND ITS EFFECTS ON POLITICAL STABILITY

For many years, the countries of the Arab world have been governed by authoritarian governments that have combined methods of repression and redistribution in order to maintain their systems of government (Malik and Awadallah, 2011). As Boukhars (2011) points out, Arab societies began to exacerbate their discontent due to economic and political deficiencies despite certain improvements in education and access to new technologies and the Internet. The culmination of this process occurs in a social outbreak by several countries in the MENA region (Middle East and North Africa) between December 2010 and June 2011, and has been called with the generic name of "Arab Spring".

Specifically, this public demonstration of discontent begins in December 2010 in the city of Sidi Bouizid (Tunisia), when Mohamend Bouazizi, a fruit vendor whose stand had been requisitioned by the police, immolated himself, triggering the general discontent of the Tunisian citizenship (Glosh, 2016). On the contrary, Chomsky (2010) dates the beginning of this process in the uprisings produced in Western Sahara in October of that same year. The riots in Tunis led to the resignation of President Ben Ali on January 14, 2011.

After the successes of neighboring Tunisia, the wave of protest spread to Egypt, where youth along with other sectors of the population got the resignation of President Mubarak on February 11, involving that the army dissolved the Parliament, suspended the Constitution and pledged to abolish the emergency laws in force for 30 years (Kirkpatrick, 2012). It is worth noting the role played by the youth sectors first, in the beginning of the riots and later, in the fall of Mubarak. What is more, it was a group of young people who years before the outbreak of the Arab spring joined the labor movement to protest the labor rights of textile workers in the city of Mahalla al Kubra (Souaiaia, 2011). This struggle led to a strike on April 6, 2008, of which this group took the name, called April 6 Movement (Wellman and Rainie 2014).

In Syria, a civil war is still ongoing facing forces loyal to President Assad's regime along with its allies and other forces opposing both the government and each other in varying constellations. This conflict has extended directly to Lebanon where it has strengthened sectarian clashes between factions in support of and opposed to the Assad regime. In Yemen, the protests led to the ouster of President Ali Abdullah Saleh, who had been in power for more than 33 years. In Libya, the protests ended with the assassination of the dictator Muammar Gaddafi and the elections to the General National Congress took place in July 2012. Although, in Morocco and in Jordan, King Mohammed VI and Jordan King Abdullah II have both stayed in power, they have been forced to make such contributions as cabinets and constitutions reforms.

The victory in both Tunisia and Egypt of the revolts can not be explained without the role of the army. He decided to disengage from the presidential orders, refusing to intervene to quell the riots (Abu-Tarbus, 2009). On the contrary, in countries like Libya, Syria or Yemen, an armed struggle was established, which in the case of Syria is still under way.

The root of the problems that led to this situation of discontent were economic, political and demographic. Among the economic causes, as Joffe (2011) points out is the rise in the prices of basic necessities, especially those related to food. According to FAO, food more than doubled its price between 1990 and 2011 (at a cumulative annual growth rate of 4.3%) that was not accompanied either similar wage increases and or low unemployment rates. Besides, there was a the drop in remittances and tourism revenues, as well as the financing difficulties of these economies, as a consequence of the financial crisis of 2007 that significantly affects its main commercial and tourist partners: the European countries (Habibi, 2009). At the political level, the lack of political freedoms linked to the repressive apparatus of the State has exasperated large sections of the population. In addition, widespread corruption and the misuse of public resources increased the degree of delegitimization of these regimes among the popular sectors (Cook, 2011).

Furthermore, the demographic component has played a key role in the outbreak of the revolution. These countries have an important proportion of young population (20% of the population is between 15 and 24 years old) that has led to an increase in education efforts by the Arab states (UNDP, 2002), which clashes head-on with fewer opportunities in access to the labor market, creating disaffection with the different regimes among young people (Bibi and Nabli, 2012). Thus, youth unemployment rates double and even triple the general rates (World Bank, 2009 figures these rates at this time in 43.8% for Libya (43.8%), 30.3% for Yemen and 29, 4% for Tunisia).

Finally, it is remarkable the decisive role that new technologies have played in the propagation of the revolts by granting alternative means of communication to citizens, especially the youngest ones (Lotan et al, 2011), despite the low level of penetration of the same, because its use does not reach more than a third of the population in the best of cases.

3 THE EFFECT OF POLITICAL AND SOCIAL INSTABILITY ON ECONOMIC AND TOURISM ACTIVITY: A QUICK REVIEW

The study of the economic effect of political instability, terrorism and violence has generated a good number of papers, especially since the September 11 attacks. Moreover, the intensity and nature of the conflicts dealt with are very broad; from strikes, protests and demonstrations to armed conflicts and various forms of terrorism (Buesa et al, 2008, Abadie and Gardeazabal, 2003 Blattman and Miguel, 2010). The strong link that sometimes exists between the different forms of instability may explain the difficulty of separating the various effects at the time of being treated (Sonmez, 1998) and hence it is usually expressed political instability in general terms.

In addition, there is a literature that analyzes the channels through which instability affects economic results. Aisen and Veiga (2013) conclude that political instability negatively affects growth. Miguel and Roland (2006) study the economic effect of the American bombings in the subsequent underdevelopment of Vietnam, concluding that the destruction of these attacks had no long-term effects on the levels of poverty, consumption, infrastructure, literacy or population density due to the rapid recovery of affected areas. Braithewaite, Kucik and Maves (2014) evaluate the effect that political instability has on the FDI, proving that markets receive less investment when violent episodes occur and when those revolts fail. Fielding (2013) finds that the episodes of violence of the "Intifada" have caused a lower level of saving of the Israeli economy compared to international standards. Justino (2010) highlights how conflicts affect human capital through shorter school time and that effect is greater for women than for men.

One of the main issues faced by these papers is both to define what is meant by political instability and to identify the beginning of the event to be studied. In fact Jong-A-Pin (2009) points out that these processes are multidimensional and hence the problem of identification. In this sense, Alesina et al. (1996), Siermann (1998) and Miljkovic and Rimal (2008) consider that a change in government can be a sign of political instability, while Alesina and Perotti (1992) identify it with any degree of social instability as political assassinations, coups d'état and deaths related to conflicts.

There is some controversy in the way that instability must be measured, since it is an unobservable. For example, latent variable models have been used to capture the effect of the probability of a change of government (Gurgul and Lach, 2012); Gwenhamo, W. Fedderke, of Kadt (2012) quantified political instability as a composite index that included the number of political detentions or declarations of states of emergency.

A classic problem in the literature is the possible existence of reverse causality caused by the relationship between economic variables and the elements of political instability. This problem has been partially solved, either through the application of the Instrumental Variables technique, through the specification of models of simultaneous equations, or

using procedures such as the synthetic control method, whenever it is eliminated in the construction of the counterfactual all the economies that have not suffered the conflict.⁵¹⁹

The study of the economic effects of instability in tourism is much more scarce (Ryu, 2005). In particular, some research has been done for the analysis of specific countries such as the partition of Cyprus (Mansfeld and Kliot, 1996), The Troubles in Ireland (Wall, 1996), or the terrorism by local groups in Greece, Israel and Turkey (Drakos and Kutan, 2003) and in Spain (Enders and Sandler, 1991). Also, some investigations have been carried out using an aggregate sample of countries (Thompson, 2011, Llorca-Vivero, 2008, Saha and Yap, 2014, Groizard, Ismael and Santana, 2016).

Regarding the political instability that emerged as a result of the Arab Spring, some papers has been written. Groizard, Ismael and Santana (2016) use a gravity equation to find the effect on the flow of tourists finding a direct effect on countries, but also evidencing a contagion effect in Algeria, Jordan, and Lebanon and a substitution effect Iraq, Saudi Arabia, Albania, Bosnia and Herzegovina, Turkey, and Spain. Perles-Ribes et al. (2016) explore the effect on the countries of the Mediterranean through the use of time series, finding a deviation of tourism towards Morocco and Turkey while Greece and Spain do not seem to have benefited. Afonso- Matta, Appleton and Bleaney (2016) estimate the effect of the AS in the GDP Tunisia using the Synthetic Control Method and finding important losses as a consequence of this phenomenon. Finally, Rodríguez and Santana-Gallego (2018) analyze the deviation of the flow of tourists to Spain using cointegration techniques, finding some evidence for the period 2008-2015.

There are multiple explanations why tourism has become the target of different terrorist groups. Ritcher (1980) points out that tourists are seen as "ambassadors of hostile governments" by terrorist factions. Enders et al (1992) consider that attacks on tourist objectives are intended to deter potential tourists and, in this way, to pressure the government to accede to their demands. In addition, these attacks assure them greater coverage in international media (Ritcher and Waugh, 1986).

One of the main consequences observed in all those papers is that political instability leads to a fall in tourist flows, regardless of whether tourism is the direct objective of the agents involved. For example, countries with authoritarian governments or where human rights are violated, at least facing the international community, experience a lower flow of tourism compared to the rest (Neumayer, 2004). Also, most of the works coincide in pointing out the existence of a lag of between three and nine months between the event being analyzed and the fall in tourism, probably as a consequence of the seasonal contracting systems of the sector (Enders and Sandler (1991), Pizam and Fleischer (2002), Bertrand et al, 2004). In terms of recovery time depends on certain factors such as the intensity of the conflict, the frequency of terrorist events and the involvement that the tourism sector has in them (Fletcher and Morakabati, 2008, Pizam, 1999, Drakos and Kutan, 2003, Bruck and Wickstorm, 2004; Frey et al, 2004; Morakabati, 2007).

Moreover, various articles have discovered the existence of two more effects of political instability in tourism: the contagion effect and the substitution effect. The first one known with the term generalization or simply spillover is provoked when a country has a negative image and that image is transmitted to a group of countries that share common characteristics. This spillover effect is the result of biased media coverage and lack of geographical knowledge among Westerns (Taylor, 2006). For example, Beck (2014) finds that Morocco is affected to belong to the same region as countries that are in conflict such as Tunisia and Egypt. On the other hand, this same author finds that UAE has benefited from the conflicts that occurred in the countries of the MENA region, experiencing a substitution effect. This effect is caused when tourists replace tourist destinations that are involved in some conflict by others with similar characteristics. The degree of substitution will depend on the specificity of the country's attractions (Neumayer, 2004). Although it is true, there is some disagreement in the literature on which of the two effects prevails in a given region (Wall, 1996).

4 SYNTHETIC CONTROL METHOD

Often, researchers have tried to evaluate the effect of an event that affects economic activity by comparing the behavior of economic agents affected by this event with others who have not been exposed to it. The main problem lies in finding appropriate controls, that is, agents or individuals that, on the one hand, resemble the treated unit as much as possible but, on the other hand, have not been affected by the event or, as specifies in these methodologies, by the treatment.

In experimental studies, this problem is solved through randomization. For example, in clinical studies, the effect of a treatment is compared between those who have been provided with such and those who have not been provided. Randomization therefore ensures that if the sample is large enough, both the units used as control and those treated will have similar characteristics.

In economics, this type of experiment is more restricted because the units are often not people, but regions or countries, making it more difficult to search for adequate controls. In order to overcome this problem, different methods have been used, as is the case of the differences in differences model. The difference in differences method contrasts the differences in the results of a population enrolled in a program (treatment group) and an unregistered population (control group), controlling for the fixed and unobservable characteristics of both groups and under the assumption that these characteristics remain unchanged. This means that this method allows the existence of unobservable confounders but restricts the effect of these confounder to be constant in time, so that they can be eliminated taking differences. This last assumption could have been relaxed thanks to the adoption of the Synthetic Control Method. This procedure, which is

⁵¹⁹ For a more detailed study of the various estimation methods see Gardeazabal (2010)

essentially similar to the previous one, allows the effect that unobservables have to vary over time (Abadie, Diamond, and Hainmueller, 2010).

Intuitively, the synthetic control method tries to estimate the effect of the treatment by comparing the effect on the observed variable and the counterfactual or synthetic construction as a weighted average of some units used as controls. This procedure is carried out in such a way that said weights are chosen so that the characteristics of the units used as controls are as similar as possible to that of the unit treated.

Formally, it is assumed that there is a sample of $J + 1$ units indexed by j , among which there is a unit that is going to be treated $j = 1$, with the remaining units ($j = 2$ to $j = J + 1$) being potential controls⁵²⁰. In this context, it is called T_0 to the periods prior to the intervention and T_1 to the subsequent periods so that the total period of study is T ,

$$T = T_0 + T_1$$

The synthetic control is represented by a vector $(J \times 1)$ of weights $W = (w_2, w_3, \dots, w_{(j+1)})$ where w_j is between $[0 - 1]$ for $j = 2 \dots J + 1$ and $w_2, w_3, \dots, w_{(j+1)} = 1$. That is, it is a set of weights that will be applied to the variable under study but for untreated units, so that they replicate the variable under study before treatment for the unit treated and serve to construct the counterfactual or synthetic after the treatment. By forcing the weights to add up to one and to be non-negative, the problem of extrapolation is avoided (Abadie and Gardeazabal, 2003). Those weights will be chosen so that the characteristics of the synthetic control are as close as possible to the characteristics of the unit treated

Let $X_1(k \times 1)$ be a vector containing the values of the characteristics belonging to the pre- treatment period for the treated unit and let X_0 be a vector $(K \times J)$ that collects the same values but for the units in the control group. These characteristics, also called predictors, will try to explain the outcome variable, so lags in the outcome variable can also be included as predictors (Abadie, Diamond, and Hainmueller, 2015). The inclusion of this type of predictors solves the problem of the omission of relevant predictors since the effect includes the effect of any variable, whether or not it has been included in the model (Ferman, Pinto, and Possebom, 2016). These variables will be used as predictors of the outcome variable in the preintervention period because they are not precisely affected.

The differences between the characteristics of the unit treated and the synthetic control in the pre-treatment period is given by the vector $X_1 - X_0W$. Those weights W^* will be chosen in such a way as to minimize the difference, that is,

$$\sum_{s=1}^k v_s (X_{1s} - X_{0s}W)^2$$

Where $s = 1 \dots k$, let X_{1s} be the value of the sth-variable for the unit affected by the treatment and let X_{0s} be the vector $(1 \times j)$ containing the values of the sth -variable for the units in the group of control and be v_s indicates the relative weight that is assigned to each predictor. There are several ways to choose the optimal weights of the predictor variables. In this paper the weights will be chosen in a way that minimizes the prediction error, that is to say that v selects the W that minimize the RMSPE during the pre-treatment period (Abadie, Diamond, and Hainmueller, 2010).

Finally, let Y_{jt} be the result variable for unit j at time t . Denote as $Y_1(T_1 \times 1)$ the vector that collects the values for the result variable after the intervention for the unit treated, that is, $Y_1 = (Y_{1T_0+1}, \dots, Y_{1T})$. Similarly, let Y_0 be a matrix $(T_1 \times J)$ where column j contains the values of the outcome variable after the intervention. The synthetic control estimator is calculated as follows:

$$Y_{1t} - \sum_{j=2}^{J+1} w_j Y_{jt}$$

One of the main advantages of the SCM is the possibility of comparing the units used as controls. This is because the synthetic control makes explicit the relative contribution of each control unit to the counterfactual of interest and the similarities or differences between the affected unit and the synthetic control in terms of the predictors. This eliminates the discretion that the researcher can impose in the selection of the control group, replacing it with a data-driven process that looks for those units within the control group that most resemble the unit treated.

On the other hand, one of the main criticisms that has been made about this method is the lack of guidance when selecting predictors (McClelland and Gault, 2017). A possible solution could be to select those predictive variables that minimize MSPE during the pre-treatment period. This is because if the model is correctly specified, the MSPE corresponding to the pre-treatment period should be close to zero because the units in the control group are not affected by it (Ferman, Pinto, and Possebom, 2016).). Furthermore, there is no guide to how many linear combinations of the outcome variable should be used as predictors. While some authors use the variable lagged result for all periods as predictors (Bilgel and Galle, 2015, Kreif et al, 2016, O'Neill et al, 2016), Klößner, Pfeifer, and Schieler (2016) discourage this specification since although it improves the adjustment during the period before the intervention, it eliminates the effect that other

⁵²⁰ It is assumed that a balanced panel is available and the sample contains a number positive of periods before and after the intervention.

covariables may have on the outcome variable. In this way, the weight given to the set of lag variables can cause a bias in the estimator since the eliminated covariables are not taken into account to predict the values of the outcome variable in the period after treatment.

In order for the synthetic control method to be correctly used, a series of conditions must be met: 1) Only the treated unit must be affected by the treatment, since it is a necessary condition for the use of the controls. It is of particular relevance to analyze the existence of spillover since, in the case of any, the affected units should be eliminated; 2) There should be no previous effects to the treatment since if there were the comparison between the synthetic control and the unit treated would be biased. If there is one, this problem can be solved through a readjustment in the year of the beginning of the treatment; 3) The counterfactual created by the synthetic control must be approximated by a fixed combination of the units used as controls; 4) Synthetic control should have a structure similar to that of the treated unit, that is, that the variables used as predictors should be similar to the observed variables of the unit treated. If there is a difference, then the divergence between the outcome variable of the unit treated and the control could be due to structural causes and not to the effect of the treatment itself (Matta, Appleton and Bleaney, 2016)

Since the series of seminal publications that gave rise to the synthetic control (Abadie and Gardeazabal, 2003, Abadie, Diamond and Hainmueller, 2010, Abadie, Diamond and Hainmueller, 2015), there has been a great profusion of papers that have used this method to analyze the effect of natural events (Du Pont and Noy, 2012; Cavallo et al., 2013), political events (Abadie et al., 2014; Gautier et al., 2009) and economic events (Billmeier And Nannicini, 2013; De Angelo and Hansen, 2014).

5. DATA AND IDENTIFICATION OF AFFECTED AND BENEFITED BY THE ARAB SPRING

The basic information used for the evaluation of the effect of political instability originated in the MENA area by the Arab Spring comes from the Compendium of Tourism Statistics prepared by UNWTO. Specifically, as a result variable (on which the analysis is carried out) the total of the visitor (overnight visitors) has been selected. As regressors, the rest of the variables included in this database were initially selected under the rubric of Basic Data and Indicators, eliminating the countries and variables that presented a greater number of omitted data. Finally, basic information has been provided in the form of a balanced data panel for 169 countries or destinations and 42 variables, although from them up to 34 additional ratios have been built. From these 76 variables have been selected those in a joint regression of all of them against the entry of tourists have a p-value less than 0.05, which has reduced the number of variables to 55 (32 of the original and 23 of the calculated ones). The list of countries and variables considered can be found in the Appendix.

As it is indicated in the introduction, one of the key issues is to define precisely both the affected countries and the beneficiaries of this political instability caused by the Arab Spring. For this, three steps are followed: a) identify the countries where the event occurs and, from them, evaluate in which the inbound tourist flows have been damaged; b) identify the origins of these tourists to see their substitutes in those markets; c) identify the countries that could have benefited from the diversion of tourists from the markets indicated in b).

To identify the affected countries, the first thing that has been done is to consult different sources in order to offer a broad list of countries that suffered some type of protest or conflict that may be related to the Arab Spring. The list of selected countries is as follows: Western Sahara, Tunisia, Algeria, Jordan, Oman, Egypt, Yemen, Djibouti, Sudan, Iraq, Bahrain, Libya, Kuwait, Morocco, Mauritania, Lebanon, Saudi Arabia, Syria and Palestine. From this list of countries and the availability of information, the evolution of tourist flows before the event (2007 to 2009) and during its effects (2012 to 2014) and after it, but coinciding with the increase in terrorism, is analyzed. in the area (2015 to 2017).

As it can be seen in Table 1, the three countries that truly seem to have suffered the effect of the Arab Spring are Tunisia, Egypt and Yemen. The rest of the countries have had changes both downward and upward, but of a moderate magnitude. Therefore, these three will be taken into consideration for the concrete analyzes of countries. However, to solve possible problems of contamination of the sample of the rest of the units with which the synthetic is calculated, the other eight economies of those previously mentioned as affected are eliminated from which data are available before and after the event⁵²¹.

Table 1. Tourist Arrivals and market share in the International Tourism Market

521 These countries eliminated from the sample of units with which to build the counterfactual are Lebanon, Saudi Arabia, Morocco, Algeria, Jordan, Oman, Bahrain and Kuwait. For Mauritania, Sudan, Djibouti, Somalia, Iraq, Syria and Libya, full information was not available, so they were previously eliminated.

	Pre-Arab Spring 2007-2009		During Arab Spring 2012-2014		Post-Arab Spring 2015-2017	
	Annual Tourist Arrivals	Market share	Annual Tourist Arrivals	Market share	Annual Tourist Arrivals	Market share
Slight impact						
Lebanon	1398	0,15	1332	0,12	1693	0,13
Sudan	432	0,05	617	0,06	800	0,06
Saudi Arabia	12395	1,35	16788	1,53	17065	1,37
Djibouti	51	0,01	63	0,01	71	0,01
Kuwait	283	0,03	268	0,02	199	0,02
Morocco	7876	0,85	9901	0,90	10608	0,84
Moderate impact						
Algeria	1809	0,20	2556	0,23	2020	0,16
Jordan	3650	0,40	4032	0,37	3967	0,32
Oman	1372	0,15	1415	0,13	2260	0,18
Irak	928	0,10	1002	0,09		
Bahrain	5319	0,58	5812	0,53	9571	0,76
Strong impact						
Tunisia	7203	0,79	7171	0,65	6043	0,48
Egypt	11607	1,27	9999	0,92	7509	0,60
Syria	5227	0,57				
Yemen	1000	0,11	961	0,09	367	0,03
Libya	36	0,00				

Once the three affected economies have been identified, we have proceeded to evaluate which are the countries of origin that have possibly diverted tourists to alternative destinations. To achieve this goal, the information provided by UNWTO on the bilateral flows of tourists received in these three countries has been used and compared information for the period before the Arab Spring (2007 to 2009) with that obtained for the post-Arab Spring period (2015 to 2016). The aggregate results for the three economies are presented in table 2. In total, the three economies lost 7.43 million tourists (in absolute terms and without considering possible growth of tourism between both periods), although this figure is the result of a loss of 8.92 million tourists from the origins that decrease their tourist flow and a gain of 1.49 million from other origins that increase it.

	Average annual tourist arrivals		Change	
	2007-2009	2015-2016	Absolute	% on total loss/gain
France	1.898.269	547.005	-1.351.265	15,15
Italy	1.462.140	310.106	-1.152.034	12,92

United States of America	337.554	208.888	-128.667	1,44
Japan	123.157	19.207	-103.951	1,17
Hungary	104.271	29.401	-74.871	0,84
Norway	77.840	12.821	-65.019	0,73
Syrian Arab Republic	124.792	61.030	-63.762	0,71
Finland	74.449	10.850	-63.599	0,71
Loss in tourist arrivals			8.919.315	100,00
China	84.306	153.808	69.502	4,67
Sudan	166.323	239.702	73.378	4,93
Belarus	0	101.807	101.807	6,84
Ukraine	0	394.293	394.293	26,49
Algeria	1.007.042	1.677.997	670.955	45,08
Gain in tourist arrivals			1.488.413	100,0

Taking into account only the 24 origins indicated in this table that represent more than 80% of the losses and 90% of the profits, we proceed to identify the possible alternative destinations that have been able to replace the three affected economies. To do this, we proceed to use information on tourist flows abroad issued by each of these 24 destinations, according to the information offered by UNWTO. To proceed with this identification, the pre-AS quota of the three affected economies (Tunisia, Egypt and Yemen) is compared in each of the indicated origins and compared with the one presented in the post-AS period. If there is a drop in the quota at the origin, the loss of quota that these three destinations haven had among the destinations that have increased their quota in the two analyzed periods is proportionally assigned.

Doing this, it is possible to estimate the possible beneficiary destinations and the amount of this deviation, as a result of the loss of quota of these three countries. The computation is carried out country by country and afterwards, the results on possible winning countries are presented in table 3. From this list, possible winners of tourists have been selected as those who have any of the following four characteristics: a) earning more than 200,000 tourists, b) earning more than 100,000 tourists and representing at least 1% of its total tourist flow; c) a profit of more than 75,000 tourists and that at least represents 2.5% of the total tourist flow; d) tourist gain that exceeds 5% of the total number of tourists. For the selection of these potential winners, not only the jump between the pre and post-AS periods has been taken into account, but also between the pre and the during and between the during and post. This has led to the exclusion of 29 potential winners: Spain, Germany, Netherlands, Portugal, USA, Croatia, Greece, Italy, Thailand, Turkey, Austria, United Kingdom, Hungary, Ireland, Qatar, Indonesia, Sri Lanka, Iceland , Malta, Alabania, Slovenia, Cape Verde, Congo, Senegal, Togo, Niger, Guinea, Central African Republic.

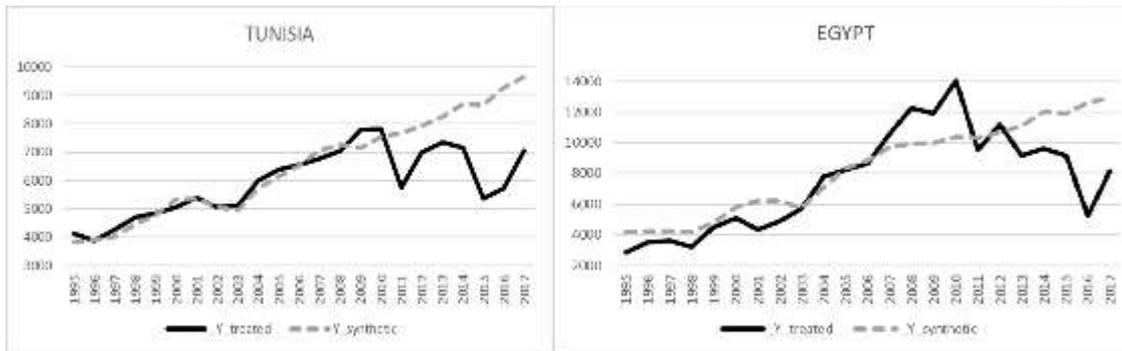

country	Estimated tourist gain	% of own tourist arrivals
Spain	1.055.590	1,47
Germany	649.539	1,84
Netherlands	503.491	3,27
Portugal	453.150	4,22
United States Of America	424.277	0,55
Croatia	337.881	2,55
Greece	317.208	1,31

Cabo Verde	44.276	7,92
Congo	22.829	10,59
French Guiana	22.344	10,87

6 RESULTS

A set of countries has been selected with the aim of capturing the effect that the AS has had on the arrival number of tourists. The time period analyzed covers from 1995 to 2016, where the period 1995-2009 represents the pre-treatment period and the years 2012-2016 the post- AS. The selected countries are the following: Egypt, Tunisia, on the side of those affected and Spain and Thailand on the side of the beneficiaries. These countries have been chosen for the following reasons:

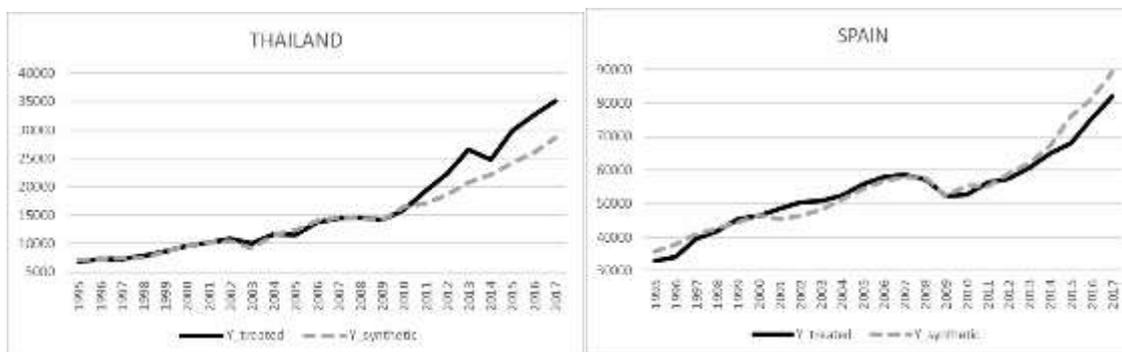

1. Because they represent beneficiary countries as affected countries, we intend to observe the substitution effect caused by political instability.
2. The choice of beneficiary countries is due to the fact that these countries, despite their different geographical situation, represent one of the markets in which the affected countries were specialized: sun and beach tourism.

Regarding the specification of the model, various specifications have been tested for the 4 countries, choosing the one that minimizes the RMSPE corresponding to the pre-treatment period. The goal is that the synthetic country replicates as well as possible the country observed during the previous years to the conflict so that any difference caused after the conflict can be attributed to the latter. To do this, apart from the variables selected in the Basic Data and Indicators from the UNWTO, several lags of the result variable have been added as a predictor variable.

As it can see in the following graphs, there are three periods clearly differentiated. First, there is the period before the AS where both countries experience a constant growth of tourism, more accentuated in the case of Egypt. Second, the period in which the Arab Spring begins coincides with the period in which Tunisia and Egypt suffer the greatest drop in the number of tourists arriving in the analyzed period. Finally, once the political conflict has ended, there is an increase in the number of tourists arriving, which is truncated with a surge in terrorist attacks in both countries.

For example, in the case of Tunisia, a drop in the number of tourists in 2015 can clearly be seen as a consequence of the attacks on the National Museum of the Bardo and the attack on Susa. As a result of these political events, Tunisia has lost about 2.5 million tourists, reaching 7 million arrivals but far from the 9.5 million that it would have reached in the absence of such conflicts. Finally, in recent years there has been a rebound in the number of tourists arriving in the Tunisian country, clearly conditioned by the absence of terrorist attacks and instability in the area.

As a consequence of the drop in the number of tourists arriving in the affected countries, it is expected to observe a displacement of those tourists to other regions or countries with similar attributes. In the case of the Southeast Asian country, the year 2010 represents a change in trend clearly influenced by political events in the MENA region. Thanks to these political events it is estimated that Thailand has gained 7.5 million tourists since the beginning of political instability.

The case of Spain deserves a separate explanation. Although at first it could seem the main beneficiary of the AS, the results obtained using the SCM indicate a negative difference with respect to the synthetic one, that is, the arrivalsof tourist to Spain should have grown more than it has happened. However, the difference between synthetic and observed is probably not significant due to the high level of RMSPE. This result coincides with previous investigations such as Perles-Ribes et al. (2016) where they find a non-significant relationship between the AS and the arrival number of tourists to Spain.

Although this result may seem paradoxical, it may actually be due to an explanation. As De la Peña et al. (2017) points out, Spain experienced a turistic crisis at the beginning of 2008, characterized by a drop in the number of tourist arrivals that does not begin to reverse until two years later. As a consequence of this change in trend, Spain would be recovering all the tourists lost during the last period.

Therefore, the increase in tourism in Spain could be due to a recovery of lost tourism and not to an increase in tourism as a result of the Arab conflict.

7. CONCLUSION

The Arab Spring has been a political event that has affected not only the countries of the area but also the rest of the world due to the importance of this region in terms of tourism. In order to calculate the displacement of tourism that has caused this political event, the main countries affected by the AS and potential beneficiaries have been selected through a procedure. Finally, the Synthetic Control Method (SCM) has been used to quantify the effect that this event has had on tourism. We have focused on analyzing two beneficiary countries (Spain and Thailand) and two countries affected (Tunisia and Egypt). In this way, we have found that the AS has meant a loss of 2.5 million tourists for the Tunisian country. While Thailand has benefited from this political conflict, for Spain no increase is observed.

This paper must be extended to the rest of affected countries and benefited with the objective of calculating the general effect that this conflict has had. Furthermore, to verify that the results we have obtained are true, various sensitivity analyzes must be carried out, such as the case of the falsification or placebo tests commonly used in this literature.

1398 MIGRATION AMONG THE TRIBAL GROUPS OF ARUNACHAL PRADESH

ABSTRACT

Migration and development are closely related. And there are numbers of studies in which this relationship and the causes for migration is widely discussed. New dynamics of migration is coming up with more and more in-depth micro level regional studies. Further Arunachal Pradesh is one of the least studied states located in the northeastern corner of India and it has been observed that the state is in the transitional phase of socio-economic development with some variation across the districts in the level of development and so the mobility pattern. The state is inhabited by more than 25 major tribes and most of them are agrarian societies in nature. Recent government induced employment and other developmental programmes are improving the economic opportunities. Social sector development varies from one tribal group to another due to socio –economic –political–historic-cultural reasons and so the migration. Given the above-mentioned background, it is noteworthy to know the nature and extent of migration among the tribals of Arunachal Pradesh. Hence in this study we have tried to assess the nature, extent causes and consequences of migration among the tribes of Arunachal Pradesh using the appropriate statistical tools.

1473 LINKING LIVING THROUGH TIME AND SPACE: STUDY ON NEWLY SETTLED RESIDENTIAL UNIT IN SONARPUR-RAJPUR MUNICIPALITY, KOLKATA

ABSTRACT

Changing residence within urban residential areas is a process that changes lives of the people involved and also different composition of neighbourhoods chosen for time being as stepping stones or permanent unit to live in. As a part of spatial mobility, residential relocation or mobility also depends on numerous decisions, i.e. social, political, economic or educational, demand for better household and so on. Decision towards changing of residential area is often associated with homeownership and housing type. Another way, residential mobility even changes demographic characteristics and land use pattern to the place of newly arrived residential area. Frequency to shift residential units before finalizing the last place of residence also might be affected by urban economy, diversity of jobs, job opportunity, daily communication system between urban and suburb, urban policy and other factors. The present initiative is taken to unfold the residential relocation behaviour of the households and special emphasis is given to the reasons for relocation in terms of duration of stay in between residential location before permanent one and their livelihood strategy at the present place of living. In order to understand the whole scenario, urban fringe area within Kolkata Metropolitan District is a perfect choice over which this empirical study has been conducted based on well designed questionnaire survey to collect the main information along with measuring the changing trends of landuse pattern over three decades around final residential units. The study begins with using random sampling method and surveyed 220 households with heterogeneous characters. Study identifies households with respect to source region, period of stay at last place of residence prior to coming at present place and assesses the push and pulls factor behind their mobility. Quality of life, suffering index and Regression analysis used to address the reasons that might act as the main principal factors that affect residential mobility several times even the frequency of residential relocation taken place two to five times. This study also discloses their economic structure and level of dependence for livelihood in different time intervals and level of adjustment to the new place of residence using priority index and housing affordability index. However, an increasing house rent, changing land value, unhealthy living environment, poor sanitation system, increase family size, terms and condition of rent house and aspiration of making a new own residential unit are key factors for further shifting household that would force them to search a residential units that are fitted for them. The whole process may help urban planner to understand the transformation nature of landuse patter over suburb areas in some alike city of Kolkata in developing countries. Key Words: Residential Relocation, Landuse Transformation, Suburb, Affordability, Livelihood

1094 UNCERTAINTY OF LIVELIHOOD AND MIGRATION: A STUDY ON JALIAKHALI AND KAIKHALI VILLAGE, KHULNA ZILLA, BANGLADESH

Riyanka Chatterjee, Utpal Roy

University of Calcutta, INDIA

ABSTRACT

The birth of Bangladesh as an independent country from the regime of Pakistan was in 1971. Since becoming the part of Pakistan in 1947, everything in Bangladesh was under the control of Pakistan. But population movement from Bangladesh to India irrespective of religion was a very common phenomenon. Interestingly after 1971, the propensity of migration of Hindu families started momentum in compare to earlier periods in Bangladesh. Primarily the reason was associated with issue in which the Hindu who became the secondary citizen by default after the declaration of Islam as the state religion in 1988 but with the course of time immigration process pushed by various factors such as environmental problem i.e cyclone, river bank erosion, flood, socio-economic problems i.e unavailability of work, low wage etc. This initiative takes an attempt to find out the factors of response to migration and to identify the crisis of Hindu families as minority in Jaliakhali & Kaikhali villages Dakope & Assasuni Upazilla, Khulna Zilla, Bangladesh. Mainly two methods have been followed- Snow ball sampling and Random sampling along with group discussion, experts view, participant's observation to address the present livelihood status of the Hindu families. The Hindu populations over the study areas have confessed their willingness to be part of migration process and most of them are prepared to leave but rest of them are at the edge where they know that they may be evicted forcefully or voluntarily by various socio-economic and environmental factor. Jaliakhali and Kaikhali both were Hindu Dominated villages, still a significant number of Hindu families are still living in both villages. The distinct nature of response to willingness of migration made the study more meaningful. Jaliakhali is a village where environmental issues more intently affect the lives of people whereas Kaikhali is influenced by socio-economic causes. People who are from the grassroots of society, are mainly vulnerable and prone to migration, which are pushing them towards a life which is completely uncertain and unknown to them.

Key words: Migration, Vulnerable, Uncertainty, Environmental issue, Socio-economic issue, Displacement

INTRODUCTION

The liberation war in 1971 gave a birth of India's another neighboring country Bangladesh. After independence, Bangladesh outlined its own Constitution where secularism was one of the four fundamental principles (the other would be Nationalism, Democracy and Socialism). The Secularism principle was removed in 1977 by the 5th Constitutional Amendment and declared Islam as state religion in 1988. Since the declaration migration of Hindu families started increasing quite remarkably on account of the consequences of biased religion based cultural freedom among the significant number of citizens belongs to Hindu religion. At the beginning of independence of Bangladesh the emigration was related with the insecurity felt by the Hindu population. The communal riots, religious violence, minority harassment forced them to leave the country. Living environment becomes more challenging to Hindu as the proportion of Hindu population is being reduced. According to Population and Housing Census 2011, the percentage of Hindu population decrease 3.59 % from 1981 to 2011. As per census report, of Bangalesh, the Hindu population was 12.13% in 1981 which drops down to 8.54 % in 2011. And the capital of Bangladesh has the lowest number of Hindu population that would be 10.5% to total population of Dhaka followed by Barisal (11.70%) & Chittagong (12.65%) ¹.

Hindu families across the study areas are in the present phase where they are aware of the fact that the motherland will no longer give them the safe shelter. Due to several of socio economic and environmental reasons have continuously been pushing them to move out. The well known many Hindu families are getting vanished from their neighborhood. The present dwellers don't know how long they can stick to their goal to not leaving their native place. People generally to response to migration when the dormant physical and socio-economic factors aggravated their decision for migration.

OBJECTIVES

The principal objectives of this study are

- To identify the factors determine migration and living condition of the Hindu families in the study areas
- To analyze the willingness and phase of preparedness for migration at present and in near future.

STUDY AREA

Jaliakhali is a village Kamarkhola Union of Dakope Upazilla, Khulna Zilla under Khulna Sub-division of Bangladesh. Dakope Upazilla has 9 Unions in which Dakope itself called an Union. On the other hand Kaikhali village is under Assasuni Union, Satkhira zilla, Khulna zilla under the Khulna subdivision. Satkhira upazilla is the easternmost upazilla which share the international border with India.

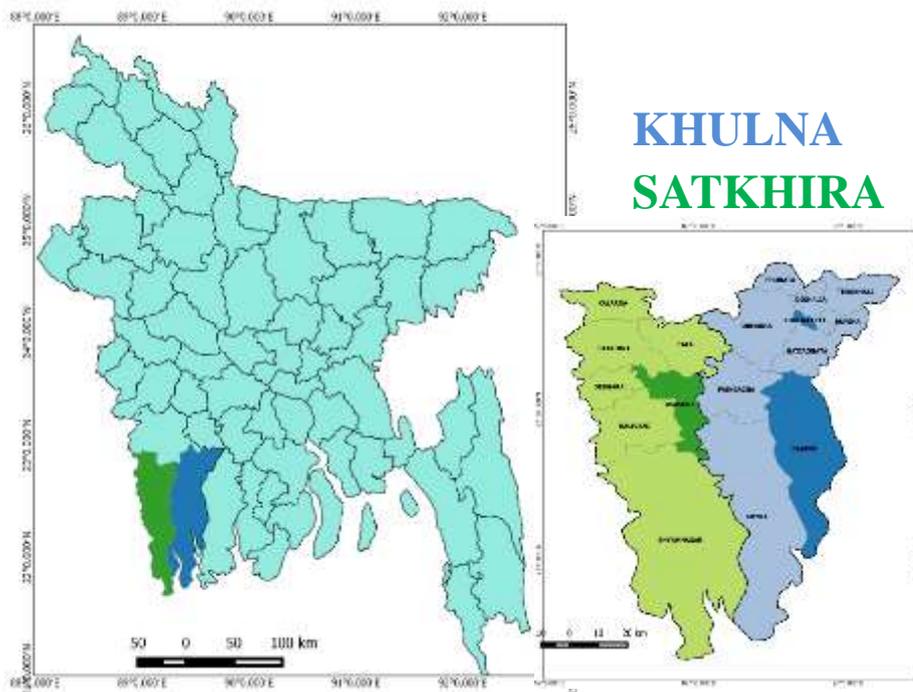

Figure 1: Location map of Study area

DATABASE AND METHODOLOGY

The work has been divided into several phases. Prior to field, in field, post field. Prior to field a detail literature study has been done following by selection of the study area and secondary data such as book, journals, census data also been collected. In field, interview & interaction, discussion with the household members has been done followed by expert's opinion and views also been considered. The post filed work mainly consists with data that have been collected from field which has been generated, compiled and processed for analysis. The primary data further divided into Qualitative and Quantitative. Group discussion, observational data and participant's observation grouped under Qualitative data and individual household survey under quantitative. The entire research work classifies into three group correlation, descriptive, explanatory research work.

RESULT AND DISCUSSION

Phase of preparedness before migration

Migration may be of forced or voluntary. When the migration is induced and caused by external forced is called forced migration and if the migration is caused by the people themselves for fulfill their own desire is called voluntary migration. In Jaliakhali, migration took place due to the embankment breaching so it is better to call as 'Displacement' instead of migration. The people of Jaliakhali were displaced from their previous residence 'Choto Jaliakhali' due to Aila in 2009. After the devastating cyclone they shifted to the backward part of previous Jaliakhali. The area is retreating due to continuous river bank erosion. Now the people of that village demand the permanent solution of every year shifting residence due to natural disaster.

On the other hand, in Kaikhali village, the Socio-economic problems are more dominant than environmental factors. Better employment opportunities, secure living environment, better future for next generation in terms of education, healthcare and other livelihood opportunities pull the people from Kaikhali and as a result voluntary movement is taking place.

As per the present survey, many Hindu families in both villages have good connection with their relatives and neighbours (who have settled themselves earlier in different parts of West Bengal, India). Among the respondents, 95.94 % have visited India and among them 53 % have own land in India mainly in West Bengal. Only 47 % did not buy land any land but still they have been trying to do the same.

Few respondents said that land buying process was not easier for them who don't have any legal document related with Indian citizenship. For them to buy land in India, firstly they need identity proof which helps to prove them as a permanent citizen. As per one of the respondents Smt. Rina Ray, 67 years old woman who had crossed international border (between India and Bangladesh) without passport with his son and husband several times and said "the land brokers are very active in those places (in West Bengal, India) where they bought the lands and for doing the so brokers have been paid a larger amount of money". So the entire process from crossing the boundary to settle down in India is done through some steps i.e. Firstly, entry to India through porous border with the help of brokers (may be called migration smugglers) who take the risk to make illegal migrants cross the international border for getting a lump sum as bribe from illegal immigrants. This kind of unlawful racket is prominent both sides of international border. Although

this illegal activity is more popular in Indian side than Bangladesh. Secondly, after crossing boundary migrants like to take a temporary shelter in those places where their relatives or people coming from Bangladesh earlier and settled up permanently in India. Thirdly, after staying some days at relatives house or or others, they try to take different ways for making different identity cards which also be done through brokers or local political leaders of India by offering bribe.

Willingness and desired place of migration

It is well known fact in the process of migration that both places mean place of origin and place of destination create opposite situations which might attract people and encourage people to leave the place. Some attracting factors at place of destination have already been mentioned earlier. Let us see the factors prominent at place of origin which lead to move out the people. Firstly, some natural factors like land loss due to flood, cyclone, extensive rainfall, river bank erosion are prominent mainly in Jaliakhali village. Secondly, a continuous changing well known traditional society's structure is being affected due to gradually reducing the number of Hindu population. Thirdly, parents of daughter with 15-19 years of age feel insecure in thinking of their daughters' future. Before facing unwanted incidence with their daughters, parents give their daughter marriage before even 18 years of age with groom of same religion. Fourthly, less job opportunity, adverse job environment along with low wage influence them to take decision for the future. Mentioned above factors are interrelated that lead to uncertainty of life. All these dormant factors might aggravate their willingness to move out from the motherland. Although they all have a wish for leading their live in a well manner at present place of living but the hidden desire for willingness to migration is gradually increasing among the Hindu families. Many of the respondents have confessed that they have an alternative shelter in West Bengal but most of them are trying to be part of the citizen of India in near future only for the insure day to day life at place of living. All of these stimulating factors that boost up or aggravated the willingness for migration for those who are at the threshold or near to threshold.

Response to migration can also be applicable for those who desire to lead their lives in coming days better than present life. But in this study the situation is applicable for the vulnerable group mainly the Hindus over the study areas who are not at the edges where they every day are experiencing the numerous challenging related with their life and livelihood. In many countries of developing world, many things in everyday life are directly and indirectly influenced by religion, caste, race, ethnicity etc. In this case, religion does play a foremost leading reason of the study area especially with them who are already minority. The existing 8.54 % Hindu population every day are leading life with different ideas, interests, liking, behaviours, and values from culture of most of the people in Bangladesh.

It can be discussed taking example from two surveyed villages. Jaliakhali is a village where environmental factors are more active in changing the life of dwellers whereas the social-economic factors are playing vital role in shaping the migration decision in Kaikhali. The people of both areas more or less suffered with all the issues discussed earlier. Viability of living condition at Jaliakhali and Kaikhali has been observed in three different manners. Firstly, living conditions that are favorable for the people having no issues with the live and livelihood can be termed as viable. Secondly, those who are gradually affected by the factors which earlier were in favor of them, but in course of time the factors interrupted their lives frequently can be termed as Moderately Viable. Lastly, those who are badly affected with the present factors to leading their lives more efficiently can be termed as less to very less Viable. It can be said that as per the level of viability, people of different categories may respond to migration process. Migrants always follow a path or routes that mainly are used by people moved out earlier or are used by the following immigrants. People try to seek a new accommodation where they can adapt fast than any other place in the world. The process of migration always needs a stimulating factor, that can be negative for the place of origin for the emigration and the same can be a advantage of the place of destination of the immigrants. Here, the environmental problems became negative for the dwellers of Jaliakhali stimulate them to migrate into the area of less frequently occurrence of natural disasters. On the other hand, less job opportunity, low wage, insecurity of young growing daughters' life and newly married wife, children and their education all are the stimulating factors for the inhabitants of Kaikhali village, where people are not able to cope up with the living environs, maximum of the residents of Kaikhali have relatives in West Bengal, India, and a significant number of Hindu families have already sent their young daughters, son or daughters who can get better education, young son who are eligible for pursuing a job to their relative who are living in West Bengal.

Response to migration prominent over Jaliakhali & Kaikhali, Bangladesh

The people who are in the state where the surrounding situation is not in favor of them are called vulnerable. If the condition is adverse to the vulnerable group they may be suffering from numerous negative conditions which are not desirable for them. The response to migration is the concept related to the most vulnerable group of society who are at the edge in which the circumstances in which earlier their living is in the challenge. The response may be induced by various factors related with Environment, political, social or economic.

In the study areas Jaliakhali & Kaikhali, living conditions are becoming difficult. Jaliakhali was affected by cyclonic disaster Aila in 2009, after that the land condition for cultivation becomes unfavorable. Salinity intrusion, destruction of living habitats, huge loss of domestic animals, embankment breaching, extension of river within agricultural field after Aila have altered the balanced condition of living. People of Jaliakhali are now living in few meters apart in the village Jaliakhali, earlier they lived into Choto Jaliakhali. Each of the villagers has lost land due to Aila event, remaining lands are now they using for dwelling purposes. A very less amount of land are left for Agricultural and fishing lands. In this situation they cannot keep faith on their destiny, because every year they cannot bear the devastative natural disasters. Flood and river bank erosion overthrowing them from their dwelling units. So the displaced person now wants a

permanent solution. These is the condition in which people of Jaliakhali do now response to migration, where some of them are prepared to take the risk of uncertain future of a new place, and some of them are waiting till the last.

The main reasons which force people out from their motherland are the **Socio-political** and **Economic** and **Environmental in Kaikhali**. Each of the reason has a push force which induces the people to leave their home land. As the environmental problems associated with the lives of the resident of Jaliakhali and Kaikhali, other two prominent forces are now showing with the help of the diagram

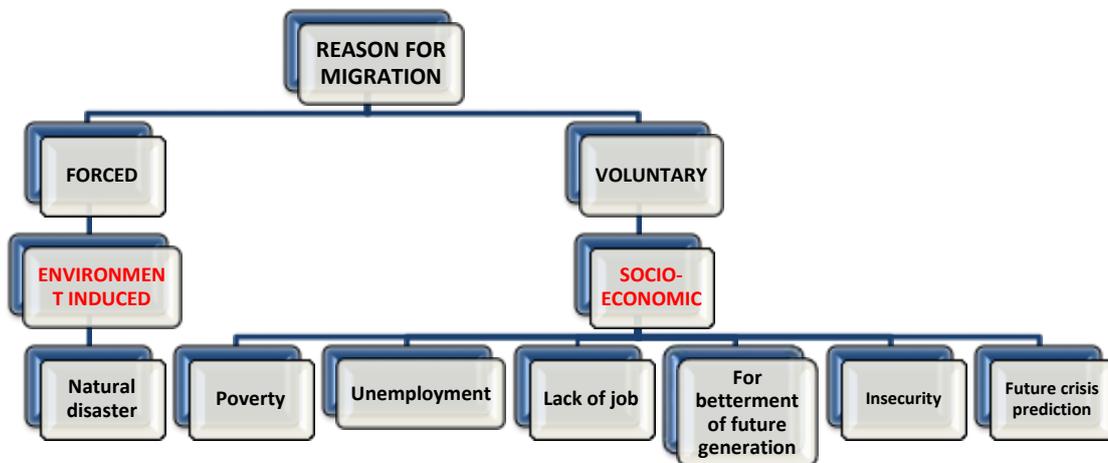

Figure 7: Reason leads to move people out from the study area (Jaliakhali & Kaikhali)

MAJOR FINDINGS:

The trend of immigration from the eight neighboring countries of India, Bangladeshi immigrants are highest in number and the proportion is gradually increasing in proportion. As per recent estimate as of 2017, about 5.2 million outsider are living in India. According to Census 2001 of India, the number was 3,084,826 from Bangladesh highest among the rest. In 1991 the amount was 591,572, so Decadal variation (in %) during 1991 –2001 for Bangladesh is - 52.7 %. According to UN data, more than 7.8 million people of Bangladeshi origin were living in 89 countries of the world in the year 2013. The main host countries are India (3.2 million Bangladeshi migrants) highest among all.³ There are some interesting findings of the present study

1. The people of Bangladesh find themselves near to the neighboring Indian people as they share the same language, culture and identity. It is very obvious for human that they try to seek accommodation where the adaptation strategy become fast. The similar cultural identity gave the comfort to the Bangladeshi’s since before India’s independent. Although better job prospect they can found anywhere the world but the communication as well as the similar identity they will not found, in this regards India has an extra advantages, especially in West Bengal where the adaptation strategy for accommodation, integration and assimilation are faster than anywhere in the world particularly for the Bengali’s
2. Bangladesh is surrounded by India and it share 4095 km of border with the nearest neighboring country. The migration took place since before the country gets there independence, and the recent trend of migration took the path or route of migration which was keep up the practice of immigration into India.
3. The history of seek for better opportunity at neighboring country India, still followed at the bordering zilla of Bangladesh, and not only that searching a better prospect for own as well as for future generation is spreading up rapidly.
4. The Land exchange process that was the exchange of land between dwellers of two difference area took place after the independence of India. the residence of India exchange their land with the residence of east Pakistan, one of them was sri Pallab Bhattacharya who exchange 65 Bighas of land with a Muslim at Khulna City Bangladesh, and get only 35 of Bigha of land at Barasat which account for Rs.... in 1968, now the 83 years old man is a permanent residence of South Kolkata, West Bengal, India.
5. In most of the cases Hindu sold the land to the Muslims in a very lower rate. The reason behind this was, **Firstly**, Hindu’s does not wants to stay in Bangladesh so Hindu Family do not buying a new land and made investment for a land in Bangladesh. **Secondly**, the Hindu families does not have the sufficient money to buy a new land, as per their view “if I bought a land, I will bought it in India” so they are not willing to stay in Bangladesh and buy a new land. So it is very obvious for a Hindu to sell the land to a Muslim and in that case they are paid a minimum amount for that land by them

CONCLUSION:

Migration is an adaptation strategy which shows how people accommodate, integrate and assimilate into a completely unknown environ. Although people try to follow those path or routes and accommodate in which previously his/her neighbor friends or relatives have pursue. It can conclude from the study that the process of immigration from Bangladesh to India has induced by various type of reason. The reasons are mainly varies with distance from main city

and differ from place to place. People who are from the bottom of the society they are mainly vulnerable and prone to migration, due to different environmental social and economic factors which are push them towards a life which is completely uncertain and unknown to them. All the factors are equally affecting the dwellers; it also varies with time and space. It is a phenomena which cannot be stopped, people would move from one place to another due to various of reason and the place of migration also be the choice of the migrants but in case of the study area as the living condition is not in favor of them so it has been predicted migration would be occur either with their own country or into their desire place India, until their uncertain future get a secure shelter.

1102 ENVIRONMENTAL CHANGE AS A 'THREAT MULTIPLIER': THE CASE OF MIGRATION

ABSTRACT

At a time when migration has become one of the biggest challenges that the European Union confronts, the debate surrounding the role of environmental factors like disasters in fuelling conflicts in the Middle East and North Africa (MENA), causing migration, is gaining momentum. After finding links between the Arab Spring and climatic factors, now climate security analysts have found ostensible links between environmental change and the ongoing civil war in Syria – mainly the mishandling of the worst long-term drought that had plagued the country since 2006. At the same time, attempts to correlate migration with climate change have also been disparaged by a significant number of scholars, according to whom this is a deterministic thesis that has no empirical basis and is an over-hyped contention, especially in a politically and ethnically divided region like MENA. In academic literature concerning climate change, the term 'climate refugee' continues to find place, especially to evoke security implications of climate change. The Paris agreement (COP21) also takes note of migration and seeks to establish a "task force" to "develop recommendations". However, the deeply political nature of the issue forced the parties to avoid any legally-binding obligations as well as the Pacific Island countries' clarion call to create a "coordination facility" for managing climate refugees. First of all, international law does not recognise "environmental refugees", which renders the act of rehabilitation and enforcement of accountability difficult. Secondly, while referring to migration, countries' position has traditionally been pinned on socio-economic and political crises rather than environmental ones. For instance, while referring to 'illegal' migrants from Bangladesh to India, the latter has insisted at the policy level mostly that this has very little to do with climate or environmental change. Thirdly, even while talking about migration caused or exacerbated by environmental change (slow disasters like droughts or sea level rise), a large amount of focus is on inter-state migration and not as much on intra-state migration, which is happening already on a large scale across the world. It has emerged as a cause for livelihood insecurity and erosion of the natural resource base, leading to rural-to-urban, coastal-to-inland and other forms of migration, putting excessive pressure on the available resources. Against this backdrop, the paper will delve into the international debates surrounding environmental migration and 'refugee' using a two-layered approach – law and policy/governance. It will look into international law dealing with 'migration' and 'refugee' and problematise them in the context of environmental security and how theoretically, migration has been recognised as a security implication of climate change. Two cases – Bangladesh (affected by not only annual flooding and cyclones but also effects of climate change like sea-level rise) and the Pacific islands (mainly climate change and increasing frequency of storms) – to provide an overview of the challenges posed by migration to international law, policy and governance mechanisms. The paper will analyse the lacunae in international and regional policies in terms of tackling environmental factors that act as 'threat multipliers' and provide recommendations on filling them through diplomatic initiatives.

1541 THE EFFECT OF IMMIGRANTS' SPATIAL CONCENTRATION ON THEIR LABOR MARKET PERFORMANCE - EVIDENCE FROM EU IMMIGRANTS LIVING IN GERMANY

ABSTRACT

Does residing in ethnic communities limit or foster the prospects of immigrants' labor market integration? This question has spurred political discussions and research in both labor and migration economics. Since the direction of the overall effect is theoretically ambiguous, the net effect is most of all an empirical question. We investigate if immigrants' labor market performance depending on whether they live in an ethnically concentrated region or not. During the last years, Germany has established its status as immigration country and as most important receiving country within the European Union. Ongoing EU enlargement, including freedom of movement and constantly declining unemployment attract further migration from Southern Europe affected by the crisis in 2008. As a result, we can observe a concentration of different migrant groups in certain local labor markets. However, also empirical evidence on the direction and magnitude is mixed. On the one hand, Edin et al. (2003) and Damm (2009) find a positive wage premium for immigrants living in ethnically-concentrated areas in Northern Europe. On the other hand, studies conducted for the US indicate that it lowers labor market integration regarding language ability and earnings (e.g. Cutler

1598 THE ENVIRONMENTAL MIGRATION OF ANDAMAN ISLANDS

ABSTRACT

Due to the direct force of nature or indirect human activities if there is any deterioration in the natural environment or hazardous situation prevails at a particular place at a particular given time which is not suitable for human settlement then the inhabitants of that place is forced to leave their original place of habitation and move to a comparatively safer places, that movement is termed as environmentally induced migration or environmental migration. To justify this statement and find out the actual problem we have chosen the Andaman Islands which is a union territory of India and located in Bay of Bengal. After 2004 so many people migrated from Andaman due to the large-scale destruction caused by tsunami and also due to fear of future natural calamities. Maximum migration took place from Andaman to mainland India. Bengali speaking people moved to West Bengal and adjoining areas and also people migrated to South India as per their ethnicity. The objective of this study was to obtain migrated population, and their pattern of migration, its effect on the socio-economic structure and behavioral changes. The study was based on the statistical analysis, for this purpose two types of investigation were carried out. One is through primary data collection and analysis which is based on field survey and second is by secondary data collection and analysis (data from the census of India and disaster-related data from the administrative office of Port Blair). Excel and SPSS were used as tools for data processing and statistical operation and also it was used for graphical representation purpose. ArcGIS was used for mapping purposes such as demarcating the study area, high and low migrated area etc. The study also included the statistical operation like central tendency, dispersion measurement. Furthermore, mapping tools was used for overlay analysis to compare the different aspect and establish spatial co-relation among migrated people and the area. After the analysis of census of India data (2001 and 2011) and field observations, it is found that the migration took place from north Andaman to south Andaman (particularly port Blair city and its surrounding area) even though tsunami affected the north Andaman less than the southern-most part of Andaman (Nicobar district). The actual causes were that the people of Nicobar were not interested to leave their place because of their ethnic attachment to culture and nature, but north Andaman people migrated due to natural phenomena and better availabilities of services like administrative, educational, employment and entertainment. The people whose economic conditions were not good, migrated on the cost of leaving their own land. That's why a new mixed neo-cultural activities started where the migrated people settled, not only in the Port Blair but also in the other places around it. This observation provides the final result of this study.

1605 BENGALI MIGRANTS IN MAJULI: NATURE, TRENDS AND CULTURAL ASSIMILATION

ABSTRACT

Human migration is a process of permanent or semi permanent change in usual residential area of an individual or a group of people from one geographical area to another. Majuli, a land with fertile soil and rich natural and cultural resources, but it is being isolated from other districts of Assam for its physical and cultural composition. The flow of Bengali immigrants started during the time of independence and continued till today due to the pull and push factors. The process and volume of Bengali migrants, from Bangladesh contributes a significant change of demographic structure of the district. The nature and dimensions of migration in the district, however, vary both spatially and temporally depending on the processes of development factors and reasons behind of migration. This illegal migration adversely effects on social, political and cultural environment and is one of the major reasons for social and ethnic violence in Assam. The Bengali migrants from Bangladesh are further classified into various residential clusters. This paper tries to identify the trend of the migration route and source area of the immigrants, to find out the role of government and to understand the basic structure of the cultural composition within the society based on both primary and secondary data. This paper entirely deals with both qualitative and quantitative methodology where non-probability sampling has been applied with the help of interviewing method, non- participatory observation method has been used for collecting primary data and the secondary data obtained from various sources. A detailed discussion about that there are physical and cultural barriers in Majuli, but still how the Bengali migrants are settled and also elicited the geographic process (temporal and spatial change) is related to the adaptation of immigrants from Bangladesh to Majuli in terms of cultural practice.

1634A STUDY ON THE REHABILITATION AND RESETTLEMENT PROCESS OF JRDA IN UNDERGROUND FIRE AND SUBSIDENCE AFFECTED AREAS OF JHARIA, JHARKHAND, INDIA

ABSTRACT

Jharia, “The coal capital of India” is situated in Chhotanagpur plateau of India where Gondwana group of coal fields are located. The mining area is leased to Bharat Coking Coal Limited(BCCL) where they are operating from pre-independence time. The long history of mining in this coalfield has led to increase in the number of sites prone to underground fire and land subsidence which was first reported in 1916. This has jeopardized the life of inhabitants in Jharia and nearby areas. Therefore, they are either compelled to leave their native places and move to comparatively safer places or they must be ready to face the curse of nature which frequency and intensity is increasing day by day. The school, colleges, market places, administrative offices, places of entertainment, means of transport etc. are constantly being put to shut down in this area. The central government has plans to resettle approximately 1 lakh residents away from burning coal mines and for its implementation, Jharia Rehabilitation and Development Authority was established in the year 2004. The objective of this paper was to first identify the sites reported to be under threat from underground fire and subsidence. Secondly, the objective was also to look at the rehabilitation and resettlement process, whether displaced people are getting the compensation as per the norm prescribed by the government. Furthermore, this study also focused on the socio-economic change in the life of displaced people. To fulfill this objective, the area was identified using government database. Most of the work was based on primary data collected through stratified random sampling. Census of India data was used to know the demographics of this area. To overview the government plans and policies reports from various government departments, offices and websites were collected and analyzed. Analyses and representation of data were done using Statistical Packages for Social Sciences(SPSS) and Microsoft Excel. Mapping such as demarcation of the study area, locating the affected area etc. in this study was carried out using ArcGIS 10.4. It is found in this study that till now only 2.04% of people have been rehabilitated. Most of the people seem not satisfied with the compensation they got. Means of livelihood was gone for many people and now they are unemployed. Socio- economic life of people is completely derailed. People do not have easy access to services such school, colleges, market, hospital, entertainment and recreational places etc. it can be said that government is not implementing it purposed plans according to it own norms. : Jharia, coal, underground fire, rehabilitation, Dhanbad, JRDA

ABSTRACT

Global warming is one of the most influencing factors for climate change of our planet. World Meteorological Organization (WMO) report that 2016 is year is hottest year and the ice at the pole is rapidly melting never seen before and increasing going ahead. The main Sources of the Global Warming gases are different Factories, fuels Vehicles, which help in different aspect of human life by giving the basics and addition needed to them. Therefore, we neither close factories, companies, vehicles nor replace far away from the residency of living life because if we replace the factory from human Shelter. Human being cannot fulfill according to their desire in time and due to transport the cost of prices is high that cannot be effort able to normal people, which indirectly affect the living life. In this paper, we discuss about the management of global warming gases especially coming from brick and other factories. Most of the factories are emitting the gases in open atmosphere, which directly contaminated the atmosphere and directly and indirectly effect near and far Peoples health and crops. So if we pass these gases throw underground tunnel whose length is according to global warming gases emitted from sources. The gases are settled down on the bottom of tunnel and we can use this solid fine powder global warming gas in our daily life. The Tunnels are constructed in two-way normal and specific way according to wealth of the factories or companies. Normal tunnel contain cooling system normal water, which is used on small companies, and factories while specific contain cooling chemical on wall of the tunnel this system is for large companies and factories. Here cooling system make the gases condense and settle down on bottom and we can use this global warming fine powder in our daily life according to the need.

The gases produce from the factories and companies when passes through tunnel contain cooling system condense the gases and the condense mass of the gases is higher than before condense and hence due to gravity of the earth gases settle on the bottom of tube and on continuous system gases fine powder particle is high. When the concentration of the gases is high, we withdraw that fine powder for different uses of human life and chemistry purposed after refined it into pure form because it contain impurities.

Therefore, in this way, we can manage the global warming gases and use in our daily life and save the climate change, which is global issue.

Key Words: Normal and Specific cooling system, Global Warming Gases, Climate Change, Global Issue etc.

REVIEW

Earth's orbit and rotation also play important role for global average temperature is believed to be approximately 5-10°C cooler than at present. John Tyndall measured the infra-red trapped strongly by water vapor, carbon dioxide, and methane. The atmospheric burden of CO₂ is increasing at a rate of 3.3±0.2GtC/yr. Intergovernmental Panel on Climate Change report has forecast that global mean surface temperature will rise by 1.4°C to 5.8°C by the end of 2100, and reported that carbon dioxide emissions from the combustion of fossil fuels are projected to range from about 5 to 35 GtC per year in the year 2100 compared to current emissions of about 6.3 GtC per year [1],[2].

Ireland's annual surface air temperature has increased by approximately 0.8°C over the last 110 years. Average annual national rainfall has increased by approximately 60mm or 5% in the period 1981 to 2010, compared to the 30 year period 1961 to 1990. The global temperature has increased by 0.85°C since records began in the mid-19th century. Atmospheric concentrations of methane have increased by about 150 percent since pre-industrial times, although the rate of increase has been declining. PFCs and SF₆ are predominantly emitted from various industrial processes including aluminum smelting, semiconductor manufacturing, electric power transmission and distribution, and magnesium casting. Since industrial revolution concentrations of CO₂ have been increased by 30 %, of methane doubled and of N₂O increased for about 15 %. It has been predicted that CO₂ will increase for another 30-150% by 2100 [3],[4].

The existence of the greenhouse effect was argued for by Joseph Fourier in 1824. The argument and the evidence was further strengthened by Claude Pouillet in 1827 and 1838, and reasoned from experimental observations by John Tyndall in 1859. The effect was more fully quantified by Svante Arrhenius in 1896. However, the term "greenhouse" was used and described first by Nils Gustaf Ekholm in 1901. Recent headlines such as "1997 Hottest Year on Record" have generated a greater awareness that the global climate may be changing. Global warming is attributed to the steady increase of atmospheric trace gases produced largely by human activities, such as carbon dioxide, methane, nitrous oxides, and chlorofluorocarbons [5],[6].

Sea level rose by an estimated average of 2 mm. per annum between 1880 and 1990, and is currently rising at the rate of about 3.4 mm per annum. About 1.6 billion metric tons of carbon is in addition emitted into the atmosphere by deforestation for agricultural and other land use purposes. The world population has continued to increase and currently stands at about 6.8 billion with an annual growth rate of about 1.39%. Atmosphere is almost completely transparent for

visible or UV part spectra or IR, penetrates directly to the surface, where its energy is being absorbed, heating the Earth cause the heat of air of atmosphere which is surrounding the earth [7],[8].

Pollution whether vehicular, electrical or industrial is the main contributor to the global warming. When sun's light reaches earth in a snow or ice area 80 percent of the light is reflected meanwhile when it reaches earth or water only 20 percent is reflected and the 80 percent is absorbed. Concentrations of two other important greenhouse gases have increased because of human activity, methane has more than doubled, and nitrous oxide has increased by about 20 percent. Tundra, Water vapor in the atmosphere increasing, carbon dioxide and other greenhouse gas variations, solar variations, volcanic eruptions, Ocean circulation, Orbital variations, Permafrost, Climate change, Greenhouse gas [9],[10].

In 2010, estimated worldwide emissions from human activities totaled nearly 46 billion metric tons of greenhouse gases, expressed as carbon dioxide equivalents. Emissions of fluorinated gases more than doubled. Carbon dioxide emissions are increasing faster in Asia, Europe, and the United States, which together accounted for 88 percent of total global emissions in 2012. A given molecule of nitrous oxide has over 300 times the impact on global warming as does a molecule of carbon dioxide [11],[12].

In 2006, Americans consumed 3.8 million GWh of electricity, producing 2.7 billion tons of CO₂. Between now and 2015, demand for diesel is projected to grow about 4 times faster than demand for gasoline; by 2030, the demand for diesel is forecast to grow 14 times as fast. Biodiesel is currently consumed at a rate of 260 million gallons annually, having grown dramatically from 18 million gallons in 2003. The World Health Organization has estimated that more than 140,000 people per year are already dying as a direct result of climate change, primarily in Africa and Southeast Asia. The distribution of CO₂ emissions among the main emitters: China (29%), the United States (15%), the European Union (11%), India (6%), Russia (5%), Japan (4%), and the rest of the world (30%). It also estimates that after 2030, climate change will result in 250,000 additional deaths per year, caused by malnutrition, malaria, diarrhea, and heat stress [13],[14].

Wildfires were once primarily a seasonal threat, taking place mainly in hot, dry summers. In May 2016, the state of Alberta was devastated by wildfires expanding over 350 miles, leading to the evacuation of the 80,000 inhabitants of the city of Fort McMurray, which suffered extensive damage. The people of Tuvalu are finding it difficult to grow their crops because the rising seas are poisoning the soil with salt. The situation is so bad that the leaders of Kiribati are considering a plan to move the entire population of 110,000 to Fiji [15],[16].

Worldwide personal transportation is expected to increase 1.7 percent annually from 2000 to 2050, while worldwide freight transportation is expected to increase by 2.3 percent annually during the same timeframe. More recently, Communauto announced a 13,000-ton reduction in CO₂ emissions because of their 11,000-carsharing users in the province of Quebec, Canada. It is estimated that effort will reduce CO₂ emissions by 15 tons per year by 2050 [17].

A study done by the World Bank in 1993 estimated that the contribution of vehicle exhaust to Total Suspended Particulate was only 3.5 percent compared to contribution of Himal Cement Factory (36%), brick kilns (31%) and domestic fuel combustion (14%). WHO estimates that approximately 3 million people die each year due to air pollution in the world. Bhaktapur is home to over 120 brick kilns registered and operating under Bhaktapur Cottage and Small industries. Kathmandu the third most polluted city in the world after Tetovo and Cairo at Pollution Index 2016 when survey is done about 3,000 locations. The annual population growth rate is in the Valley 4.3 % and the annual motorization rate is 12%. Study on exposure to airborne particulate matter shows in Kathmandu valley in 2009 showed high personal PM_{2.5} exposures with hourly personal PM_{2.5} levels reached >500 µg/m³ and averaged 51.2 µg/m³. Annual consumption of coal in brick kilns in Kathmandu valley is 56100 tons and other fuel around 330 tons. About 350 tons of coal is coming to valley daily, and majority of it is used in brick industries and industries with furnaces. Assuming only 10 tons is used for commercial cooking purposes in the valley, it is used 3650 tons annually [18],[19],[20],[21].

At a global scale, the 20 percent of the world's population living in developed countries account for 46.4 percent of global greenhouse gas emissions, while the 80 percent of the world's population living in developing countries account for the remaining 53.6 percent. Globally, the combined share of CH₄, N₂O and F-gas emissions is about 28% in total GHG emissions, of which F-gases show the highest growth rate of about 3% in 2016, followed by N₂O of about 1.3%, whereas methane has remained at 2015 levels in 2016. It shows there is at least 95% certainty that human activities are the main cause of climate change. The result is less food, which is a big problem because the world's population is set to increase from 7 billion today to 9 billion by 2050, so we will need more food, not less [22],[23],[24].

Compared with a future without climate change by 2030, 38,000 due to heat exposure, 48,000 due to diarrhea, 60,000 due to malaria, and 95,000 due to childhood under nutrition. By 2050, impacts of climate change on mortality are projected to be greatest in south Asia. It is estimated approximately 250 000 additional deaths due to climate change per year between 2030 and 2050. Presidents of the United States and China announced their respective post-2020 actions on climate change, recognizing that these actions are part of the longer range effort to transition to low-carbon economies, mindful of the global temperature goal of 2°C [25],[26].

If the same mass of methane and carbon dioxide were emission into the atmosphere, methane will trap 25 times more heat than carbon dioxide. Natural sources emit about 770 billion metric tons of carbon dioxide each year from the ocean, animal and plant respiration, organic matter decomposition, forest fires, and volcanic eruptions. Anthropogenic or human carbon dioxide emissions originating from fossil fuel burning, cement production and farmland plowing produce an additional 34 billion metric tons of carbon dioxide annually. Electric power, transportation, and industry account for 33 percent, 28 percent, and 20 percent, respectively. The IPCC predictions published in 2000 in the Third Assessment

Report (IPCC, 2000) suggest that in 2100 climate change may cause the temperatures to grow from 1 to 6°C, contributing to a sea level rise of about 90 cm and a significant growth of such climatic events as droughts, floods, periodical spells of cold weather and strong storms [27],[28].

The amount of CO₂ in the air is 280 ppm in 1850 and 367 ppm in 2000. This is a raise of 31 percent within 110 years. The consequence is a higher temperature in the atmosphere. A large proportion of CO₂ production arises from industrial activities. The United Nations Environment Programme by 2010 has noted that “doubling of wealth leads to 80% higher CO₂ emissions” [29],[30].

Cars, factories, and power plants pump billions of tons of carbon dioxide into the atmosphere every year. Worldwide measurements of sea level show a rise of about 0.17 meters during the twentieth century. The problem is serious because as much as 10 percent of the world’s population lives in coastal areas less than 10 meters above sea level. The IPCC estimates that 20-30 percent of plant and animal species will be at risk of extinction if temperatures climb more than 1.5° to 2.5°C. The 90 companies on the list of top emitters produced 63% of the cumulative global emissions of industrial carbon dioxide and methane from 1751 to 2010 amounting to about 914 gigatonne CO₂ emissions according to the research. According to the Environmental Protection Agency, it has been estimated that industrial pollution is responsible for almost 50% of the pollution worldwide [31],[32],[33].

Production of Natural Gas in the Middle East and Asia Pacific increased in the year 2009 due to growth in Iran, Qatar, India and China. China has become the world’s largest energy-related GHG emitter surpassing the United States. Between 1971 and 2007, global emission doubled with developing countries, led by Asia, increased economic activity at a much faster rate. Between 1990 and 2007, CO₂ emissions rose more than double for Asia due to striking rate of economic development particularly within China and India. It also estimates that after 2030, climate change will result in 250,000 additional deaths per year, caused by malnutrition, malaria, diarrhea, and heat stress. The two major terrestrial carbon sinks are plant biomass, currently a repository of 550 Gt of carbon, and soils, containing 2,300 gigatons [34],[35].

About 19% of European CO₂ emissions are attributed to road transportation, giving it a strong social responsibility. In February 2007, the EU confirmed its targets for the reduction of CO₂ emissions in cars and light commercial vehicles: automobiles are to produce no more than 120 g/km of CO₂ by 2012, bearing two separate provisions. According to the Stern Review, 14% of the world is greenhouse emissions stem from transport. The current Kyoto agreement states it will achieve around a 5% cut in greenhouse gas emissions from industrialized countries by 2012 over 1990 levels, European Environment Agency calculations however suggest CO₂ emissions from the industrialised world must be reduced by 35% to 55% by 2010 if ecologically dangerous climate change is to be avoided [36],[37].

Overall, over the last five years, 140 petrochemical projects have been proposed or approved that are expected to produce 179 million tons of greenhouse gases per year. Environmental Protection Agency and state websites that have federal Clean Air Act permits or permit applications for large construction projects that would increase greenhouse gas emissions by at least 100,000 tons annually [38].

Intergovernmental Panel on Climate Change reported, GHG emissions from industry in 2010 is about 13.99 GtCO₂, among which 5.27 GtCO₂ is from direct burn of fuels for energy and another 5.25 GtCO₂ from electricity and heat consumption. Total process CO₂ emissions were 2.59 GtCO₂, out of which 1.35 GtCO₂ came from cement production. Non-CO₂GHGs made up 0.89 GtCO₂. Through this project, 240 tons of HCFC-22 were phased-out, with an impact of more than 960,000 tCO₂ eq per year. The total annual turnover of carbon between global forests and the atmosphere is in the range of 55 to 85 Gt per year by IPCC in 2000. Enormous amounts of carbon are stored by forests and cycled between forests and the atmosphere. Losses of forested area, mostly owing to deforestation in the tropics, are causing transfers of 0.5 to 2.7 Gt carbons to the atmosphere every year [39],[40].

In Finland, the annual mean temperature is predicted to increase by 2-6 degrees by the end 2100, increase in winter months of 3-9 degrees and summer months 1-5 degrees. According to the IPCC, 1 tonne of methane has the warming effect of around 25 and 72 tonnes of CO₂ over 100- and 20-year periods, respectively. China has the largest country-level methane emissions in the world with 3.84 million tonnes; Western Europe produces 4.08 million tonnes, North America 3.39 million tonnes, and Central and South America 1.41 million tonnes. Globally, methane released from animal manure totals nearly 18 million tonnes annually [41],[42].

INTRODUCTION

Global warming gases are those gases that cause to increase the temperature of the planets or earth or atmosphere. The major global warming gases are Carbon dioxide, Methane, Nitrogen oxides, Compound of Carbon and Fluorine. These gases are known as global warming gases because they absorbed the different radiation of sun and other radiation coming from outer atmosphere. When they observed the incoming radiation from the outer atmosphere the wavelength of the incoming radiation is decrease and the radiation have no more energy to escape from our atmosphere. The absorption agent may be soil, building and monument, and global warming gases. When they do not escape from the earth atmosphere, they collision each other and generated heat energy and cause to increase the temperature of the atmosphere. Global warming gases are created by both human activities and nature. Natural emission of green house gases are mainly CO₂, CH₄ and Nitrogen oxides while green house gases emission by human activities are CFC, SF₆, CO₂, CH₄ and nitrous oxides. In the present situation the emission of green houses gases due to human activities is more than that of nature due to industrial revolution. The main agent of global warming are unmanagement of gases emitted from

industries, vehicles using the fuel generate global warming gases, unmanagement global warming gases from house activities like cooking burring the dry biomass and so on, wildfires and so on.

METHODOLOGY

This method needed tunnel at surface below the earth surface 0.5 to 1 meter. Tunnel may be on cylindrical or rectangular the diameter is according the sources i.e. how much amount of gases released during the combustion of the raw materials. If we consider Brick kin or any Factories, we run the tunnel out of the boundary, which at inclined below 45 degrees that help to passes the global warming gases. Tunnel cover with water at different place, according global warming gases emission from the sources and the fasting cooling settle down the gases as powder on tunnel bottom. Tunnel is open at the end that helps to passes the gases from sources point to whole the tunnel up to open ends of tunnel. The open end of tunnel has slight height.

On the other hand we may also passes the emitted global warming gases through the solution which formed there respective compound like CO₂ formed Carbonic acid when passes through water, SO₂ formed sulphuric acid when passes with water, NO₂ formed nitric acid when passes through water and similar other global warming gases. These product are useful in our daily life and we can used as required by saving our planets.

In this way we can control the global warming gases which is more effective than traditional way that is emitting the gases directly in atmosphere.

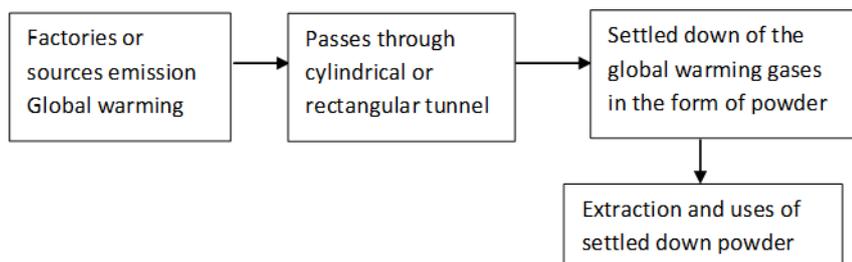

Diagram: Extraction of global warming gases for different purposes in our daily life.

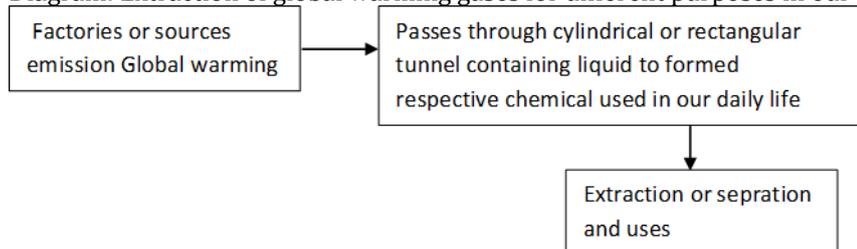

Diagram: Extraction of global warming gases for different purposes in our daily life.

Advantage:

- a. Control Global Warming Gases emitted from factories, which is more dangerous than global warming gases emitted from other sources.
- b. Utilization of global warming gases for different laboratory purpose by extraction.
- c. Safety than traditional ways

Disadvantage:

- a. Expensive slightly than traditional ways manufacturing
- b. Take Little more time to settled down or formation of respective chemical compound

RESULT AND CONCLUSION

From above method, we can control global warming and the impact of the global warming on our planet and can use these global warming gases in our daily life for the different purpose as required.

1081 AN ANALYSIS ON THE DUOPOLY LOCATIONS AND SOCIAL WELFARE IN A HOTELLING MARKET

ABSTRACT

It is well known that the equilibrium locations in an unbounded Hotelling (1929) model with a quadratic transport cost function are one quarter outside of the unit-length market (i.e., $-1/4$ and $5/4$) a la Tabuchi and Thisse (1995). The total transport cost under these equilibrium locations is $13t/48$, where t is the transport rate. However, the socially optimal locations for the duopoly firms are $1/4$ and $3/4$, so that both firms locate at their market centers, respectively, and the total transport cost is $t/48$. A mild intervention in which the firms enter the market sequentially is only welfare superior to that of the no-intervention case. A strong intervention is that the government runs a welfare-maximization public firm to compete with the private firm. The socially optimal locations can only be obtained either by simultaneous entry, or by sequential entry such that the public firm enters earlier than the private firm.

1270 IS ISLAMIC TERRORISM A NEW TERRITORIAL AND SOCIO-SPATIAL HAZARD AND A POLITICAL THREAT TO WESTERN DEMOCRACIES?

ABSTRACT

In France, the attacks committed by Mohammed Merah in 2012 and the following ones on the Islamic State of Irak and the Levant (ISIL) behalf have established Islamic terrorist threat as a new territorial hazard. This is a direct result of changes regarding the resources and means of actions, the operational patterns, the proximity between the places involved in the action and the targets (both types of people and types of places). From that time on, how could geographers avoid addressing these new territorial hazards? Their processes and consequences have to be analysed carefully as they have an unquestionable influence on the way democracy and social life will move in the future in West-European countries. It is then of paramount importance to review the current state of research in territorial and regional sciences as regards terrorist hazards. The French and European cases will be the main focus of this review. Even though quite extended research has been done on extreme ideas and behaviours connected to far-right or far-left organisations, little has been conducted by geographers. The North American research sphere is much engaged in academic research about Islamic terrorism. One needs only mention the START Research Consortium (University of Maryland). Nevertheless, the contribution of geographers to this research effort remains almost invisible. On this basis, it has to be demonstrated why Islamic terrorism related to ISIL is a new socio-spatial hazard. This is due to its specific strategic orientation, its more or less specific ideological frame, and its new tactics. Two kinds of data are analysed under their socio-spatial angle: the statistical data provided by the START programme and the textual data provided by the online magazines ISIL has released in many languages since 2014, including in French and English. The latter analysis is obtained with the help of ALCESTE, a software designed for textometrics. Those two approaches have allowed defending the following hypotheses: 1/ Islamic terrorism regarding its lethal intensity index is primarily a very local phenomenon with very specific localizations; 2/ The new tactics promoted by ISIL generated the emergence of new perceptions of socio- spatial hazards, which impose to national, regional and local authorities to manage them despite their low lethal intensity in Western democracies. As a result, countries like France have to manage a paradox: a situation of high exposure with low actual vulnerability. Then the design of more accurate public security policies has to be stimulated, taking into account both the evolutions of the stakes and exposures, and the preservation of effective democratic societies. Indeed, any terrorist attack (no matter whether it has been achieved or prevented) is related to place effects, including the socio-spatial diffusion of fear-related perceptions and behaviours. The understanding of the actual socio-spatial impacts of Islamic terrorism is then a critical need, as any terrorist attack does not reach its goal in the attack itself but through the orientations of collective behaviours resulting from the attack, including policies.

1466 INDIAN REGIONAL SCIENCE AT FIFTY: TRENDS, RETROSPECT AND PROSPECT

ABSTRACT

Regional Science (RS) is defined as a multi-disciplinary field of inquiry in the study of the theories and methods of spatial development analysis. RS integrates the disciplines of economics, geography and planning in this research enterprise. Jackson et al., (2017, 2011) examines the trends and methodological advancements in RS, and elsewhere makes a case for a critical examination of the ‘core and boundary’ of the multi-disciplinary nature of RS. Fisher and Nijkamp (2013) provide a comprehensive and state-of-art review of the field of RS. Rey’s (2000) exemplary analysis of the publications patterns, citations and impacts of publications in RS journals provides substantial insight about the nature, growth and contributions of the RS discipline to knowledge development.

Haddad (2017) examined the development of RS in Brazil and noted a marked dissemination of insights to peripheral regions. Murray (2017) in the wake of the significance of big data and regional analytics posits RS can contribute immensely to the development, understanding and insights to national and regional systems. Thakur (2006 and 2000) examined the field of Indian RS. This was the first study of the growth and development of RS in the Indian subcontinent. The Indian Regional Science Association (IRSA) was established in 1968 and has conducted annual meetings and published biannual issues of the Indian Journal of Regional Science since then.

Given this overview, this research utilizes the publications from four journals that publishes RS related research. These journals are: Indian Journal of Regional Science, Indian Journal of Spatial Science, Indian Economic Review, and Regional Symbiosis. The time period for inclusion of sample papers for a ‘content analysis’ varies across journals. This research is a follow up of earlier work by Thakur and Dutt (2006) and Thakur (2000) in reviewing and analyzing the development of RS as a multi-disciplinary research endeavor in India. The major areas of research focus are: regional development and planning, agriculture, urban, transport, location and infrastructure, regional disparities, natural resources, rural studies, industry, regional patterns, migration and employment, quantitative regional analysis, geographic information systems and spatial linkages. Several questions are addressed in this research: 1)What are the disciplinary orientations of publications? 2) What data have been used in RS research? 3) What spatial scale of analysis has been used in RS research? 4) What are the philosophical and methodological bases of RS research in India? 5)What are the citations and impacts of RS publications in India and abroad? 6) What are the prominent sub-fields within RS in India? In addition, a critique with prospects for future research are provided.

1530 REGIONALIZATION OF SEASONAL CROPPING PATTERN USING IRS LISS-III IMAGES IN ANAND DISTRICT OF GUJARAT, INDIA

ABSTRACT

Geospatial techniques and information have become one of the keystone aspect for efficient and timely identification of seasonal characteristics as it is associated with diversified multi spatio-temporal dynamics. Better spectral responses coupled with enhanced spatial resolution lead to extraction of required result in faster and efficient manner. Hence, there is a need to incorporate some semiautomated techniques which can lessen the effort to extract the component of interest in association with manual digitization and ground truthing so that level of accuracy can be increased. In the present study, an attempt has been made to incorporate both the conventional and band rationing techniques for the extraction of seasonal cropping pattern of Anand district of Gujarat, India using Indian Remote Sensing satellite (IRS), Resourcesat 2, LISS III satellite images. Anand district encompasses an area of 3204 km² and located in adjacent to Gulf of Khambhat. The base economy of the district depends upon agriculture. To understand the seasonal pattern of cropping (Karif, Rabi and Zaid), satellite images of three seasons were taken into considerations. For semiautomatic extraction of cropping pattern, three vegetation indices, Normalized Differential Vegetation Index (NDVI), Enhanced Differential Vegetation Index (EVI) and Normalized Differential Short wave -infrared Based Vegetation Index (NDSBVI) were calculated in the GIS platform. For differentiating between crop and non-crop areas and regionalization them, training samples were applied on different seasonal vegetation indices based on threshold reference value. For accuracy assessment of the vegetation indices, digitized reference maps of different seasons were generated. In the study, it was also found that the combination of different vegetation indices gave better result in terms extraction of crop combinations in different seasons. : cropping pattern, NDVI, EVI, NDSBVI.

1761 REGIONAL SCIENCE: IT'S PAST AND FUTURE FRONTIERS

ABSTRACT

Regional Science has a spectacular history as a new social science discipline during the last fifty years. Walter Isard University of Pennsylvania was its founder. I had the privilege as his student and colleague for forty years. He was my mentor. We established Regional Science Association (International) many years ago. It has now branches in more than fifty countries. Indian section which I co-organized with Professor Pathak is almost fifty years old. I also co-established the Chinese section. So I am in a position to make some comments on Regional Science as a student, teacher and a professional person in that area. I shall discuss its relationship with geography, economics, political science, management, public policies, urban, and environmental studies etc. I shall then indicate the possible future frontiers of Regional Science particularly related to Globalization, Peace Science, Information Technology, Spatial Econometrics, Disaster Management, and Income Inequality.

SS18.1. Natural and Man-Made Disaster Management

1188 CARBON SEQUESTRATION POTENTIALITY AND ITS ECONOMIC ANALYSIS OF DIFFERENT LAND USE SYSTEMS IN THE NORTHERN PART OF BANGLADESH**M S Bari¹, M.B Abubakar²**¹ Department of Agroforestry and Environment, Hajee Mohammad Danesh Science and technology University, Dinajpur, Bangladesh.²Department of Forestry, Audu Bako College of Agriculture, Kano, Nigeria.Corresponding author (M S Bari) Email: barimdshafiqul@gmail.com**ABSTRACT**

This study was conducted to evaluate the carbon sequestration potentiality in different land use systems in the Northern part of Bangladesh. Common land use system (Cropland, roadside, homestead and orchard) were used. Data were recorded from tree growth parameters (height and diameter at breast height) and under storied vegetation (herbs, shrubs and crops) in order to estimate the total land use biomass accumulation. Complete measure of 20 m line transects in cropland, 20×5m quadrant in roadside, 20 × 20 m quadrant in orchard and homestead were used. At every sampling point, under stories biomass sample were taken from 1 × 1 m quadrant. The results showed that there was significant difference of carbon sequestration potentiality of different land use systems. For the main effect of different land use systems on carbon sequestration, there was significantly difference in respect of tree height (m), DBH (cm), tree carbon sequestration (t/ha) and total land use system carbon sequestration (t/ha). The highest total land use carbon sequestration (325.33 t/ha) was recorded from double roadside and the lowest (36.51 t/ha) was obtained from cropland was determined by DMRT at $p < 0.05$. From the agro-ecological zones (AEZ), the highest carbon sequestration (155.23 t/ha) was obtained from AEZ- 25 and the lowest (109.28 t/ha) was recorded from AEZ-3. However, in case of economic of carbon sequestration, among the six land use systems double roadside gave maximum (4879.95\$ t/ha) monetary returned. So, double roadside tree plantation is a better land use option for reducing atmospheric carbon. Therefore, more emphasis should be given in roadside plantation for mitigating the green house effects.

Keywords: Carbon sequestration; Land use system; Agroforestry; Potentiality**1 INTRODUCTION**

Tropical forests play an important role in the global carbon cycle (Maser *et al.*, 2003). They contain about 40% of global terrestrial carbon, account for more than half of global gross primary productivity, and sequester large amounts of carbon dioxide (CO₂) from the atmosphere (Beer *et al.*, 2010; Grace, 2004; Pan *et al.*, 2011). Carbon is stored in forests predominantly in live biomass and in soils, with smaller amounts in coarse woody debris (Malhi *et al.*, 2009). In tropical forests worldwide, about 50% of the total carbon is stored in aboveground biomass and 50% is stored in the top 1 m of the soil (Dixon *et al.*, 1994). The problem of global climate change is considered to be one of the most important to the environment; it has been at the center of scientific debate in recent years. Carbon dioxide (CO₂) emissions from land use and land use changes, predominantly from forested areas, account for 33% of global CO₂ emissions between 1850 and 1998 (Bolin and Sukumar 2000). Increasing demand for food, fodder, fuel and round wood is increasing the pressure on land-use systems, and conservation and sustainable development of land-use systems are critical for meeting those demands sustainably and stabilizing CO₂ concentration in the atmosphere to mitigate global climate change (Ravindranath and Madelene, 2008). The carbon storage capacity in agroforestry varies across species and geography (Newaj and Dhyani, 2008). Trees and shrubs in agroforestry systems act as carbon sinks. They absorb carbon (as CO₂) through photosynthesis and store it in their aboveground and belowground biomass. This process is called 'carbon sequestration'. IPCC (2000) described carbon sequestration as the process of removal of carbon from the atmosphere and stored it in the biosphere. Moreover, the amount of carbon in any agroforestry system depends on the structure and function of different components within the systems put into practice (Schroeder, 1993; Albrecht and Kandji 2003). The developing countries are bearing the maximum brunt of global warming and climate change, although their contribution to greenhouse gas emissions is much less than that of the developed countries. It is, therefore, important that countries like Bangladesh to take serious steps which contribute in fighting climate change through the role of land use practices to mitigation the climate change. The establishment of agroforestry based land use system will help in substantial and productive agriculture and climate change mitigation. However, in Bangladesh, the amounts of carbon sequestration by different land use system are unknown. The study therefore seeks to assess the potentiality of different agroforestry land use systems for carbon sequestration as a way of mitigating climate change through reduction of carbon dioxide in the atmosphere in the Northern region of Bangladesh. The objectives of the study was to assess the aboveground C stock and accumulation in some commonly practiced land use systems in three agro-ecological zones of Bangladesh and to identify the best land use system that can contribute to C sequestration.

2 MATERIALS AND METHODS**2.1 Study Area**

The study was conducted in the northern part of Bangladesh located in the districts of Dinajpur. A stratified random sampling method was used in a randomized complete block design (RCBD) with three (3) replications as representative areas where different agroforestry like homestead agroforestry, cropland agroforestry and orchard based agroforestry are practiced. Indeed, Dinajpur district includes three Agro-ecological Regions: Old Himalyan Piedmont Plain (AEZ-1), Tista Meander Flood Plain (AEZ-3) and Level Barind Tract (AEZ-25) and land use practices vary among the AEZs. Therefore, one site from each of the AEZs was selected. The experiments consist of six (6) land use system and three (3)

agro-ecological zones. Thus, the simple random sampling design was used to collect data from each sampling units (observations) within the sampling plots. However, eighteen observations were recorded from each AEZ having total of fifty four (54) observations. Each sampling unit consist of six (6) land use systems (treatments) viz; Boundary crop land, single roadside plantations, double roadside plantations, homestead agroforestry, litchi orchard and mango orchard. In each case, three replications were recorded.

The methodological procedure for sampling of this experiment varies due to different land use system. However, seven (7) year Eucalyptus tree was selected as an experimental tree in cropland and Roadside plantations. Similarly, same age was also considered in case of Orchard. In homestead, age was not used due high variability and species diversity. Hence, only matured trees with diameter greater than 5cm (DBH) were considered for this experiment. On the other hand, leaf litter, herb, grass or rice biomass was sampled using 1×1m quadrant method. All biomass was collected and fresh weight was recorded and then taken to laboratory and dried it at 70°C for 48 hours. Dry weight was also recoded. Table 1 below shows the size of sample unit and total area estimated.

Land use system	Sample unit	Total area estimated
Boundary cropland	20 m (transect)	400 m
Roadside plantations	20×5 m (quadrant)	200 m
Homestead agroforestry	20×20 m (quadrant)	400 m ²
Orchard	20×20 m (quadrant)	400 m ²
Understory Biomass	1×1 m (quadrant)	1 m ²

2.2 Tree Biomass Estimation

The biomass of tree is the sum of aboveground and belowground biomass content. For accurate measure of biomass in tree, it has to be felled. To avoid this, the standing woody biomass has been estimated using important growth parameter such as DBH and height. Tree height and DBH are the most common independent variables needed for the estimation of tree volume (Avery and Burkhart, 2001).

2.3 Tree height (m)

Tree height is the height of the seedling from the root-collar to the highest terminal bud (Gazal et al., 2004). The height of tree was measured from ground level to the tip of the tree with the help of Haga Altimeter. The height of all trees per sample unit per replication was recorded and its average was calculated.

2.4 Diameter at Breast Height (cm)

The Diameter at Breast Height (DBH) of stem of the trees was measured in centimeters (cm) at breast height (1.37 cm from ground level) with the help of Tree caliper. The observations of diameter were taken on all the trees per sample unit per replications and its average was also calculated in each land use systems.

2.5 Aboveground biomass estimation (AGB)

AGB include all living biomass above the soil. The aboveground biomass (AGB) has been calculated by multiplying volume of biomass and wood density the volume were calculated based on diameter and height (Pandya et al., 2013). In this system, the following allometric equation for estimating biomass (kg/tree) of tree diameter 5–60 cm of different zones developed by (Chave et al., 2005) were used.

$$(AGB)_{est} = 0.0509 \times \rho D^2 H \quad (\text{Chave et al., 2005})$$

Note: (AGB)_{est} = Estimated aboveground tree biomass (kg/tree)

D = DBH, diameter at breast height (cm)

H = tree height (m)

ρ = Wood specific gravity (Mg m⁻³)

2.6 Belowground Tree biomass (BGB)

Belowground tree biomass (BGTB) of trees was calculated by multiplying the above ground biomass (AGTB) with a default value of 0.26, provided by (Hangarge et al., 2012) as a factor of root: shoot ratio. Average root biomass content of all trees was 26% of aboveground biomass.

$$\text{Below ground biomass} = \text{Aboveground biomass} \times 0.26$$

2.7 Total Biomass

Total tree biomass (TTB) is the sum of the above and below ground biomass. (Sheikhet al., 2011).

$$\text{Total biomass} = \text{AGB} + \text{BGB}$$

2.8 Estimation of carbon stock in trees (tC/ha)

Generally, for any plant species 50% of its biomass is considered as carbon storage (Pearson *et al.*, 2005).
 $Carbon\ Storage = Biomass \times 0.5$

2.9 Estimation of carbon stock in Leaf litter, herb, and grass (LHG) or under stories biomass (t C/ha)

The carbon content in under stories biomass (LHG) was calculated by multiplying with IPCC (2006) default carbon fraction of 0.47. $LHG\ (kg/m^2) = Biomass \times 0.47$

2.10 Estimation of Carbon Sequestered (t/ha)

To estimate carbon sequestration of crops and trees the biomass carbon was multiplied with a factor of 3.67 for all species a formula used by Rajput (2010).

$$Estimated\ Carbon\ sequestration\ (t/ha) = Biomass\ carbon \times 3.67$$

Hence, the factor 3.67 was determined from weight of carbon as calculated below: CO₂ is composed of one molecule of C and two molecules of oxygen.

The atomic weight of C is 12.001115

The atomic weight of O₂ is 15.9994

The weight of CO₂ is C + O × 2 = 43.999915

The ratio of CO₂ to C is 43.999915/12.001115 = 3.6663

Therefore, to estimate the carbon sequestration in tree, multiply the carbon biomass weight by 3.6663.

2.11 Total Land use carbon sequestration (t/ha)

In order to achieve the total carbon sequestration by a particular land use system, total of trees and belowground litter fall, shrubs, herbs or rice were summed (Pearson *et al.*, 2007)

$$Total\ land\ use\ carbon\ sequestration = Tree\ CO_2\ sequestration + LHG\ CO_2\ sequestration$$

2.12 Estimation of Economic Value of Carbon Credits (\$ t/ha)

One ton of net sequestered or mitigated carbon dioxide from plant biomass in a land use is equal to one carbon credit. Therefore, total carbon credit in a land use systems was calculated from CO₂-eq values of retained biomass in respective land use systems. The carbon credits were calculated from the total land use carbon sequestration from tree and crop biomass using the guidelines of IPCC (1996). However, according to Vivian (2010) the monetary value of one ton CO₂ equivalent to US15 Dollars. In this study, the value of Vivian was used.

All data were statistically analyzed using computer package R-studio and MS Excel 2007.

3 RESULT AND DISCUSSION

3.1 Effects of tree Biomass on different Land use system

The study found that the total tree biomass (TTB) was significantly varied with the land use systems (Table 2). The highest TTB (147.1 kg) per tree was found from Single Roadside (T₂) which was followed by Mango orchard (T₆) and Double Roadside. On the other hand, the lowest TTB (67.07 kg) per tree was recorded from Homestead (T₄) which was followed by Cropland (T₁) and Litchi Orchard (T₅). Wide variation of total biomass occurs due to heterogeneity of different land use systems. Khaki and Wani (2011) estimated maximum total ground biomass (181.34 t/ha) in *Shorea robusta* pure forest, which was followed by Agrisilviculture system (46.02 t/ha) and lowest in natural grass land (4.47 t/ha).

3.2 Effects of Carbon stock on different Land use system

The total tree carbon stock (TTCS) per tree was also influenced significantly by different land use systems (Table 3). The highest TTCS (73.55 kg C) was recorded from Single Roadside (T₂) which was followed by Mango orchard (T₆) and Double Roadside (T₃) and the lowest TTCS (33.53 kg C) was found from Homestead (T₄) which was followed by Cropland (T₁) and Litchi orchard (T₅). The above results thus have indicated that biomass components *viz.*, aboveground biomass, belowground biomass and total biomass produced by particular land use system was influenced by variation in biomass allocation pattern and might be attributed due to the divergence in these land use systems or wide range of habitat or bushy nature of growth and age variations. This occurs due to variation in different land use system in the study area. Thus we can say that the rate of carbon stock depend upon the nature of the crop, intensity of the management and soil types. Similar finding were reported by Goswami (2008) and Rajput (2010).

Table 2: Main effect of different land use system on biomass production and estimation

Land Use System	TH (m)	DBH (cm)	AGB (kg/tree)	BGB (kg/tree)	TTB (kg/tree)
Boundary Cropland (T ₁)	11.32b	13.52e	63.48cd	16.51bc	79.99cd

3.3 Effects of Land use on carbon sequestration

The study found that, the total land use system on carbon sequestrations per hectares (TLUCseq) was highly influenced by the effects of different land use systems (Table 4). The highest TLUCseq (325.33t/ha) was recorded from Double Roadside (T₃) which was followed by Single Roadside (T₂) and Homestead (T₄). However, the lowest TLUCseq (36.51t/ha) was recorded from Cropland (T₁) which was followed by Litchi orchard (T₅) and Mango orchard (T₆). Several studies have been conducted to explore the effects of land use systems on Carbon sequestration and other biophysical factors that affect the systems (Lal *et al.*, 1989; Lal *et al.*, 1999). According to Kursten (2000), stated that by adding trees in a system, it can increase the C storage capacity of the land use systems.

Table 4: Main effect of different land use system on Carbon sequestrations

Land Use System	NT/ha	TTCS (tC/ha)	LHG/RCS (tC/ha)	TTCseq (t/ha)	LGCseq (t/ha)	TLUCseq (t/ha)
Boundary Cropland(T ₁)	158.9e	6.39d	3.56d	23.47d	13.05d	36.51c
Single Roadside (T ₂)	420.0c	30.68b	11.52b	112.58b	42.29b	154.87b

*** = significant at 0.1% level of probability.

3.4 Effects of tree Biomass on different Agro-ecological zones (AEZ)

Again, the total tree biomass per tree (TTB) was significantly influenced by different Agro-ecological zones (AEZ) (Table 5). The highest TTB (124.83 kg) was recorded from AEZ 25 (S₃) which was followed by AEZ 1 (S₁) and the lowest TTB (96.48 kg) was recorded from AEZ 3 (S₂). Maximum biomass produced by AZE 25 was influenced by variation in biomass allocation pattern, might be attributed due to stand density and wide range of habitat variation and soil condition habit of growth. The similar findings were confronted with Jadhav (2001), Patel (2006), and Patel and Patel (2010).

3.5 Effects of Carbon stock on different Agro-ecological zones (AEZ)

The total tree carbon stock (TTCS) per tree was significantly influenced by different agro-ecological zones (Table 6). The highest (62.41 C kg) was recorded from AEZ 25 (S₃) which is followed by AEZ 1 (S₁). Similarly, the lowest (48.24 C kg) was recorded from AEZ 3 (S₂). The amount of carbon in any agroforestry system depends on the structure and function of different components within the systems put into practice (Schroeder, 1993; Albrecht and Kandji, 2003).

Table 5: Main effect of AEZ on biomass production and estimation

AEZ	TH (m)	DBH (cm)	AGB (kg/tree)	BGB (kg/tree)	TTB (kg/tree)
AEZ 1 (S ₁)	10.41	16.86ab	84.72b	22.03b	106.74b
AEZ 3 (S ₂)	9.98	16.32b	78.58b	19.91b	96.49b
AEZ 25 (S ₃)	11.17	17.48a	99.06a	25.76a	124.83a

AEZ 3 (S ₂)	38.29b	9.96b	48.24b
AEZ 25 (S ₃)	49.53a	12.88a	62.41a
Level of Sig.	*	*	*
CV%	19.5	19.5	19.5

In a column, figures having similar letter(s) do not differ significantly where as figure's bearing different letter(s) differ significantly (as per DMRT).

* = significant at 5% level of probability.

3.6 Effects of Land use system on carbon sequestration in different Agro-ecological zones

The total land use system carbon sequestration (TLSCseq) per hectare was significantly influenced by different agro-ecological zones (Table 7). The highest TLSCseq (155.23 t/ha) was recorded from AEZ 25 (S₃) which was followed by AEZ 1 (S₁). Similarly, the lowest TLSCseq (109.28t/ha) was recorded from AEZ 3 (S₂). Tree crop sequestered Carbon at a higher rate than those containing only annual crops or grass lands (Brakas and Aune, 2011). It can be shown that variability in the carbon sequestration potential under various agro-ecological zones depends primarily on climatic factors as rainfall, temperature and soil, which influenced the stand density and finally carbon sequestration ability. Rajput (2010) reported similar result with mean maximum rate of CO₂ sequestration potential (30.86 t/ha/yr) by Orchard + cereal land use system followed by pure orchard. He also revealed that the rate of CO₂ sequestration potential (27.27 t/ha/yr) was higher in Agrisilviculture land use system, which however remained significantly higher than horticulture land use system and forest, respectively.

Table 7: Main effect of AEZ on carbon sequestrations

AEZ	NT/ha	TTCS (tC/ha)	LHGCS (tC/ha)	TTCseq (t/ha)	LHGCseq (t/ha)	TLSCseq (t/ha)
AEZ 1 (S ₁)	527a	27.57b	6.514b	101.02b	23.91b	124.92b
AEZ 3 (S ₂)	498a	23.27c	6.51b	85.4c	23.89b	109.28c
AEZ 25 (S ₃)	561a	34.93a	7.37a	128.19a	27.04a	155.23a

In a column, figures having similar letter(s) do not differ significantly where as figure's bearing different letter(s) differ significantly (as per DMRT).

* = significant at 5% level of probability, ** = significant at 1% level of probability

3.7 Economic value of carbon sequestration (US\$ t/ha)

The economic value of carbon sequestration provides market for GHG reduction in monetary value (Fig 1). According to Vivian (2010) 1 ton of carbon was sold at US\$ 15. So, the highest carbon price (4879.95 \$ t/ha) was recorded from Double roadside (T₃) which was followed by single roadside (T₂) and Homestead (T₄). On the other hand, the lowest carbon price (547.65 \$ t/ha) was obtained from Cropland (T₁) which was followed by Litchi orchard (T₅) and Mango orchard (T₆). Vivian (2010) estimated the economic value of carbon trading for Kakamega forest and its environs. He observed that the carbon sequestration potential for Kakamega forest was 334Mg C/ha, then the economic value of carbon trading was US\$ 5010 per hectare. On comparison to that of the farms which was US\$ 3045 per hectare, it implies that the forest has a higher capacity to generate revenue to the country if it participated in carbon trading.

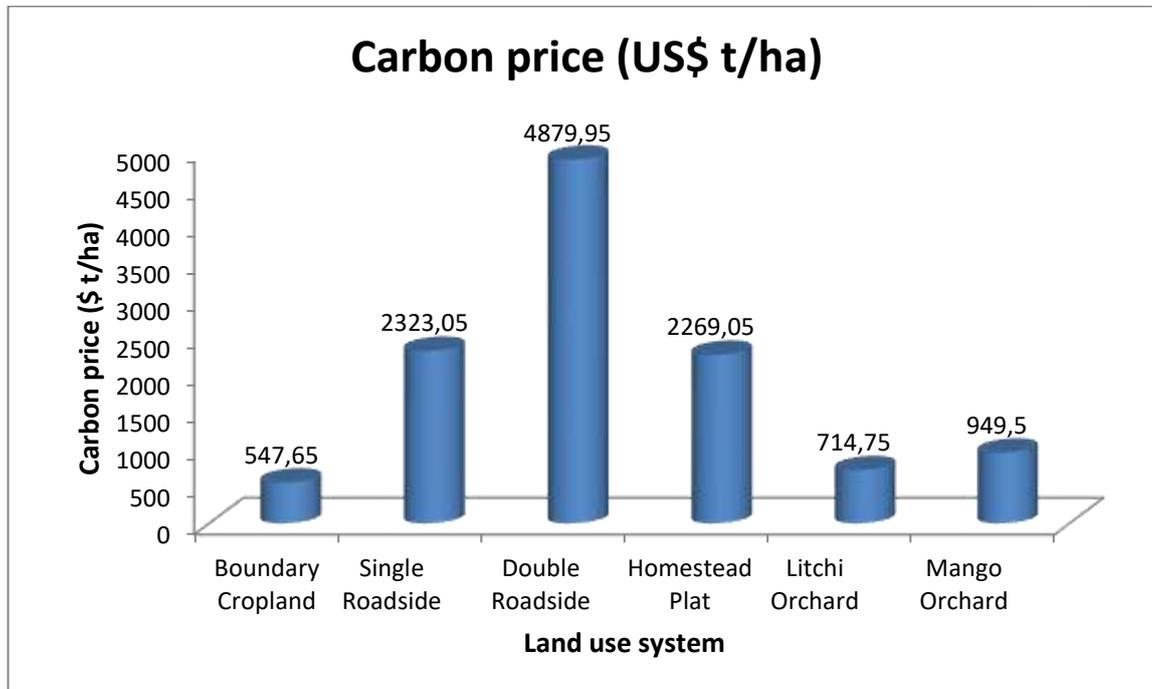

Fig 12: Economic value of carbon sequestration (US\$ t/ha)

4 CONCLUSIONS

The finding of this study showed that agroforestry land use system had significant effects on biomass and carbon accumulation. Planting of multipurpose tree species in non-forest land like cropland, roadside, homestead etc can serve a dual purpose by promoting carbon sequestration and production of non timber forest product for local people. The present investigation finds out that 7 year old Eucalyptus plantation in double roadside strip gave the highest sequestration ability of CO₂ due to its high biomass stand density. The study also found that, among the three AEZ's, AEZ 25 have greater ability for carbon sequestration due to climatic influence and more awareness of farmers in tree management practices. The economic value of carbon sequestration provides market for GHG reduction in monetary value. Finally, it may be concluded that since forest plantations cannot be extended to many large areas of Bangladesh due to high population pressure and demand of agricultural land, roadside agroforestry land use system will be a better option for larger tree plantation coverage and reduction in GHGs effects.

1255 LIVELIHOOD CHALLENGES IN WATER LOGGING: A VIEW FROM SOUTH-WESTERN REGION OF BANGLADESH

ABSTRACT

The impact of climate change has drawn highest concentration of the present world particularly in Bangladesh. Evidently water logging is a pervasive scenario and ‘slow onset persistent disaster’ prevalent in south-western region of Bangladesh. The situation is not unusual in the country, which is fleeting in nature. Due to increasing threat and challenges of climate variability, the vulnerable people particularly women and children face immense problem in the south-western region is known as the disaster zone. In these areas cyclone, water logging, floods are observed very common among the other natural threats. Coastal region is most intensively disaster prone area where livelihood is extremely vulnerable for the last 30-35 years. The study is an attempt to understand and assess how the vulnerable women and children of coastal belt take challenges for their livelihood in the locked life situation. The study also extensively tried to assess waterlogged victims’ indigenous coping mechanism and comprehensive disaster management process adopted by Bangladesh government. Methods of research mainly based on primary survey thus, it includes field interview, content analysis, focus group discussions and case studies. For this purpose both qualitative and quantitative data have been used. The study depicts that a slow onset disaster increased frequency and unpredictability year by year, making communities more vulnerable and frequent mobility of women and children have been narrowing and restricted. As study showed impact of water logging widespread over short-term, medium-term and long-term. The other common impacts are hardship, coping strategies, educational, health, displacement and migration issues etc. The prolonged water logging has caused humanitarian challenges in safe water supply, sanitation, shelter, food security, employment opportunity and so on. 49% respondents were living in refugee centre with their children at the time of disaster, 34% of the respondents livelihood changed due to water logging. 63% frequently affected diarrhea and cold, 68% does not take purify water. Inadequate transportation system is a major cause of high drop-out rate of the children from school. Hence, the study find out a consecutive resolution with empirical views, in considering the social, technical, and governance aspects aims to enhance resilience of people from the frequent water logging. A comprehensive women and child sensitive action plan can be taken with the help of regional and international cooperation. Need based private and public interventions is necessary to overcome the situation and the possible ramification should be in considering the real field situation.

1297 ROLE OF ORGANIZATIONS IN PREPAREDNESS AND EMERGENCY RESPONSE TO DISASTERS: VIEWS FROM THE FIELD

ABSTRACT

Bangladesh is one of the natural disaster prone countries in the world and almost every year natural disasters trouble people’s lives and properties without discrimination and differentiation. In such situation, assistance from governmental and non-governmental organizations is very important for the rehabilitation, recovery of damages, alleviation of poverty and reorganization of the disaster affected people. In Bangladesh, sustainable development is closely linked with disaster reduction which needs effective disaster management plan. Within disaster management plan, preparedness and emergency measures are taken by the government and the non-government organizations to minimize the loss and damages caused by the natural disasters and also for its restoration. The general objective of this study is to know the role of organizations and make an assessment on their performances regarding preparedness and emergency response of natural disaster affected people. The study is exploratory in nature and its approach is predominantly qualitative. Data have been collected from both primary and secondary sources. Cyclone affected people were the respondents to evaluate organizational role. In selecting study area, multistage area sampling method and in selecting respondents simple random sampling method have been applied. Department of Disaster Management under the Ministry of Disaster Management and Relief coordinates overall disaster management activities. The NGOs play the key roles immediately after the disasters by providing means of restoring emergency response, rescuing and sending first aid, sanitation and hygiene, helping in damage assessment and extending assistance to external agencies to bring relief materials. To minimize the loss and damages caused by the cyclonic disaster, the government and non-government organizations take different initiatives before any disaster. Regarding arrangement of preparatory meetings and preparing shelter centers, the GOs play very effective role and on the other hand, regarding making arrangements for awareness-building trainings, the NGOs play very effective role. During the emergency period after SIDR, the GOs played comparatively better role in providing CI sheets and cash money as relief for establishing housing facilities and emergency support. The NGOs played comparatively a better role in providing food, water, clothes, medicine etc. The NGOs also provided monetary help in the form of interest-free loan to initiate income generating activities. This paper suggests that problems like limited sanctions, disrupted communications, lack of awareness of the victims, overlapping

1327 IMPACT OF NATURAL DISASTERS ON INCOME INEQUALITY IN INDONESIA

ABSTRACT

Natural disasters are exogenous shocks that may have socio-economic impacts. As natural disasters affect the poor, it is often assumed that these natural shocks increase income inequality. This is an important issue, especially for developing countries that vulnerable to natural disasters. However, research on the impact of natural disasters on income inequality is still in its infancy. The purpose of this study is to explore the relationship between natural disasters and income inequality in Indonesia, a developing country that has a high risk from natural hazards and high population densities in disaster-prone regions. This paper uses cross-province panel data during the period between 2000 and 2016 provided by CBS Indonesia for socio-economic factors and the Indonesian Disaster Data and Information/’Desinventar’ for natural disasters statistics. The main indicator of income inequality is Gini index, in which we focus on its annual change as the independent variable. Our variable of interest is natural disaster impact measured as density of the number of disaster events and the number of victims; including their lagged variables. Considering various type of natural disasters, we also disaggregated our natural disaster indicators into five groups (biological, climatic, geophysical, hydrological, and meteorological). We also add more control variables in further estimations such as regional income per capita, population density, and an index of regional economic diversity.

SS18.2. Natural and Man-Made Disaster Management

1118 IMPACTS OF INVASIVE SPECIES ON COMMUNITIES AROUND MULANJE MOUNTAIN FOREST RESERVE, MALAWI**Laura Makhambera¹, Parita Shah^{2*}**¹Malawi Forest Service, Lilongwe²Department of Geography and Environmental Studies, University of Nairobi*Contact person Email – suryasuru@yahoo.co.uk**ABSTRACT**

Invasive species are mostly considered a global, regional and national threat. In most cases these species are known to be having negative impacts on ecosystems, species and livelihoods, although there are exceptions to cases where they are even regarded beneficial. This research was conducted to find out the impacts of invasive species on communities living around the Mulanje Mountain Forest Reserve (MMFR) in Malawi. The invasive species are seen to be amongst the highest threat to the forest species especially the Mulanje cedar. In order to find out the impact of the invasive species on the communities, 30 respondents were selected using systematic sampling from five villages surrounding the forest. The chi-square was used to test the hypothesis that the invasive species had no positive impacts on communities neighbouring the forest reserve. The findings indicated that invasive species hardly had positive impacts on communities neighbouring the MMFR. The results showed that the communities identified reducing agricultural yields as the main threat which was at 47%, followed by competition with medicinal plants, firewood, reducing tourism, damaging infrastructure and reducing water supply. In terms of the recommendations, education and awareness was found to be the key as people must be made to realize that invasive species can also generate positive impacts; there should be the implementation of policies and legal frameworks aimed at reducing the importation of invasive species and the issue of invasive species must be incorporated in management plans.

Key words: Invasive species, threats, communities, education**1 INTRODUCTION**

While the United Nations and other international organizations are trying to improve the livelihoods of the majority of the world's population, more challenges like climate change, terrorism and invasive species are appearing to hinder this progress. Globalization which is aimed at improving the economic well being of individual countries has become a global threat and has resulted in spreading of invasive species (Keller *et al.*, 2011). Invasive species are also spread by climate change and environmental alterations (Levine *et al.*, 2003; Sanu & Newport, 2010). These species being "alien" are a threat to sustainable development and are increasing with global warming. These species are in the form of plants, animals and microbes (Preston & Williams 2003). Moreover these species are introduced accidentally or intentionally (Hurka *et al.*, 2003). Invasive species can survive, reproduce and spread unaided and sometimes at alarming rates across an ecosystem causing detrimental effects on the healthy ecosystems (Van Wilgen & Van Wyk, 1999). Thus these species are termed as predators and competitors within an ecosystem (Sanu & Newport, 2010) and are known to colonize ecosystems within a short time. They are also known to deplete species diversity thus being a threat to indigenous biodiversity (Preisser *et al.*, 2008; Lenda *et al.*, 2013). Invasive alien species are known to threaten local biodiversity on land and in water through direct and indirect competition, predation and habitat degradation and have devastating socio-economic impacts (Pechar & Mooney 2009; Nienhuis *et al.*, 2014). Globally invasive species are considered as the second greatest threat to biodiversity (Bellard *et al.*, 2017).

Invasive species (IS) are species that are non-native (or alien) to the ecosystem under consideration and whose introduction is so unique that it causes or is likely to cause economic or environmental harm (CBD, 2002). Today all continents namely Europe, Africa, Asia, North and South America are affected by these species. Examples of invasive species include Tick bury *Lantana camara L.*, Zebra mussel *Dreissena polymorpha*, Mexican Pine *Pinus patula* and the Himalayan yellow Raspberry *Rubus ellipticus*. They are known to cause damage worth billions of dollars. For example in New Zealand the introduction of a pollinating wasp was accidentally done from Australia and it caused seed setting by the alien Morton Bay Fig tree (IUCN, 2000). In the Americas as the harsh winters of British Columbia begin, pine beetles become the conquerors of the British Columbian forests (Maness *et al.*, 2012). In Africa and Asia *L. Camara* and *P. hysterophorus* are amongst the fastest spreading invasive species from the Americas (Kohli *et al.*, 2004). They have had a devastating impact on some of the natural ecosystems of high value like in Kenya where *L. camara* has been devouring Karura Forest in the city of Nairobi (Shah & Irandu, 2015) and Lake Nakuru National Park in Nakuru town. The *L. camara* is amongst the world's top ten species known for its fast spreading (Sharma *et al.*, 2005; Dobhal *et al.*, 2010; Bhagwat *et al.*, 2012). In India the *L. camara* was introduced as a garden ornamental by the British colonists in 1807. Since then it has spread and covered much of Southern India (Kannan *et al.*, 2013). According to a study conducted by Aravind *et al.* in 2010 amongst the Soliga Community who are hunters and gatherers in the Malai Mahadeshwara Hills Wildlife Sanctuary of Southern Karnataka, the community has reported that they can no longer graze their cattle in the forest nor collect bamboo due to the density and spread on *L. Camara*. Japan being an island nation is severely affected by invasive species especially the cherry trees which have now begun to bloom early due to shorter winters and is an inconvenience to annual festivities and result in incurring economic expenditures (Maness *et al.*, 2012).

Invasions by alien species are considered to be one of the largest threats to both terrestrial and aquatic ecosystems of the earth. In fact the Strategic Plan for Biodiversity 2011-2020 (CBD, 2010) Target 9 states that by 2020, IS and pathways

should be identified and prioritized, priority species controlled or eradicated and measures put in place to manage pathways and prevent their introduction and establishment.

Alien invasive species are known to generate substantial costs to biodiversity as they alter ecosystems (Hulme, 2009). The forest ecosystem is one of the most affected especially in terms of lost revenues, in expenses for their control and in lost conservation values and ecosystem services. Richardson (1998) asserts that the most direct economic impact of alien invasive species on the forest sector is related to the loss or reduced efficiency of production. This in turn affects the surrounding communities as their livelihood depends on the forest ecosystems. For example the introduction of the salt cedar *Tamarix spp.* has led to loss in ecosystem services in the western USA which have been estimated at US\$ 7-16 billion over a total of fifty-five years (GISP, 2001). According to a research carried out by Obiri in 2010 on invasive plant species and their disaster-effects in dry tropical forests and rangelands of Kenya and Tanzania, he found that invasive plants are a hazard in the tropical dry forests and rangelands of East Africa and result in increasing poverty to communities living around these ecosystems. Another study conducted by Pratt *et. al.* (2017) in Eastern Africa indicates that these species are a real threat to food security.

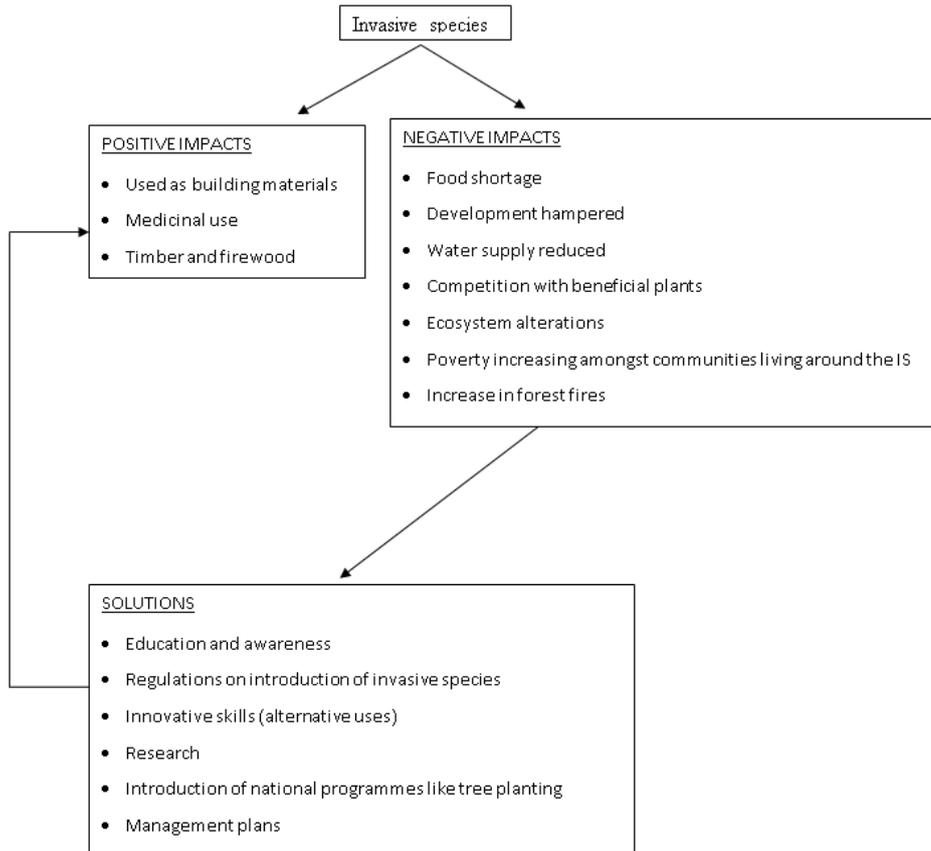

Invasive species are known to have ecological, social and economic impacts and are the key drivers behind the global change. Although most research works show that invasive species have negative impacts, there is evidence to show that the invasive species also have positive impacts (Davis *et. al.*, 2011; Gleditsch & Carlo 2011; Schlaepfer *et. al.*, 2011). They are known to provide habitats or food to species and enhance survival rates on endemic species (Bartomeus *et. al.*, 2016). Research carried out by Gribben *et. al.* (2013) in Southeastern Australia on the impact of invasive green alga *Caulerpa taxifolia* indicated that the alga was very positively associated with the composition and abundance of the epifaunal community. Another example is of fisheries which has resulted in increasing the food stock. Another research conducted by Gleditsch and Carlo (2010) in the USA on the correlation of the invasive fruit tree honeysuckles *Lonicera spp.* and bird communities in Pennsylvania showed positive impacts whereby with the availability of the fruit, the native birds were again sighted in plenty.

The focus of this study was to find out about the socio-economic impacts of invasive species in the Mulanje Mountain Forest Reserve (MMFR) in Malawi. Malawi is facing a major disaster in terms of livelihoods due to the introduction of IS. According to Malawi's National Biodiversity and Strategic Action Plan (NBSAP), the country is highly prone to twenty-nine invasive species due to its geographical position, tropical climate and agriculturally based economy and also the country's heavy reliance on imported products. These species include 17 plants, 3 fish and 9 invertebrates. Some of the key invasive species in Malawi include *Pinus patula*, Himalayan Raspberry *Rubus ellipticus*, Bracken fern *Pteridium aquilinum* and blue gum *Eucalyptus spp.* (Government of Malawi [GoM], 2010) The water hyacinth *Eichhornia crassipes* is the most common and wide spread aquatic invasive species (Phiri *et. al.*, 2001). The *Lantana camara* is the threatening terrestrial alien species and is known to be the largest attacker of native vegetation in areas like the Majete Wildlife Reserve. In some cases the IS are specifically introduced on both land and in water. The best example is the new aquaculture push in Lake Malawi which is also known as the "Galapagos Islands of freshwater" because of its hundreds of cichlid species of endemic fish. These cichlid species have started to disappear fast because of the introduction of the Nile Tilapia which has affected the lake ecologically.

In Malawi, some people have begun to adapt to the use of invasive species for their economic gains and improving livelihoods. This is also seen to be good for the country's economy (Shackleton *et. al.*, 2007; Kull *et. al.*, 2011; van Wilgen *et. al.*, 2011). However, the use of the IS for benefits is very limited. In many parts of the world, these species have been found to have greater benefits and are also used as a mechanism to solve food security issues (Wilson *et. al.*, 2014). While people across most parts of the world see the threats and benefits of the IS differently, in MMFR the IS is amongst four major threats. The IS has been increasing abundantly across the country and as a result its associated costs have been rising. As the IS increases, it affects the access to other natural resources (Wise *et. al.*, 2012). This is similar to India where it has also been noticed that as the IS increases, costs increase and benefits decrease and this leads to the negative perceptions of the IS (Pasiiecznik *et. al.*, 2001). In MMFR the other threats include resource use stemming from high population density, pervasive poverty and lack of awareness and weak incentives for sound conservation practices; agricultural encroachment on the lower slopes due to a combination of population pressure and insecure land tenure and bush fires due to an incomplete system of fire breaks and inadequate response capacity (GoM, 2010).

The authors have shown that IS has a high negative impact on the communities in comparison to positive impacts. This is because of lack of dissemination of knowledge and awareness on the benefits of IS like *prosopis*. This indicates that due to lack of knowledge they drive communities towards food shortages, hamper development and reduce water supply and in turn, make communities poorer than they already are (Food and Agriculture Organization [FAO], 2008). In this research this was done by testing the null hypothesis which stated that the invasive species have no positive impacts on communities neighbouring the MMFR.

In order to understand the impacts of the IS, a conceptual framework has been developed (Figure 1). The conceptual framework shows both positive and negative impacts of invasive species. The framework shows the negative impacts to be the highest. In order to reduce these impacts, solutions are needed which would increase the positive impacts of these species.

Figure 1: Conceptual framework showing impacts driven solutions towards invasive species

2. STUDY AREA

Mulanje Mountain Forest Reserve (MMFR) is situated in the far southeast corner of Malawi. It is the largest mountainous massif in the afro-montane archipelago (15°75'S 35°38E) (Figure 2). The massif itself is a huge syenite intrusion of 640km², rising steeply and abruptly from the south-central African plains to form a broad plateau of basins and deep river gorges at 1800m, and steep rocky peaks that reach 2800m.

Source: Makhambera and Shah, 2015

Figure 2: Map of Mulanje Forest Reserve and the sampling villages

The forest reserve was gazetted in 1927. It is an ecological island of unique biodiversity as well as a critical water catchment area. It has rich and diverse flora and fauna including at least 30 endemic plants including the Mulanje cedar (a distinctive conifer and national icon tree of Malawi) which only grows to a full height of 40m on the mountain.

MMFR experiences mean annual temperature of 20°C with an annual rainfall of 800mm. Mulanje Mountain boasts a variety of ecosystems - the Likhubula dry woodlands areas are unique with cycad species found nowhere else in the world. The Ruo River has tropical rain forest vegetation as it receives up to 100 inches of rain annually.

Mulanje Mountain Forest Reserve spans the two districts of Mulanje and Phalombe. There were an estimated 37,000 people living in 85 villages when this research was undertaken. Mulanje is considered a maize-deficit area that contains approximately 66% of the poorer households of the population. The outskirts of the mountain are mainly surrounded by tea estates and the majority of the local people attain their livelihoods by working in the tea estates.

3 METHODOLOGY

The study used primary data which was collected along settlement patterns targeting villages surrounding MMFR. A sample of five villages namely Nakhonyo, Mbewa, Kambenje, Nnesa, and Mandanda were purposively selected for the study from the Eastern, Western and southern part of the reserve so as to consider various sides of the reserve. This is shown in Figure 2. These villages represent the communities that surround the Reserve.

Systematic random sampling method was used to select the number of households in the selected villages whereby every 11th household was included in the sample. There were a total of 320 households in the five villages. A total of 30 respondents were selected from these five villages namely Nnesa, Kambenje, Mandanda, Nakhonyo and Mbewa. Systematic sampling of respondents was done using a list of households which was obtained from the village headmen.

The distribution of respondents per village is shown in Table 1.

Table 1: Respondent distribution

Village	Total Number of Households	Number of households sampled
Nnesa	72	7
Kambenje	81	7
Mandanda	75	7
Nakhonyo	49	5
Mbewa	43	4
Total	320	30

Source: Makhambura and Shah, 2015

In terms of the characteristics of the respondents, there were 18 (60%) women and 12 (40%) male respondents. A total of 27 (90%) indicated that they were married while 3 (10%) stated that they were single. In terms of occupation, majority of them were in the farming business indicating that they understood the impact of the IS from the farmers point of view (Figure 3).

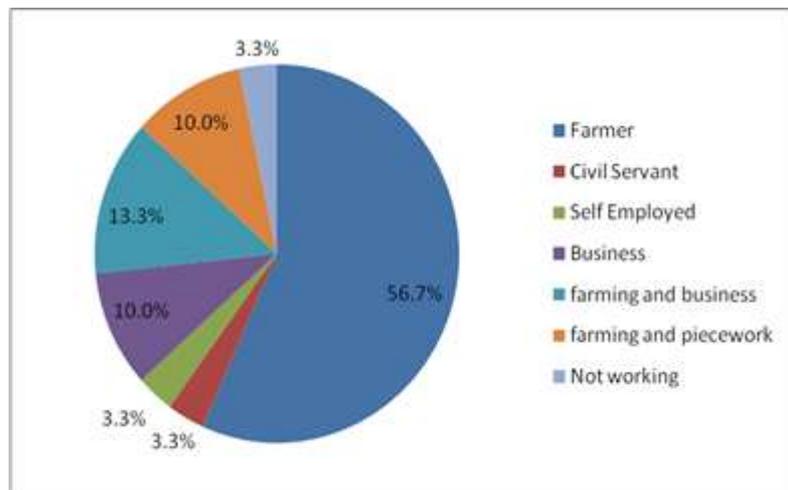

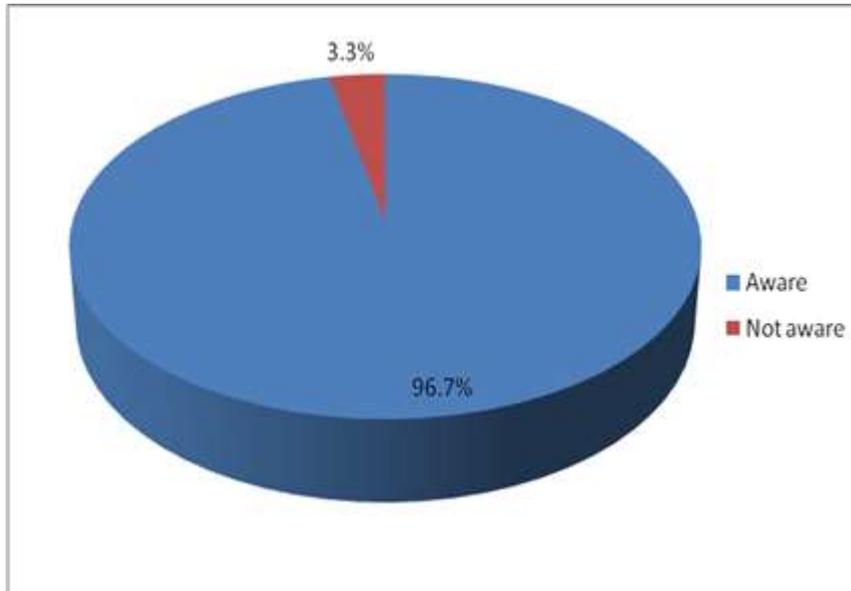

Figure 3: Occupation of respondents

The majority of respondents which were 16 (53.4%) were aged between 31 to 60 years while 14 were in the age group of 21-30 years (46.6%). In the age group of 31-60 years, the majority which was 8 (26.6%) were in the cluster of 31-40 years. In terms of the education levels, majority – 22 (73.3%) had basic education, 3 (10%) had secondary while only 5 (16.7%) had no education. Data from the respondents was also collected based on their knowledge in terms of their awareness of IS and whether the IS had any impacts in terms of benefits or problems.

4 RESULTS AND DISCUSSION

This research indicated that around the MMFR, 96.7% of the respondents were aware that there existed invasive species in comparison to 3.3% who stated that they were not aware (Figure 4). This is in line with the Convention of Biological Diversity’s (CBD) Article 13 on public education and awareness which the Government of Malawi has taken into account and in accordance has educated their citizens on the invasive species.

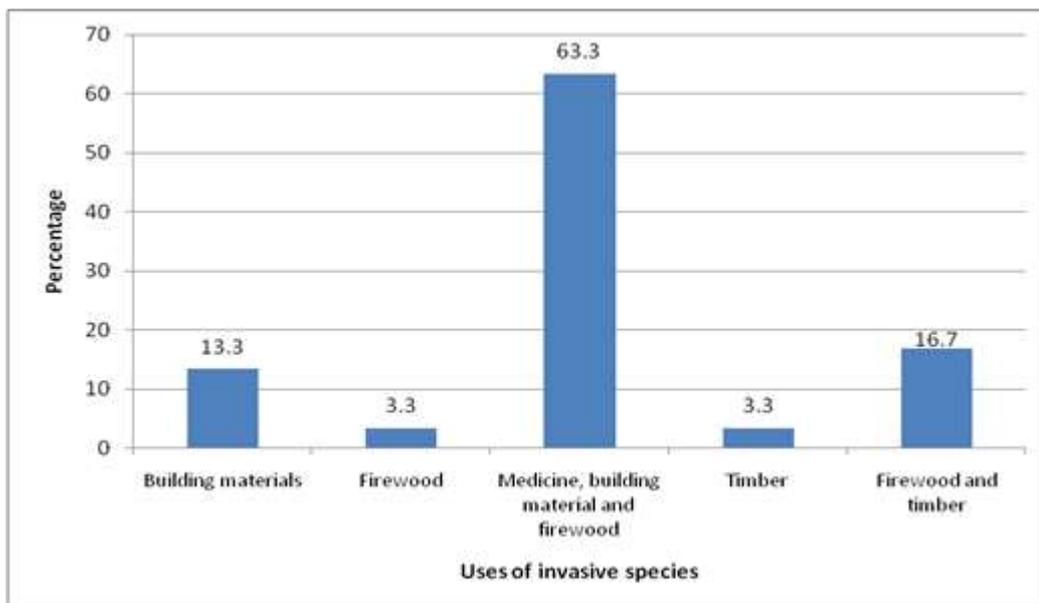

Source: Makhambra and Shah, 2015

Figure 4: Awareness on invasive species

In other developing countries which have paid attention to food security, people are aware of the IS. For India and Pakistan there is documented data on the awareness of the IS by the citizens. The same is the case for Kenya, South Africa as well as parts of Ethiopia and Djibouti (Shackleton *et. al.*, 2004). Furthermore, it is through this awareness that they are benefitting through the use of the IS unlike in places where the knowledge is not there (Choge *et. al.*, 2012).

4.1 Positive impacts of invasive species

As stated by Choge *et. al.* (2012), those aware of IS have been using the IS for benefits in comparison to those who are unaware. This knowledge is making people benefit enormously and improve their livelihoods. When the positive impacts of the respondents were analyzed, the results indicated that the people used the invasive species as building materials, timber, medicine and firewood. Majority of the respondents used these species for medicine, building materials and firewood (Figure 5).

Source: Makhambra and Shah, 2015

Figure 5: Positive impacts of invasive species on local communities

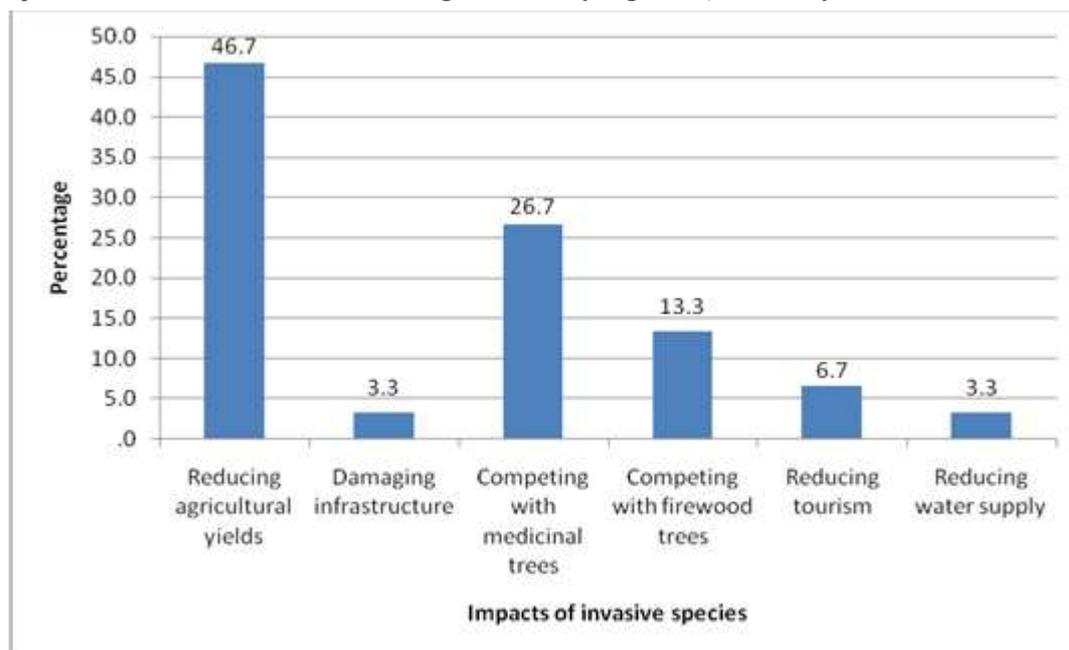

If the respondents are able to use the invasive species positively, it is very good as this helps them to understand the species better. The use of invasive species as firewood is known around the Ranthambore Tiger Reserve in Rajasthan in India. The local community has been using the invasive species *prosopis juliflora* as a source of firewood whereby they make charcoal and sell, thus trying to make income out of the species (Alers *et. al.*, 2007). Kenya has also undertaken research on the use of invasive species especially for firewood and charcoal production. The pilot project was conducted in two places - namely at the Muka Mukuu Cooperative Society in Machakos and the Elangate Wuas Game Ranch in Kajiado. The results indicated very good profits if invasive species were used (Ministry of Environment, Water and Natural Resources of Kenya (MEWNR) & Ministry for Foreign Affairs (MFA) of Finland, 2013). Furthermore, FAO together with Kenya Forest Research Institute (KEFRI) have been working with Non-Governmental Organizations (NGOs) to utilize goods and services from IS. The *prosopis* is one good example where local communities are encouraged to

make *prosopis* flour and they use it for their meals (Choge *et. al.*, 2006). Statistics by Choge *et. al.* (2002) show that in 2002 trade in Kenya for *prosopis* goods was worth US\$ 122 per household in some villages in Baringo District while in 2012 in the same areas it was over US\$ 1.5 million (Choge *et. al.*, 2012). In spite of this benefit, 50-80% of the people in Baringo want the *prosopis* to be eradicated totally. At the same time there are plans to build a power station in Baringo to trap power from *prosopis* biomass (Choge *et. al.*, 2012). This is a technology Kenya wants to borrow from India. At the same time, if invasive species were used instead of acacia species for firewood, environmental deterioration would be reduced. This has been proved by the use of the eucalyptus trees which are grown as plantations and used for fire wood and charcoal. Similarly in Sudan, the National Forest Cooperation has also carried out research on the same and has found that invasive species are a valuable source of firewood and charcoal (Ministry of Environment, Water and Natural Resources of Kenya (MEWNR) & Ministry for Foreign Affairs (MFA) of Finland, 2013).

Besides having positive socio-economic values, they also have to some extent positive ecological values. Examples include of pollinators which use IS as additional food as their habitats are greatly affected by disturbances (Williams *et. al.*, 2011). The same is the case for herbivores which also feed on IS due to habitat disturbances (Bartomeus *et. al.*, 2016). Another example includes the Capricorn Beetle which has adapted to feeding on the pedunculate oak *Quercus robur* (Oleksa and Klejdysz, 2017).

4.2 Negative impacts of invasive species

Although people are aware of the IS having benefits, most people associate IS with negative impacts. In this research the respondents indicated five impacts which were reducing agricultural yields, damaging infrastructure, competing with medicinal trees and firewood trees and reducing tourism and water supply. Reducing agricultural yields had the highest negative impact (Figure 6). This indicates that the communities living around the MMFR are greatly affected in terms of food supply as the invasive species compete for space and do not allow the food crops to grow well. This is in line with what Howard and Matindi (2003) and McGeoch *et. al.* (2010) found out when conducting a research on the threats of invasive species in Africa. These species have been found to grow fast in soils rich in nutrients and they tend to occupy any gaps in disturbed forests. These species destroy soil and during decay release toxic materials and prevent grazing from taking place. These plants are also found in agricultural fields and reduce yields for farmers. At the same time these species tolerate harsh conditions and grow faster (Wagh and Jain, 2015).

Source: Makhambera and Shah, 2015

Figure 6: Negative impacts of invasive species on local communities

The negative effects have also been highlighted in the research conducted by Moroñ *et. al.* (2009); Vila *et. al.* (2011) and Lenda *et. al.* (2013) where they have indicated that these species affect natural ecosystems and take over the indigenous species and in turn affect the food chains. Moreover they also reduce species diversity and density (Ortega and Pearson, 2005). There is dominance of the IS over other species as indicated in the studies by Dogra *et. al.* (2009) on the Shivalak Hills in India. However in this study the negative impacts have been classified by respondents in terms of the socio-economic impacts.

Studies by Osunkoya and Perret (2011) in Queensland, Australia and studies carried out by Simba *et. al.* (2013) in Nairobi National Park, Kenya have shown that the soil pH is very high in areas invaded by *Lantana Camara*. This indicates that the soils are no longer agriculturally productive. At the same time IS are known to increase the nutrient uptake from soil especially nitrogen and phosphorous and in turn reducing their uptake by other plants resulting in lower agricultural yields.

Research by Lui (2011) have shown that IS affect food for livestock as the plants compete with native plants and grow fast thus limiting food for herbivores. These herbivores avoid IS plants like *Lantana* as it is found toxic by some livestock as well as its unpleasant aroma. Moreover the livestock as well as the wild herbivores do not find these species nutritious (Kamau, 1986). Kamau (1986) and Boutton *et. al.* (1988) found that the IS uptake by animals affects their digestive systems negatively and thus poor forage.

Research carried out by Kent and Dorward (2012) in the forests of Kambudikki, India have indicated that the IS has been a real economic challenge to the Soliga and Lingayat communities. These communities have been using the forests for cattle grazing and the bamboo for weaving baskets. However IS have been a threat to the cattle grazing and bamboo stocks have reduced due to competition. This has resulted in cattle becoming underfed and malnourished making them vulnerable to diseases and wildlife predators.

Researchers like Oleksa and Klejdysz (2017) in the United States of America have shown that IS have a huge negative impact on infrastructure. For example *arundo donax* giant reed which has touch fibrous roots penetrates soil. It is known to choke riversides and stream channels, increase forest fires and makes the framework of bridges, dams, roads and culverts very weak. It also competes with all native plants including medicinal (Invasive Species Advisory Committee [ISAC], 2016). Another destructive IS is the red oak *Q rubra* which was introduced in Europe from North America. This species spreads very fast as it begins to occupy rail track and road zones and any empty lands (Riepšas and Straigytė 2008; Woziwoda *et. al.*, 2014a). Furthermore it has negative impacts on the forest biodiversity as it is very in decomposition of its fallen leaves (Chmura, 2013; Woziwoda *et. al.*, 2014b).

As shown in this research, IS have resulted in a fall out in the tourism industry and reduced food security. For example the European Green Crabs are known to eat large quantity of native shell fish resulting in loss of commercial shell fish industries. Another example is in Kenya where the water hyacinth *Eichhornia crassipes* which grows like a carpet and reduces sunlight and in turn affects the water quality, recreational fishing and swimming. As both swimming and recreational fishing are reduced, tourism has been a big blow around Lake Victoria and Naivasha (Waithaka, 2013). Another IS threatening tourism and endangering flora and fauna species is the mikania *mikania micrantha*. It is found in the humid tropical and sub tropical regions of the Pacific and Asia (Waterhouse, 1994). This species is very common in Nepal and is threatening protected areas like the Chitwan National Park, a UNESCO World Heritage Site. Research carried out by Murphy *et. al.* (2013) shows a correlation between mikania and the Indian rhinoceros *Rhinoceros unicornis* (greater one-horned rhinoceros) whereby this mammal has greatly declined in areas of mikania infestation.

The data collected in this research was further analyzed by testing the null hypothesis which stated that the invasive species have no positive impacts on communities neighbouring the MMFR. Table 2 shows the results of the hypothesis which were obtained through the use of the chi square.

Table 2: Results of chi square

	Value	df	Asymp. Sig. (2-sided)
Pearson Chi-Square	.599 ^a	4	.963
Likelihood Ratio	.933	4	.920
N of Valid Cases	30		

Source: Makhambera and Shah, 2015

The results indicate that the calculated chi of 0.599 is lesser than the critical thus failing to reject the null hypothesis which states that the invasive species have no positive impacts on communities neighbouring the MMFR. This finding concurs with the findings of most researches on invasive species. Research conducted by Sanu and Newport (2010) in the Indian Peninsular, Macharia *et. al.*, (2010) in Central Kenya and Keller *et. al.* (2011) in Europe indicate that the invasive species have negative impacts on local communities. They all indicate a heavy loss in terms of food due to competition from these species resulting in food shortage. This is closely followed by impacts on the ecosystem like deficits in the water supply (Sanu & Newport, 2010).

5 CONCLUSION

This study supports previous work done by FAO (2008), Hulme (2009), Obiri (2010) and the

Ministry of Environment, Water and Natural Resources (MEWNR) and Ministry for Foreign Affairs of Finland (MFA) (2013) on dealing with the negative impacts on invasive species. Education and awareness on invasive species is a key in overcoming threats caused by invasive species. Once people are aware, they would not spread the invasive species, at least knowingly through attractions like souvenirs. It is also very important to put the message of invasive species in schools through the official school curriculum so as to create a country wide education and awareness programme. More stakeholders especially the private and NGOs should be involved so that they help in spreading this message, help in conducting research, help in developing innovative skills on how best the invasive species can be used like in Kisumu, Kenya form the water hyacinth the local people are making furniture and coffins. A unique example is the Nobel Prize winner, Wangari Mathaai who, when she died was cremated in a coffin made of the water hyacinth! The aim is sound environmental practice and positive use of these species which can contribute to poverty alleviation. Malawi should also introduce strict regulations on invasive species especially in relation to transport, trade and tourism. The country should also develop national programmes whereby tree planting using indigenous trees is done and also poverty reduction strategies should indicate link between poverty alleviation and biodiversity conservation. Management plans of national

forest reserves should also take invasive species into consideration under the issue of threats as outlined in the CBD Article 8h on prevention of invasive species.

In order to understand more about the impacts of invasive species, more data as well as the extent of the spread of invasive species at national level should be made available for research. At the same time there should be more funding dedicated to the eradication of the invasive species.

1120 SPATIAL DIMENSION OF DISASTER MANAGEMENT IN GREATER MUMBAI

ABSTRACT

The concept of “space” in geography can be absolute, relative or cognitive. Unlike, absolute space, which is fixed, is asocial and timeless; relative space describes space in a wider concept as it is socially made and remade over a period of time. Thus relative space is dynamic, fluid and ever changing. It can refer to territories with respect to political boundaries or environmental regions such as forests, water-bodies etc. or Land use-Land cover of an area. However, if the study of relative spaces is carried out with a perspective of a socio-environmental issue taking into consideration its dimensions, impact and distribution; it can lead to a detailed analysis, observation of patterns, future trends and solutions to tackle the issue in future. Thus, in the present study, space is studied with relation to disasters and through the perspective of disaster management. In the study of geography, the spatial dimension describes and compares patterns where environmental factors are located. These patterns are determined by using quantitative and qualitative research to compare areas with one another in relation to a particular variable. The aim of this approach is to amend these factors and create more equity in relation to the variable being studied. In the study an attempt is made to understand the disasters for different wards of Greater Mumbai. The comparison is done to bring forth the patterns and disparities. Further, locations of key facilities, connectivity of roads and accessibility of resources and relief parameters is interpreted and presented with an aim of promoting and providing an equitable approach to disaster management in Greater Mumbai. The methodology used for the study includes perception analysis using questionnaire surveys and mental maps. Geospatial analytical techniques were applied for the purpose. With reference to Kate’s model of hazard perception and response respondents were interviewed adopting stratified random sampling technique for 24 Wards of Greater Mumbai. Perception of people regarding disasters, its impact, and safety measures adopted by them and how management of disasters was presumed was evaluated. Their idea of safe zones, safe routes, direction and resilience was noted and mental maps were prepared. Levels of communications in-terms of disaster management were confirmed and anomalies if any were taken into account. Expectation of local people in terms of disaster management varies with space and time. Detailed geospatial mapping was carried out and an attempt is made to incorporate the same in a GIS tool as a web map, in-order to build a Disaster Information System which would help to disseminate information to local people and build a resilient city in the future.

1141 BUILDING THE 'DISASTER RISK ASSESSMENT INDEX'

ABSTRACT

The paper provides a comprehensive assessment of hazard, vulnerability, resilience and exposure related to natural disasters for the population of Italian municipalities. We employ state-of-the-art methods to build indicators of the various components of risk assessment and devote a particular attention to the consideration of various different aspects of the economic exposure of municipalities. The combination of these four dimensions is particularly useful to identify hot spot areas that are characterized by high hazard, exposure and vulnerability and by low resilience. A tool like the one proposed in our paper that helps policy makers to identify priority areas of intervention is likely to be very valuable in presence of tight public budgets in order to take effective choices about mitigation and prevention strategies.

1222 COMMUNITY RESPONSE AND CYCLONE SIGNALING IN COASTAL BANGLADESH

ABSTRACT

Bangladesh is one of the countries which have been significantly affected by natural disasters. This study was an attempt to investigate people’s response to cyclone preparedness and cyclone shelter of the disaster affected people in south western region of Bangladesh. The study was carried out in costal Bangladesh from the two most cyclone affected areas Shyamnagar upazila, Gabura union under Satkhira District and Moharajpur union in Koyra Upazila under Khulna District of Bangladesh. This paper is descriptive in nature using qualitative and quantitative approaches. In quantitative phase, data were collected through interview schedule technique and in qualitative phase data were collected by using semi structured interview questions along with a checklist was used to gain in- depth information using FGDs and case study method. The result from this study showed that most people of this area were illiterate and have very poor education which leads them lower occupational status as well as lower income level. Most of the people were very little familiar about the term climate change and most of the people get information about climate change from various NGOs. The study revealed that most of the people thought that salinity intrusion were more serious than any other disaster. The Majority of the people did not have any concerns about the loss of the properties and livestock. Almost all the people use mobile Phone and half of them depend on radio as a media source of evacuation order. Almost three-fourth of the people trust CPP volunteers as their personal sources. And more than half of the people trust mosque as their personal sources of evacuation order and the entire respondents had knowledge regarding nearest cyclone shelter and only few respondents did not have any knowledge regarding nearest cyclone shelter. The paper also attempts to identify that people do not follow the evacuation orders due to mistrust of the warning messages which can deter from early evacuation; and insufficient number of shelters and poor transportation facilities which discourage late evacuation. The present paper highlights the community response and cyclone signaling which will help policymakers to create awareness in mitigating cyclone vulnerability among coastal people. Key Words: Vulnerability, Cyclone, Community

1364 A STUDY OF EFFECT "SOCIAL LOAFING" TOWARD DISASTER PREPAREDNESS

Ryoya TOMENO*, **Hiroari SHIMIZU**, **Yusuke TOYODA**

Graduate school of Ritsumeikan University, Japan, *ps0185vf@ed.ritsumei.ac.jp

ABSTRACT

Recently, it is assumed to occur large scale and wide area earthquake, when those kinds of disasters will be occurred. Thus, there is limitations to much work helping residents as public-help. In the great Hanshin-Awaji-earthquake and the great East-Japan-earthquake, it couldn't work much to help them. In the great Hanshin-Awaji-earthquake, administration had to do relief activities and firefighting, therefore administrative could not have enough support for victims. When it was occurred the great East-Japan-earthquake, administration had huge damage by a lot of administrative officer died by tsunami, the office could not work well to help residents. It is necessary to consider comprehensive strategy including not only public-help but also mutual-help and self-help when disaster happen. In this case, it may be occurred "social loafing" in the field of group-psychology in the disaster preparedness. It means that the more citizen trust measurements and support by public-help, it may be decreased intension of disaster preparedness oneself. In this sense, it must not be keeping with action and intention. Katada et al., (2011) discussed about high resident's dependent for public-help is affected to be decreased intention of self-help. But it was not clarified that relationship among resident's dependent for public-help and intention of self- help and social loafing. A questionnaire-based survey was administered to person (N=1000) living in japan. The items ware devise to probe for attitude of person toward disaster preparedness, risk perception about earthquake, trust in public-help and community-help, and others.

Therefore, it is clarified that effect of social loafing preparedness toward disaster preparedness based on disaster preparedness, not action quantity because intentions and actions are disagreement. It will be provided new approach for promoting to the preparedness.

Keywords: disaster preparedness, risk, social loafing, disaster

1, BACKGROUND

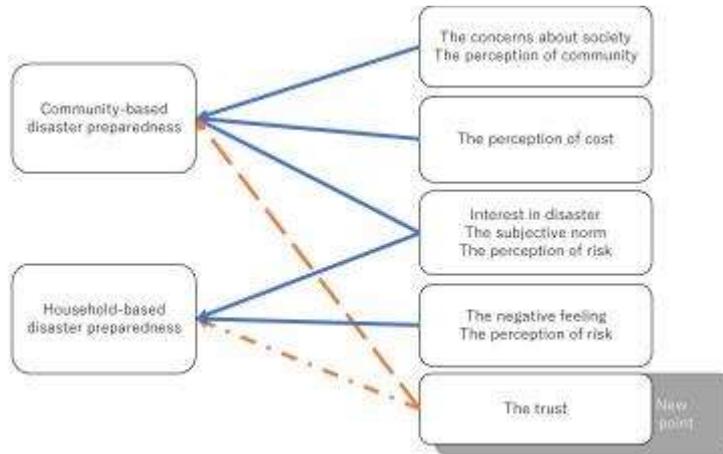

There is great loss of people's lives and prospect is Japan due to natural disaster. Thereafter, with the progress of society's capabilities to respond to disasters and mitigate vulnerabilities to disasters by developing management system and more, disaster damage has shown decline tendency. However, these functions toward disaster are not working normally. For example, In the great Hanshin-Awaji-earthquake (1995), the administration had to do relief activities and firefighting, therefore administration could not have enough support for the victims. In the great East-Japan-earthquake (2011), the administration had huge damage by a lot of administrative officer who supporter of disaster died from the tsunami, the office could not work well to help residents. There is also a high probability of the occurrence of large-scale earthquake in near future, including impending possibilities of Nankai Trough Earthquake and Tokyo inland Earthquake. Various researches and efforts are carried out to promote the disaster preparedness. However, it cannot be promoted due to the problem of administrative dependence awareness such as excessive expectations for disaster support and prevention such as disaster information. Katada et al., pointed out that in areas with flood risk in Gunma Kiryu City, Japan, people with lower administrative awareness take disaster preparedness, and people with high dependency have indicated that the disaster prevention should be taken by the administration. this previous study focus on dependence. However, it is supposed that result is affected by social loafing which is one of group psychology. Because not only the administration but also local resident's organizations, companies, NPOs, etc., carry out disaster prevention and support, it is supposed that it is the same effects on these.

In this study, it is clarified that disaster preparedness is affected by group psychological effect such as social loafing, and what kind of people are strongly affected. it is clarified that new ways from social tear-off which is one of collective psychological phenomena to promote disaster- prevention

2. THE EFFECT OF GROUP PSYCHOLOGY ON DISASTER PREPAREDNESS

2.1. Designs of the hypothesis model of disaster preparedness

There are many studies related to disaster preparedness. Motoyoshi et el (2008) point out based on the theory of reasoned action, factors of disaster preparedness due to disagreement about disaster preparedness and behavior, additionally that disaster preparedness is sort of two type: household -and community-based disaster preparedness, each of which has difference factors such as the interest in earthquake, the subjective norm, the concerns about society, etc. in this study, it is designed that hypothetical model incorporating the trust which is one factor of group psychological effect such as social loafing, these factor of disaster preparedness used in previous study. It is clarified that disaster preparedness affected by group psychological factor because of the verification of the hypothesis model. The object of trust is only the administration which is the body of public-help, and is local resident's organization which is one of body of mutual-help.

Based on Tadahiro Motoyoshi, Kenji Takao, Saburo Ikeda 'Determinates of household-and based disaster preparedness'2008, study of social psychology, vol.23,218

Fig1. hypothesis model of disaster preparedness

2.2. The Validation of the hypothesis model

the contents of the questionnaire are consisted of the hypothesis model's factor based on disaster preparedness model and of items that previous studies used (Motoyoshi et al,2009, Yoshida et al,2009). For hypothetical models, it is conduct questionnaire surveys and verify validity. The abstract for questionnaire survey about disaster preparedness. Table1is display the questionnaire contents. It is conducted an exploratory factor analysis to construct a measure for the composition concept based on the hypothesis model. Additionally, internal consistencies are confirmed.

Table1 abstract of questionnaire

Questionnaire survey	
date	form September 7th to 11 th, 2017
target of the survey	over the age of 18 in Japan
number	1000 sample
contents	the parceptation of risk negative feeling the interest in earthquake theparceptation of benefit and cost the subjective norm the disaster preparedness the commitement to the community the attachment to the community the trust in public-help and mutua-help the personal attribute other

Table2. The structure of answers in this web survey

age	men	(%)	women	(%)
18~19	4	0.8	2	0.4

do you think that you can deal with an earthquake if disaster response is taken at home	0.404	0.24	-0.277	0.231	0.469
do you think it is difficult to make opportunities for families to talk about earthquake disaster sufficiently	0.069	0.763	-0.046	-0.111	0.527
do you think it is difficult to prepare disaster prevention supplies from the usual time	-0.012	0.726	0.045	0.018	0.402
do you think that it will take time to earthquake disaster response at home?	0.069	0.647	0.131	0.014	0.592
it takes time for community member to engage in disaster-prevention activities.	-0.071	0.029	0.846	0.06	0.621
it is difficult for community member to engage in disaster-prevention activities to prepare for an earthquake	0.135	0.114	0.599	0.006	0.321
it is difficult to take time for you to engage in disaster-prevention activities	-0.166	0.375	0.446	0.022	0.467
do you think that it will be useful when an earthquake if you talk about earthquake disaster prevention plans in your family?	0.115	-0.033	0.047	0.78	0.403
do you think that it will be useful when an earthquake occurs if you prepare disaster prevention goods at home?	0.069	-0.059	0.073	0.77	0.441
Factor Correlation Matrix					
Factor	1	2	3	4	
benefit(community-based)	1	0.203	0.402	0.635	
cost(household-based)	0.203	1	0.508	0.241	
cost(community-based)	0.402	0.508	1	0.515	
benefit(household-based)	0.635	0.241	0.515	1	

It is detected 4 factor by factor analysis (maximum likelihood method, promax rotation) for 14 items consisting of perception of benefit and cost of household and community-based disaster preparedness. It was possible to interpret 3 factors; however, it was adopted 4 factors due to simply analyze. It is interpreted that factor1 is the perception of benefit of community-based disaster preparedness, the factor 2 is the perception of cost of household-based disaster preparedness, factor 3 is perception of cost of community-based disaster preparedness, factor 4 is the perception of benefit of household-based disaster preparedness. Reliability coefficient of subscale is $\alpha=.856$ about factor1 and is $\alpha=.782$ about factor 2, is $\alpha=.763$ about factor 3, is $\alpha=.848$ about factor 4. table 5. the result of factor analysis on the subjective norm items

	Pattern Matrixa		
	Factor 1	2	h2
people who is your around you think you want to engage in local disaster-prevention activities.	0.825	-0.029	0.512
do you think that local people have worked eagerly on disaster prevention	0.79	-0.051	0.461
do you think that local people will be delight if you engage in the local disaster activities.	0.74	0.103	0.536
Do you think your family will be delighted if you take the earthquake disaster prevention at home?	-0.15	0.867	0.446
Do you think that your family want you to do earthquake disaster response at your home?	0.111	0.67	0.474
Do you think that your family wants you to think about disaster prevention?	0.157	0.656	0.414
Factor Correlation Matrix			
Factor	1	2	
the subjective norm about community-based disaster preparedness	1	0.606	
the subjective norm about household-based disaster preparedness	0.606	1	

It is detected 2 factors by factor analysis (maximum likelihood method, promax rotation) for 6 items consisting of the subjective norms. It is interpreted that factor1 is the subjective norm of community-based disaster preparedness, the factor 2 is the subjective norm of household-based disaster preparedness. Reliability coefficient of subscale is $\alpha=.83$ about factor1 and is $\alpha=.795$ about factor 2.

It is detected only one factor by factor analysis (maximum likelihood method, promax rotation) for 6 items the trust in public-help and mutual-help because the factor was deleted 2 item that is factor loading value of 0.4 or less (0.254, 277). In additionally, it is judged that it was useful to verify the hypothesis model by dividing it into the trust is public-help and the trust in mutual-help, thus, it is interpreted two factors. Factor1 is the trust is public-help that is consist of 2 items. Factor2 is the trust is mutual-help that is consist of 2 items Reliability coefficient of subscale is $\alpha=.816$ about factor1 and is $\alpha=.827$ about factor 2.

Table6. the results of Factor analysis on disaster preparedness items

Pattern Matrixa

Factor Correlation Matrix

Factor	1	2
the community-based disaster preparedness	1	0.7
the household-based disaster preparedness	0.7	1

It is detected 2 factors by factor analysis (maximum likelihood method, promax rotation) for 8 items consisting of the disaster preparedness. It is interpreted that factor1 is the community- based disaster preparedness, the factor 2 is the household disaster preparedness. Reliability coefficient of subscale is $\alpha=.944$ about factor1 and is $\alpha=.903$ about factor 2.

It is conducted only reliability analysis for Other factors such as the interest in disaster, concerns of society etc., because of it is detected only one factor each item.

Reliability coefficient of subscale is $\alpha=.916$ about the attachment to the community and is $\alpha=.911$ about the concerns of society , is $\alpha=.893$ about the interest in earthquake. About the attachment to the community, it is inappropriate as factor, because that is consists of only one item; however, it is included as the factor due to that factor does not have the effects in this study, Based on these results of factor analysis, it is examined the factors that have affected disaster preparedness using multiple regression analysis.

Table7 the result of hypothesis model of disaster preparedness

	household-baseddisaster preparedness	community-based disaster preparedness	community-based disaster preparedness(caseA)	community-based disaster preparedness (caseB)

**p<.01,*p<.05

ns: not significant , -: not variable inputed

The table 8 is indicated result by multiple regression analysis (stepwise method). Regarding household-disaster preparedness, this case is not affected by the trust which is one factor of group psychological effects. By contrast, community-based disaster preparedness is affected by the trust in mutual-help. In addition, it is conducted cases analysis to clarify the attributes of those who strongly affected. In this analysis, it was defined that case A was citizens who answered “the efforts by mutual-help is important”, and that case B was citizens who answered “the efforts by self-help, mutual-help, public-help in disaster prevention is important” was case B

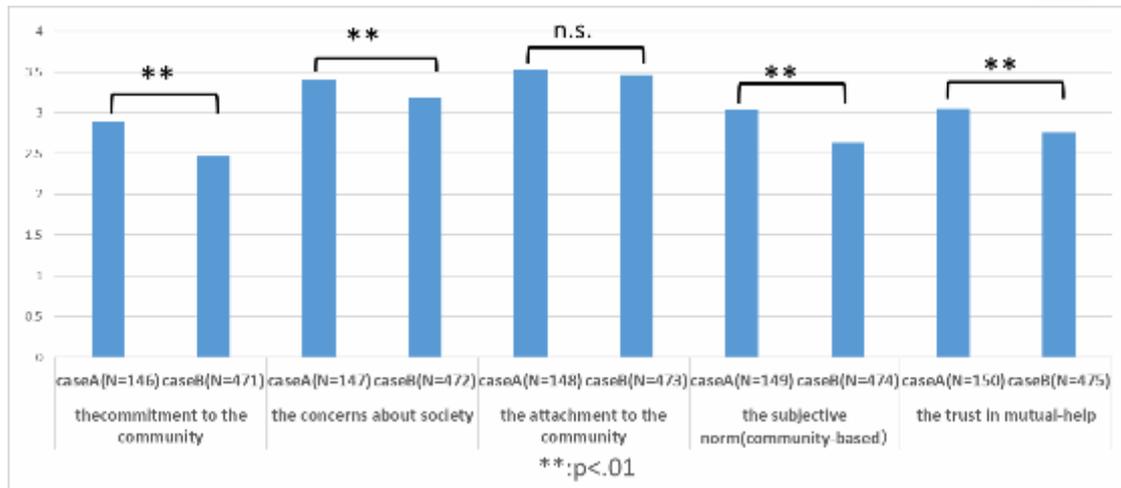

Fig2.the result of the different between the average value of the factor in case A and case B

Figure 2 indicates that there is a significant difference in factors related to social consciousness and community consciousness in the case of community-based disaster preparedness between case A and case B by t-test. It was clarified that compared to case B, case A has significantly higher the commitment to the community ($t=4.648$, $df=615$), the concerns about society ($t=2.924$, $df=615$), the subjective norm of community-based disaster preparedness ($t=5.248$, $df=615$), the trust in mutual-help ($t=3.695$, $df=615$). by contrast, there was no significant difference between case A and case B about the attachment to the community ($t=0.83$, $df=615$). As the result, it clarified that case A is totally more social and community consciousness that is group consciousness than case B.

3. CONCLUSIONS

It was clarified that community-based earthquake disaster preparedness is affected group psychologically affects by the trust in mutual-help. Particularly, case B that answered "public-help, mutual-help and self-help is important" has a stronger effect than case of other case including case A. In addition, Case B has a lower consciousness of society and the community, such as the concerns about society and the commitment to the community than case A. Although it is not clear why case B tends to have low group consciousness and is affected strongly by group psychology, it is supposed that the need for disaster preparedness of case B decline by reason that group size related disaster prevention become big due to the case B understand that the participation by diverse bodies is important. In this study, it could not be clear that characteristics of people who is affected social loafing. Therefore, it is needed additional investigation with another factor.

In this result at the present, it is could not make any concrete suggestion. However, it is necessary to raise various factors concerns about social and community the same as previous study related social loafing and to point out the importance of community-based disaster preparedness. However, that is pointed out in various scenes such as school disaster prevention education and administrative disaster prevention information. Therefore, another method is required for case B that is affected by the group psychological effect such as trust. It is needed to develop methods and tools to strengthen various factors of society and the community, in addition to the previous methods showing the importance of community-based disaster preparedness behavior and disaster risk.

1560 THE ANALYSIS OF FLOOD HAZARD IN THE GHATAL CD BLOCK OF PASCHIM MEDINIPUR DISTRICT, WEST BENGAL, INDIA

ABSTRACT

Located in the Indian state of West Bengal, the Ghatal Community Development (CD) Block of Paschim Medinipur District is highly susceptible to the flood hazard. This area is a low-lying inter-sedimentary lobe pocket between the floodplains of Kangsabati and Damodar Rivers. The rivers like Kangsabati, Shilabati, Darakeswar etc., which are originated in the Chhotanagpur Plateau and flowing through the Ghatal region, struggle to carry surplus runoff during the high discharge events and eventually cause flooding. These rivers receive runoff from the upstream reservoirs built under the Damodar Valley Corporation (DVC) and Kangsabati Reservoir Projects. The Ghatal region usually gets flooded every year and the floodwater may remain stagnated for months at a number of places. In recent times, major floods occurred here in October 2013 and July-August 2017. The 2013 event occurred due to the landfall of the ‘Phailin’ cyclone that resulted into torrential rainfall in the Chhotanagpur Plateau region of Jharkhand State and the western part of West Bengal. Whereas, the 2017 event was triggered by a monsoonal low pressure system that brought incessant rains in the same catchment area. This study attempts to figure out the characteristics of flood hazard in the Ghatal CD Block from the analysis of different satellite images (IRS LISS-III, Landsat-5TM, Landsat-8 OLI, Sentinel-2), field surveys and secondary information. The areas located on the left bank of Shilabati River were mostly affected during the flood events prior to the monsoons of 2017. Whereas, the areas located on the right bank of Shilabati River, including the towns like Ghatal and Daspur, were safeguarded by the circuit embankments constructed during the British Raj. The longest circuit embankment—Chetua—was breached at Pratappur during the high stages in the monsoon of 2017. The circuit embankments in the adjacent areas prevented the floodwater to get back to the channels. As a consequence, the inundation scenario was severe at Ghatal town and its surroundings. About 60% area in the Ghatal CD Block remained inundated for three weeks during July-August 2017. Very low regional slope and tidal activity in the Rupnarayan River, which is the principal drainage outlet of the region, ensure long periods of inundation.

1606 CLIMATE CHANGE AND DECLINING NATURAL AND SOCIAL CAPITAL IN THE PORTUGUESE MOUNTAINOUS PROTECTED AREAS: A RECIPE FOR NATURAL DISASTERS AND AN OPPORTUNITY FOR INNOVATIVE TERRITORIAL POLICES

ABSTRACT

Portuguese mountainous areas experienced a long term decline in both their natural and social capital. Within the later 30 years the mountainous agroforestry and pastoral agro-ecosystems which shaped the landscape of these areas have been progressively abandoned in association with major sociodemographic and economical changes, which have led to depopulation, population ageing, farmland abandonment and grazing decline. The interrelated decline in both natural and social capital enhanced the expansion of recurrent wild fires that accentuated the impoverished of natural capital stocks and flows of regulating ecosystem services. Climate change are aggravating the problem with uncontrollable large wild fires with devastating consequences for the local populations, the ecosystems as the country as whole. Along with the declining stock and flows of ecosystems services such as landscape fire resilience, soil, water services and the rural landscape aesthetics, tourism and the demand for cultural services in these areas have exhibited an opposite trend, what has led to the expansion of the tourism supply, including accommodation and the offer of recreation services. Agri-environmental EU schemes have had a limited success, varying between practically unsuccessful in same protected areas to a successful policy measure on another, mainly depending on the role of common land (collectively ownership) to pasture. The traditional natural protected areas policies had contradictory impacts and show somehow exhausted. Local products promotion policies, such as the protected denomination origin show as well a limited success. This paper bases on empirical evidence collected to the Natural Park (NP) of Serra da Estrela (NPSE) to illustrate the decline on both the social and natural capital, and on the respective flow of services (social and natural capital based), along with the increase on the demand of cultural services. Ecosystem mapping and economic valuation methods have been employed, along with the regional data available to estimate some indicators for green accountability. Empirical data have been collected through an interdisciplinary and participatory approach involving local stakeholders in focus groups and group discussions. The main goal of the paper is to use the evidence abovementioned to anchor a discussion on innovative territorial policies able to underpin collective-based solutions for the value capture of the services of natural capital at the local level. These build largely on the acknowledgement of the scarcity and the cost (and value) of the provisioning, regulating and cultural services supplied by the mountainous areas by both: 1) the various direct and indirect beneficiary populations, including the local population, tourists and visitors, urban water consumers, among others; 2) the economic and political actors at local, regional and supra-regional scale.

1621 IMPACT OF COAL FIRED THERMAL POWER PLANT ON THE DRINKING WATER QUALITY OF ANPARA, SONBHADRA, UTTAR PRADESH, INDIA

ABSTRACT

Anpara is a town in Sonbhadra district of Uttar Pradesh state in India which is well surrounded by small hills. It hosts the Anpara Thermal Power Station(ATPS) which is built aside the Govind Ballabh Pant Sagar dam on Rihand river, a tributary of river Son which also serves as a water source for the boilers of this power plant. This power plant has four stages and total 9 units of which stage A, B, and D are under UPRVUNL and C is under LANCO with a total installed capacity of 3830MW (2630MW under UPRVUNL and 1200MW under LANCO). The waste generated, from a coal-fired thermal power plant contains harmful elements such as Arsenic, Cadmium, Chromium, Mercury, Nickel, Lead etc. The fly ash generated from these units are either converted into a slurry and deposited in the ash ponds or kept in the dry state from where it is carried away by different industries like cement and brick industry. This fly ash, when deposited in ponds or kept for further transportation, contaminate the soil and surface water bodies through leaching process and then infiltrates to the aquifer where it contaminates groundwater. The quality of water bodies also deteriorates by the release of water from cooling towers which use chlorine as a coolant, responsible for algal bloom in water bodies. This study tries to find out the impact of this fly ash on the drinking water sources (surface water and groundwater) of nearby areas which are located near fly ash dumping sites. To fulfill this objective, samples were collected from handpumps and surface water bodies making concentric circles with an interval of 2 km in all four directions centering the fly ash dumping sites. The coordinates of sample collecting point were recorded and henceforth plotted on a map with the help of ArcGIS 10.5. The samples collected were taken to environmental science laboratory of Indian Institute of Technology (Indian School of Mines) Dhanbad to measure the concentration of elements such as Arsenic, Cadmium, Lead and Nickel with the help of Atomic Absorption Spectrophotometer. pH, conductivity, TDS, and turbidity was measured in Central Research Facility at the same institute as well. It was found that all the samples collected and tested have the concentration greater than the prescribed limit of World Health Organization for Drinking water. It is also found that there is a trend of decrement in concentration of elements in samples each time the collection point shifts away from the fly ash dumping ground. Key Words: Anpara, groundwater, fly ash, ash pond, thermal power plants, UPRVUNL

1652 MONITORING OF AGRICULTURAL DROUGHT USING PRECIPITATION AND VEGETATION INDICES- A STUDY IN THE SOUTH-WESTERN PART OF WEST BENGAL

ABSTRACT

Indian agriculture is very much dependent on precipitation, especially of the Summer Monsoon Rainfall (SMR). Hence, delay of SMR may result in damaging effect on agriculture and thereby rural economy of India. The south- western part of West Bengal, the present study area, experiences drought in the state of West Bengal, mainly due to erratic SMR along with its typical soil and drainage characteristics. Drought has multi-dimensional effects, of which the most prominent is obviously reduction of agricultural productivity and, to a great extent, food security of the region. So, drought monitoring is an essential task for climatic hazard management. Application of geospatial techniques can be essentially useful for spatial analysis and planning to mitigate the hazard. In this study, agricultural drought has been assessed using both precipitation based and vegetation response indices. Gridded precipitation dataset of CRU T 3.21.4 and Moderate Resolution Imaging Spectro-radiometer (MODIS) Normalized Deference Vegetation Index (NDVI) and Land Surface Temperature (LST) have been used to assign the drought conditions across the study area. Crop production data of Kharif season (July-October) have been used to produce Yield Anomaly Index (YAI). On comparative analysis of both the precipitation based indices and vegetation response indices, a positive relationship has been found between vegetation based drought indices with the crop productivity in the study area. Keywords: MODIS, NDVI, LST, Yield Anomaly Index (YAI)

1661 RISK SENSITIVE LAND USE MODELS FOR DISASTER RESILIENT URBAN DEVELOPMENT

ABSTRACT

Urban areas, due to their inherent nature of population and activity concentration pertaining to development are faced with severe challenges. Rapid and uncontrolled urbanisation has given rise to metropolitan and megacities in India that have complex urban problems like population explosion, high density, lack in physical infrastructure, informal housing, non-compatible land uses and magnified disaster risks. The development patterns of the cities, unplanned development turn both natural as well as manmade hazards into disasters which in turn adversely impact development; the sprawl of cities in ecologically sensitive areas/ unsuitable areas also result in increased vulnerability of built environment. Land use and urban development often do not take into account the vulnerability of environmental resources and thus in turn contributes towards increasing the risk of disasters. Land use planning and the city development processes also do not take into account the vulnerability, hazard and imminent disaster risks; risks reduction is not mainstreamed in the spatial planning processes. The significant impacts of urbanisation pertain to the high amount of land consumption, high density and low share of open areas among others. Also, the inadequate coping capacities of the cities limit the cities from overcoming and withstanding the adverse impacts. The disaster risk is for the city populace in general and the low income communities in particular as they don't have the resources to avert the ill-effects of a disaster. The vulnerability of the city is also associated with activity areas and work places, business districts, high density areas, public property and infrastructure, heritage structures, intense movement corridors, environmental resources/ eco sensitive and vulnerable areas. The consequences of disasters in metropolitan cities and megacities are closely linked to spatial distribution of activities. The development pathway of the present and future cities is thus dominated by increased vulnerability, growing hazards and amplified disaster risks. The future of the development of cities is thus unsustainable and untenable considering the impending unaddressed risks and the consequent severity of impacts. Hence the cities need to be resilient i.e. increase the ability to survive, withstand, adapt and grow in the face of stress and shocks, even transform when conditions require and recover quickly from any plausible hazards. Disaster resilient development is thus the sustainable trajectory for the cities in future. Hence disaster risk reduction needs to be mainstreamed into urban planning and development processes and land use planning has a significant role in resilient city development. Risk sensitive land use models is imperative for disaster resilient development so as to achieve sustainable urban growth without creating new risks; risk mitigation related to land development practices; reduction of vulnerability of people and places; address and reduce anticipated damages and losses and increase people's coping strategy and ability to recover through rehabilitation.

1041 EVALUATING THE ECONOMIC DAMAGES BY TSUNAMI AND REGILIENCE: A MUNICIPALITY INPUT-OUTPUT APPROACH

ABSTRACT

This study aims to investigate how the production activities in 54 municipalities of Aichi Prefecture recover these activities stop due to a tsunami caused by Nankai Megathrust Earthquakes. We propose sequential dynamic bottleneck model using non-competitive import-type inter-regional input-output tables among 54 municipalities. By applying sequential hypothetical extraction method, we clarify the recovery process of municipal economy caused by production activities stop and restoration in coastal area of Aichi Prefecture by simulation analysis. As a disaster area, we focus on the surrounding areas of Mikawa Port and the flooded areas in the hazard map published by Aichi Prefecture.

SS18.5. Natural and Man-Made Disaster Management

1697 AN EXTREME EVENT ON THE UPPER GANGA DELTA: A CASE STUDY OF 2000 FLOOD IN WEST BENGAL, INDIA

ABSTRACT

The Indian part of the Upper Ganga Delta is traversed by the Ganga River and its distributary system. As most of these distributaries—in their present condition—are unable to contain the monsoon discharge within their banks, the region has become susceptible to flood hazard in almost every year. The topography of the region is mainly characterized by natural levee systems and earthen embankments alongside the rivers. Also, quite a few palaeochannels are found near the rivers in the form of oxbow lakes, meander scars etc., pointing towards shifting of the channels through meander formation and avulsion. In some parts, due to channel siltation, elevation of the river bed is higher than the surroundings, causing stagnation of floodwater till it is percolated down or drained out using some abandoned river course. Moreover, the levees often act as barriers and prevent the water from getting back into the main channel. The largest flood in living memory occurred here in 2000. In September 2000, the remnant of a cyclonic depression triggered heavy downpour in the northwestern part of the Upper Ganga Delta and created an unprecedented flood that simultaneously breached a dyke and a railway embankment at Kalukhali in Murshidabad District (24.289°N, 88.292°E) on 21 September 2000. The flood inundated 46% of the Upper Ganga Delta region and many areas remained waterlogged for over a month. The floodwater surged southward following a non-descript palaeodistributary of the Ganga called Gobra Nala and caused most of the inundations (IRS-1D LISS-3 image: Path-108/Row-55/Subscene-A of 24-09-2000; Landsat-7 ETM image: Path-138/Rows-43, 44 of 30-09-2000). Following the regional slope, the floodwater then moved along the Jalangi, Mathabhanga– Churni and Ichhamati courses to flow southeastward into the Jessore District in Bangladesh (Landsat-5 TM image: Path-138/Rows-43, 44 of 08-10-2000). The palaeocourses present in the Bhagirathi–Jalangi and Jalangi–Churni Interfluves carried the floodwater along the regional slope, as found from different satellite images and digital elevation models. The flood took a week to reach the North 24 Parganas District from the central part of the Murshidabad District, covering a distance of about 150 km. The pre- and post-event satellite images of the 2000 disaster show very minimal alterations in channel orientations and floodplain morphology. The existing channel configuration and floodplain morphology of the Upper Ganga Delta are the outcomes of slower and less devastating fluvial processes. Floods are traditionally thought of as a devastating natural disaster, which led to the policies to prevent the flood completely. However, the inhabitants, residing in the mid-channel bars and near the river channels, have become quite accustomed to live with the floods. In view of the fact that the flow in the rivers is quite erratic during the monsoons, the flood prevention strategies may create more problems than solving them. Instead of being considered as a problem, the floodwater should be treated as a useful resource.

1703 REGIONAL DEVELOPMENT AND ADAPTATION TO FLOODS: AN EMPIRICAL ASSESSMENT OF GENERIC AND STATE'S EMPLOYED DISASTER SPECIFIC MEASURES IN THE FLOOD AFFECTED DISTRICTS OF BIHAR, INDIA

ABSTRACT

Scientific evidences from the extent empirical literature are still tenuous in establishing relationship between rising income and reduction in disaster casualties. Further, at the varying institutional, environmental, and spatial settings, studies pertaining to the effectiveness of disaster specific and generic adaptation measures, and the state's intervention are sparse as well as inconclusive. In this paper, in the background of regional development and adaptation connections, we attempt to address these challenges and try answering the following: (i) do disaster specific and generic adaptation measures reduce damages from disasters?; and (ii) is the state intervention in facilitating adaptation measures effective in reducing the disaster outcome? Using data from the secondary sources we construct an unbalanced panel for the period 1973-2016 to empirically examine the conceptual risk-hazard model in the flood affected districts of Bihar. We consider flood fatalities as a function of (i) exposure elements represented by river water level, rainfall, and affected population; (ii) demographic attributes; (iii) generic adaptive capacity reflected by per capita district domestic product, female literacy, infrastructure, medical facilities; and (iv) the disaster specific adaptation measures such as learning from the number of past flood events, annually employed number of relief and health care centers, and boats in operation for the evacuation. As the flood fatalities are the non-negative count variable, we employ count data model; more specifically to account for the over-dispersion, we incorporate the fixed effect Poisson and negative binomial models. Additionally, to mitigate the potential endogeneity problem one period lag has been introduced among the explanatory variables. Controlling for the climate exposure and demography variables, our empirical exercise culminates into three major statistically significant findings. First, experiencing past flood events does not equip people to adapt reflecting that the flood prevention measures are not adequate. Second, generic adaptive capacity such as rising income and female's awareness help in reducing the flood fatalities. Finally, the disaster-specific measures are proved essential and immediate adaptation intervention from the state to enable a region experiencing less number of death. Overall, the findings also lay importance to the adaptive disaster prevention measures in the flood affected districts of Bihar. From the policy perspective, this study suggests that the state should adopt a comprehensive strategy in ensuring that generic and disaster specific adaptation measures are required to be complemented with the disaster specific prevention measures. With measures such as flood warning systems, regular and efficient monitoring and maintenance of embankments, and flood awareness programs among the others, government with the help of local institution should adopt a wider adaptation plans. Additionally, the transboundary dimension of flooding should be addressed involving the government of Bihar, Nepal, and India.

1721 ASSESSING SOCIAL VULNERABILITY TO FLOODS IN BIHAR, INDIA

ABSTRACT

Assessing social vulnerability to natural disaster using composite indices enables and provides critical information to the policy makers to comprehend why disaster events have varying outcomes within and between the locales. In the various spatial and environmental settings, although adequate research contributions in the field of social vulnerability have emerged, we do not find much contribution based on Bihar even though the region’s experience to flooding has been frequent. This study, while assuming vulnerability is a state rather outcome, incorporates a host of indicators and further categorizes them in the conceptual cast of exposure, sensitivity, and adaptive capacity in its assessment. Subsequently, principal component analysis is used to identify the dominant factors at the subcomponent levels which influence the vulnerability of the flood affected districts. With standardization and aggregation across the sub-indices, followed by the use of the Geographic Information Systems (GIS), the social vulnerability index is demonstrated as spatially varying. Concomitant to the varying degree of exposure, sensitivity, and the adaptive capacity, the composite social vulnerability index indicates that (i) among the disaster management department declared flood prone districts, the concentration of highest level of social vulnerability is in north Bihar; (ii) most of the districts which are ranked next to the highest level are in the neighborhood showing a spatial pattern; (iii) districts coming in the bottom two categories although do not show any such spatial pattern, however, they lie mostly in the south of river Ganges; (iv) most vulnerable districts have many flood causing rivers passing through them; and (v) district Patna although is one of the significantly high exposed districts to floods, because of the highest adaptive capacity with least sensitivity, it emerges as the least socially vulnerable district. Besides, the overall vulnerability in Bihar is significantly high. This suggests that the policy at the ‘start point’ level needs to address both the disaster prevention, risk reduction, and the mitigation measures as well as enhancing the efforts to makes inhabitants capable to reduce the risk to floods.

1054 CRIME ANALYSIS AND PREDICTIVE MODELLING USING GEOINFORMATICS

ABSTRACT

Crime is not only related to human mind, but is deeply associated with geographical space. It is also evident that specific crime takes place in the specific geographical locations and areas. Crime studies from decades are based on tabular or textual representation in the records. However, with the advent of geospatial technology especially, Geographic Information System, there is a turning point in the crime study and analysis. With rapid advancement in the sophisticated technology in combination of GIS, Remote Sensing, GPS and very advanced information and communications system, the analysis and modelling has been very simpler and rela time or near real time. It gives an opportunity to spatially enabled eGovernance in the area of crime analysis and management and expected to help immensely if used properly combining various factors of crime in the modelling. This paper is an endeavour to develop spatially enabled analysis and modelling for crime management through the case study of Shimla City. The database used is the crime records obtained by the police department in terms of FIRs for the years 2001, 2006 and 2012. It analyses the crime types, spatial pattern, hotspots, seasonality and diurnality integrating associated probable factors related to geographical and socio-economic aspects to develop an intelligence system through modelling for prediction and management. It is expected to provide a base for highlighting the importance of geographical factors in crime analysis, prediction and management.

1077 REGIONAL SCIENCE IN THE PAST: WHAT CAN ARCHIVES TELL US?

ABSTRACT

This presentation focuses upon the use of archives to explore regional science in the past. It examines three main aspects: institutional histories; the history of the contributions of key individuals; and the history of particular ideas, techniques and theories. The RSAI Archives are held at Cornell University in Ithaca, New York State and contain a large amount of material about the founding of the RSA in the mid-1950s and the setting up of RSA sections throughout the world, including the establishment of the Indian Section in the late 1960s. It also includes Walter Isard's papers and correspondence' as well as those of a number of important American regional scientists. The presentation provides examples of how the Archives have been used to construct an institutional history of particular sections and supra-regional groupings within the RSAI. It also demonstrates the use of the so-called Wayback Machine to record websites and their changes over time. Finally, the presentation shows how archives may be used to build up a detailed account of the work of particular regional scientists, using the examples of Philip Sargant Florence, one of the earliest regional scientists. and the work that has been done to record RSAI activities through the so-called Wayback Machine, an online system for storing past web-pages. In addition, I would include two presentations in this session, drawing on my own archival research: one focusing on the institutional history of RSAI and the other exploring the role of an early regional scientist, Philip Sargant Florence.

1113A STUDY ON 'GALAPAGOS SYNDROME' ON MOBILE HANDSET MANUFACTURERS IN SMARTPHONES ERA IN JAPAN

ABSTRACT

The purpose of this paper is to study the “Galapagos Syndrome,” in which many Japanese mobile handset manufacturers left the market in smartphones era, by comparing with trilateral such as Europe, U.S. and Japan. Previous studies: Kushida (2011) describes “Galapagos effect,” in which winning in an isolated domestic market led to losing in global markets.” This paper adds the viewpoints of analysis for the relationship in competition among mobile carriers located inside and outside one country. Analysis: This paper mainly focuses on the feature phones era and second generation (=2G) of mobile service launched in 1993 in Japan, whereas the smartphones launched in 2007, such as iPhone and Android, use 3G and 4G mobile services. (i) EU In 2G, EU launched new policy, as directive with legal basis, which enable the mobile user be convenient by defining only one standard and realize one mobile handset available in all EU member states. Unifying into only one standard of mobile system in 2G, if one incumbent mobile carrier outstandingly dominates the standard, all other mobile carriers would be dominated from the viewpoint of technology. In result, it is said not mobile carriers but the equipment manufacturer led standardization of mobile system (=GSM) in 2G, and mobile carriers accepted it without the dreadfulness of being acquired by other mobile carriers. It is categorized EU as “one standard in multiple incumbent mobile carriers in one country (=EU).” (ii) U.S. There were several mobile incumbent carriers, including Baby Bells, in U.S., U.S. launched the policy of frequency assignment in up to 493 regions. All mobile carriers including incumbent need roaming with other mobile carriers to make services available in nationwide. To avoid the control and taking over bit by other mobile carrier, major mobile carriers voluntarily selected the GSM, led by equipment manufacturers. It is categorized U.S. as “one standard in multiple incumbent mobile carriers in one country.” (iii) Japan The condition in Japan was different. There was only one dominant mobile carrier, NTT DOCOMO, in Japan. And, Government of Japan (GOJ) requested only one standard in 2G. It is categorized Japan as “one standard in one incumbent mobile carrier in one country.” NTT DOCOMO and its families (=equipment manufacturers which had the closest relationship with DOCOMO) outstandingly led the standardization (Kushida (2011)), and they took enclosure strategy and launched fabulous services such as i-mode launched in 1999. After launch of smartphones, such as iPhone and Android after 2007, many Japanese equipment manufacturers could not leave the closest relationship with DOCOMO, and finally lost the market share in handset in smartphones era and left equipment market. Result and discussion This paper revealed why Japanese mobile services became “Galapagos,” by comparing trilateral.

1139 GEOECONOMICS IN CENTRAL AND EASTERN EUROPE: ECONOMIC DEPENDENCIES OF THE EUROPEAN PERIPHERIES REVISITED

ABSTRACT

The paper investigates the long-term historical problems of capital accumulation in the context of dependency models of varieties of capitalism (Nölke and Vliegenhart, 2009, Myant and Drahokoupil 2011) and the “world system” models (Wallerstein, 1974, Arrighi et al. 2003, Amin, 1977), the systemic and geo-economic features of Central Europe’s post-socialist integration process. The major pattern that emerges is one of a high dependency on FDI, foreign multinational firms, European Union funds and exports to Western Europe. The economic transition of Central and Eastern Europe, and Visegrad 4 countries in particular, was fuelled by neoliberal ideologies and political agendas of “East-West convergence” that involved marketization and privatization. Both of these created a moral, legal and structural environment that rapidly cemented new modes of dependent integration into the EU and the global division of labour. At the same time, the most important historical dependencies of the CEE region, such as financial, technological and market ones, have remained constant (Gál and Schmidt, 2017). This is complemented with the large energy dependency of CEECs on Russia and the increasing Chinese economic interest towards this gateway region.. This not only further strengthens the external vulnerability of the region, but also makes re-interpretable the geopolitical and geoeconomic features of Central Europe as a ‘buffer zone’ situated between German and Russian spheres of interest. We will first examine the geo-economic features of the externally managed and financed integration of post-socialist transition countries of CEE into the global economy and the European Union. We will also focus on the impacts of FDI and European Union structural funds on growth, gross fixed capital accumulation, per capita GNI and export in selected Central European countries using OLS regression for the period between 1995-2015. Preliminary results do not indicate a strong correlation between convergence and FDI, rather domestic savings and higher incomes are the most important factors. As a result, domestic policies based on wage competition and that give little support to small and medium-sized enterprises exacerbate core-periphery asymmetries and support an economic buffer zone narrative. In conclusion, we suggest that such economic gaps within the EU could have long-term consequences for political and economic cohesion in the EU as a whole. The research also contributes to policy debates in terms of achievement of transition, EU accession and the impact of the crisis on regional imbalances and tries to answer the question why even the most successful CEECs, being too dependent on foreign capital and multinationals, suffer setbacks from time to time and cannot fill the income gap existing between CEE and Western Europe.

1743 THE LIFE AND DEATH OF CITIES IN A SPATIAL MODEL WITH HETEROGENEOUS AGENTS

ABSTRACT

We develop an agent-based platform to broaden the empirical grounding of the canonical model of geographical economics. The benchmark algorithm preserves the theoretical base of spatial agglomeration as the replication of the “tomahawk diagram” demonstrates. The paper then makes two contributions, introducing new bottom-up features that produce anomalies that deviate from the canon. First, giving identical agents the full autonomy to move simultaneously causes population to oscillate between regions. Autonomy is thus one impetus driving the rise and fall of cities. Second, the model addresses the heterogeneous nature of migration dynamics brought about by cognitive abilities that differ across individuals. We show that heterogeneity can lead to a complete reversal of the relationship between agglomeration and transportation costs embodied in the tomahawk diagram. In particular, small fortuitous noise can break the symmetry that prevails in the original model at high transport costs. The bottom-up approach thus allows us to explore previously intractable emergent properties that may hold the key to understanding more fully the behavior of complex spatial systems.

1174 ANALYSIS ON THE STRUCTURE OF INTRA-REGIONAL TRADE IN THE GREATER MEKONG SUB-REGION

Kenji Nozaki

Takasaki City University of Economics

ABSTRACT

With the industrialization of Cambodia, Lao PDR and Myanmar, economic linkage within the Greater Mekong Sub-region (GMS) has been strengthening in recent years. It is expected that production network is formulating in the region. Under such situation, this paper aims to verify the structure of production network in the GMS, through the analysis on mutual trade figures. Following the literatures, this paper introduced Grubel and Lloyd index and the unit value of trade ratio to decide the types of division of labor.

The author found that both vertical and horizontal division of labor are taking place with Thailand in the ‘machinery and electric’ industry. Among them, the relationship between Thailand and Vietnam is the key partners of this industry. In the meantime, there are some division of labor in ‘transportation’ industry, and almost all of them are vertical. However, some of them are not only between Thailand and Vietnam, cases between Thailand and Cambodia seem to exist. As the trades are explaining the vertical division of labor, they are consistent with the establishment of satellite plants in Cambodia. However, comparing to the cases between Mexico and the US, production network in the automobile industry in the GMS is still on the primitive stage. If the production of automobile in Vietnam increases, regional division of labor can expand.

Keywords: intra-industry trade, division of labor, Greater Mekong Sub-region (GMS), Grubel and Lloyd index

JEL: F14, F15, R11

1. INTRODUCTION

In this paper, the author tries to verify the formulation of the production network within the Greater Mekong Sub-region⁵²² (GMS). In the GMS, Thailand is relatively the most industrialized country with foreign manufactures since 1980s, followed by other for countries. For example, the production of the automobile is advanced, almost 2 million vehicles were produced in 2015, and it is ranked at 12th in the world (Table 1).

Table 1. Motor vehicle production

Country	2015	2005	Rank in 2005
China	24,567,250	5,717,619	4
USA	12,105,988	11,946,653	1
Japan	9,278,238	10,799,659	2
Germany	6,033,364	5,757,710	3
South Korea	4,555,957	3,699,350	5
India	4,160,585	1,638,674	12
Mexco	3,565,218	1,684,238	11
Spain	2,733,201	2,752,500	7
Brazil	2,429,421	2,530,840	9
Canada	2,283,307	2,687,892	8
France	1,972,000	3,549,008	6
Thailand	1,911,751	1,122,712	14
Vietnam	171,753	—	—

(Note) Statistics of 'International Organization of Motor Vehicle Manufacturers (OICA)'

The progress of industrialization means that per capita income, which can be translated as wage level, has increased. As a result, Thailand is facing the difficulty to continue all the production process inside country, especially labor intensive process. Then the idea that a part of production process is divided and shifted to neighboring countries such as Cambodia and Lao PDR is emerged. Such division of labor in the production process can be observed by trade statistics, because a part of the parts of a product is produced in a different country. For example, according to the press release of Toyota-Boshoku in 2014⁵²³, satellite plant in Lao PDR started production of car sheet in order to complement the sheet production in Thai plant. Other than that, Yazaki started satellite plant in Cambodia to complement the wire harness

522 In this paper, the GMS is defined to be formulated by five countries; Cambodia, Lao PDR, Myanmar, Thailand and Vietnam. Other definition, for example, Mekong Committee, includes Yunnan and Guangxi in China.

523 <https://www.toyota-boshoku.com/jp/news/release/detail.php?id=686> : dated on May 19, 2014 (in Japanese).

production in Thai plant in 2012⁵²⁴. In addition to automobile industry, Nikon, which is a digital camera manufacturer, started its satellite plant operation in 2013 in order to supplement production in Thai plant⁵²⁵.

If these kinds of operation increased, the intra-regional trade of intra-industry should increase. Before observing in detail, the author would like to overview the trend of intra-regional trades in the GMS. Table 2 shows that the share of intra-regional trade in the GMS is increasing in these years. As the trade volume itself has been increasing, the amount of intra-regional trade has increased significantly. We may be able to expect that the accumulation of above mentioned examples has promoted division of labor in the production process.

Table 2. Direction of exports from GMS (Ratio: %)

Direction	2000	2005	2010	2015
GMS: Intra-regional trade	3.6	5.6	7.1	8.7
Japan	14.8	13.1	10.2	8.9
China	5.1	8.4	10.7	11.8
United States	19.2	16.4	13.1	15.1
World total	100.0	100.0	100.0	100.0

(Note) IMF 'Direction of Trade Statistics'.

Under the recognition mentioned above, the author verifies production network in the GMS. After referring the previous literature in the next section, the author analyzed the trade figures to study the division of labor in the production in section 3. This section is divided into three parts. In the first part, intra-regional trade by industry is calculated to distinguish the division of labor in production and only the mutual trade after the categorical aggregation effects. The 'machinery and electric' and 'transportation' industry were selected for further analysis. Secondly, these trades of two industries are precisely analyzed. Finally, comparing to Mexico and the US case of automobile industry, progress of the division of labor in the GMS is discussed. Section four is the conclusion.

2. LITERATURE REVIEW

As for the study in the division of labor in production in the GMS, Nozaki (2016) conducted an empirical study. It tried to clarify that 'transportation' industry has just started vertical division of labor in the GMS. This paper is to extend the analysis of Nozaki (2016), because the latest data of the analysis is of year 2012 and the studied industries are only 'textile' and 'transportation' industries.

In order to measure the progress of division of labor in production, a combination of Grubel and Lloyd index (hereinafter, GL index) and unit value ratio is a popular method. GL index was introduced in Grubel and Lloyd (1971). The definition of the index is expressed as: $GL_i = \frac{(X_i + M_i) - |X_i - M_i|}{X_i + M_i}$

where X_i presents exports of a country to a partner country for item i , and M_i is imports from the partner country (equal to exports of the partner country to that country). This GL index runs from 0 to 1; when the index is near to 1, intra-industry trade is active, whereas it is inactive when the index is near to 0. This index has been used in many empirical studies. At the same time, the GL index has structural shortage. It is expressed as the influence of categorical aggregation, pointed out by Greenaway and Milner (1983). When we investigate the trade figures more precisely, the high value of GL index sometimes disappears. It does not express the mutual trade of same item but different items which belong to a same rough category. Therefore, we should break down into the most detailed category to know the mutual trade.

The next question is whether such division of labor is vertical or horizontal, when we find mutual trade in a detailed item. One answer is proposed by Greenaway et al. (1995). When the type of intra-industry trade is considered using the GL index, additional information on the relative unit value is helpful in distinguishing the vertical division of labor from the horizontal division of labor. If the ratio of unit values between exports and imports is similar, the trades can be understood as a horizontal division of labor. If the ratio is very different, the trades may be vertical. Greenaway et al. (1995) proposed the threshold line of the unit value gap as plus or minus 15%, which gives a wedge of 30%. With imperfect information the threshold is widened to plus or minus 25%, which gives a wedge of 50%.

3. RESULTS OF ANALYSIS

3.1 Intra-regional trade by industry

Firstly, the author analyzed the intra-regional trade volume by industry. Industries whose GL indexes are more than 0.3 in 2015 are described on Table 3. It shows that intra-regional trades seem to be occurring in almost all industries. Then we notice that some of the industries are not fit in intra-industry trade. They are 'animal and animal products', 'vegetable products', 'mineral products', 'plastics and rubbers' and so on. In this context, we find the effects of categorical aggregation as Greenaway and Milner (1983) pointed out.

524 Press release by Obayashi Corp., http://www.obayashi.co.jp/news/news_20121227_1: dated on Jan. 11, 2013 (in Japanese).

525 Press release by Nikon, https://www.nikon.co.jp/news/2013/0321_01.htm: dated on Mar. 21, 2013 (in Japanese).

Table 3. GL indexes by industry in 2015

Industry	Country A	Country B	GL Index	Industry	Country A	Country B	GL Index
Animal & Animal Products	Cambodia	Lao PDR	0.340	Footwear / Headgear	Cambodia	Thailand	0.453
	Myanmar	Thailand	0.521		Lao PDR	Thailand	0.784
	Thailand	Vietnam	0.852		Lao PDR	Vietnam	0.968
			Thailand		Vietnam	0.407	
Vegetable Products	Cambodia	Thailand	0.724	Stone / Glass	Cambodia	Vietnam	0.401
	Lao PDR	Thailand	0.997		Lao PDR	Vietnam	0.909
	Myanmar	Thailand	0.626		Thailand	Vietnam	0.475
Foodstuffs	Lao PDR	Vietnam	0.906	Metals	Lao PDR	Thailand	0.965
	Thailand	Vietnam	0.312		Thailand	Vietnam	0.802
Mineral Products	Lao PDR	Thailand	0.759	Machinery / Electrical	Cambodia	Lao PDR	0.948
	Myanmar	Thailand	0.326		Cambodia	Thailand	0.374
Plastics / Rubbers	Cambodia	Lao PDR	0.773		Lao PDR	Thailand	0.648
	Cambodia	Vietnam	0.793		Lao PDR	Vietnam	0.421
	Lao PDR	Vietnam	0.420	Thailand	Vietnam	0.749	
Raw Hides, Skins, Leather, & Furs	Lao PDR	Vietnam	0.955	Transportation	Cambodia	Lao PDR	0.593
	Myanmar	Vietnam	0.392		Cambodia	Myanmar	0.507
Wood & Wood Products	Cambodia	Lao PDR	0.667		Thailand	Vietnam	0.411
	Lao PDR	Vietnam	0.561	Miscellaneous	Cambodia	Myanmar	0.768
	Myanmar	Thailand	0.642		Lao PDR	Thailand	0.387
			Thailand		Vietnam	0.761	
Textiles	Cambodia	Myanmar	0.479				
	Lao PDR	Vietnam	0.830				
	Thailand	Vietnam	0.622				

(Note) The United Nations 'UN-Comtrade Database'

The author selected two industries; 'mineral products' and 'plastics and rubbers'. Their HS 2-digit codes are HS 25-27 and HS 39-40, respectively. As for the 'mineral products', high score of GL index was recorded between Thailand and Lao PDR, Thailand and Myanmar, and as for 'plastic and rubbers', high score of GL index was recorded between Cambodia and Lao PDR, Cambodia and Vietnam, Lao PDR and Vietnam. When the author broke down HS 2-digit level, it was found that not all HS 2-digit items formulated large GL index. HS 27 between Thailand and Lao PDR, HS 39 between Vietnam and Lao PDR, and HS 40 between Cambodia and Vietnam. With further breaking down into HS 6-digit level, only three items recorded GL indexes of 0.3 or more in 2015. They are HS 271600 (electrical energy) between Thailand and Lao PDR, HS 390210 (plastics; plates, sheets, film, foiled strip of polymers of ethylene) between Vietnam and Lao PDR, and HS 401590 (Rubber; vulcanized, article of apparel and clothing accessories) between Cambodia and Vietnam. Furthermore, even three items remained, they do not seem to formulate division of labor in production process. Trade volume of HS 390210 and HS 401590 are not so much; each amount of one-way trade are less than 100,000 US dollars. Another item of HS 271600 is a specific item. Needless to say, production process of electric energy cannot be divided into parts. This mutual trade happens due to the cost of power transmission. Although the Lao PDR has long exported hydro power to Thailand, remote area from power plants in Lao PDR should import electricity from Thailand in cheaper price than to convey from Lao plants. In any case, it is not the scope of intra-industry trade.

Accordingly, the author verified the effects of categorical aggregation, in particular, in the industries whose production process is not so complicated. On the other hand, in industries of complicated production process such as 'machinery and electrical' and 'transportation', we can expect the phenomenon to explain division of labor in production, although we may face the same categorical aggregation effects

3.2 Intra-regional trade in the selected sector

In this sub-section, analysis on 'machinery and electrical' and 'transportation' is focused on. On the industrial base, between Cambodia and Lao PDR, Cambodia and Thailand, Lao PDR and Thailand, Lao PDR and Vietnam, and Thailand and Vietnam are the combinations which GL indexes recorded high score in 2015 for 'machinery and electrical'. As for the 'transportation', between Cambodia and Lao PDR, Cambodia and Myanmar, and Thailand and Vietnam are the combinations of high GL index score.

Before investigating the individual items of HS 6-digit level, the author verifies the HS 2-digit level, namely HS 84 to 85 for 'machinery and electric' and HS 86 to 89 for 'transportation'. The combinations with high GL index in 2015 are between Cambodia and Lao PDR, Cambodia and Vietnam, Lao PDR and Vietnam, Myanmar and Thailand, and Thailand and Vietnam for HS 84. As for HS 85, they are between Cambodia and Thailand, Lao PDR and Thailand, Lao PDR and Vietnam, and Thailand and Vietnam. As for HS 86 and HS 88, there is no combination with high score of GL index. As for HS 87, between Cambodia and Lao PDR, Cambodia and Myanmar, Thailand and Vietnam are the high score. As for HS 89, between Lao PDR and Thailand and Vietnam are such combination. However, the transaction volume of HS 89 was small, and it also means that categorical aggregation effects appeared in these industries. Therefore, the author calculated the indicators of HS 6-digit level of HS 84, HS 85, and HS 87.

The author calculated GL indexes of all items of bilateral trades in the GMS in 2015. When we see HS 6-digit, there are 569, 381 and 87 items for HS 84, HS85, and HS 87, respectively. Among them, 99 combinations whose GL indexes are 0.3 or more. In detail, 88 combinations are 'machinery and electric', and 11 combinations are 'transportation'. Then the

author calculated GL indexes and unit value ratio for 10 years (from 2006 to 2015) of such 99 combinations. The result of the calculation is as follows.

3.2.1 Machinery and electric

It is possible to categorize the 88 combinations by two dimensions. One dimension is whether bilateral trade has occurred for long years or just for recent years. Another dimension is whether the unit value is similar or not, in this paper, criteria is set as plus or minus 25%. The list of the combinations is on Table 4. We found that Thailand is almost always the partner of bilateral trades, only two cases between Vietnam and Lao PDR (HS 841451), and Vietnam and Cambodia (HS854420) are exceptional. We can say that production network is centered by Thailand in the ‘machinery and electric’ sector. When we observe in detail, most of mutual trades for long years are between Thailand and Vietnam, 39 cases among 44 cases. On the other hand, newly started mutual trades include between Thailand and Cambodia, between Thailand and Myanmar, and between Thailand and Lao PDR, although trades between Thailand and Vietnam are still majority, 26 cases among 44 cases.

Table 4. Mutual trade items in machinery and electric

Trade type	Trade partner	HS code
A	Thailand-Lao PDR	850431
	Thailand-Vietnam	841451, 841480, 842123, 844331, 847989, 848310, 850110, 850152, 850431, 851680, 851762, 854449
B	Thailand-Vietnam	841459, 848390, 851290, 851829, 853650
C	Lao PDR-Vietnam	841451
	Thailand-Lao PDR	850450, 854430, 854442
	Thailand-Vietnam	840999, 841490, 841899, 845290, 846694, 847330, 848079, 848140, 848410, 848490, 850300, 850450, 852990, 853400, 853630, 853690, 853929, 854419, 854420, 854430, 854442, 854890
D	Cambodia-Vietnam	854420
	Thailand-Cambodia	847989, 850110, 851770, 852990, 853650, 854449
	Thailand-Lao PDR	847330, 850490, 850590, 851718, 852990, 854411, 854449
	Thailand-Myanmar	841391, 842940, 850790, 854390
	Thailand-Vietnam	841330, 841370, 841590, 842121, 843131, 844332, 844399, 847180, 847710, 848071, 848180, 848340, 848790, 850140, 850151, 850490, 850720, 850819, 851220, 852859, 853620, 853641, 853720, 854232, 854239, 854520

(Note) 1. United Nations 'UN-Comtrade Database'.
 2. 'Trade type' is defined as A: Mutual trade started before 2010 and the unit value of exports are close. B: Mutual trade started before 2010 and the unit value of exports are close only in recent years. C: Mutual trade started before 2010 and the unit value of exports are different.
 D: Mutual trade started after 2010.

As for the long year transaction of 44 cases, 13 cases can be considered to formulate horizontal division of labor, while 26 cases are considered vertical division of labor. The rest of 5 cases are difficult to determine, perhaps they are shifting from vertical division of labor to horizontal. This means that the quality of items, which Vietnam has produced and exported for long years, is high enough to substitute the Thai products.

As for the recent transaction of 44 cases, only one case can be considered as a horizontal division of labor. The rest of 43 cases are vertical division of labor or unclear. Production of these items has not been matured yet to formulate horizontal division of labor. Furthermore, we found that some items seem to be substitute the production from in Vietnam to Cambodia or Lao PDR. In this category, there are 6 cases between Thailand and Cambodia, and 6 cases between Thailand and Lao PDR among 18 cases, which are not cases between Thailand and Vietnam. 6 cases, equivalent to a half of 12 cases, are the items of which mutual trade have continued for long years between Thailand and Vietnam. No similar case is not observed between Thailand and Myanmar. This phenomenon may have happened because logistic cost is cheaper to have a production base at the mid-point of Thailand and Vietnam. It also explains that Cambodia and Lao PDR have increased the capability to produce such items, and the division of labor in production is progressing.

To summarize the analysis on ‘machinery and electric’, we found that some items have been mutually traded between Thailand and Vietnam, some of which formulated horizontal division of labor. In addition to that, some of such items have started to be produced in Cambodia or Lao PDR to supplement the production in Vietnam.

3.2.2 Transportation

As the number of items of ‘transportation’ is 94, around one tenth of ‘machinery and electric’, the number of items, whose GL index is 0.3 or more, is not so large, 11 items (Table 5). Among such 11 items, 4 of them are for motorcycle or bicycle. Then 7 items are vehicle parts. Although one item, HS 870790 between Thailand and Vietnam, has been traded for long

years and the unit value is close, which we understand that it is a horizontal division of labor, it is body of tractor. Therefore, it is difficult to say that horizontal division of labor is occurring in automobile industry. However, regarding on vertical division of labor, we could find some items of parts or accessories of vehicle.

As for the regional characteristics, although we could not find mutual trade items between Thailand and Lao PDR, we found 3 vehicle items between Thailand and Cambodia. Although Nozaki (2016) pointed that vertical division of labor between Thailand and Vietnam was observed, the present research suggests that the production network is expanding.

Table 5. Mutual trade items in transportation

Trade type	Trade partner	HS code
A	Thailand-Vietnam	870790
B	Thailand-Vietnam	870895
C	Thailand-Cambodia	870323, 870422
	Thailand-Vietnam	871492
D	Thailand-Cambodia	870421
	Thailand-Vietnam	870829, 870840, 871120, 871410, 871499

- (Note) 1. United Nations 'UN-Comtrade Database'.
 2. 'Trade type' is defined as Note of Table 4.
 3. Contents of each HS codes are listed at Appendix.

3.3 Automobile industry in Mexico

Focusing on the automobile industry in the GMS, a characteristic is production of the finished car is concentrated in Thailand, although the number in Vietnam has just started to increase. In this sub-section, relationship between the US and Mexico, both of them are major automobile producers, is studied. According to the Table 1, while the US keeps the number of automobile production around 12 million, both Mexico and Thailand increased the production. The circumstances for automobile production in Thailand are then different from that in Mexico because Thailand does not have a large supplier and market like the US for Mexico. It is easy to imagine that the structure of automobile industry in Mexico is different from that in Thailand. Then the author calculated GL index and unit value ratio between Mexico and the US. The result is on Table 6.

Table 6. Mutual trade items in transportation between Mexico and the US

Trade type	HS code
A	870324, 870810, 870829, 870830, 870840, 870850, 870870, 870880, 870891, 870892, 870893, 870894, 870895, 870899, 871690
B	871499
C	870190, 870210, 870710, 870919, 871120, 871420, 871492, 871493, 871620, 871640, 871680
D	870130, 870432, 870490, 870600, 871410, 871494

- (Note) 1. United Nations 'UN-Comtrade Database'.
 2. 'Trade type' is defined as Note of Table 4.
 3. Contents of each HS codes are listed at Appendix.

Different from the GMS situation, there are 33 items whose GL index is 0.3 or more among 99 items. Even eliminating of bicycle-related and motorcycle-related, 26 items remain. Among them, 15 items including the vehicle parts are traded under the horizontal division of labor. It is explained that manufacturers exchange the parts, which are used for the same purpose but have different function, between Mexico and the US. It may mean that the production capacities of some parts in Mexico is as advanced as in the US. At the same time, 11 items conform the vertical division of labor, which may mean that the wage gap between Mexico and the US facilitated the production fragmentation.

Through the comparative research to the case of the US and Mexico, the production network in the automobile industry in the GMS is still a primitive stage. In the future, when Vietnam increased the number of automobile production, we can expect the more advanced production network.

4. CONCLUSION

This paper analyzed trade figures in the GMS. The author found that both vertical and horizontal division of labor are taking place with Thailand in the 'machinery and electric' industry. Among them, the relationship between Thailand and Vietnam is the key partners of this industry. In the meantime, there are some division of labor in 'transportation' industry, and almost all of them are vertical. However, some of them are not only between Thailand and Vietnam, cases between Thailand and Cambodia seem to exist. As the trades are explaining the vertical division of labor, they are consistent with the establishment of satellite plants in Cambodia. However, we could not find the evidence of division of labor, between Thailand and Lao PDR. We should wait and see the newer information. In any case, comparing to the cases between

Mexico and the US, production network in the automobile industry in the GMS is relatively primitive stage. If the production of automobile in Vietnam increases, regional division of labor can expand.

Appendix: List of the HS code and Item

(1) HS 84	
Code	Item
840999	Engines; parts for internal combustion piston engines (excluding spark-ignition)
841330	Pumps; fuel, lubricating or cooling medium pumps for internal combustion piston engines
841370	Pumps; centrifugal, n.e.c. in heading no. 8413, for liquids
841391	Pumps; parts thereof
841451	Fans; table, floor, wall, window, ceiling or roof fans, with a self-contained electric motor of an output not exceeding 125W
841459	Fans; n.e.c. in item no. 8414.51
841480	Pumps and compressors; for air, vacuum or gas, n.e.c. in heading no. 8414
841490	Pumps and compressors; parts, of air or vacuum pumps, air or other gas compressors and fans, ventilating or recycling hoods incorporating a fan
841590	Air conditioning machines; with motor driven fan and elements for temperature control, parts thereof
841899	Refrigerating or freezing equipment; parts thereof, other than furniture
842121	Machinery; for filtering or purifying water
842123	Machinery; filtering or purifying machinery, oil or petrol filters for internal combustion engines
842940	Tamping machines and road rollers; self-propelled
843131	Lifts, skip hoists or escalators; parts thereof
844331	Printing, copying, and facsimile machines; machines which perform two or more of the functions of printing, copying or facsimile transmission, capable of connecting to an automatic data processing machine or to a network
844332	Printing, copying, and facsimile machines; single-function printing, copying or facsimile machines, capable of connecting to an automatic data processing machine or to a network
844399	Printing machinery; parts and accessories, n.e.c. in item no. 8443.91
845290	Sewing machines; furniture, bases and covers for sewing machines and parts thereof, and other parts of sewing machines
846694	Machine-tools; parts and accessories, for the machines of heading no. 8462 or 8463, n.e.c. in heading no. 8466
847180	Units of automatic data processing machines; n.e.c. in item no. 8471.50, 8471.60 or 8471.70
847330	Machinery; parts and accessories of the machines of heading no. 8471 (other than covers, carrying cases and the like)
847710	Machinery; injection-moulding machines, for working rubber or plastics or for the manufacture of products from these materials
847989	Machines and mechanical appliances; having individual functions, n.e.c. or included in this chapter
848071	Moulds; for rubber or plastics, injection or compression types
848079	Moulds; for rubber or plastics, other than injection or compression types
848140	Valves; safety or relief valves, for pipes, boiler shells, tanks, vats or the like
848180	Taps, cocks, valves and similar appliances; for pipes, boiler shells, tanks, vats or the like, including thermostatically controlled valves
848310	Transmission shafts (including cam shafts and crank shafts) and cranks
848340	Gears and gearing; (not toothed wheels, chain sprockets and other transmission elements presented separately); ball or roller screws; gear boxes and other speed changers, including torque converters
848390	Transmission components; toothed wheels, chain sprockets and other transmission elements presented separately; parts
848410	Gaskets and similar joints; of metal sheeting combined with other material or two or more layers of metal
848490	Gasket sets or assortments of gaskets and similar joints; dissimilar in composition, put up in pouches, envelopes or similar packings
848790	Machinery parts; not containing electrical connectors, insulators, coils, contacts or other electrical features, n.e.c. in chapter 84

(2) HS 85	
Code	Item
850110	Electric motors; of an output not exceeding 37.5W
850140	Electric motors; AC motors, single-phase
850151	Electric motors; AC motors, multi-phase, of an output not exceeding 750W
850152	Electric motors; AC motors, multi-phase, of an output exceeding 750W but not exceeding 75kW
850300	Electric motors and generators; parts suitable for use solely or principally with the machines of heading no. 8501 or 8502
850431	Electrical transformers; n.e.c. in item no. 8504.2, having a power handling capacity not exceeding 1kVA
850450	Electrical inductors; n.e.c. in heading no. 8504
850490	Electrical transformers, static converters and inductors; parts thereof
850590	Magnets; electro-magnets, holding devices and parts n.e.c. in heading no. 8505
850720	Electric accumulators; lead-acid, (other than for starting piston engines), including separators, whether or not rectangular (including square)
850790	Electric accumulators; parts n.e.c. in heading no. 8507
850819	Vacuum cleaners, with self-contained electric motor, n.e.c. in item no. 8508.1
851220	Lighting or visual signalling equipment; electrical, of a kind used on motor vehicles (excluding articles of heading no. 8539)
851290	Lighting or signalling equipment; electrical, (excluding articles of heading no. 8539), windscreen wipers, defrosters and demisters; parts, of those kinds used for cycles or motor vehicles
851680	Resistors; electric heating, other than those of heading no. 8545
851718	Telephone sets n.e.c. in item no. 8517.1
851762	Communication apparatus (excluding telephone sets or base stations); machines for the reception, conversion and transmission or regeneration of voice, images or other data, including switching and routing apparatus
851770	Telephone sets and other apparatus for the transmission or reception of voice, images or other data, via a wired or wireless network; parts
851829	Loudspeakers; not mounted in their enclosures
852859	Monitors other than cathode-ray tube; other than of a kind solely or principally used in an automatic data processing system of heading 84.71
852990	Reception and transmission apparatus; for use with the apparatus of heading no. 8525 to 8528, excluding aerials and aerial reflectors
853400	Circuits; printed
853620	Electrical apparatus; automatic circuit breakers, for a voltage not exceeding 1000 volts
853630	Electrical apparatus; for protecting electrical circuits, n.e.c. in heading no. 8536, for a voltage not exceeding 1000 volts
853641	Electrical apparatus; relays, (for a voltage not exceeding 60 volts)
853650	Electrical apparatus; switches n.e.c. in heading no. 8536, for a voltage not exceeding 1000 volts
853690	Electrical apparatus; n.e.c. in heading no. 8536, for switching or protecting electrical circuits, for a voltage not exceeding 1000 volts
853720	Boards, panels, consoles, desks and other bases; for electric control or the distribution of electricity, (other than switching apparatus of heading no. 8517), for a voltage exceeding 1000 volts
853929	Lamps; filament, (excluding ultra-violet or infra-red), n.e.c. in item no. 8539.2
854232	Electronic integrated circuits; memories
854239	Electronic integrated circuits; n.e.c. in heading no. 8542
854390	Electrical machines and apparatus; parts of the electrical goods of heading no. 8543
854411	Insulated electric conductors; winding wire, of copper
854419	Insulated electric conductors; winding wire, (of other than copper)
854420	Insulated electric conductors; co-axial cable and other co-axial electric conductors
854430	Insulated electric conductors; ignition wiring sets and other wiring sets of a kind used in vehicles, aircraft or ships
854442	Insulated electric conductors; for a voltage not exceeding 1000 volts, fitted with connectors
854449	Insulated electric conductors; for a voltage not exceeding 1000 volts, not fitted with connectors
854520	Carbon brushes; with or without metal, used for electrical purposes
854890	Electrical parts of machinery or apparatus; n.e.c. in chapter 85

(3) HS 87	
Code	Item
870130	Track-laying tractors
870190	Wheeled tractors nes
870210	Motor vehicles for the transport of 10/more persons incl. the driver, with C-I internal combustion piston engine (diesel/semi-diesel)
870323	Vehicles; spark-ignition internal combustion reciprocating piston engine, cylinder capacity exceeding 1500cc but not exceeding 3000cc
870421	Vehicles; compression-ignition internal combustion piston engine (diesel or semi-diesel), for transport of goods, (of a gvw not exceeding 5 tonnes), n.e.c. in item no 8704.1
870422	Vehicles; compression-ignition internal combustion piston engine (diesel or semi-diesel), for transport of goods, (of a g.v.w. exceeding 5 tonnes but not exceeding 20 tonnes), n.e.c. in item no 8704.1
870432	Vehicles; spark-ignition internal combustion piston engine, for transport of goods, (of a g.v.w. exceeding 5 tonnes), n.e.c. in item no 8704.1
870490	Vehicles; for transport of goods, n.e.c. in heading no. 8704
870600	Chassis; fitted with engines, for the motor vehicles of heading no. 8701 to 8705
870710	Vehicles; bodies (including cabs) for the motor vehicles of heading no. 8703
870790	Vehicles; bodies (including cabs) for the motor vehicles of heading no. 8701, 8702, 8704 or 8705
870829	Vehicles; parts and accessories, of bodies, other than safety seat belts
870840	Vehicle parts; gear boxes and parts thereof
870870	Vehicle parts; road wheels and parts and accessories thereof
870880	Vehicle parts; suspension systems and parts thereof (including shock-absorbers)
870891	Vehicle parts; radiators and parts thereof
870892	Vehicle parts; silencers (mufflers) and exhaust pipes; parts thereof
870893	Vehicle parts; clutches and parts thereof
870894	Vehicle parts; steering wheels, steering columns and steering boxes; parts thereof
870895	Vehicle parts; safety airbags with inflator system; parts thereof
870899	Vehicle parts and accessories; n.e.c. in heading no. 8708
870919	Vehicles; (not electrical), self-propelled, without handling equipment, used for short distance transport of goods in factories, airports and such, and tractors of the type used on railway station platforms
871120	Motorcycles (including mopeds) and cycles; fitted with an auxiliary motor, reciprocating internal combustion piston engine, of cylinder capacity exceeding 50cc but not exceeding 250cc, with or without side-cars; side-cars
871410	Motorcycles (including mopeds); parts and accessories
871420	Carriages for disabled persons; parts and accessories thereof
871492	Cycles; parts thereof, wheel rims and spokes
871493	Cycles; parts thereof, hubs (other than coaster braking hubs and hub brakes) and free-wheel sprocket-wheels
871494	Cycles; parts thereof, brakes, including coaster braking hubs and hub-brakes, and parts thereof
871499	Cycles; parts thereof, n.e.c. in item no. 8714.9
871620	Trailers and semi-trailers; self-loading or self-unloading, for agricultural purposes
871640	Trailers and semi-trailers; n.e.c. in item no. 8716.3
871680	Vehicles; n.e.c. in heading no. 8716
871690	Trailers, semi-trailers and other vehicles not mechanically propelled; parts thereof for heading no. 8716

1232 TRANSFORMATION OF ECONOMIC POSITION OF CAPITAL CITIES IN CENTRAL AND EASTERN EUROPE

ABSTRACT

The main driving force of economic growth continues to be the service sector which is concentrated in the capital cities in Central and Eastern Europe (CEE) and South Eastern Europe (SEE). The unambiguous winners of the post-socialist transition process are capital regions, exploiting their role as metropolitan growth areas. Flows will orient even more towards national capitals, and advanced producer services concentration in capital cities can be expected to encourage not only the backwash of local resources from the periphery (capital and human resources alike) but further de-industrialisation and accelerated tertiarization; the clear winners are the capital-city regions resulting in a dramatic increase in regional disparities. Convergence processes have been most beneficial for capital cities. Nowadays, many studies focusing on the ranking of cities, as well as the classification of the world's leading cities (world cities, global cities) on the basis of ABS concentration. Central and Eastern European big cities are given just a minor role in these researches. The paper focuses on the growth and spatial expansion of the advanced producer service sector (APS) in Central and Eastern European and South Eastern European capital cities based on the methodology elaborated by Taylor and the GAWC (2001) for the examination of global cities, global hierarchies. This process highlights the heavily metropolitan character of knowledge-intensive high-technology services concentration, as well as the command and control functions. The first part of the paper will determine the ranking of large cities in the Central European region primarily with respect to their foreign direct investment, the revenue of the TOP companies and the APS concentration in relation to the quality-driven services investments. Accordingly the paper classifies these capital cities according to the GAWC methodology demonstrating changing global hierarchy of CEE/SEE capitals. The study argues that the development of the APS in CEE is characterized by external dependency, which appears in the form of hierarchical command and control functions over CEE APS and financial services subsidiaries within global MNCs network. The second part of the paper examines the concentration of quality-driven services investments. Three selected service industries differ in terms of their vertical or horizontal nature: in business services FDI is predominantly vertical, in financial services predominantly horizontal, while in ICT-related services both types can be found. It was found that the export oriented vertical services due to their less embedded nature do not contribute to the same extent to the metropolitanization process than services firms founded by horizontal investments.

1234 GLOBALIZATION AND CONVERGENCE AMONG BIG-CITIES

Fernando Barreiro-Pereira

Universidad Nacional de Educacion a Distancia (UNED University), Faculty of Economics and Business Administration, Dptm. Analisis Economico, Paseo Senda del Rey 11, 28040 Madrid, Spain. Email: fbarreiro@cee.uned.es

ABSTRACT

A new urban revolution begun in the second half of the XX century and it is going to challenge the relation between the size and economic role of cities: on one side, the last decades have witnessed the emergence and the never seen growth of a number of Mega-cities, with more than 9 million inhabitants, most of them being located in less developed countries. On the other side, the globalization of the post-industrial economy generates a new urban spatial organization where a few number of cities concentrate a disproportionate part of economic power, creation, decision and control. These global cities have been called World-cities or World metropolises. Most of the largest cities are in the less developed countries, while the most powerful world cities are mainly located in the developed countries. It results that size seems to be neither a necessary nor a sufficient condition for obtaining the status of global city. A condition to be a global city is the access to the economic power. The convergence or divergence processes among Mega and Global cities could be related to the level of development of the countries where Mega-cities are located, and its globalization degree. The main aim of this paper is to analyze the comparison between the real convergence-divergence among 43 Mega-cities of the World, and the convergence-divergence among its corresponding countries, using several growth models, studying the possible existence of Clubs convergence among Megacities.

1. INTRODUCTION

According to the theorists of global capitalism it was during the 1960's that the organization of economic activity entered a new period expressed by the altered structure of the world economy: the dismantling of industrial centers in the United States, Europe and Japan; accelerated industrialization of several Third World nations; and increased internationalization of the financial industry into a global network of transactions. On the other hand, the globalization of the post-industrial economy generates a new urban spatial organization where a few number of cities, so-called Global cities, concentrate a disproportionate part of economic power, creation, decision and control. Throughout the XX Century these global cities were growing in quantity and inhabitants until transforming in megacities. At the same time, other cities without economic power, generally belonging to emergent and poor countries were growing until become megacities. (see Figures 1 and 2)

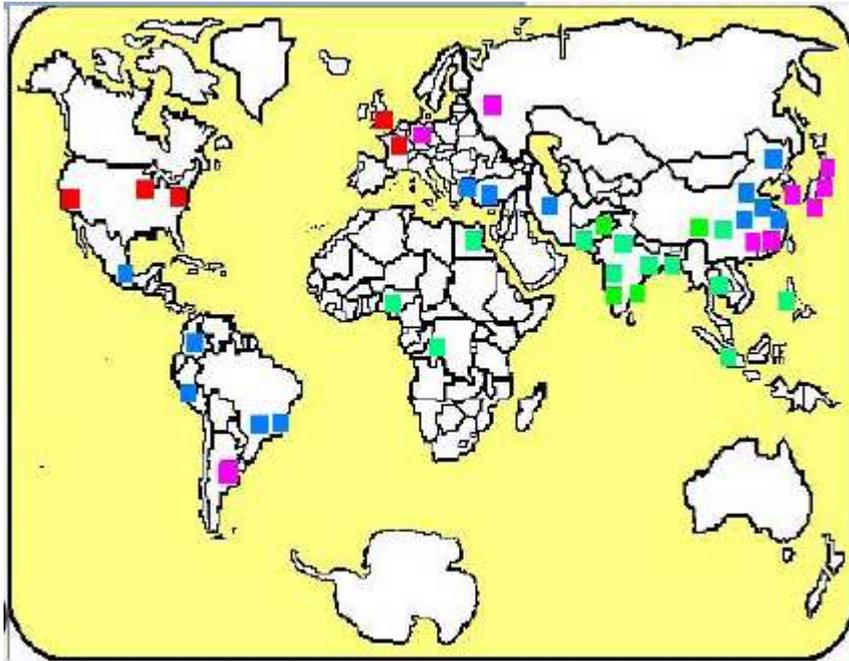

Figure 1. Megacities evolution

Source: own elaboration.

A global city, also called World city or sometimes alpha city, is a city generally considered to be an important node in the global economic system. The most complex of these entities is the Global city, whereby the linkages binding a city have a direct and tangible effect on global affairs through socio-economic means. The use of Global city, as opposed to Mega-city, was popularized by Saskia Sassen (1991), though the term World city to describe cities that control a disproportionate amount of global business is used by Patrick Geddes (1915).

Figure 2. Distribution of the Megacities across the World (2014)

Source: own elaboration.

With the emerging spatial organization of the new international division of labor, John Friedmann (1986) identified a set of these known as the World city hypotheses concerning the contradictory relations between production in the era of global management and political determination of territorial interests. Saskia Sassen (2001, 2000), Brenner 1998, Yeoh 1999, Hall 1996, and Friedmann 1995) have further re-elaborated the global city hypotheses. Global cities, it is argued, have acquired new functions beyond acting as centers of international trade and banking. They have become: i) concentrated command points in the organization of the World-economy that use advanced telecommunication facilities; ii) important centers for finance and specialized producer service firms; iii) coordinators of state power; iv) sites of innovative forms of industrialization and production, and v) markets for the products and innovations produced. These structural shifts in the functioning of cities are argued to have impacted both the international economic activity and urban form where major cities concentrate control over vast resources, while financial and specialized service industries have restructured the urban social and economic order. The big cities enter in some specialization and competition processes. It occurs that during the 1990's New York has specialized in equity trading, London in currency trading, and Tokyo in size of bank deposits. A similar situation happened with Hong Kong: it was said, before China regained control of Hong Kong, that their financial services centers would be in international competition with each other. It turns out that Hong Kong is today the international financial centre for China, while Shanghai is the national financial center. It could be said that there's a comparable difference in the UK between London and Edinburgh. Within the US, again in the financial sector, Chicago is the centre for commodities futures, while New York is the centre for futures on interest rates. Chicago is a centre for commodity futures because of its history as the meatpacking and food processing centre for the mid-west. There exist a kinds of strategic games among the World cities. Some economists argue that competition between cities is indirect, as it derives from competition among businesses based chiefly on productivity. One of these economists is Krugman (1996), who has been critical of promoting competitiveness between cities. His view of competition is between companies, not between cities, regions or countries. Krugman states that cities do not have competitive advantages, only comparative advantages. Comparative advantages occur due to the access of resources others don't have. A competitive advantage can be realized when superior value for customers and profits are achieved by efforts from the provider of the service or product. The competitiveness of cities is, according to Krugman, nothing more than an appropriate aggregate of the competitiveness of the firms they contain. Other economists disagree with Krugman and claim that cities compete directly with other cities. Porter (1996), for example, states that the environment affects the competitive position of firms. Governments can play a role in shaping an environment in which firms can operate optimally. Therefore, cities have according to Porter competitive advantages and do compete with other cities. The behavior of the World cities among them could be explained by means of a spatial competition model, like the core-periphery model in Krugman and Venables (1990), by substituting regions by metropolitan areas. In the other side, like the Mega cities are not necessarily Global or World cities, it can occur that Mega cities and World cities could be diverging, depending partially of its globalization degree. The sequence of this work is the following: section 2 analyses the role of the globalization in general and on the urban process. Section 3 studies the impact of globalization on the convergence-divergence process in the most important World metropolises, and finally section 4 contains some findings.

2. THE ROLE OF THE GLOBALIZATION

The major driving force of economic globalization is the reduction of the transport costs in the private sector, due basically to the fact that technological progress and innovation has reduced the costs of transport and communication. Although globalization was a defining term of the 1990s, O'Rourke and Williamson (2000) distinguish at least three waves of the phenomenon which have taken place through the modern and contemporary history: From 1400 to the 18th

century, facts such as the Renaissance of sciences and arts, the creation of the modern concept of state and the discovery of America gave rise to the first wave of globalization in the modern era which generated a series of small bordering states in the European zone that had similar cultures, technologies and were of a similar size. From this perspective, one can say that Europe was the focus of globalization in its first wave and although not the focus continues to have an important role. The second wave of globalization started in the early 19th century when the rise of trade was centred in basic tradable goods, coincided with the Industrial Revolution, and it was slowly being felt in other regions, besides Europe, especially in North America with USA as a leading country. The third wave of globalization applies to recent times in which trade takes place in both basic and highly differentiated manufactured commodities. This current wave is also generating a new focus of globalization in the Pacific Rim zone. This wave is characterized by the management of the financial markets and the production of the new technologies controlled by Multinational companies (MNCs) established in zones with high levels of human capital, population density and very low levels of labour costs. In this zone, Japan was the initial leading country with Hong Kong and the rest of China, Singapore, Taiwan, and Malaysia following. This third wave of economic globalization shows some specific stylized events. In basic terms these are the fact that trade, investment in research and development (R&D), foreign direct investment and technology links are increasing on a worldwide basis. Other factors include the liberalization of the telecommunications system and the rise of the internet which creates a truly global marketplace that has given rise to new opportunities for the international exchange of information. In addition, the enormous advances made in computer technologies, the fall in computer prices and recent technical progress in telecommunications facilitate access to information and reduce the price of communication, especially in those countries where deregulation and privatization has taken place. Similarly, the worldwide web is reducing cross border barriers to zero. However, distance is still an important barrier to trade, not only due to the existence of transport costs but also due to the role of what is called social distance. There are two forms to eliminate the physical distance: good communications and telecommunications, or to generate cities that contain all goods, markets, services and amenities. Perhaps it can explain the high growth rate and size of some cities until transforming in Mega cities. Another driving force of the globalization is the reduction of policy barriers to trade and investment. The economic analysis of the impact of informational barriers to trade, following Rauch and Cassella (1998), is different to that of conventional barriers because the impact of trade on relative wages across countries causes changes in relative labour supplies. The combined effects of efficient communication systems spanning the globe and the emergence of an internationally mobile community of professionals work towards cultural globalization. These unleashed forces of globalization are crucial drivers in the intensified competition between regions and even more so between big cities which are vying for the best talents and high potentials in the workforce, tourists, grant money from national or international organizations and seek to attract or retain business corporations or mega events. In addition, new telecommunication systems are creating a great service sector that does not depend on the locations of technology production sites but does require advanced technological solutions. This structural change is also accompanied by an increasing proportion of highly qualified employees and an associated increase in wages. These changes are also related to a migration process of skilled labour. Apart from the symptoms of informational globalization in labour markets, capital flow volumes are in themselves an important indicator of globalization, and following Baldwin and Martin (1999), the most spectacular indications of financial globalization in the 1990s are the consecutive financial crisis around 1994 in Latin-America and 1997 in the Pacific Rim countries. Starting from 2007, it is necessary to add to these crises, the current financial crises that affect the developed countries of Europe and North America, among others. The accelerated speed of data exchange and transactions, the upturn of the service sector at the expense of the manufacturing industries as well as the multinational organization of production processes are among the major attributes of the current phase of globalization. With the fall in industrial jobs in large cities, a relatively small group of selected World cities serve as home bases for many multinational headquarters with important ramifications for the local and regional economies of those Global cities.

3. THE CONVERGENCE-DIVERGENCE PROCESS AMONG GLOBAL CITIES

With regard to the last two waves of globalization several authors have analyzed the effects of globalization on income per capita distribution and they have studied some types of resulting disparities. The second wave of globalization (1820-1914) resulted in the industrialized of the North (Europe and the North-American continents) and the de-industrialization of the South, a pattern that was not changed during the period between the second and third waves (1914-70). In the present wave of globalization some income divergence between groups of countries that were not initially disparate has been generated and this amounts to the most important implication of the Industrial Revolution in Europe. The second wave is also influenced by high transport costs and the fact that there was little trade and primitive industry. In the second stage of the process the cost of exchanging goods fell faster than the cost of exchanging ideas and innovations and, once transport costs were sufficiently diminished, the distribution of the industry was achieved by means of agglomeration forces. The third wave of globalization (from 1970 to the present day) began with the consequences of the second wave. In specific terms, it resulted from a very large income gap and a consequential de-industrialization of the North and industrialization of the South, largely caused by the significant fall in the transports costs of technological innovations. In the South, industrial investment rose and income grew whereas the North experienced some de-industrialization and tended to specialize in services. It is in this way that globalization forces first generated a huge divergence of real incomes and later tended to cause an increase in the development and likelihood of income convergence. Considering that, we will observe now if among the big cities of the World there is divergence or convergence in terms of real GDP per capita during the period 2005-2013.

The concept of convergence is based on the principle that poor economies with steady-state low production levels *per capita* tend to grow more rapidly than wealthier economies. Barro (1991) in his first empirical work on growth showed that if differences in the initial level of human capital are controlled for, then the correlation between the initial level of income and subsequent growth rate turn out be negative even in wider sample of countries. This is called absolute beta convergence (also called unconditional convergence because it implies that all countries or regions are converging to common steady state level of income). However, these structural parameters differ across countries and regions and countries may not converge to a common level of income per capita but to their own steady state level (long run potential level of income). When steady states vary from one economy to the next, the concept of convergence used is that of conditional convergence, being a more real concept. The first contributions to this debate came from W. Baumol (1986), who studied convergence among certain countries (Japan and Italy versus the U.S. and Canada), and J. De Long (1988). Barro and Sala-i-Martin (1992) analyzed convergence among the different states in the U.S., whereas Barro (1991) and N.G. Mankiw, D. Romer, and D.N. Weil (1992) point at the importance of educational levels to explain divergence in terms of growth. Boldrin and Canova (2001) using a similar methodology severely criticized the previous results. Using a different data set, which includes 185 EU regions during the period 1980-1986, they concluded that the results are mixed and not supportive of convergence on regional per capita income. Canova and Marcet (1995) also, basing the analysis on per capita incomes for 144 EU regions, found only limited signals of convergence during the period 1980-1982. Others have studied different regions of new developed countries: Keller (1994) for Austria and Germany, Cashin (1995) for Australia and Coulombe and Lee (1993) for regions in Canada; Kangasharju (1999) for Finland and Sala-i-Martin (1996) for the Japanese Prefectures.

The concept of conditional convergence found its more explicit formulation in Barro and Sala-i-Martin(1992) and Mankiw, Romer and Weil(1992). Both these papers emphasized the fact that the neoclassical growth model did not imply that the all countries are converging to the same steady state per capita income. Instead what it implied is that countries would reach their respective steady states. Notwithstanding, from Quah (1996) other concept of convergence emerges: Clubs convergence. This concept explains that the countries belonging to a group spread not to one but to a few steady states. The present study tests the convergence of GDP per-capita within and across 43 Mega cities (population more high than 9 million inhabitants), and other 10 World cities or agglomerations with some economic power: Toronto, Sydney, Amsterdam-Rotterdam, Frankfurt, Zurich, Hong Kong, Johannesburg, Milan, Singapore and Madrid (see Table 1).

Formally, the starting point for analyzing real convergence is the neoclassical growth model, which we consider to be the only one able to predict conditional convergence if the speed (β) at which any given economy converges towards its own steady state is inversely proportional to the time difference separating the current economy from its own steady state.

Table 1. Population of the agglomerations analysed

Source: United Nations-Habitat and Price Waterhouse Cooper.

According to Barro (1997), convergence speed is an indicator of the time spent by a country or region to achieve its own steady state. On the other hand, non neoclassical or endogenous growth models are not able to predict convergence,

except for the endogenous growth model with technological dissemination, where technology is spread gradually at no cost; for instance, Rebelo's AK endogenous growth model predicts zero convergence speed, that is, no convergence at all. If we assume some heterogeneity and differences in development levels among the cities analyzed in the present paper, it would be unwise to assume identical steady states for all, and consequently we resorted to the concept of conditional convergence. As we mentioned above, the best model to predict such convergence is the neoclassical growth model developed by R.M. Solow (1956) and T.W. Swan (1956), subsequently widened by N.G. Mankiw, D. Romer and D.N. Weil (1992) through the introduction of the capital production factor, including human capital (H). The way these authors incorporated human capital into the equation was through an indicator (S_H) that remains constant so that no increasing returns to scale are generated in the production function, which would in turn result in creating an endogenous growth model unable to predict convergence. The human capital indicator is related to the steady state in such a way that the interaction parameter is not necessarily related to the steady state, already linked to the human capital indicator. Our aim is to model the growth and convergence processes of any given economy endowed with exogenous technical progress, promoting the labor factor and neutral in the sense of Harrod, symbolized by the letter A , which we assume to grow externally at a constant rate, g_A . In order to maintain the basic hypotheses for the neoclassical growth model, we need the production function to include globally constant returns to scale, nevertheless decreasing with respect to physical capital, which may be expressed as follows:

$$y = K^\alpha \cdot H^\gamma \cdot [A \cdot L]^{1-\alpha-\gamma} \tag{1}$$

Where y stands for production, L for labor factor, K for physical capital factor and α and γ for two parameters such that: $\alpha + \gamma = 1$. Expressing (1) in values *per capita*, we find that:

$$Y = \frac{y}{L} = K^\alpha \cdot H^\gamma \cdot A^{1-\alpha-\gamma} \cdot L^{-(\alpha+\gamma)} \tag{2}$$

Using natural logarithms and operating according to Mankiw, Romer and Weil's method (1992), we obtain the expression for the conditional convergence equation, which explains in turn the value for the real income *per capita* logarithm during a generic period t as a function of some determining factors of the steady state:

$$\ln Y_t - \ln Y_0 = [g_A \cdot t + (1-b) \ln A_0] + \sigma \ln(n + 0.05) + \lambda \ln S_K + \mu \ln S_H - (1-b) \ln Y_0 \tag{3}$$

But the growth rate of real per capita income with respect to the average per capita income accumulated during the

period $(0, T)$ will be $\sum_{t=0}^{t=T} \frac{\Delta Y_t}{Y_t}$; and taking the limit we have:

$$\int_0^T \frac{dY}{Y} = \ln Y_T - \ln Y_0 = \ln \frac{Y_T}{Y_0} \tag{4}$$

Once the equation (3) has been regressed, convergence speed rate (β) is measured by estimator b for the initial income logarithm, since the relationship between both is: $b = e^{-\beta t}$. If coefficient β is larger than or equal to zero then, given convergence, relatively poorer regions should grow faster than wealthier ones. If coefficient β takes on a negative value, it means that for the period analyzed the regions should be experiencing a divergence process in their income *per capita*. In equation (3), S_K and S_H stand for certain levels of physical and human capital that reveal a steady state, staying constant in order to avoid the appearance of increasing returns in these accumulative factors; S_K and S_H are ratios between final and initial amounts; t reflects the time lapsed between the initial and final situation and the current one. We can chose as indicator of human capital the enrollment rate in high schools that takes into account the proportion of individuals with high school and university education. The indicator can be obtained from the 2000-2011 reports on human development for the United Nations Development Program (UNDP). As for physical capital, we used the ratio between private investment and real income as a *proxy* for the frequency of use of the capital factor in the steady state. A_0 is the initial value for the coefficient of technical progress; n represents population growth rate; and Y_0 stands for initial level of real income *per capita*. The interaction parameter of the equation's regression (3) is $[g_A \cdot t + (1-b) \ln A_0]$.

Moreover, into a globalization process, many world cities tend to have similar determinants of their steady-states, mainly on the determinants on the human capital, like education, enrollment in schools or high quality in secondary schools. Hence it could be interesting testing absolute convergence among these world cities rather conditional convergence, although it is know that it does not occur among their respective countries. In this sense we will take as the intercept parameter (a) the term:

$$a = ([g_A \cdot t + (1-b) \ln A_0] + \sigma \ln(n + 0.05) + \lambda \ln S_K + \mu \ln S_H) / T \tag{5}$$

And the parameter (a) embodies all the determinants of the common steady-state. The equation to determine the speed of absolute convergence has hence the following aspect:

$$\ln \frac{Y_T}{Y_0} = \ln B - (1-b) \ln Y_0 \tag{6}$$

where $b = e^{-\beta T}$, and β is, in the dynamic transition toward the steady-state, the coefficient that indicates the speed of convergence of the real per capita income towards steady state. Then, the average rate of per capita real income in relative terms will be:

$$\frac{1}{T} \cdot \ln \frac{Y_T}{Y_0} = a - \left[\frac{1 - e^{-\beta \cdot T}}{T} \right] \cdot \ln Y_0 \tag{7}$$

By developing the term $e^{-\beta T}$ by means of a Taylor-McLaurin series we have that:

$$e^{-\beta t} = 1 - \beta t, \text{ that is, } \beta = \frac{1 - e^{-\beta t}}{t} . \text{ And the equation (7) will be transformed then in:}$$

$$\frac{1}{t} \sum_{t=0}^t \frac{\Delta Y_t}{Y_t} = \frac{1}{t} \ln \frac{Y_t}{Y_0} = a - \beta \ln Y_0 \tag{8}$$

This expression denotes how the growth rate of relative real per capita income is related negatively with the logarithm of the initial level of relative real per capita income ($\ln Y_0$). Alternatively explained, for a determined level of the interaction term (a) related with each steady state, the higher the per capita income in a country the lower the growth rate will tend to be. If the value of b is positive, and a is the same in all countries of the sample, then there will exist absolute convergence; if b is zero or negative it means that there is divergence. The coefficient β represents the speed of convergence, and if $\beta \geq 0$ and the interaction term (a) is the same for all countries, then the poor economies grow more quickly than the richer ones, and in such cases absolute convergence is said to exist.

Notwithstanding, our purpose in this analysis is to verify whether among the group of World cities considered can exist one only or several steady states. In this sense we can remember the concept of clubs convergence. Quah (1996, 1997) noticed that, in 1960, the world distribution of income was uni-modal whereas, in the 1990s, the distribution became bi-modal. He then used Markov transitional matrices and non-parametric methods to estimate the probabilities that countries improve their position in the world distribution. Using these matrices, he then forecasted the evolution of this distribution overtime. His conclusion was that, in the long run, the distribution would remain bi-modal. Cheung and Pascual (2004), however, use panel time series procedures for cross section correlated panels because their ability to reject a false null hypothesis is higher than the corresponding univariate procedures.

In our analysis we will use panel data techniques applied to the absolute convergence equation (8) across 47 World cities and Mega-cities during the period 2005-2011 with annual data, using a fixed effects model for knowing the fixed effect of each city. These fixed effects reflect the complete determinants of the steady state of the corresponding city. Therefore when after the regression of the convergence equation, some fixed effects appear concentrated around a certain value, this will reflect the existence of a steady state common to the cities that belong to this group of concentrated fixed effects. On the contrary, big separations among groups of fixed effects will reflect different steady states. Hence the fixed effects model can help us to find clubs convergence in our sample. Other subject is the estimation of the speed of convergence. In this case, compared with cross country analysis, the time series approach generally used to predict clubs convergence, yields less convincing findings for the absolute and conditional convergence hypothesis. Consequently, with a panel data, we will use first a fixed effects model to find in our sample some clubs convergence corresponding to several steady states, and secondly, we will use a panel cross sectional model (between groups) to analyse the speed of convergence among cities towards one or several steady states.

The equation used to estimate the speed of convergence among all cities considered, by means of panel data techniques, came from the equation (8):

$$\left(\frac{\Delta Y}{Y} \right)_{it} = \alpha + \mu_i - \beta \ln Y_{0it} + \varepsilon_{it} \tag{8}$$

Where the endogenous variable is the real per capita GDP growth rate measured in power parity purchasing units, Y_{0it} is the initial real per capita GDP (in 2005) and its coefficient β reflects the speed of convergence towards the steady state; α is the intercept parameter when there is not significant the fixed effects model, and μ_{it} are the spatial fixed effects when the fixed effects model is significant. The data necessary for analyzing the structure of the world city system are difficult to obtain because most statistical information is aggregated at the national level rather than at the city level, mainly with respect to the indicators of the human and physical capital at the respective steady states. However, the data of the 53 metropolitan areas for the period 2005-2015 on GDP, population, and per capita GDP at power parity purchasing has been collected by several data bases: Penn. World Tables version 7.1, International Monetary Fund, United Nations, United Nations-Habitat, U.S. Department of Commerce, Brookings Institution, and Price Waterhouse Coopers. The results of the estimation are collected in Table 2. Following the Table 2, the best regression to predict is coming from the fixed

effects model. Notwithstanding, between groups model explain convergence better than fixed effects, excepting Clubs convergence.

Table 2. Estimation of the absolute convergence among Mega and World cities

Endogenous variable	OLSQ-AR1	Between Groups	Fixed Effects model (within groups)	Random Effects model (variance component model)
Growth rate				
Explanatory Variables				
Ln Yo (-β)	-0.034066 (-4.015)	-0.025534 (-2.706)	-0.301895 (-14.871)	-0.093257 (-4.284)
Rho	-0.29825 (-0.288)			
Intercept	0.15416 (6.199)	0.130772 (4.729)	Fixed Effects	0.316767 (4.872)
Tests				
DW	2.0128			
Lagrange Multiplier			1.08	1.08
Hausman			152.417	152.417
R ² -Adjusted	0.13	0.12	0.84	-
R ²	0.14	0.14	0.92	0.28

Note: t ratios in parenthesis

The high value of the Hausman test rejects the random effect model in favour the fixed effects model. Moreover, the low value of the Lagrange multiplier test does not reject the OLSQ plains, nor the between groups models. The best model to predict the economic growth rate in cities is also the fixed effects model (R² = 92 %). All methods yield absolute convergence among all cities because the coefficient of LnYo (-β) is negative and significant in all cases. The value of this coefficient in the fixed effects model is overestimated with respect to the speed of convergence because it embodies a temporary component in the variable LnYo. Notwithstanding, the intercepts estimated this model (the fixed effects) reflect the determinants of each steady state corresponding with each city. When the values of several fixed effects are very similar, this minds the existence of a steady state common to the cities which its fixed effects appear together. In reverse, when the separation between two groups of fixed effects is too large, this reflects different steady states for each group. Table 3 collects the ordered fixed effects of cities coming from the estimation of the within groups model, and the first differences among these fixed effects, for assessing the existence of several steady states in the sample (clubs convergence). In this sense, from Table 3 we can deduce seven groups of fixed effects separated by intervals more high than 0.04, which reflect seven possible steady states for all considered cities, although it can be reduced to tree: the first, which contains cities of high economic power and development level.

Notes: 1) Main Stock Exchanges in the World (SE). 2) Main Commodity Markets (CM)

Source: International Monetary Fund, Brookings Institution, and own elaboration.

The second group contains Mega cities corresponding to emerging economic areas, and the third group with Mega cities belonging to less developed areas. The highest steady state is common to the cities 1 (New York) to 23 (Seoul), included. The following group is separated from the first one by an interval of 0.04028. The cities belonging to the first group have high economic power. These cities have the most important stock exchanges (SE) and commodity markets (CM) in the World (see Table 3). All these cities are World or Global cities and are situated generally in developed areas. The most part of these agglomerations are also Mega-cities (more than 9 million inhabitants) but others have less inhabiting, like Zurich, Frankfurt or Amsterdam-Rotterdam. In the following group, the cities belong to some emerging countries or areas. In this group only a few number of cities have World economic power: mainly Sao Paulo, Shanghai and Mumbai. The group includes cities from 24 (Sao Paulo) to 42 (Chongqing). The separation between this second group and the third is very high (0.18639), but into the second group there are other two irrelevant separations. The third group of cities contains the poorest Mega cities in the World, which belong to less-developed countries: Kolkata (India), Karachi (Pakistan), Dhaka (Bangladesh), Lagos (Nigeria) and Kinshasa (Congo Democratic Republic).

With respect to the estimation of the speed of absolute convergence, we must use cross country regression approach instead time series approach, which is used to analyze clubs convergence. The speed of convergence obtained from a panel data by means of the fixed effects model is related with the clubs convergence concept, but not with the absolute convergence, because the initial per capita GDP is different for each panel data time period. In this sense, knowing that in the regression of the equation (8), the Lagrange Multiplier statistic does not reject OLSQ neither Between groups, the cross country regression must be applied to estimate the speed of absolute convergence, and the best method for that is the Between groups model, rather than OLSQ. The results of the regression of the equation (8) indicate that there is absolute convergence among all cities of the sample, and the speed of convergence towards a hypothetical common steady state is 0.0255. That implies a speed of convergence among all cities of 2.55 % annually. This speed of convergence among the Mega cities considered is higher than among the corresponding countries, where there is normally divergence. Moreover, following the clubs convergence concept, the speed of absolute convergence towards the specific steady state of each group of cities must be bigger and significant than among all cities considered in this work.

Table 4. Estimation results for Megacities and Countries convergence

Megacities Convergence toward its own Steady States		Method: Between groups
Endogenous variable: Per capita Income Growth rate		<i>t</i>

Convergence among Countries that have Megacities		Method: Between groups
Endogenous variable: Per capita Income Growth rate		<i>t</i>
lnYo (-β)	-0.0070035	-2.109
Intercept parameter	0.0410390	5.279
R ² Adjusted: 0.18		

Source: own elaboration.

In the other hand, the evidence seems to be unequivocal: different regions in different countries are converging. Most rates of convergence are around 2% per annum. However, the same cannot be said about the whole world. With data of the past 30 years for 110 countries, the evidence shows that the world is not converging. They are diverging. Poor countries are getting relatively poorer and the rich countries getting richer. The argument put forth to reconcile these two facts is that there is not too much diffusion of technology across different countries. However, within a country, regions are more closely related. But due to the globalization, the rise of high technology applied to the telecom networks, the expansion of the financial markets, generally located around the big cities, together the great multinational companies, and the strong development in multimodal transportation networks, cause a great growth in some places of the World, attracting immigration and amenities. Nevertheless, although it seems to have convergence among all big cities considered in this work, not all these cities are similar. There are many differences among the three groups of cities above mentioned and within each group. Measuring inequality, whereas the Gini coefficient of Johannesburg is 0.75 (strong social inequality), in Beijing is only 0.22. Or with respect to the poverty, while Mexico has a 14.4 percent of slum population in the urban area, Dhaka has 70.8 percent.

4. FINDINGS

At the end of the XX Century, a great part of the global economic activity is developed mainly around metropolitan areas, which are converting in big cities that compete among them for the economic power. Competition makes economic convergence, and it explains that although among the different countries of the World usually exist divergence, this is not the case among the Global cities, as the results of this work indicate. Due to the revolution in communication and transportation technologies the Global city has more in common with, and more closely integrated with other Global cities than its own hinterlands. A conventional city has a region behind, and there is no region without city, neither city without region. But a Mega city has, at least, a country behind. When in a country there are several Mega cities, competition for the specialization emerges among them. However, as the results of this work indicate, there are at least three steady states among the group of 53 cities analysed. Globalization mainly affects to the cities which have the steady state more high. Almost all of these 23 cities have high economic power and possess strong indicators of a globalization process, such as the major stock exchanges in the World, the main commodity markets, the most important airports and hubs; these cities are very important nodes in the communication network by air, road, railways or boat. Around these cities the most important banks and multinational companies devoted to new technologies and tele-communications have its headquarters. These cities are hence Global or World cities and generally are situated in high developed countries. In the second group of cities, corresponding with an intermediate steady state, there are a few number of them that have a strong economic power, such as Sao Paulo or Shanghai, but normally the effects of the globalization on these sub-group of cities is lower than in the first group. These cities belong to emerging countries and some of them can to become in World cities. In the third group, the cities belong to less developed countries, and no globalization effects have had. They are very populous cities, but there is not any economic power. This implies that they are not World or Global cities, but only Mega cities. However, as a result of our research, we can say that there is absolute convergence in real per capita income among all 53 big cities analysed, although really in the group of cities there are at least three steady states. In reverse, among the countries they belong there is normally divergence. This implies that the relation among big cities is not the same than among countries whose cities belong. Globalization seems stronger in cities than in countries.

1242 SUSTAINABILITY IN THE WORLD'S ENERGY RICH REGIONS: A WEALTH APPROACH

ABSTRACT

Regions around the world endowed with energy resources have experienced the unprecedented inflow of capital investments in the form of megaprojects to explore, extract, refine or transport these resources. In some cases, barren lands have turned into vibrant regions with extensive transportation and telecommunication networks and other infrastructure supporting flourishing urban population centers. In other cases, energy boomtowns have turned into ghost towns as soon as the resources are depleted. Energy-rich regions (ERRs) produce the world’s energy and collectively play a crucial role in the world economy. More efficient and transportable energy sources developed in these regions since the mid-19th century has had a marked effect on the state of the world’s energy, environment, and economics. Financial capital will continue to flow to energy-rich economies, particularly those with abundant oil and gas, and will continue to do so in the foreseeable future as the world transitions from its dependence on exhaustible resources to renewables. These substantial investments alter the composition of wealth and capital within these regions and determine sustainability and regional development path. There is a growing necessity for comprehensive frameworks for analyzing the sustainability of economic development in ERRs and understanding of the national and global implications of such regional development pattern. There is an increased recognition of wealth as a key indicator of well-being and economic sustainability. Wealth is generally measured in the various assets or capital forms in which it is embodied. The World Bank, for example, uses three capital forms of natural, produced, and intangible assets. On the other hand, the UN

1347 GEOGRAPHICAL PERSPECTIVES ON INDIA'S INTERNATIONAL TRADE

ABSTRACT

Regionalisation is a widespread feature of globalisation via international trade. Regional economic and trade cooperation, including bilateral and regional trade agreements (RTAs), has intensified in a number of developing economies. Regional arrangements offer important possibilities to enlarge economic space, attract FDI to the region on better terms, and pool economic, human, institutional, technological and infrastructural resources and networks of participating countries. The regional arrangements were slow to take off in the beginning, which is still the case with many. However, as complementarities among economies emerged, confidence in opening up to one another also developed. More recently, developing countries have joined their developed partners under new varieties of regional arrangements, such as North-South RTAs and North-South-South RTAs, reflecting growing North-South interdependence. Deepening integration among developing countries can provide further opportunities for enhanced South-South trade. Trade between India and ASEAN is one such example. It is important to note that the Southeast Asian countries and India are not only geographically proximate, but also share deep rooted historical, cultural and economic ties. Connectivity is important as it encourages trade, and brings regions closer and integrates economy with the world. However, at present the market is fragmented and is often a hindrance to free flow of goods and services, and technical barriers in the market lead to expensive mobility within Asia. Undoubtedly, distance is a key determinant of a region's trade prospects and in the absence of an adequate connectivity, vast opportunities created by the dynamic growth poles of Asia may fade at their international borders. India's trade with ASEAN 3 countries is the most acknowledged development that the world has experienced in the recent years. ASEAN has become India's one of the largest trading partners in recent years. India-ASEAN trade and investment relations have been growing steadily, with ASEAN being India's fourth largest trading partner. India's trade with ASEAN has increased from US\$ 7.13 billion in 2000 to US\$ 65.04 billion in 2015-16. India's trade, primarily due to FTAs, is expected to increase manifolds in the coming years. ASEAN-India FTA is central to India's growing engagement with her eastern neighbours. Accompanying this growth will be an increase in the demand of both national and international infrastructure, for both production and consumption, and international trade purposes. Undoubtedly, failure to respond to this demand will slow down the regional integration and growth process. In this context, the current paper attempts to analyse the nature and pattern of regional inter dependencies via trade flows existing between India and ASEAN economies from the geographical perspectives. The major objectives are: (i.) to compare the volume of trade, and commodity composition of export and import between India and ASEAN members; (ii.) to study the relationship between economic attributes/distance and trade. The major techniques used in the paper are regression models for relating the economic structures/distance and trade pattern, residual mapping, flow maps etc. Data analysis is done for the period covering 1990 to 2015.

SS19.3. Globalization and Regional Science

1261 REPRESENTATION OF SOCIO-ECONOMIC CLASS IN THE MASSACHUSETTS LEGISLATURE**Jason D. Wright**

Doctoral Student, University of Massachusetts Boston

Minorities, women, and the working-class are all under-represented in state legislatures. However, representation of the working-class has declined even as gains have been made for minorities and women. Descriptive representation matters for policy outcomes that affect the lives of each of these groups. While existing research on class representation is rigorous, it has relied only on cross-sectional data. The current study will add to prior research by investigating long-run trends in class representation in Massachusetts as well as the effects of class representation on policy outcomes.

LITERATURE REVIEW**Operationalizing “Working Class”**

It is critical to operationalize “working-class” before investigating representation of this group or the effects of such representation on policy outcomes. Socio-economic class can be defined in multiple ways, and there has long been debate over which definition is superior for research purposes. Wodtke (2017) notes two main divisions in the literature: the technical perspective and the social-relational perspective. The technical perspective emphasizes division based on types of industries or occupations, whereas the social-relational perspective emphasizes “the distribution of effective control over resources deployed within the production process (Wodtke, 2017, p. 1482).” The social-relational perspective divides the population into proprietors (e.g., business owners), managers, and workers. In other words, the social-relational perspectives emphasizes the level of control over productive resources rather than the educational attainment, skill, or prestige associated with specific occupational classes. Carnes (2016) claims that there is agreement among many contemporary class analysts that measures of class should be rooted in occupational data. However, Wodtke (2017) used longitudinal data to demonstrate that the social-relational perspective is useful for explaining class differences in life conditions and political attitudes, even when controlling for occupation type.

Yet, there are good methodological reasons to use an occupation-based definition of class. For instance, Connelly, Gale, and Lambert (2016, p. 1) note that sociologists have long recognized occupation as “...the most powerful single indicator of levels of material reward, social standing, and life chances” in industrialized societies. Furthermore, occupation may be a more stable measure of lifetime earning potential, and hence social position, in modern capitalist societies (Connelly et al., 2016, p. 2). Finally, it is difficult to access data on the degree to which individual legislators control the means of production, making it difficult to use the social-relational perspective. Thus, the author used the technical perspective of class for reasons largely rooted in pragmatism and lack of access to appropriate data.

Measures of class built on occupation must account for changing occupational structures over time. This is especially challenging in the current study given that the data on legislator occupation are available back to the 1920 legislative session. Fortunately, while specific occupations have changed over time, occupational groupings can be compared across periods.

How does one sort occupational groups by class structure in the United States? Wright, Costella, Hachen, and Sprague (1982) examined the class structure underlying specific occupational categories and found that the professional, teacher, manager, technician, farmer, and foreman categories were less likely to contain workers (as opposed to managers). Occupational categories are often called “Major Occupational Groupings (MOGs),” and these have been used to compare the distribution of jobs in the economy over time. For instance, Leon (2016) demonstrated a rise in professional and technical jobs since 1915. Thus, this study will utilize the technical definition of class, operationalized as the share of legislator occupations falling into specific MOGs.

Descriptive Representation of Class

The working-class has held less than two percent of seats in Congress since 1901 (Carnes, 2016, Figure 1, p. 84). Furthermore, representation of the working-class in state legislatures fell from five to three percent from 1976 to 2007 (Carnes, 2016, p. 100). This figure varies widely by state, with 10 percent of Alaska’s legislative seats held by the working class in 2007 compared to less than one percent in New York and California. In this research, working-class includes those engaged in manual labor or service industry jobs in their last occupation before taking office (Carnes, 2016). How does representation compare to the size of the working-class in society? Data on education requirements of existing jobs, the percentage of workers earning the minimum wage, and the share of workers in specific occupations (e.g., construction and production) all suggest that the working-class is under-represented in state legislatures.

An important limitation of this research is its reliance on cross-sectional data. This is because the use of cross-sectional data prevents researchers from establishing historical trends. Cross-sectional data on occupation is available from two sources, the National Conference of State Legislatures (data for 1993, 1995, 2007) and the Insurance Information Institute (data for 1979). The present study utilizes a new data set, from the State Library of Massachusetts, to examine class representation from 1920 to 2004.

Importance of Descriptive Representation

Descriptive representation in legislatures is a critical issue because under-representation has been shown to bias policy outcomes against women (Berkman & O'Conner, 1993), minorities (Owens, 2005), and the working-class (Carnes, 2012). For instance, controlling for demand and both citizen and government ideology, greater African American representation in state legislatures is associated with higher spending on healthcare and welfare (Owens, 2005). Moreover, Temporary Aid for Needy Families (TANF) eligibility criteria are less restrictive in states with more, and more powerful, women legislators (Reingold & Smith, 2012).

The study of legislative outcomes has emphasized gender and race over class (Carnes, 2016), but class effects have been demonstrated. For instance, Griffin and Anewalt-Rensburg (2013) found that, controlling for constituent views and other factors, wealthier members of Congress were more likely to vote for and cosponsor legislation to reduce or repeal the Estate Tax. Carnes (2012) found that the average member of Congress would have voted with the AFL-CIO more frequently had Congress been representative of the population in terms of class. Moreover, Carnes (2013, p. 124) found that, controlling for factors like per capita income, intergovernmental transfers, poverty, racial composition, political ideology, and union density, a 10-point increase in the percentage of working class legislators is associated with a four- to five-point increase in the percentage of the state budget devoted to welfare programs. Given the very low participation of working-class individuals in most U.S. lawmaking bodies, increases of that magnitude are not impossible. Carnes (2013) also found that states with lower working-class representation had higher income inequality. Furthermore, Scruggs and Hayes (2017) find that income replacement rates for welfare and unemployment benefits, which are the average benefit divided by the average after-tax wage, have decreased over time and that the "plutocratic tendencies" of state political economies are a contributing factor. In other words, low working-class representation has led to reduced public benefit generosity at the state level.

Mechanisms of Effects

By what mechanisms may more descriptive representation translate into policy outcomes that are less biased toward traditionally under-represented groups? A key potential mechanism is the inclusion of a more diverse set of views in the policymaking process. Prior research makes it clear that Americans with lower incomes are more liberal on economic issues (e.g., favor more redistribution) than their wealthier counterparts (Gilens, 2009; Rigby & Wright, 2013; Page, Bartels, & Seawright, 2013). Furthermore, differences in psychology have been identified between social classes that may function as a potential source of these different attitudes. That is, social psychologists have demonstrated that increased economic well-being is associated with less pro-social behavior, decreased empathy, and increased narcissism (Scruggs & Hayes, 2017). Thus, both material interests and psychological factors may drive class differences in attitudes toward economic policies.

In turn, the connection between representation of a more diverse set of views and policy action could manifest through an effect on the public agenda. For instance, Brown and Banks (2014) demonstrated that African American women legislators had a unique effect on the legislative agenda in Maryland in 2005 and 2011. Items on the public agenda are more likely to gain attention and receive public action. So, working-class legislators may have different views on economic issues that are reflected in the public agenda, and putting issues of relevance to the working-class on the agenda increases the likelihood of public action.

The Case of Massachusetts

Existing research on class representation in the Massachusetts General Court also utilized cross-sectional data and employed the technical view of class. These data suggest that working-class individuals held less than one percent of seats in the Massachusetts General Court in 2007 (Carnes, 2016). The present study will add to our understanding of class representation in the Massachusetts General Court by providing descriptive evidence of representation over a long period (1920 to 2004). This study will also examine if some relationships observed in studies of cross-sectional data hold over the long run in one state. There is an important caveat: *this study will actually use the share of non-working-class occupations in the legislature as a way to measure working-class representation*. This is because available historical data on the occupational profile of Massachusetts state legislators is voluminous and the author did not have adequate time to fully code working-class occupations into MOGs. It makes sense to code the professional occupations first given that there are a smaller number of these professions and their titles are more stable. For instance, lawyer and doctor/physician are quite stable titles in this dataset. Specifically, the following hypotheses will be tested:

Hypothesis one. Considering documentation of declining working-class representation in prior research, the share of Massachusetts legislators with professional occupations should have increased over time.

Hypothesis two. Considering the findings of prior research on the effect of descriptive representation, an increasing share of legislators with professional occupations in Massachusetts should be associated with lower top state tax rates, reduced spending on unemployment, and higher inequality. This is assuming the inclusion of relevant control variables, as available and appropriate.

METHOD

One of the main outcomes of this project will be a descriptive analysis of class in the Massachusetts General Court from 1920 to 2004. The author is unaware of any such analysis in the existing body of literature. Descriptive analyses are an important first step in understanding the ultimate effects of representation of class on policymaking in the long run. Why is it important to examine historical trends? Time series data allow for the identification and analysis of patterns like trends and cycles (Montgomery, Jennings, & Kulahci, 2008, p. 5).

An important part of data analysis involves examining the data, because this helps the researcher understand how to best go about analyzing the data. That is, time series plots, numerical summaries (e.g., mean, standard deviation), and scatter plots help to identify patterns and outliers in the data (Montgomery et al., 2008, p. 13). The primary outcome of this study as of now is a descriptive analysis along with preliminary inferential analyses based on correlations. These analyses will help identify trends in class representation in the Massachusetts legislature and provide a starting point for further analysis. The author plans to continue the analysis using multivariate regression where possible and appropriate.

Main Variable: Legislator Occupation

The main independent variable in the current study will be the share of legislators in each legislative session who disclosed holding occupations in specific Major Occupational Groups (MOGs). Data on the occupation of each state legislator from 1919 to 2004 are available from the State Library of Massachusetts (2017). These data were compiled by the State Library from *Public Officers of the Commonwealth of Massachusetts*, which is a periodical published by the state government that tracks the demographic characteristics of legislators for each legislative session. Thus, this is a state-level administrative dataset. The State Library transcribed data from *Public Officers of the Commonwealth of Massachusetts*. This transcription stopped at 2004, so future work will include transcribing additional issues of this periodical. Moreover, the author will take care to ensure the accuracy of the transcription, although this is an ongoing effort due to the size of the dataset.

Occupations will be assigned the class status of the occupational grouping to which they belong, which is consistent with the technical approach to class discussed earlier. The broader framework of Wright et al. (1982) will be used to operationalize the class status of occupational groupings. For instance, lawyers are not working-class because that occupation is part of the professional occupational grouping, which itself contains significantly fewer workers (as opposed to managers) than other groupings. The author coded occupations into Major Occupational Groupings (MOGs) based on the list of occupations in each MOG provided by the Bureau of Labor Statistics (BLS, 2001). For instance, an elementary or secondary school teacher was coded as a professional worker (MOG A), consistent with the BLS guidelines. The author performed the initial coding.

As previously referenced, the author will take multiple actions to ensure the reliability of the data. First, random samples of individual cases will be cross-checked in both the electronic dataset and the original publication to ensure that data were not incorrectly transcribed. Second, the data will be coded by a second researcher when funds become available to do so. Third, the proportion of legislators reporting each occupation will be cross-checked between this dataset and the cross-sectional datasets available for 1993, 1995, and 2007 from the National Conference of State Legislatures (NCSL). This will establish the level correspondence between this dataset and prior datasets used in published research.

The exact form of the legislator occupation variable will be the percent of legislators in each legislative session reporting occupations in a specific MOG. It is important to note that legislative sessions in Massachusetts are two years in length, so the other relevant variables must be transformed from annual to two-year figures. This will be accomplished by taking the unweighted average of the variable in both years.

Dependent variables. The literature suggests that class representation will affect the following variables: taxes (Griffin & Anewalt-Remsburg, 2013), unemployment benefit generosity (Scruggs & Hayes, 2017), and inequality (Carnes, 2013; Franko, Kelly, & Witko, 2016; Kraus & Callaghan, 2014). Annual top state income and capital gains tax rates are available from the National Bureau of Economic Research (Feenberg, n.d.). Unemployment benefit data are available from the U.S. Bureau of Economic Analysis (BEA, 2017b), and these data will be transformed into constant dollars for inclusion in the regressions. Inequality in this analysis will be operationalized as the share of income going to the top one percent of earners. Data on the annual share of income (in percent) held by the top one percent of earners is available from Frank (n.d.).

Control variables. Statistical control is used in social science research to see if the relationship between X and Y remains after holding constant the effect of confounding variables (Agresti & Finlay, 2009, p. 304). Carnes (2013, p. 124) controlled for the following in an analysis of the effect of class representation in state legislatures on the share of state budgets devoted to social spending: per capita income, intergovernmental transfers, poverty, racial composition, political ideology, and union density. Per capita income is an indicator of well-being, albeit an imperfect one (Valdmanis, 2015). Annual per capita income data, in dollars, are available from the U.S. Bureau of Economic Analysis (BEA, 2017a). Data on intergovernmental transfers are not available over the period under consideration. Poverty is a proxy for the demand for social welfare spending, and annual poverty rate data are available from the Census Bureau (2017, September 8). Racial composition of states has been shown to affect social welfare spending (Hahn et al., 2017, June), and annual racial data are available from the National Cancer Institute (NCI; 2017, December). These data are specially tabulated for the NCI by the Census Bureau. Political ideology and union density reflect the changing political environment in which spending decisions are made. For instance, declining union density is associated with increased inequality, holding other factors constant (Jacobs & Myers, 2014). Annual union density data, which is the percent of nonagricultural workers who are union members, are available from Hirsch, Macpherson, and Vroman (2017). Voter enrollment data, which includes the total number enrolled as well as the number enrolled by each party, are available from the Massachusetts Secretary of State (Galvin, n.d.). These data will be transformed into percentages of voters enrolled as Democrats, Republicans, or Unenrolled and will be used as a proxy for voter ideology. The cost of campaigns is an important barrier to taking office and would thus be an important control variable. However, the author is not aware of any existing sources of data on campaign costs over the time periods under consideration in this study.

Control variables will only be included in later regression analyses of the data. Thus, they will not be referred to in the preliminary results. However, control variables are worth mentioning now to point out the future direction of this research. Unfortunately, none of the control variables are available back to 1920, so regression analyses will be restricted to years for which control variables are available.

PRELIMINARY RESULTS

Professions by Occupational Group

The first step in analyzing the occupational data involved visual examination of each variable followed by the generation of descriptive statistics. Figure 1 displays the change in the share of all state legislators in each legislative session who reported an occupation in one of four Major Occupational Groups (MOGs). The MOGs are described by the Bureau of Labor Statistics (2001) and are designed to assist in the classification of jobs into larger categories. "MOG A" consists of professional and technical occupations such as doctor, lawyer, and teacher. While there is variation over time in the share of legislators reporting MOG A occupations, representation of MOG A in the legislature increased between the 1920 and 2004 legislative sessions. Moreover, the share of all legislators reporting a MOG A occupation increased steadily since the legislative session ending in 1980. The increase in MOG A occupations among legislators in Massachusetts is consistent with the rise in employees working in MOG A occupations over time (Leon, 2016). Moreover, the rise in MOG A occupations supports hypothesis one.

Two major MOG A occupations are lawyers and public school teachers, and these are the MOG A occupations with the most representation in the legislature. Figure 2 presents the share of legislators working in these two occupations. The share of legislators working as lawyers increased from the 1920s to the 1960s, after which the share of lawyers declined before increasing again in the 1990s. The share of legislators working as teachers increased from the 1940s through the legislative session ending in 1990, after which the share of teachers declined.

Table 1 summarizes each occupational variable. Professional occupations (i.e., MOG A) have played a consistent and substantial role in the legislature since 1920. That is, at least 23.5 percent of Massachusetts state legislators disclosed having professional occupations in each legislative session between 1920 and 2004. Lawyers, part of MOG A, have also played a consistent role in the legislature. At least 16 percent of legislators disclosed working as lawyers in all legislative sessions between 1920 and 2004. One interesting finding from descriptive analysis is that MOG A occupations were represented at a higher rate in the legislature than they are in the workforce at various points in the data series. For instance, 32.5 percent of all legislators disclosed having a MOG A occupation in 2004, but MOG A occupations represented 22.2 percent of all jobs nationally in 2005 (Hajiha, n.d.). Unfortunately, 2005 is the closest year for which the Bureau of Labor Statistics performed an analysis of the breakdown of jobs in occupational categories.

The next step in analyzing the occupational data involved examining scatterplots displaying the relationship between relevant independent (i.e., occupation variables) and dependent variables. These scatterplots revealed some non-linear relationships. This presents a challenge in analyzing the data. Either the data can be transformed or methods can be utilized that are not as sensitive to non-linearity. Spearman correlations were used to examine the association between occupational variables and relevant dependent variables because this method can be used for non-linear relationships and is less sensitive to outliers (Gravetter, & Wallnau, 2007). Regression analyses will be utilized in the future as additional resources become available.

Income inequality was the primary dependent variable because it is the only dependent variable for which data are available back to the beginning of the occupational data series (i.e., 1920). Income inequality in this study is operationalized as the share of income held by the top one percent of earners. The following results show significant relationships between multiple occupational variables and income inequality. The share of legislators with MOG A occupations was significantly positively associated with the share of income held by the top one percent of earners ($r_s = .27$, $n = 43$, $p < .01$). Note that this association was only significant at the 10 percent significance level. Of course, correlation does not demonstrate causation. However, this association is consistent with prior research demonstrating that increased representation of professional occupations across states is associated with higher inequality (Carnes, 2013). Interestingly, the share of legislators indicating a primary occupation of public school teacher was significantly negatively related to the share of income held by the top one percent of earners ($r_s = -.37$, $n = 43$, $p < .05$). The author is unaware of prior research examining the effect of representation of specific occupations on inequality. The following were not significantly related to the share of income held by the top one percent of earners: MOG B/C share, MOG D share, and lawyer share of legislators. Thus, even though professional occupations (i.e., MOG A) are related to inequality as an occupational group, the two main occupations in this group (i.e., lawyer and teacher) are differentially related to inequality. Regression analyses of this relationship will be included in a later version of this paper.

Taxes were specified as another dependent variable because wealthier legislators are more likely to cut taxes, even when controlling for constituent views (Griffin & Anewalt-Remsburg, 2013). Data are available for state tax rates on both capital gains and wages, but only between the 1978 and 2004 legislative sessions. This is too little data for a regression. However, a spearman correlation was performed to examine the relationship between occupational variables and tax rates. The share of legislators reporting MOG A occupations was significantly negatively associated with the capital gains tax rate ($r_s = -.47$, $n = 14$, $p < .10$). Note that this association was only significant at the 10 percent significance level. This highlights the role of legislature professionalization in policy outcomes and will be discussed later. These results are

weak evidence because of the small sample size, so additional data is needed. Nonetheless, results from prior research support the existence of the relationship between representation of professional occupations and tax rates.

State unemployment benefit expenditures were also examined due to the relationship between occupational representation and unemployment insurance policy (Scruggs & Hayes, 2017). Unemployment expenditure data are available back to the 1948 legislative session. These data were adjusted for inflation prior to analysis by utilizing the Consumer Price Index for All Urban Consumers (CPI-U), which is indexed to 1982 dollars. Representation of all MOG A occupations was not related to unemployment expenditure, but two of the main occupations within this category were. That is, the share of legislators reporting lawyer as an occupation was significantly negatively associated with unemployment expenditures ($r_s = -.54$, $n = 29$, $p < .05$), and the share of legislators reporting public school teacher as an occupation was significantly positively associated with unemployment expenditures ($r_s = .73$, $n = 29$, $p < .05$).

Professionalization

An interesting finding was that the share of legislators reporting a primary occupation of “legislator” increased dramatically since the 1960s. This trend was not an original focus of this study, but it is addressed below. Figure 4 below shows the share of all Massachusetts state legislators who indicated a primary occupation of “legislator.” There is a break in the data around 1963. This corresponds to the rise in full-time state legislators from at least the 1970s, the earliest data available from the National Conference of State Legislators (NCSL, 2009).

Professionalization of legislatures involves increases in legislator salary and resources along with changes in legislative sessions (often longer). Results from Bowen and Zachary (2014) also confirm the trend toward legislative professionalization across the states from the mid-1970s to the mid-2000s. See Figure 5 below for trends in legislator salary and per-legislator expenditures in Massachusetts. Moreover, Bowen and Zachary (2014, p. 288) categorize Massachusetts as a “...professional, full-time” legislature in recent times.

The share of legislators reporting their primary occupation as “legislator” can serve as an indicator, albeit a rough one, of how professionalization was internalized by legislators. “Legislator” was only embraced as an occupational identity by a substantial share of legislators near the end of the data series (e.g., 43 percent in 2004). This is interesting because the General Court had been professionalized for decades by this point.

What effect has professionalization had on policy and economic outcomes? The share of legislators reporting a primary occupation of “legislator” was significantly positively associated with income inequality ($r_s = .86$, $n = 21$, $p < .05$) and unemployment benefit expenditures (real dollars, indexed to 1982; $r_s = .97$, $n = 21$, $p < .05$). These analyses involve only data from 1963 on because this is the point at which the Massachusetts legislature began to professionalize significantly. Furthermore, the share of legislators reporting “legislator” as their primary occupation was significantly negatively associated with a decrease in the state capital gains tax rate ($r_s = -.64$, $n = 14$, $p < .05$).

CONCLUSION

Research on descriptive representation suggests that, on average, state legislatures do not look like state populations in terms of class, gender, and race. This is not because these populations are incapable of serving as legislators, but rather because they face barriers to entering politics (Carnes, 2016). Critically, under-representation in state legislatures has been shown to bias state policy outcomes and increase inequality.

While prior research has been rigorous, it has relied on cross-sectional data over a limited time frame. This study complements prior work by examining class representation in the Massachusetts General Court from 1920 to 2004. In addition to describing the long-run trend in descriptive representation of the class in Massachusetts, the analyses performed in this study examined, in a preliminary manner, the relationship between class representation and policy outcomes and income inequality. Spearman correlations demonstrated that the share of legislators with professional occupations was significantly associated with capital gains tax rates, income inequality, and spending on unemployment benefits. The only difference between the results and the hypotheses was that the share of professional occupations in the legislature was positively related to unemployment expenditures rather than negatively related.

The preliminary analysis also identified the influence of legislature professionalization. The share of legislators reporting “legislator” as their primary occupation increased starting in the 1960s. Professionalization was significantly associated with capital gains tax rates, income inequality, and spending on unemployment benefits. While this was not the original focus of this study, it is an interesting finding that should be pursued further.

It is critical to state that the significant correlations do not demonstrate causality. However, these significant associations are mostly consistent with the results of prior research using cross-sectional data across states. The author intends to extend the analysis, especially using multivariate regression. However, this will occur only after the author is able to fully verify the reliability and validity of the transcription and coding. This will require additional resources, most notably a second coder.

One major drawback of this study is that it relies on data from one state. However, Massachusetts does make an interesting case to study because, at least in recent history, it is a liberal state (Caughey & Warshaw, 2015) with low working-class representation in the General Court. This seems anomalous in the context of prior research. Tavory and Timmermans (2014) note that such anomalous cases can help to improve existing theory and generate new theory through the logic of abduction. Thus, examination of the case of Massachusetts may help to improve existing theories on descriptive representation.

1275 AGRICULTURAL LAND PROPERTY RIGHTS AND HOUSEHOLD FOOD INSECURITY IN RURAL CAMBODIA

ABSTRACT

My study examines the empirical link between land property rights and food insecurity, using primary data from a household survey in which I participated in conducting in 2014 among rice-growing households in 32 rural villages in Cambodia. The results show that a 1-unit increase in land property rights (from the average of 8.22) is associated with a 2-percent lower probability of household food insecurity annually. Similarly, a 1-unit increase in land property rights from the average of 8.22 is likely to reduce the length of food insecurity by about half a day to one day per annum per household. The results also indicate that land property rights potentially improve farmers' access to credit, land-based collateral usage and rice revenue-cost ratio, or 'input efficiency'. Relatedly, a wider usage of titled agricultural land as collateral to obtain a loan and enhanced rice revenue-cost ratio through the strengthening of agricultural land property rights can be an option for reducing rural food security in Cambodia.

1304 ENERGY AND EMISSIONS CONFLICTS IN A GLOBALIZED WORLD: THE ASIAN CASE STUDY

Touria Abdelkader-Benmesaud Conde, Fernando Barreiro-Pereira

Tutor Industrial Engineer, Universidad Nacional de Educacion a Distancia (UNED University), Madrid, Spain. Email: tabdelkader@madrid.uned.es

Professor of Economic Theory and Spatial Economics, Universidad Nacional de Education a Distancia (UNED University), Faculty of Economics and Business Administration, Dptm. of Analisis Economico, 11 Paseo Senda del Rey, 28040 Madrid, Spain. Email: fbarreiro@cee.uned.es

ABSTRACT

The main aim of this paper is to observe the environmental behaviour in some countries of the world, focusing the study on the Asian case, by analyzing the trend of the energy consumption and emissions indicators in each country. At the same time, we also consider the life expectancy at birth as an endogenous variable to observe the carbon dioxide (CO₂) effects on the population health. The paper also examines some conflicts coming from competition for energy resources, energy dependence and the spillover effects of the emissions on the proper and neighboring areas. To quantify how affect changes in carbon dioxide emissions, and energy consumption on some countries life expectancy, climate change, and labour and energy productivities, we use econometric techniques across some Asian countries and also some metropolitan areas, considering IEA annual data. Only carbon dioxide emissions are addressed in this paper, but it does not address other emissions such as NO_x or SO_x. The paper relates issues to central questions of international politics and theoretical debates concerning to the levels of energy consumption, carbon dioxide emissions and the role of the renewable energies on the climate change and the wellbeing of the consumers.

Keywords: Emissions, Renewable Energy, Cities, Economic Conflicts, Political Conflicts.

ECONOMIC INTRODUCTION TO THE ASIAN COUNTRIES

The environment is an area of complex study where physical, chemical, biological, cultural and social factors are involved and related, and where the hand of man is omnipresent. The environment becomes part of a globalized world. The involvement of every continent, country, city, or village is important for managing and channeling energy resources, and use of them must be made in the most optimal way possible. Much has been done and written about the use of energy resources produced in each location: how to get them, exploit them, treat them, use them, recycle and manage waste. But when a man hits on the environment, the environment, in turn, impacts on man by air pollutants, water and earth, causing sometimes illness and even deaths. Technology is an important factor to obtain a better management of energy resources. Increased technology is usually associated with less pollution, and the application of technology can solve some environmental problems associated with technological development. The problem associated with the global overpopulation is a factor to consider in terms of environment and waste aggression. We will focus on the air pollution and its impact on cities and megacities in terms of pollution, health, potential border disputes; and possible solutions.

The Asian countries, have a large population, estimated in more of 40% of the world population; an extensive territory; a lot of natural resources; common views on global economic problems; a very high growth of its gross domestic product, estimating a joint GDP of approximately 135 billion dollars, and participation in world trade in recent years, being countries very attractive to investors. The World Bank's requirement to promote equality among countries and greater participation in the International Monetary Fund and the obtaining of concessions for the granting of intellectual property rights have been common objectives at the economic-political level.

The Asian countries, are dominant global providers of technology and services, Russia become dominant as suppliers of raw materials, including food, with a large increase in their industrial resources. These countries may form a powerful economic bloc. To can compete, these countries must obtain greatly strengthened education, direct investment, internal consumption and spirit of domestic enterprise. According to the study, the Asian countries, especially India and China, have the fastest growth potential among the countries for the next 30 years. An important reason for that is the decline in the working-age population.

India is considered as the third world energy power, since it produces coal, biofuels and waste, crude oil and natural gas. Its majority consumption is in biofuel, oil products, coal, electricity and natural gas. India has been involved in the use of renewables betting on wind and solar energy. China is today the first energy power in the world, but above all in the development of renewable energy. The production of coal, crude oil, bio-fuels, hydro and nuclear is still very prominent, but it is betting very strongly on wind energy, solar photovoltaic and thermal, geothermal and marine energy. Russia produces natural gas, crude oil, coal, nuclear energy and hydro, in this order, being its majority consumption natural gas, oil products, heat and electricity. The great extension of Russia allows the development of renewable energies, being the most developed the geothermal energy, followed by solar and wind energy. Its consumption coming from coal, oil products, electricity, natural gas, biofuel, heat and renewable energy.

A MICROECONOMIC MODEL FOR ENERGY CONSUMPTION

Although a prediction model is not the same as a causal model, a prediction model must be designed based on the past data and available theory. If such a theory does not exist, then the prediction model will be based only on the sequence

of historical data. But respect to demand functions, and hence demand of energy, theory exists. And not only the theory exist, but also the econometric specification for a linear regression model, as is the case of the linear demand systems or almost ideal demand systems (Deaton and Muellbauer 1980). The theoretical specification of energy demand is very simple: Energy is a consumption good and at the same time a production factor, with a behavior similar to that of land.

Simplifying Hypotheses:

Suppose then that in the economy there are a small number F of oligopolistic companies in charge of supplying energy to the population, H consumers and a large number N of firms that for simplicity we assume in perfect competition. By assuming no political or governmental intervention, being e quantity of energy and c and R respectively the sets of goods and production factors different from the energy and p_e, p_c and p_R its respective unitary prices, assuming by simplicity Cobb-Douglas utility function:

$$U(e, c) = e^\alpha c^{1-\alpha} \tag{1}$$

And knowing that m is the consumer monetary income or monetary per capita income and P the general level price of the X goods, if each firm produces a similar good X , the behaviour of the individual agents in each period will be the following:

Consumer behaviour.

It consist in to maximize the utility sbject to the budget constraint:

$$Max\langle U(e, c) = e^\alpha c^{1-\alpha} \rangle \text{ subject to: } p_e + p_c = m. \tag{2}$$

Solving this maximization we have: $m = \frac{p_e}{\alpha} e$, but $Hm = Y$ (total monetary income), hence $Y = \frac{p_e}{\alpha} He$. Therefore, the aggregate demand of energy as consumption good will be:

$$He = \frac{\alpha Y}{p_e} \tag{3}$$

Firms behaviour.

It consist in to maximize the profit to shell the good X , by assuming that the production function of the X good has a Cobb-Douglas features:

$$X = Ae^\beta R^{1-\beta} \tag{4}$$

where A is the technical progress coefficient or total factor productivity. The producer problema is:

$$Max\langle Benefit \rangle = Max\langle PAe^\beta R^{1-\beta} - p_e e - p_R R \rangle \tag{5}$$

From the first condition for maximizing benefit (B), we have:

$$B'_e = 0 = \beta PA \frac{e^{\beta-1}}{e} R^{1-\beta} - p_e = \frac{\beta PX}{e} - p_e = 0 \tag{6}$$

Hence: $e = \frac{\beta PX}{p_e}$. The aggregate demand of energy as production factor will be then:

$$Ne = \frac{\beta Y}{p_e} \tag{7}$$

And the total energy demand (E_D):

$$E_D = He + Ne = (\alpha + \beta) \frac{Y}{p_e} \tag{8}.$$

Energy supplier companies.

We will assume that energy supply companies, which generally are oligopolistic companies, are similar and, by simplicity, have a quadratic cost function of type:

$C = p_R R + \frac{1}{2} e^2$. Then the unit price to which they sell the energy (p_e) is imposed by a mark-up ($\mu > 1$) on their marginal costs: $p_e = \mu C'_e$, that is: $p_e = \mu e$. Hence: $p_e F = \mu(Fe)$. But Fe is the total energy supplied (E_S) by all companies in the global market and therefore:

$$E_S = \frac{p_e F}{\mu} \tag{9}$$

Equilibrium:

Equaling supply and demand of energy, $E_S = E_D = E$, by means of the equations 8 and 9 we have that:

$$E = \frac{p_e F}{\mu} = (\alpha + \beta) \frac{Y}{p_e} \tag{10}$$

but from the first part of equation 10, or form 9, we know that the enegy price is: $p_e = \frac{\mu E}{F}$ and substituting this result in the second par of the equation 10 we will know the total consumption of energy in the market: $E^2 = \frac{(\alpha+\beta)F}{\mu} Y$. And so-calling $\frac{(\alpha+\beta)F}{\mu}$ as λ^2 , we have that:

$$E = \lambda \sqrt{Y} \tag{11}$$

And taking natural logarithms: $\log_e E = \log_e \lambda + \frac{1}{2} \log_e Y$. Generalizing it, the final equation to be estimate for energy consumption is:

$$\log_e E = \gamma_0 + \gamma_1 \log_e Y + \varepsilon \tag{12}$$

where E is the effective energy consumption and Y the nominal income or GDP at current prices. The term γ_0 must collect the rest of the explanatory variables including the intercept parameter and climatic variables. Another econometric specification may come from the breakdown of nominal income into its two components:

$$\log_e E = \gamma_0 + \eta_1 \log_e y + \eta_2 \log_e P + \varepsilon \tag{13}$$

where y is now the real income or GDP at constant prices. If the period for the forecast horizon were longer it would have to resort to growth models. By assuming that the growth model were neoclassical and suppsing that energy is a cumulative factor without depreciation rate, then at the steady state we will have that:

$$E = \left(\frac{s}{n+g}\right) y \tag{14}$$

being y the real income, s the saving rate, n the population growth rate and g the technology growth rate.

Suppose now that a percentage of the contaminant emissions (Em) are coming from energy consumption (E); then: $Em = \rho E^\theta$, where ρ and θ are parameters. Taking natural logarithms we have: $\ln (Em) = \ln \rho + \theta \ln E$. Hence, we have found the following lognormal relationship between emissions (Em) and energy consumption (E):

$$\log_e (Em) = \vartheta_0 + \vartheta_1 \log_e E + \varepsilon \tag{15}$$

to estimate.

DATA AND EMPIRICAL RESULTS FOR EMISSION IMPACTS

From the World Bank, a series of estimates have been made relating energy consumption to nominal GDP, as well as the relationship between carbon dioxide emissions with the energy consumption. The ratio between emissions and energy consumption gives us a value that if it turns out to be greater than the ratio between energy consumption and GDP, would indicate a great use of fossil fuels and great emissions that would affect proper cities and even neighboring countries, affecting the health of the people exposed to these emissions. On the other hand, if the relationship between emissions and energy consumption turns out to be lower than the ratio between consumption and GDP, it would indicate that fossil fuels are being replaced by alternative and renewable or green energies without or small pollution.

Based on the model developed in section 2, an application has been made with data of the five BRICS countries in a period between 2000 and 2015, with annual data collected in the IEA and the World Bank. The equation that is applied as the first estimate is equation (12) that relates the consumption of energy with nominal GDP, that is, how much the nominal GDP consumption depends; then the equation (15) that relates the carbon dioxide emissions to the energy consumption is applied as a second estimate, that is, how much CO2 emissions depend on the energy consumption. The estimation of these both relationships are collected in Table 1 and Table 2. In the Table 1 the dependent variable is the total energy consumption by country, represented by E and the independent variable used is the natural logarithm of the nominal GDP of each country. We have compared with some economically and energetically emerging countries like Brazil or South Africa.

Source: own elaboration

In these two regressions, the estimated parameters of the coefficients for lnGDP and lnE mind respectively the elasticity of the energy consumption (E) respect to the GDP, and the elasticity of the emissions with respect to energy consumption. That is respectively:

$\frac{\partial \ln E}{\partial \ln Y} = \frac{\Delta E/E}{\Delta Y/Y} = \varepsilon_{E,Y}$, and $\frac{\partial \ln(Em)}{\partial \ln E} = \frac{\Delta Em/Em}{\Delta E/E} = \varepsilon_{Em,E}$ The product of $\varepsilon_{E,Y}$ by $\varepsilon_{Em,E}$ is equal to $\frac{\Delta Em/Em}{\Delta Y/Y} = \varepsilon_{Em,Y}$. This allow us to compare the emission growth rate in relation to the nominal income and energy consumption growth rates. When comparing the growth rates it will be possible to observe what causes more number of emissions, whether the consumption of energy or the nominal product of economic activity. The values of the elasticity $\varepsilon_{Em,Y}$ for each country are: Brazil: 0.1897; Russia: 0.0003; India: 0.8259; China: 0.8638; South Africa: 0.9547. The values of the elasticity $\varepsilon_{Em,E}$ for each country are: Brazil: 0.0021; Russia: 0.000005; India: 0.0045; China: 0.0053; South Africa: 0.0080.

Table 3.- Estimation of the relation between elasticity $\varepsilon_{Em,Y}$ and elasticity $\varepsilon_{Em,E}$ (2000-2015)

	Brazil	Russia	India	China	South Africa
$\varepsilon_{Em,Y}$	0.1897	0.0003	0.8259	0.8638	0.9547
$\varepsilon_{Em,E}$	0.0021	0.000005	0.0045	0.0053	0.0080

Source: own elaboration

As we can observe in Table 3, the values of the elasticity $\varepsilon_{Em,Y}$ are greater than the values of $\varepsilon_{Em,E}$, indicating that the greater emissions come from the all production are more higher than of which coming from the consumption of energy. By countries, there is greater pollution by energy production in South Africa, followed by China, India, Brazil and Russia. In a much smaller proportion and by countries, there is a greater number of emissions per energy consumption in South Africa, followed by China, India, Brazil and Russia.

EFFECTS OF AIR POLLUTION ON CITIES

Air pollution has negative influences in the environment and in humans. Increasing the carbon dioxide concentration in the atmosphere (CO₂), because of different combustion processes of different materials, means that there is a greater absorption of infrared radiation escapes off the earth, which causes an increase in the atmosphere temperature and in the Earth's temperature, causing the ice caps to melt and a greenhouse effect. Acid rain, destruction of the ozone layer and smog are problems associated with air pollution. But it is at the local level where pollution control is important, especially to the people. It is important to know the standard values of air quality.

Dust, fiber, soot, fumes, mist, fog, haze and smog (the union of both the smoke haze and photochemical due to solar radiation), load the environment so that these particles greater or lesser degree affecting not only the health of individuals, but also the visibility and environmental degradation.

The CO₂ in natural proportions is not harmful, but as mentioned above, as a result of the combustion of fossil fuels, the concentration in the atmosphere is increasing, become a pollutant greenhouse gas. Other pollutants that directly affect health are: i) Carbon monoxide (CO), mainly associated with traffic and the effect on man is the interference of oxygen transport in the blood, causing intoxication and whose symptoms are drowsiness, headache, fatigue, dysfunction in the central nervous system, heart and lung, followed by coma, respiratory failure and ultimately death; ii) Sulphur dioxide (SO₂), associated with the combustion of coal and petroleum products. The effect in man focuses on respiratory and whose symptoms are irritation of nose and throat, runny nose, breathing problems, pulmonary edema and death; iii) Nitrogen oxides (NO_x), associated with the combustion of fossil fuels, with the effect in humans reducing blood oxygen transport to a lesser extent than the CO and inflammation of lung tissue; iv) Suspended particles, called aerosols, are particles depending on their size can be inhaled (deleted by mucus) or respirable. It influences the formation of sulfurous smog; v) Hydrocarbons (CH_x), substances that contain only hydrogen and carbon and influences the formation of photochemical smog; vi) Lead (Pb), toxic element affecting the hematopoietic, nervous system and kidney.

The union of the concentration of pollutants in the atmosphere, the weather and the topographical conditions are the problem of air pollution, where we must pay attention to the source of the contaminant, to the proper contaminant and to the receptor of pollution when it is dispersed. All these affects the health of human beings, but also fossil fuels can be a source of conflict between neighboring countries and even between neighboring cities, due to contamination by toxic gas emissions to a less polluted area. Energy production, energy consumption, the PM10 pollution index, life expectancy, deaths from emissions, CO₂ emissions, to clean the environment and the relationship between population and area, are the main indicators to be treated in this paper.

We performed a study on megacities and countries ranging from the poorest to the richest in the world, considering that most populous places with small technology to less populated places with highest technology, also considering the area in km² of each city and country. Besides the countries which contains mega-cities, other countries that have been analyzed in this paper are: Saudi Arabia, Azerbaijan, Bahrain, Belgium, Brunei Darussalam, Canada, United Arab Emirates, Finland, Iceland, Kazakhstan, Kuwait, Luxembourg, Malaysia, Norway, Oman, Qatar, Singapore, Turkmenistan and Uzbekistan. The megacities studied are collected in Table 4.

The indicators used in this paper for estimating the effects of pollution on health are those indicated below: i) POP / S: population density, is the ratio between the population and the urban area or country. A high value indicates a higher concentration of inhabitants per km², which leads to a mass per unit area and greater possibility of contamination per capita, especially in less developed or emerging countries, because they could use more dirty energy for consumption. Turn to be more exposed to contamination risk to health is higher, and increased risk of mortality. In fossil fuel producing countries, a high value indicates that although there is high technology, the level of contamination is high. The processes of production and distribution are the major cause of environmental emissions, followed by the transport and the use of energy industries, businesses, institutions and homes. In developed countries, a high value indicates a high technology and low emissions, as there are no industries that require combustion of fossil fuels. The crowds here are usually temporary, the most important being the risk of CO₂ emissions due to traffic. In Table 5 are listed some megacities with a high population density.

Table 5.- Megacities with high population density

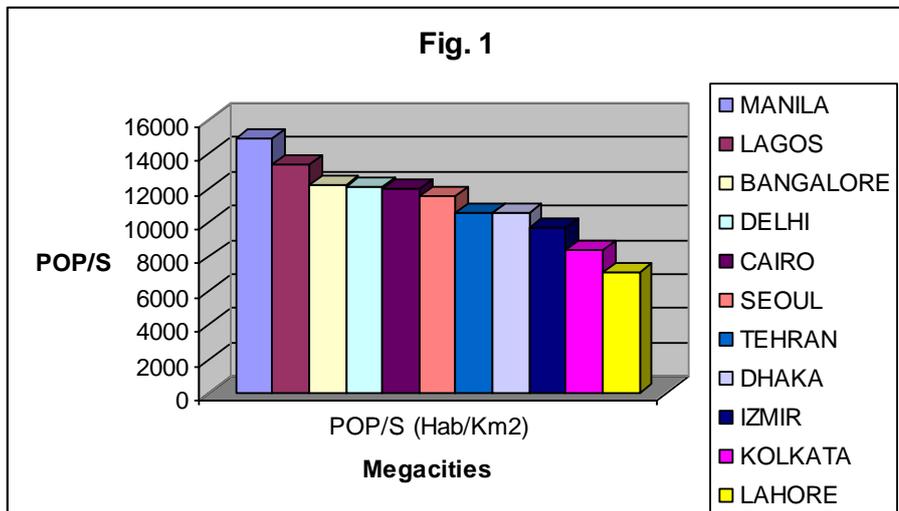

CITY	POP/S (Hab/Km ²)
MANILA*	14882,03

IZMIR*	9706,28
KOLKATA*	8391,62
LAHORE*	7054,17

*Cities in development process; **Emerging Cities; ***Developed Cities

Source: World Bank Data

It is noted that in the case of Manila, Lagos, Delhi, Bangalore, Cairo, Dhaka or Tehran population density is very high, being between megacities and developed process emerging, fulfilling the first case. Seoul's case is peculiar, since there is high level of contamination, and a high concentration of inhabitants per km². (See Figure 1).

Figure 1. Megacities with high population density.

Source: own elaboration

This may be due to the use of other energy sources alternative such as nuclear, which employs about 18% of the total energy produced. Some megacities with low population density are below in Table 6 and Figure 2:

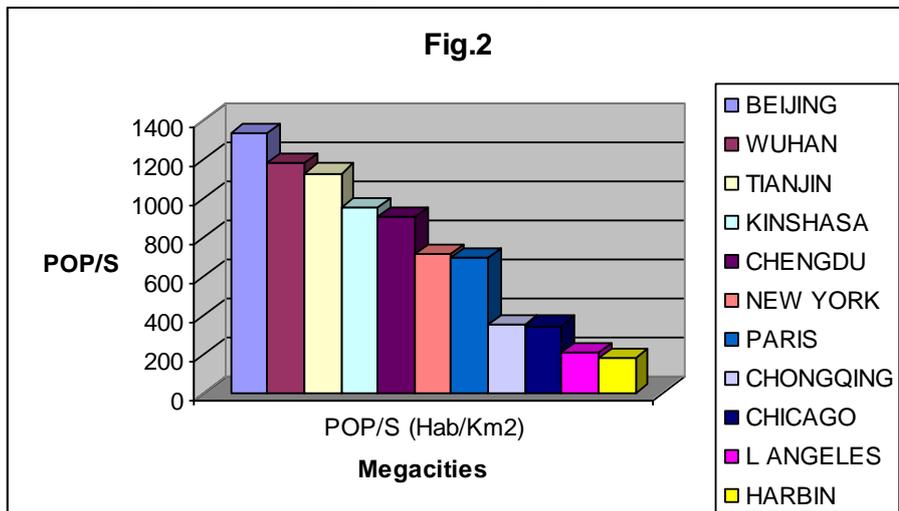

Table 6.- Megacities with low population density

CITY	POP/S (Hab/Km ²)

Source: World Bank Data

Figure 2. Megacities with low population density

Source: own elaboration

In this case, it appears that less-developed or emerging megacities have a very low population density, because they have a large area, despite having more than 9 million people. This does not indicate that pollutes less, but has much more surface to pollute. The most developed cities like Los Angeles, Chicago, Paris or New York, have a high tech and less pollution index, mainly due to traffic and some industries outside the urban core. Countries like Bangladesh, South Korea, India, Japan and Bahrain are overcrowded and cover all ranges of development. Conversely if you have a small population country like Iceland with 3.0 inhabitants per square kilometer, Canada with 3.3 Inh/Km², Oman, Norway, Finland and Brunei, all with a population density of less than 100 Inh/Km². ii) PM10, particulate matter, are small solid or liquid particles of dust, ashes, soot, metal particles, cement or pollen dispersed in the atmosphere. The PM10 includes values less than 10 microns (micrometers). The daily limit value for the protection of human health is 50 ug/m³ PM10 not to be

exceeded more than 7 times per year and the annual limit value for the protection of human health is 20 ug/m³. Megacities of further development are most close to the limit of PM10, which could be interpreted as the safest places for health and are indicated in the following table 7:

Table 7.- No air pollution Megacities

CITY	PM10

Source: World Bank Data

If the PM10 limit is exceeded, it may imply a less developed technology, being very harmful to health and, therefore, life expectancy will be lower. (See Table 8).

Source: World Bank Data

For countries that have an index close to PM10 are Russia, Brazil, France, Argentina, USA, UK, Germany, Japan, Iceland, Finland, Norway, Belgium, Canada, Luxembourg and Malaysia. The highest PM10 countries are Pakistan, Bangladesh, Nigeria, Egypt, India, China, Saudi Arabia, UAE and Kuwait, this latter, associated with the production and distribution of fossil fuels.

CONCLUSIONS

We can conclude by saying that one of the most important reasons in the emissions of polluting gases is the total production of economic activity, above the consumption of energy. There is a commitment in the Asian countries to reduce the consumption of fossil fuels and to invest in renewable energies or even to recycle pollutants, converting them into heat or using other technologies to cleanse these pollutants. The main conclusions on the sources of conflicts are the energy dependence between neighbouring countries or cities, CO2 emissions to a neighbouring country or city, and the neighboring countries with different levels of development. As to the impact of emissions, the impact on health, especially in the respiratory tract and blood oxygen, the environmental impact and the emissions cause conflicts in neighbouring countries. Finally, on the solutions of conflicts, we must reach a compromise for reduce CO2 emissions, if possible, it is necessary to reduce fossil energy (coal and oil) using a convenient treatment in the production of recycling the gases expelled, the augment the use of renewable energy (non-dependence between countries).

1360 EMPIRICAL ANALYSIS OF LOCATION CHOICE FOR JAPANESE MNFS IN EAST ASIA: THE CASES OF ELECTRONICS AND AUTOMOTIVE AUTOMOBILE INDUSTRIES

ABSTRACT

This paper conducted an empirical analysis using an NEG model to investigate the relationship between industrial agglomeration and overseas location choice for target Japanese MNF's' final and intermediate production sites from 1995 through 2009 in East Asia. In doing so, the researcher focused on three major Japanese industries: the Japanese food industry, which has a relatively high proportion of its business overseas in order to source agricultural products, natural resources, and other local resources; the global-type Japanese electrical/electronics industry; and the pyramid-type Japanese automotive industry. Then, the researcher divided the Japanese companies' production sites into those producing final goods and those producing intermediate goods, because of the vertical structure of coagglomeration and in view of the important role played by the intermediate goods sector, as set forth by Venables (1996). The results illustrate the following four points. The results showed the importance not only of the traditional location factors of the wage and infrastructure variables, but also of such variables based on the NEG model as market potential and domestic supplier access variables and Japanese industrial agglomeration variables, especially the Japanese horizontal industrial agglomeration and vertical industrial agglomeration variables.

1406 SOCIO-ECONOMIC DEPRIVATIONS IN NORTH EAST INDIAN STATES

ABSTRACT

Deprivation is a condition of living below the majority of the population in a particular society. It restricts individual to satisfy their basic needs and hinders active social participation in the development process. Economic transformation, globalisation and privatisation are enhancing deprivations among human beings by increasing the incidences of spatial segregation, social polarisation and spatial inequalities. The present paper is an attempt to evaluate the general socio-economic condition of the North-Eastern States of India and to map the various areas of deprivation. An examination of various socio-economic factors is done to measure deprivations indirectly for the state at urban and rural levels. A set of 17 indicators are drawn from the Census of India 2011, representing the physical environment, socio-economic environment and distribution of opportunities and accessibility. Various statistical techniques like descriptive statistics and so on are used to analyse the data. An analysis of the gaps between best and worst-performing regions is also done to identify the intensity of deprivation across the states. Also, deprivation Index is devised to have a general representation of the importance of this phenomenon in the space using Z score. The Results are then mapped to have a visual illustration of the spatial distribution of the socio-economic deprivations. The politico-geographic region of North East is unique and diverse in terms of topography, natural resources, socio-economic and geographic characteristics making it stand apart from the rest of the country. This heterogeneous region, however, is relatively similar in terms of underdevelopment and deprivations. The region lags behind in most of the social, economic and human development parameters when compared to the rest of the country. Its isolation and poor connectivity, from the mainland; ethnic conflicts and insurgency further add to its backwardness. The region consists of less than 4 percent of the total population of India, but on the other end, it accounts for over 12 percent of India’s total tribal population. Except for Assam and Tripura, most of the North-Eastern states are mainly rural with a relatively low density of population but comparatively high population growth owing to the high influx of international migrants from Bangladesh and Myanmar. In the context of literacy, the regions seem to have done better compared to the national average. However, huge inter disparities exist between different states of North-East. Despite high literacy, the educational attainment levels are quite poor in the region with high drop-out levels and a wide gap between male and female literacy. The region is again quite poor in terms of housing and basic amenities. Most of the region shows great inadequacy with respect to toilet and sanitation facilities. Other facilities like electricity, clean drinking water, availability of electricity, LPC connections are again far from satisfactory. Moreover, massive inter disparities exist in the NER. The region is also lacking in adequate banking facilities, entertainment and communication facilities. The foregoing discussion brings to the fore the spatial variations in socio-economic deprivations in the Northeast region. The deprivation Index is a pointer to this effect.

1535 ADEQUATE EMPLOYMENT AND MOBILITY OF DOCTORAL GRADUATES IN GERMANY

ABSTRACT

In the past decades numbers of granted doctoral degrees have increased rapidly in many OECD countries. This has raised concerns about potentially negative consequences of skill misallocation in the labor market. In this paper we report first results from a large-scale record matching project that links data on all doctoral dissertations completed in Germany with social security records providing detailed information about individual career trajectories. This approach allows us to reconstruct the non-academic careers of doctoral graduates for different fields and gender over a 10-year period after graduation. We find that a substantial share of doctoral graduates are overeducated for their positions. There is considerable variation in outcomes across fields. In addition, while few doctoral graduates are unemployed, less than 60 per cent of the female doctorate holders are in full-time employment ten years after graduation, and those who are have a lower likelihood of obtaining a high income. Those doctoral graduates who leave the university region after degree awarded are more likely to find a job that matches their academic skills. In addition, the results show that the regional environment determines the probability of adequate employment among doctoral graduates at earlier and later stages of their careers. In this respect, the degree of agglomeration, and the regional economic conditions (e.g., unemployment rate) play a decisive role.

1544 TESTING THE ROBUSTNESS OF TRADE AND FOREIGN DIRECT INVESTMENT BARRIERS IN GRAVITY MODELS

ABSTRACT

This paper tests the robustness of the various types of trade and investment barriers identified in the literature. Taking advantage of a large number of datasets, the paper provides a comprehensive analysis of the gravity literature on trade and FDI. We use multiple dimensions of distance, including cultural distance, institutional quality, costs of importing and exporting and political stability of both country of origin and destination. The paper assesses multiple dimensions of robustness: not only the sign and significance of coefficient estimates, but also the variation in the magnitude of the estimated effects by using response surface analyses. Preliminary results show that cultural distance, and the dummy variables for colony and a shared religion have a robust effect on FDI. The effect of cultural distance on FDI is negative and statistically significant in over 95 per cent of the regressions. This confirms that cultural distance is an important barrier to FDI. As for trade, we find that, within the overall barrier consisting of contracting costs and insecurity, only cultural aspects have a robust effect. Institutions, whether level or distance, do not appear to matter. Interestingly, we find that preferential trade agreements or common trade blocs have a robust, negative effect on FDI. The effect of the depth index for increasing integration is negative as well (though not always statistically significant). So, where integration has a positive effect on trade, this is not the case for FDI. These results indicate that (deepening) integration does not raise FDI. Overall, one third of the variables we tested are robust for trade and only one fourth for FDI.

1599 GLOBALIZATION AND WATER. THE DYNAMICS OF PRIVATIZATION IN THE RURAL DRINKING WATER SECTOR

Raina Ghosh

M.Phil. Research Scholar (1st Semester), Centre for the Study of Regional Development, School of Social Sciences, Jawaharlal Nehru University, New Delhi- 110067, rainaghosh@hotmail.com | +91 9830380981

ABSTRACT

Semantics behind the Washington Consensus have given rise to free market shibboleths, which in tune with the neoliberal intellectual air, find market as a 'solution' to efficiently manage scarce resources. According to Scholte⁵²⁶, the analytical lynchpin for understanding social change in the contemporary world is provided by the intuitive concept of 'globalization' that renders the best entry point for such an enquiry. For the water sector, this has translated into a corporate theft of 'blue gold' – simply put, a process of commodification of water, meant to be an unfettered trade and sale of water within informal or formal institutional arrangements. Interestingly this has been possible courtesy the increasing mediation of public opinion by the State as well as the supra national institutions, backed by the advent of globalization, that has successfully woven the imagery of 'safe drinking water' as a precondition for healthy and standard living. The alarming imposition is that, its provision is not solely a State responsibility anymore, inviting newer players in the supply side of the drinking water sector.

Keywords: Globalisation, privatisation, water policies, safe drinking water, rural water sector

INTRODUCTION

The crux of the paradigmatic shift in the water sector policies is to be understood in the light of the broader economic thinking in the era of globalisation, allowing the primacy of the social sector provisioning to be replaced by a central focus on the 'markets'. This reinstates the changing role from 'welfare' to a 'neoliberal state' as neoliberalism emerged as a radical anti-Keynesian movement that sought to dismantle major Keynesian institutions and policies and viewed the former entity as a part of the 'problem' that should be subject to the neoliberal 'solution' (Kus, 2006)⁵²⁷. However, the narrative of this change unfolds under the initiative of the supra-national institutions advocating for the demand responsive approaches in water sector thereby packaging the water reforms as a sugar-coated welfare enhancing scheme. The seemingly neutral, technical policy provisions are in fact deeply political because they entail far-reaching redistributions of water and of water rights, water power and water based profits (Boelens and Zwartveen, 2005, 2010)⁵²⁸. The rational choice paradigm of neoliberalism clinging on to the language of efficiency, utility maximisation and private property rights intends to turn the 'backward' water delivery and management institutions into more efficient 'modern' ones drawing on its inspirations from the 'neoliberalist utopian dreams' to pave the way for an unequivocal celebration of market forces and private ownership. These are justified on grounds of looming water crisis and by constructing the 'new moral political project' of instillation of fear about health if one is not consuming 'safe water', delivered through prior treatment processes. The construction of the larger economic cum social imaginary resting on the ideas that scarcity hinders the economy's potential growth and more specifically in case of water – posing a threat for the very human existence, makes it convincing enough for the public to attest for the market mechanisms to be favoured, to operate at the earliest. Locally and practically this translate into efforts to build 'unconscious and uncritical habitual modes of thought of ordinary citizens, useful for the governing regime which is ruling the country on behalf of the domestic and corporate interests' (Sood & Baruah, 2017:1).

Bakker ⁵²⁹ identifies neoliberalism as a heterogenous and contested political project, consisting of an 'interaction of two processes of transformation- privatization and commercialization which are concerned with the reorganization of water allocation, with resources and assets that used to be publicly owned being made available for private ownership and for idle capital to invest in and speculate with'. Implicitly making water resources, land (for further ground water exploitation) and other services available to the market at 'very low or zero cost' and putting them to the centre of profitable use goes behind the very essence as well as the economics of Harvey's 'accumulation by dispossession' ⁵³⁰ that characterise 'water privatization' as part and parcel of such larger on-going processes of capitalist transformation. The utopian project thus skilfully etches out a theoretical design for the reorganisation of international capitalism or to re-establish the conditions for capital accumulation through economic deregulation as well as institutional devolution to create competitive markets, encashing on the 'scarcity' as an opportunity to enter the market or expand it for more surpluses. Moreover, the riveting fact is that despite the call for the withdrawal of the state in providing public utilities and services, the implicit idea of neoliberal governance is to use the state machinery for legal, administrative and social measures to facilitate private entrepreneurs and 'appropriate functioning of markets', making the deregulation associated with globalisation- a sort of re-regulation in its creation of new governing structures and discourses that

530Accumulation by dispossession refers specifically to practices that operate and evolve through the violent expulsion of peasants through land privatization, the conversion of common property rights, the suppression of alternative and indigenous forms of production and consumption, and the appropriation of natural resources (Harvey, 2003)

sustain neoliberalism (Harvey, 2005: 19; 2007⁵³¹; Boelens and Zwartveen, 2010: 45⁵³², Peck and Tickell, 2002⁵³³; Castree, 2008⁵³⁴).

Understanding the dynamics of social change that is inevitably associated with the institutionalisation of these ideas brings to fore the conflicting interests of the irreconcilable economic classes which have their basis in the structure of the society. Using the dialectical method to interpret the superstructural manifestations of the structural contradictions, it is evident how these conflicts spell out in the water sector in terms of the tensions between the market forces and its players, that treat water as an economic good versus the consensus of viewing water as a basic human right when at the superstructural realm, commercialization of water supply across globe, posits the 'blue gold' as 'an increasingly vital component in the relentless quest of capital for new sources of accumulation', creating newer 'enclosure of the commons' - an objective of state policies (Swyngedouw, 2005: 87⁵³⁵; Luxemburg, 2003⁵³⁶).

Objectives: The paper aims to sketch out the dynamics of water privatization in the rural drinking water sector in India whereby it intends to introspect the various dimensions that have shaped up the interplay between State and Non-State actors regarding issues of provision of potable water for people. The objectives are –

- ✓ To trace the policy trajectory that provides the backdrop behind the emergence of private players in drinking water sector
- ✓ To review the changing role of the State associated with such developments
- ✓ To analyze rural water market scenario in India, primarily looking into the Water ATM business and Community Purifier Systems and locating them within a broader theoretical framework of understanding the logic of capital behind its operations

Research Question: What is the extent of privatization in the rural drinking water sector and how has its dynamics being shaped up in India?

Data Sources: The data on the status of access to drinking water sources have been obtained from-

1. *Format H4 (A) RWS coverage of Habitation in ODF Verified Villages, NRDWP, Miscellaneous Reports, 2016-2017*
2. *Table HH-6, Household by Main Source of Drinking Water and Location, Census House and House-listing Data, 2011*

Data on the private companies involved in the water purification business in rural areas have been compiled from various company websites while the three National Water policies of 1987, 2002 and 2012 have been referred to for the textual references on provisions.

Methodology: The paper intends to carry out an exploratory research on the topic based on the secondary information available over online sources like individual company websites, blogs, newspaper articles and reports that help in listing out the major players in the water sector in rural areas and the market operations in general. Since, drinking water in India is a part of the broader sub-head of 'Water Supply and Sanitation', some of the major policy documents in this field have been critically reviewed in relation to the national and international developments in the water sector to understand the subtle nuances in policy language that have often fuelled considerable changes in terms of State schemes and programs. Maps have been prepared to show the spatial correlation between the bases of the private water players if any with coverage status in the rural areas of those districts.

The feminist analytical framework for defining the changing role of the State and the dialectical method are used as lenses to carry out the analysis to understand the deeper logic of capital sculpting out the structural changes in the concerned sector.

1. A LOOK BACK AT THE POLICY LANDSCAPE

A look back at the international and national milestones and policies in the water sector, illustrates before us the journey unfolded so far and how brilliantly the policy texts have paved the way for the unravelling of privatization and advent of water markets even in case of rural drinking water.

Phase 1. Before 1987 : The early laws of the land

In case of hydraulic civilizations such as India, water rights have been mostly understood in terms of riparian rights since ancient times. These rights were primarily customary rights over water resources enjoyed by the communities and subject to mutual settlements. At the domestic level, colonial legislation first focused explicitly on the regulation of water for economic reasons, commercial interests; for instance, through the development of legislation concerning irrigation and navigation (Cullet, 2007: 1). Otherwise water law in India closely associated with the land policies. India Easements Act of 1882 granted 'every landowner with the right to collect and dispose, within his own limits, all water under the land and on the surface'. As a consequence of this law, owner of a piece of land has been allowed to dig wells and extract water based on availability and his discretion without any legal liability for any damage caused to water resources as a result

of over-extraction. Interestingly, the focus on drinking water in India comes much later in the country, in the form of the Bhore Committee on hygiene which pointed out that causes behind the low status of health in India was primarily because (among other reasons), **totally inadequate provision of protected water supply and drainage, recommending the safe supply of water to cover 90% of India's population in a time frame of 40 years**, ie. by 1989 (Bhore Committee Report, 1946 : 11) In the absence of any comprehensive water law in the colonial phase, the state could only exert its explicit control in the post independence era, following the **declaration of water as a State subject** (Entry 17 of List II ie. State List, 7th Schedule) under Article 246 of the Indian Constitution in 1950. The Constitution also mandated through Article 47, conferring the duty to the State to provide safe drinking water in order to raise the standard of living in the country and improve public health conditions. Thus the focus on drinking water supply was more of a ramification of the alarming concern on 'hygiene' borne out of the escalating morbidity, mortality rates in the country. The post Independence era saw the translations of the then relevant nation building perspectives backed by Nehruvian socialist, nationalist ideals in the structure and design of welfare and development projects undertaken by the State (**National Rural Drinking Water Supply program of 1969, Accelerated Rural Drinking Water Supply Programme of 1972-73, Minimum Needs Programme** etc.)

Rationale behind the inception of NWP

The need for national water policies was raised in the **Mar del Plata Action Plan** (following the United Nations Water Conference, held in Mar del Plata, Argentina in March 14-25, 1977) which made sure, there is a commitment on behalf of the national governments to '*provide all people with water of safe quality and adequate quantity and basic sanitary facilities by 1990, according priority to the poor and less privileged and to water scarce areas*' while Part B of the recommendations for action, framed provisions for each country to establish '*goals for 1990 which match as far as possible the global targets*'.

During the 1960s and 1970s, international and national efforts focused on the achievement of coverage figures (Nicol, 2000) with a **strong footing on qualitative assessment of water meant for provision**, bringing to the fore, a comprehensive lens of viewing water supply issues along with sanitation facilities. Although, it was long back in 1954 that Water Supply and Sanitation were brought under the purview of the Central Public Health and Engineering Organization (CPHEO) of the Ministry of Works and Housing, Government of India, '**Rural Sanitation Programme**' in India had been receiving consistent attention ever since the formulation of the **Centrally Sponsored Rural Sanitation Programme (CRSP)** in 1986 and subsequent inclusion of Rural Sanitation in the **Minimum Needs programme (MNP)** in 1987. These were given a series of institutional backing through the setting up of a multi-donor partnership programme called Water and Sanitation Programme (WSP) launched by UNDP and World Bank in 1978, the WHO Guidelines on the Drinking Water Quality, 1983-'84, 1st Edition, nationally - the establishment of a separate Department of Drinking Water Supply in 1980 and **National Drinking Water Mission** in 1986 under the MoRD and most importantly, in compliance with the spirit imbibed by the proclamation of the **International Drinking Water Supply and Sanitation Decade between 1980-1991**⁵³⁷, during which '*member states would assume a commitment to bring about a substantial improvement in the standards and levels of services in drinking water supply and sanitation by the year 1990*'. This decade coincided with the 6th and 7th FYP (1980-'85, 1985-'90) in India and led to the formulation of a 'common set of technical guidelines for the rural drinking water sector, established nationally and applied across different state governments in the early 1970s' (Joshi, 2002). The nuances in language of technical guidelines (Joshi, 2004: 8), underpinned the state's increasing priorities towards **quality provisions than quantity concerns**. These were –

- **Complete coverage for all no-source problem villages and partially covered villages**
- **Water supply to be provided within the stipulated norms of 40 lpcd within a maximum distance of 1.6km or at an elevation of 100m in the hilly regions.**
- **Priority of safe water provision where the existing supply sources exhibit health- harming characteristics.**

1987 : Formulation of the National Water Policy

The National Water Policy (NWP) adopted in September 1987 recognised water as a '**basic human need; a precious national asset and one of the most crucial elements in development planning**' (1.1, 1.8, NWP, 1987), something that is repeatedly acknowledged in the national policy documents to follow. The stress on the need for an integrated and environmentally sound management approach in the planning, development and conservation of a '**scarce**' resource like water to cater to the increasing **demands** from rural society made the economic thinking behind it more evident. Interestingly, keeping a separate sub-section on '**water rates**', the policy called for the promotion of **conservation awareness** about the '**efficient utilisation**' of the '**scarce resource**' through '**education, regulation, incentives and disincentives**' and imposition of **water rates for surface and ground water, 'adequate to cover the annual maintenance and operation charges and a part of the fixed costs'** (although that should be '**rationalized with due regard to the interests of small and marginal farmers**') (11. Water Rates; 15. Conservation of Water; 21. Conclusion, NWP, 1987)

Phase 2. Between 1987 and the Revision of Policy in 2002

Pushing the slogan '**Some For All Rather Than More For Some**', the 1990 Global Consultation on safe Water and sanitation, New Delhi Statement preceded the ill famous Dublin Statement of 1992 and was significant for heralding the

⁵³⁷As per the General Assembly Resolution 34/191 of 18th December 1979 and Resolution 25, entitled International Drinking Water Supply and Sanitation Decade, 39th July 1980 adopted by World Conference of the United Nations Decade for Women: Equality, Development and Peace.

ideological battle regarding the role of the State as it provisioned the Government's roles to become that of **'promoters and facilitators'** reasserting the failures of the supply-led approaches of Government programmes of 1980s, as it highlighted the need for a focus on education, training, social mobilisation, **decentralisation of service delivery and community involvements**.

Changing Perspectives: Right to Water – recognition in India

Economic liberalisation marks the year 1991 as the milestone in India's economic history for the reforms initiated thereafter. But for the water sector in India, 1991 marked a different milestone altogether as the then existing legal framework concerning water got complemented by a human rights dimension with Supreme Court recognizing that, **right to life 'includes the right of enjoyment of pollution free water and air for full enjoyment of life'**, implied in Article 21 (right to life) as per *Subhash Kumar v. State of Bihar, 1991*. A watershed in the history of evolution of global water policies has been the **Dublin Statement on Water and Sustainable Development**, issued by the **International Conference on Water and the Environment** (IWCE, held in Dublin, Ireland on 26-31st January 1992) that created major fault lines in policy trajectories so far. Principles 1-3 recognised the **'vulnerability'** and **'finite'** nature of fresh water as a resource whose management requires a participatory approach involving *'users, planners, policy makers at all levels'*. However, these were far outweighed by the impact generated by its **fourth principle** acknowledging that **'water has an economic value in all its competing uses and should be recognized as an economic good'**. The argument put forward vouched for a clear cut deviation from the role assigned to the State so far, dictating a trade off for one's basic right - to have access to clean water and sanitation at an affordable price, for achieving efficient and equitable use, encouraging conservation and protection of water resources and the fact that **'past failure to recognize the economic value of water has led to wasteful and environmentally damaging uses of the resource'**. Winpenny (1994: 18) argued that this new approach to valuation would increase water supply coverage and **encourage private investment as 'low prices depress the profitability of investment in the water sector'**. World Bank and later the Washington Consensus encashed upon the economic valuation of the resource which was eventually to become the core of the emerging consensus and changing paradigm of viewing water (or other environmental resources per se) as an 'economic good', whereby State's role was expected to shrink with the advent of free-market capitalism, legitimising the commoditisation of resources and justifying scope for its privatisation (Finger and Allouche, 2002 ; Mehta, 2010). The Dublin Principle on water as an economic good, Phillip Cullet⁵³⁸ argues, has been the single most important change to water policy, leading to a **focus on demand management and increases in water use efficiency**, for such **economic connotations usually privilege certain types of meaning and beliefs** into cultural and public good aspects that makes it easier to defend the massive gap in access to water supply and sanitation that has persisted till today.

Millennium Declaration – Foundation stone for the future developments goals

Building upon the events like Earth Summit, 1992 (Rio de Janeiro), the First World Water Forum of 1997, followed by the Marrakech Declaration in 1997, 1999- Protocol on Water & Health, United Nations General Assembly adopted the [United Nations Millennium Declaration at the UN Millennium Summit \(Resolution A/res/55/2\)](#) in New York, 2000, which set out the future developmental pillars in the form of 8 [Millennium Development Goals \(MDGs\)](#). With respect to access to drinking water and sanitation, through the set target 7.C of the MDGs, States committed themselves to *"halving, by 2015, the proportion of people without sustainable access to safe drinking water"*, thereby laying the international policy and service level benchmark for the countries worldwide. By the Johannesburg Targets adopted at the 2002 World Summit on Sustainable Development, States committed themselves to the additional target of *"halving, by the year 2015, the proportion of people who do not have access to basic sanitation."* An important event in the global arena concerning water, took place in November 2002 -- with the adoption of the **General Comment No.15, on the 'Right to Water' by the Committee on Economic, Social and Cultural Rights (CESCR)**, presenting a continuum between the provisions formulated in human rights language and other provisions formulated in a regulatory language.

Article 1.1 stated that –

"The human right to water is indispensable for leading a life in human dignity; a prerequisite for the realisation of other human rights".

Comment No.15 also defined 'right to water' as the **right of everyone, to sufficient, safe, acceptable and physically accessible and affordable** water for personal and domestic uses.

Phase 3. Need for a Revision: NWP, 2002 and the period till 2012

A review of the 1987 policy was initiated with the publication of a revised National Water Policy-2002, which in line with the developments made at the larger international level *'underscored the need for the utmost efficiency in water utilisation and a public awareness of the importance of its conservation'*, given the inevitable increase in *'demands for water for diverse purposes'*, due to expansion of growth and economic activities in the period concerned, bearing the potential threat to make a scarce resource like water *'even scarcer in future'* (1.7, NWP,2002). Stress was also laid on the need to monitor quality of water, maintenance of water resources, specially the physical and financial sustainability of existing facilities, to bring about *improvements in existing technologies, innovation of new technology base* resting on science and technical training through a *'multi-sectoral, multi-disciplinary and participatory approach'*. Taking cue from the earlier version of

538Cullet, P. (2007). Water law in India: overview of existing framework and proposed reforms. Geneva: International Environmental Law Research Centre.

NWP, the World Bank recommendations of its 1998 review, the policy of 2002 extended the argument for '*a need to ensure that the **water charges for various uses should be fixed in such a way that they cover at least the operation and maintenance charges of providing the service initially and a part of the capital costs subsequently***' and as a **major digression from its welfare approach**, encouraged **wherever feasible, various combinations of 'private sector participation in planning, development and management of water resources projects'** promoting their potential in '*introducing innovative ideas, generating financial resources and introducing corporate management and improving service efficiency and accountability to users*'.(11. *Financial and Physical Sustainability*; 13. *Private Sector Participation, NWP, 2002*).

In various aspects, the 2002 policy reflected the provisions made by the 73rd and 74th Constitutional Amendment Act to **decentralise power** and pave way for **local governance** in rural and urban areas by **involving Water Users' Associations, local bodies such as municipalities and gram panchayats** (12. *Participatory Approach to Water Resources Management, NWP, 2002*). But the exposition of utmost importance, carrying the impressions of the predominant shift in policy legacy during that phase, is interpreted from clause 22, stating '*there is an **urgent need of paradigm shift in the emphasis in the management of water resources sector; from the present emphasis on the creation and expansion of water resources infrastructures for diverse uses, to the need to give greater emphasis on the improvement of the performance of the existing water resources facilities***' and the 'optimal, economical and equitable use' of the resource, bearing its implications on the changing priorities of allocation of funds and in outlining the guidelines to improve the performance of this sector. To conclude, the policy mandates the **formulation of a State Water Policy**, backed with an operational action plan within two years, also sanctioning provisions for the periodic revision of National Water Policy '*as and when need arises*'.

The Swajal project of 1996, **piloted by World Bank in UP as a Sector Reform Programme in 67 districts across 26 states** was scaled to the **Swajaldhara Programme, initiated on 25th December, 2002**, that emphasized the need for taking up of community based rural water supply programs and initiate reform initiatives in rural drinking water sector, upholding the principles of '**decentralisation and participation**' as mandated by the 73rd Constitutional Amendment Act, reflecting the market ideals as promoted by the World Bank. The Swajaldhara guidelines also suggested that water users have to take up partial responsibility for the capital cost of new drinking water infrastructure and full responsibility for operation and maintenance, **reinforcing the notion that water is an economic good and that all water services must be based on the principle of (full) cost-recovery**. This was a **demand-driven**, integrated approach to rural water supply and sanitation requiring partial (10%) capital cost recovery and 100% O&M financing by users. The guidelines meant to foster a **change in the role of the government from direct service delivery to that of facilitating activities**, largely undertaken by people themselves, proposing the **progressive withdrawal of the state** from the provision of the fundamental right to drinking water.

The stress on water quality, the emphasis on the need to provide 'safe drinking water' through technology based water treatment plants and the projection of water-related services as determined by economic principles continued at the international front with the **Bonn Charter for Safe Drinking Water, framed by the International Water Association in September 2004**, assigning the goal to provide '*good, safe water which has the trust of consumers*', the publication of the **WHO Revised Guidelines for Drinking Water Quality, 3rd Edition** revising its earlier guidelines to focus on the prevention of microbial and chemical contamination of drinking water supplies through the **use of a comprehensive risk assessment and risk management approach that encompasses all steps in water supply from catchment to consumers, called Water safety plans (WSPs)**.

'Water for life' Decade

With a goal to promote efforts to fulfil 'long term sustainable international commitments' (Millennium Declaration, the Johannesburg Plan of Implementation of the World Summit for Sustainable Development and Agenda 21) made on water and water-related issues, 'in terms of both quantity and quality and measures to improve sanitation', by 2015, the United Nations General Assembly in December 2003, proclaimed as per the General Assembly [Resolution A/RES/58/217](#), the period 2005-2015 as the '**International Decade for Action 'Water for Life'**⁵³⁹. The decade also saw the recognition of the '**right to clean water services**' the UN General Assembly Resolution (Resolution 64/292) on the '**Right to Water and Sanitation**' on July 28th, 2010 explicitly recognising the '**human right to water and sanitation**', acknowledging that '**clean drinking water and sanitation are essential for the realisation of all other human rights**' -- all of which provided the legal basis of rights through the decadal developments of right to water and sanitation in the field of international human rights and humanitarian law.

In the Indian context, the decade witnessed the launching of the **National Rural Drinking Water Quality Monitoring and Surveillance Programme** in February 2006, envisaging institutionalisation of community participation for monitoring and surveillance of drinking water sources at the grassroots level by Gram Panchayats and Village Water and Sanitation Committees, followed by checking the positively tested samples at the district and state level laboratories; followed by the upgradation of the former ARWSP to NRDWP (National Rural Drinking Water Program that brought under it all rural submissions. In 2010, Department of Drinking water and Sanitation was set up and the NRDWP operationalised as per the Strategic Plan 2010-2022, ensuring that '*all citizens living in rural areas have access to safe,*

⁵³⁹Resolution adopted by the General Assembly on 23rd Dec 2003, Fifty-Eighth session, Agenda Item-95, [on the report of the Second Committee (A/58/485)] 58/217. International Decade for Action, "Water for Life", 2005-2015

clean water for drinking, cooking, and other domestic needs with the intention of eventually providing piped water to every rural household.'

Phase 4. National Water Policy 2012 and beyond

On June 7, 2012, the Ministry of Water Resources published its Draft National Water Policy 2012 (NWP) seeking to address issues such as the scarcity of water, inequities in its distribution and the lack of a unified perspective in planning, management and use of water resources which was adopted by the National Water Resources Council on August 9, 2012.

The Preamble to the policy and its draft, brought to fore the '**low public consciousness about the overall scarcity and economic value of water results in its wastage and inefficient use**', asserting that the '*objective of the National Water Policy is to take cognizance of the existing situation, to propose a framework for creation of a system of laws and institutions and for a plan of action with a unified national perspective*'. It pointed out that the '**principle of equity and social justice must inform use and allocation of water**' which needs to be managed as a '**common pool community resource held, by the state, under public trust doctrine to achieve food security, support livelihood, and ensure equitable and sustainable development for all**' - clauses that draw the background behind the provisions outlined by the Acts of 2013 and 2016.

National Water Law and Draft national Water Framework Bill, 2013, GOI, MoWR

In the spirit of the precedence set by the European Water Framework Directive of 2000, the South African National Water Act of 1998 and so on, this law incorporates all major legal pronouncements by the Supreme Court with reference to water such as the **Public Trust Doctrine** and the recognition of the **right to water, the principle of subsidiarity** as explicated in the 73rd and 74th Constitutional amendments. Formally defined to be a '*bill based on the emphasis laid by the National Water Policy (2012), adopted by the National Water Resources Council on the need to evolve a National Framework Law it recognizes water as a limited natural resource that has to be protected and preserved for generations*' through '*continuous and cohesive action*', translating into the Act of 2013. It unambiguously lists down the definitions pertaining to water resources sector including terms that are often come across in water resources management literature and specifically in the national water policy documents like -'common pool resources', 'community-based institutions', 'corporatisation', 'livelihood', 'pre-emptive needs', 'participatory management', 'principle of differential pricing', 'privatisation', 'public trust' etc. [2. Definitions.(iv), (v), (vi), (xiii), (xviii), (xix), (xxii), (xxiii), (xxiv), Draft National Water framework Bill, 2013].

Interestingly, on one hand it identifies water as a '**common pool resource of the community and shall be managed, protected and preserved as such by community based institutions**', held by the state as a trustee for the benefit of all '**in public trust for the people**', obliging it to '*protect water resources*' and affirming that this responsibility to the state as public trustee '**shall remain even if some of the functions of the state in relation to water are entrusted to any public or private agency**' [Clauses (4),(5), Chapter II, Basic Principles for Water Management]. On the other, the Act prioritises allocation of water for the drinking water and sanitation, food security, as livelihood-support for the poor, exempting it from the '*principle of differential pricing*' while making sure that for other uses, '*water shall increasingly be subjected to allocation and pricing on economic principles to ensure its development costs, efficient use and reward conservation*' with prior '*consultation with all stakeholders*', through '*independent statutory Water Regulatory Authority, set up by each State*' [Clause(6), Chapter II, Basic Principles for Water Management].

Legitimising the basic rights to water, the Act avers that '*every individual has a right to a minimum quantity of potable water for essential health and hygiene and within easy reach of the household*' which '*shall not be less than 25 litres per capita per day*', complying with the quality standards set by the Government and '**despite corporatisation or privatisation of water services shall remain the State's responsibility to ensure the people's right to water**'. [Clause 4.(1) and (3), Right to Water, Chapter III, Rights to Water, Preservation of Water Quality and Water Pricing, Draft National Water Framework bill, 2013]. The concept of determination of water charges on a '**volumetric basis, reviewed periodically to meet equity, efficiency and economic principles**' based on the '*principle of differential pricing*', compulsion to '*ensure conformance to the Service Level Benchmarks for water supply, sanitation and the practice of regular water audits to sensitize communities for reduction of nonrevenue water*' are also notified in the Act. [Clause (6). Water Pricing,; Clause 13.(1),(2 and (3), Urban Water Management, Chapter III, Rights to Water, Preservation of Water Quality and Water Pricing, Draft National Water Framework bill, 2013].

Draft National Water Framework Bill, 2016

A revision to the earlier 2013 Act, the National Water Framework Act, 2016 adds on to the previous set of directives of 2013, new definitions like 'full cost recovery pricing', 'water footprint', 'water for life' [2. Definitions.(i), (z).(aa), Chapter I. Preliminary, Draft National Water framework Bill, 2016] and the terms of pricing whereby '*water as a part of water for life as defined herein, shall not be denied to anyone on the ground of inability to pay*' [Clause 22.1.(a) Water Pricing and Water Regulators Chapter V. Planning for Water Security, Draft National Water framework Bill, 2016]. Acknowledging its commitment to the United Nations Sustainable Development Goals to be attained by 2030, it conceives the '**Right to Water for Life**' for every person, regardless of, among others, caste, creed, religion, community, class, gender, age, disability, economic status, land ownership and place of residence complying with the standards set by '*The Manual of the Central Public Health and Environmental Engineering Organization, Bureau of Indian Standards specifications or standards adopted by the appropriate government as modified or revised from time to time*' [3. Right to Water for Life, Clause.3.(1), (2). Chapter I. Preliminary, Draft National Water framework Bill, 2016]. Insisting for the **convergence of all**

water sector schemes (14,), it advocates for the preparation of '**Water Security Plans**' at the '*lowest possible administrative level*' that would be '*valid for a period of five years*'. [Clause 14, Chapter III Basic Principles, Clause.15, (2), Chapter V : Planning for Water Security, Draft National Water framework Bill, 2016] and the '**conservation, protection, regulation and management**' of groundwater as per the '**Model Bill for the Conservation, Protection, Regulation and Management of Groundwater, 2016**' [Clause 18, Chapter V : Planning for Water Security, Draft National Water framework Bill, 2016].

2015 marked the initiation of the era of sustainable development as per the UN Agenda for Sustainable Development (2016-2030) held on 25th September 2015, listing out 17 goals to be achieved by 2030. Goal 6 of the 17 SDGs stated that by 2030, universal and equitable access to safe and affordable drinking water for all needs to be achieved. The SDGs, together with the provisions of Paris Climate Change Conference have led to the UN Water GLAAS, 2017 (Global Assessment of Sanitation and Drinking Water) and the UN General Assembly Resolution for the **Proclamation of International Decade for Action, "Water for Sustainable Development (2018-2028)"**, promising further developments in the water sector.

2. CRITICAL POLICY REVIEW: CHANGING ROLE OF THE STATE AND A FEMINIST ANALYTICAL FRAMEWORK

Besides stage-crafting 'water' as an economic good, water reforms through policy reversals have implied an important shift in terms of the rights of control over and access to water, recasting the perspectives of looking at water from a public trust thing to the introduction of water rights and the possibility to trade water entitlements. The novelty introduced by the reforms is that water rights are now created in favour of water users (Cullet, 2007:7) expediting the trading process of the entitlements. Endorsements for decentralisation in decision-making to the lowest level and participation of 'all stakeholders' have been based on the crafted as well as perceived inability of the state to deliver appropriate services, thus proclaiming the role of the state from that of a 'service provider' to that of a 'regulator'. The other attributes added on to water through such characterisation is that its services should be based on the principle of (full) cost-recovery, making water users pay at least for the operation and maintenance charges linked to the 'supply' of water - seen by the Asian Development Bank as the first instrument for conserving water ⁵⁴⁰. Tracing back the role of the state in this entire policy spectrum, it is seen that in the initial years after independence, the state was a dominant entity in rendering the social sector services to the people. Skocpol calls this 'explanatory centrality of the states as potent and autonomous organisational actors', whereby 'impulses shaping the major policies and actions within the state' were thought to be outcomes of what Miliband calls the state's conception of national interest, as a trustee of nation's normative aspirations. Sudipta Kaviraj describes this phase as the ideational revolution within the Indian State that carried with it significant transformatory potential (Kaviraj, 1997) but this was soon punctuated by exogenous shocks in the global water arena, that were harbingers of massive changes to follow. The critical juncture brought about substantial changes in policy ideas within the Indian State conforming to the then significant prescriptions of deregulation and globalisation in the liberalisation phase. The Eighth Five-Year Plan period thus forced the State to admit that 'under-performance of the rural water supply sector is likely to continue unless there is a fundamental reform of the service arrangements' and an explicit warning that the State will not be able to provide necessary expansion of services to a growing population' (GoI, 1997). In the same spirit, Swajaldhara guidelines were announced in December 2002 as 'non-negotiable reform principles, which supersede all earlier guidelines' (GoI, 2003) only to arrive at the Eleventh Plan (2007-2012) where despite acknowledging the basic right to water, approach to pricing water was further highlighted. The emphasis now was on flexible cost sharing arrangements between the Centre, State, and Local Governments, Markets and User Communities. In the years to follow, the Governments at the Centre have taken up the projects like JNNURM, Swachh Bharat Mission that have created backdoor favouring of corporate entities to run business encashing on the country-wide reforms drive. Be it the coalition or right at the Centre, the State slowly has got into the role, similar to Poulantzas's Neo-Marxian view of defining the State as a 'relatively autonomous entity', enjoying its autonomy from the dominant economic class even though it acts on behalf of it, safeguarding its interests.

Table elaborating the changing role of the state by contrasting the policy features of the supply driven approach and the demand- driven approach.

⁵⁴⁰ Section 37 and Section E, Asian Development Bank, Water for All – The Water Policy of the Asian Development Bank (2003).

Criteria	Supply-driven approach	Sector Reform Programme
Central role	Government	People/users/clients
Goal	Coverage	Process, Demand-based
Basis for service	Water a welfare good to be provided free of cost	Water a social and economic good demonstrated by willingness to pay
Role of government	Provider	Promoter
Role for people	Recipient	Manager
Role for women	Low	High
Actors	State monopoly	Users, Panchayats, NGO, state and private sector
Partnership scope	Low	High
Capital contribution	100% Government (50/50 state and Gol)	10% community contribution
O&M	State	Users
Level of management	State	Users – habitation level
Dependence on government	High	Low
Source protection	No clauses	Integral part of programme
Political patronage	High, provides for free riders	Relatively low, because users have to pay
Incentive for officials	High because of their role in decision-making, control of finances	Disincentive, power taken away by users

Feminist analytical Framework

To critically assess the policy trajectory so far, it is essential to not only pinpoint the market dimensions attached to it, but also how the aspects of equity, social justice have been dealt in the policy language. A feminist analysis of water security places politics and power at the centre of its framework, entailing a more 'refined analysis of questions of water allocation and distribution' plus also 'dismantling the conceptual abstractions that reify and reproduce boundaries and binaries such as those between the natural and the human or between the private and the public', accruing to strong linkages between 'local' water struggles to larger historical and economic trends and forces'(Ahlers&Zwarteveen, 2009: 418) ⁵⁴¹.

In the context of empowerment of the backward sections, the changing relational equations under the reforms project, focuses solely on its material underpinning rather than truly building their bargaining power for in its very theoretical essence, the neo-liberal water domain treats all actors as equal or compels them to be treated as equal; rubbing off their differences and setting the rules of the water game they follow, same to everyone.

Strangely, the neoliberal demand-led projects seem to focus more on 'engaging women' compared to their welfare-based supply-driven counterparts primarily on basis of the argument of efficiency. But what they eventually end up doing in its course is portraying them as 'tokens and showpieces' as an attempt to 'mainstream' gender issues in the framework of social sector programmes pivoting on the presumption that prior to this women were not key actors in the development process (Ramachandran, 1998:49 ⁵⁴², Vina Mazumdar⁵⁴³). Assigning roles to women in project implementation, their representation in community decision making platforms like Village Water & Sanitation Committees, as agents in campaigning about the health and hygiene concerns as well as their participation in income generation activities, the opportunity cost of which is the time spent to fetch water – sum up few of the project norms that 'water sector professionals claim to result not only in positive service outcomes but also in positive gender outcomes' (Dayal et. al., 2000 ⁵⁴⁴). This clearly reflects the recent efforts to make development policies more gender aware, essentially based on two types of considerations – one being the integrationist tactics 'to shift the basis of claims on behalf of women, from earlier emphasis on need - to an emphasis on merit' and the other - transformative or agenda setting, more politically ambitious strategies that promise to go beyond the 'trend of just seeking to integrate gender issues into the development agenda, broaden its goals to enable it to address issues of social justice' (Cleaver & Elson, 1995 ⁵⁴⁵; Jahan, 1995 ⁵⁴⁶; Jaquette, 1990 ⁵⁴⁷). 'Inclusion' or 'integration' in formal decision-making bodies and in markets is presumed to be gainful given that it acts as a sort of a 'equalizer' from the developmental perspective on one hand and on the other, supposedly enhances the performance of water institutions. However, these equalizing measures fail to mention about the inequity by caste or the social, cultural and historical dimensions of gendered inequities rooted in 'gendered divisions of labour and in gendered kinship and inheritance structures', by unreservedly denying the policy-level 'need to change the culture

of the water institutions and only a cyclic shift of drinking water responsibilities from the community to the state' (Joshi, 2011: 62⁵⁴⁸). So, the policy reforms on caste and gender in India's drinking water sector have been little other than rhetorical changes in policy on paper.

What comes up as a stronger critique to this routine integrationist inclusion is regarding the approach of misinterpreting the theory of gender, and thus identifying 'gender' as a 'homogenised social category- called women', isolating them from the context of social relations (Baden and Goetz, 1998 ;Kabeer and Subrahmanian, 1999⁵⁴⁹). Moreover the casual and liberal use of the terms 'empowerment' and 'participation' in water policy guidelines makes it lose its deep rooted relevance in the context of development and their inherent political connotations. As discussed by Deepa Joshi, the practice of eulogizing the term empowerment, making it equivalent to the meaning – 'to enable a sharing of power' erases out the innate notion of power that the term as a theoretical concept essentially bears for in its truest sense, it expresses the interests of those - long distanced from power and authority, to challenge and define the agenda for development on the basis of their own priorities and interests (Kabeer, 1994⁵⁵⁰). Similarly, 'participation', due to its lackadaisical usage in policy papers becomes a mere synonym for the term 'integration'. This calls for the critical examination of the success of the development projects in mainstreaming gender, caste issues and bringing about the much hyped 'empowerment' of the concerned disadvantaged groups.

Why to use this framework ?

Although there is no single correct framework for 'doing gender' in the most comprehensive way possible, in the policy domain, in relation to the water sector - it is important for the feminist framework to 'explicitly situate its analysis in the structural transformation currently taking place, embedding gender dynamics in the world historical process of privatisation' (Ahlers&Zwarteveen, 2009: 419). The idea is to come up with a different 'window on reality', recognise the multi-layeredness of the entitlements, the cultural and social embeddedness in the discourse of understanding water ownership and security because their relational nature enables them to serve as political and economic vehicles to exploit the hidden power relations. Gender sensitisation instead of being treated as an add-on, has to be premised on the notion of social justice, rather than on a search for formal equality of opportunity, making it integral and central to the programme at its conceptual, design, implementation and monitoring levels (Ramachandran, 1998: 51).The framework raises subtle questions like what has been the underlying causes of gaps in the gendered outcomes in the water sector and whether the welfare oriented policy provisions or the market driven service delivery programs have the skill to weave a gender -just perspective in their approaches. Given the very fluid characteristics of water as a resource, the right over water creates a fuzziness in terms of delineating rights over it. Carrying with it an economic as well as social agency, the right over water envisages not only the right over the resource but right over its distribution, granting a certain authority to the right holders, tagging along other social privileges or obligations linked to it and hence redefining the 'question about access to a resource, not merely its control but the difference it makes to the shifting socio-economic inequalities' (Kabeer, 1999: 45)⁵⁵¹.

3. ANALYSIS

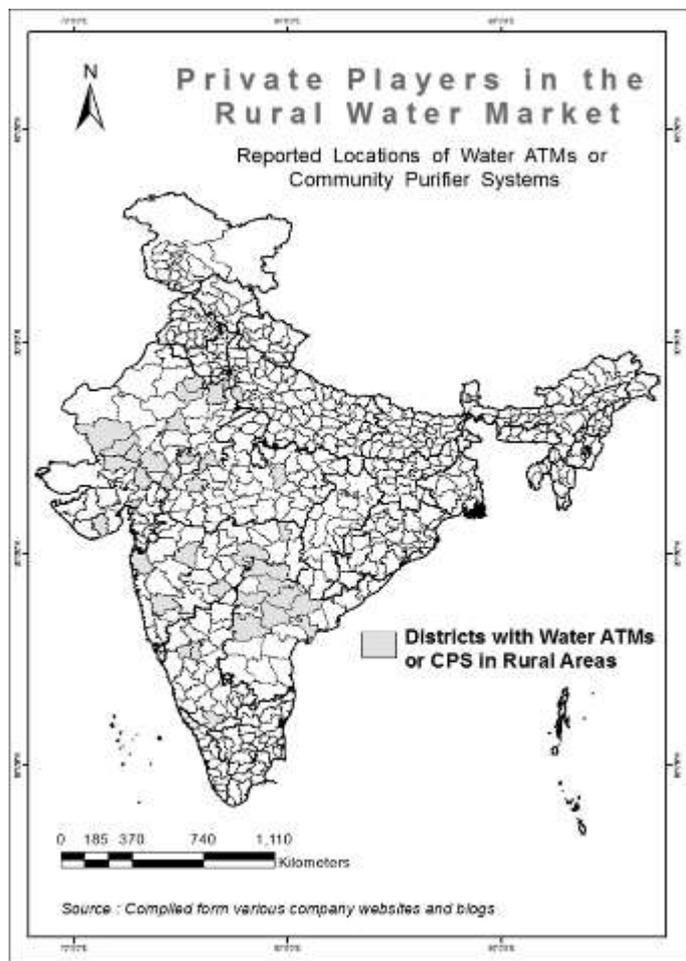

The concept of Water-ATMs - a market based solution packaged in the name of social entrepreneurship is not something new to India and in fact has gained pretty much of popularity and public support over the years, in the pretext of inadequacy of State arrangements to ensure safe water access to all. Given the rising informality in the form of tankers, the proliferation of the local packaged water businesses, these technology based, low-cost water vending machines automatically earn an edge over the other alternate arrangements on grounds of its assured provision of drinking water as per WHO conformed quality standards and the fact that via cloud technology it apparently promises the constant monitoring of quality and operations of the purification system within. Besides, many corporate organisations have sought to install community purification systems in rural areas in India in partnership with local governing bodies or charitable organisations These systems run on a nominal pay- per-use mechanism as preached by donor organisations like ADB, World Bank, IMF accepting coins or prepaid RFID cards to access water from these water stations.

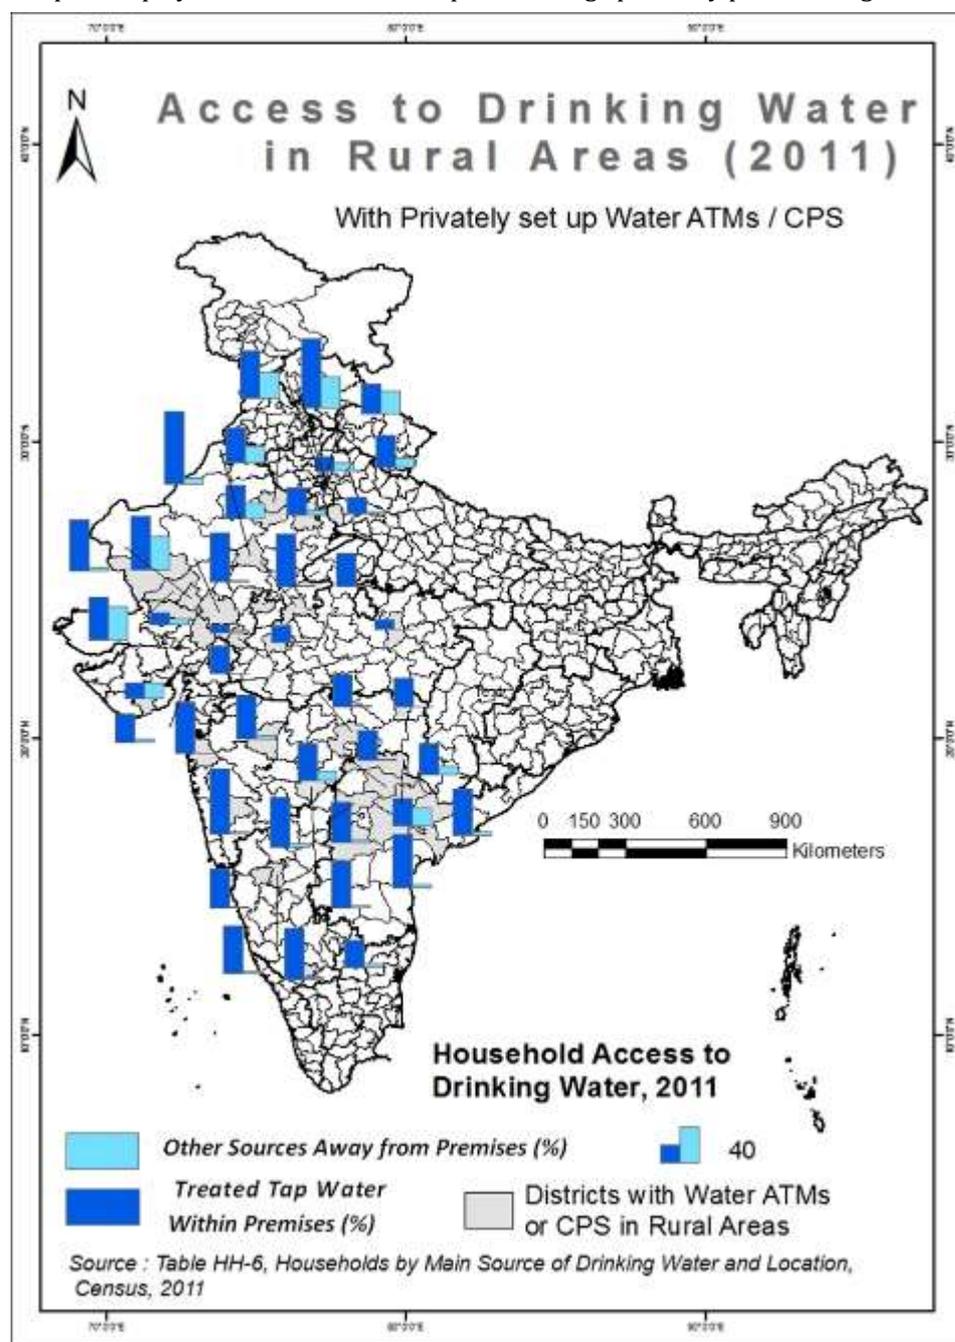

Map 1. Districts reported to have Water ATMs or Community Purifier Systems, installed by renowned or large corporate bodies in rural areas in India.

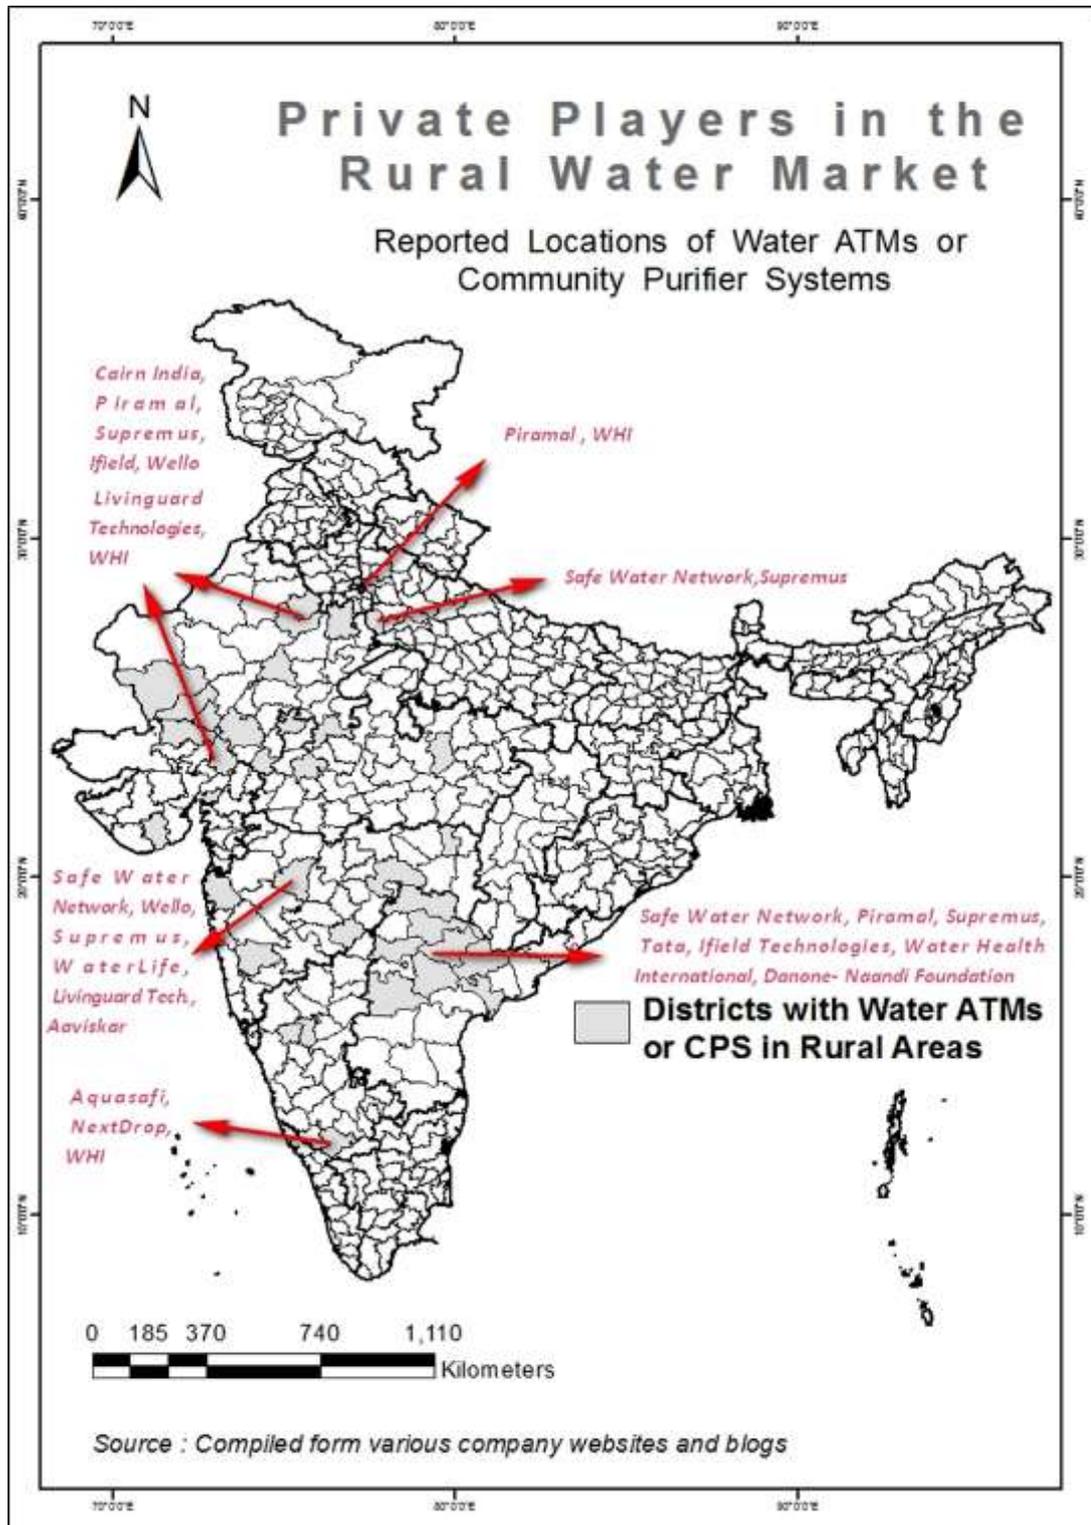

Source : Format H4 (A) RWS coverage of Habitation in ODF Verified Villages, NRDWP, Miscellaneous Reports, 2016-2017

Map 2. (left), shows us the Rural Water Supply Status in case of ODF Declared Villages under the SBM (Gramin) Yojana in 2016.

The Swachh Bharat Mission- Gol's flagship program since 2014 on water and sanitation, formed on the structures of the Nirmal Bharat Abhiyan promised to improve the coverage status in rural areas in terms of both access to safe water and sanitation facilities. In this map, at the state aggregate level, the states of Haryana, Gujarat, Tamil Nadu, Himachal Pradesh, Jammu and Kashmir show very high coverage status compared to the states of Rajasthan, Madhya Pradesh, Uttar Pradesh, Karnataka etc. This however fails to provide the real situation prevalent in the smaller units of districts and how access issues have come up within better performing states also. The map in the next page (Map no.3), essentially shows the district wise access to drinking water among the rural households considering both formal and informal sources of treated tap water within premises as well as informal sources like tankers or any other informal arrangement of household water delivery. These districts are specifically the ones where private players are found to operate their ATMs or CPSs. Interestingly what comes out from this is the fact that these specified districts despite having considerable access to treated tap water sources within premises are fairly dependent on the other sources which constitute the Non-State supply mechanisms including these supplementary water provisioning arrangements in the form of ATMs or Community Purifiers. The district wise household dependence is found to exist on these secondary sources of drinking water despite fulfilling the coverage criteria of 'access to treated tap water' among the rural households. This implies that the quality of water even after State treated mechanisms fail to match with the standards delivered after private treatment processes as available through ATMs or water purifiers. Moreover, the assured supply from these walk-in water vending systems guarantees access more than the irregular piped water supply as provided by the State, making it conducive enough for the private players to work from their profit vantage points by proliferating their market bases in the rural areas.

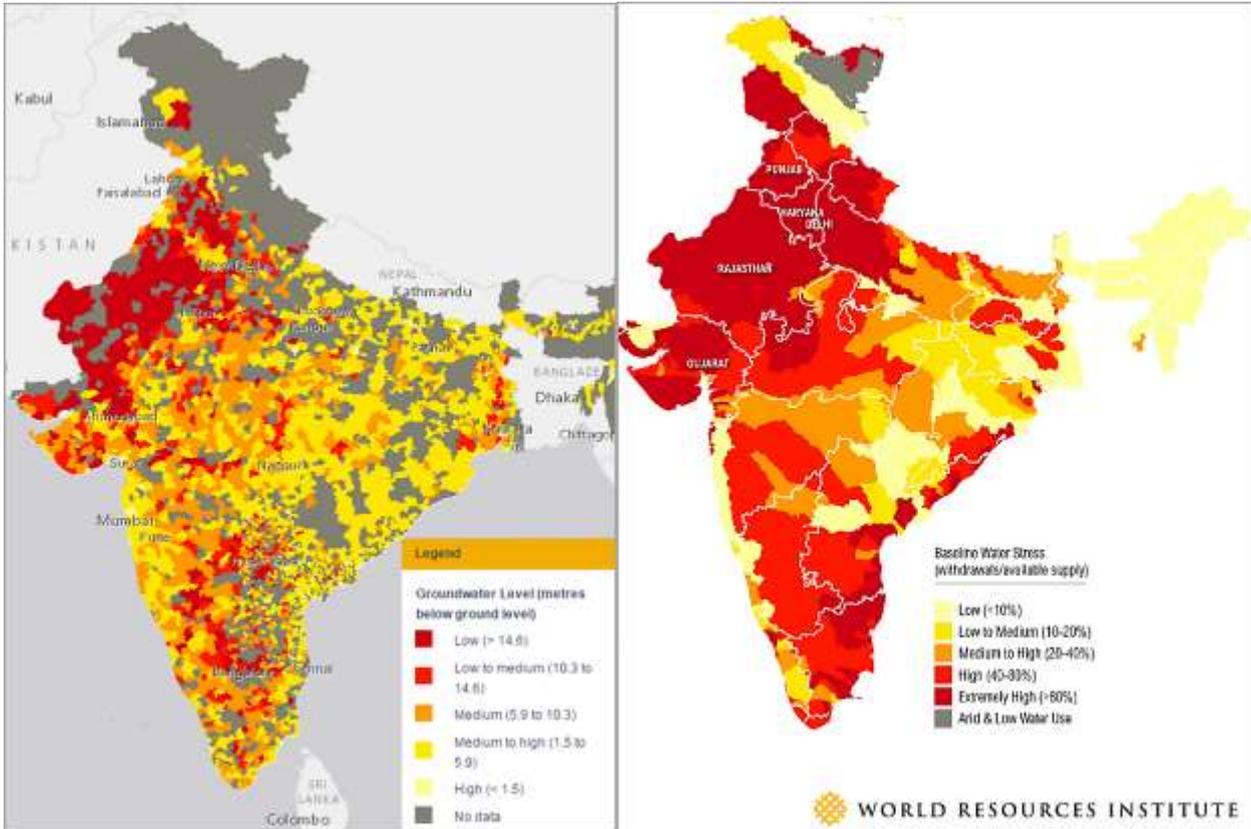

Map 3. Rural household Access to Drinking Water (in terms of treated tap water within premises and dependence on 'other sources' far from premises - in the districts shown before

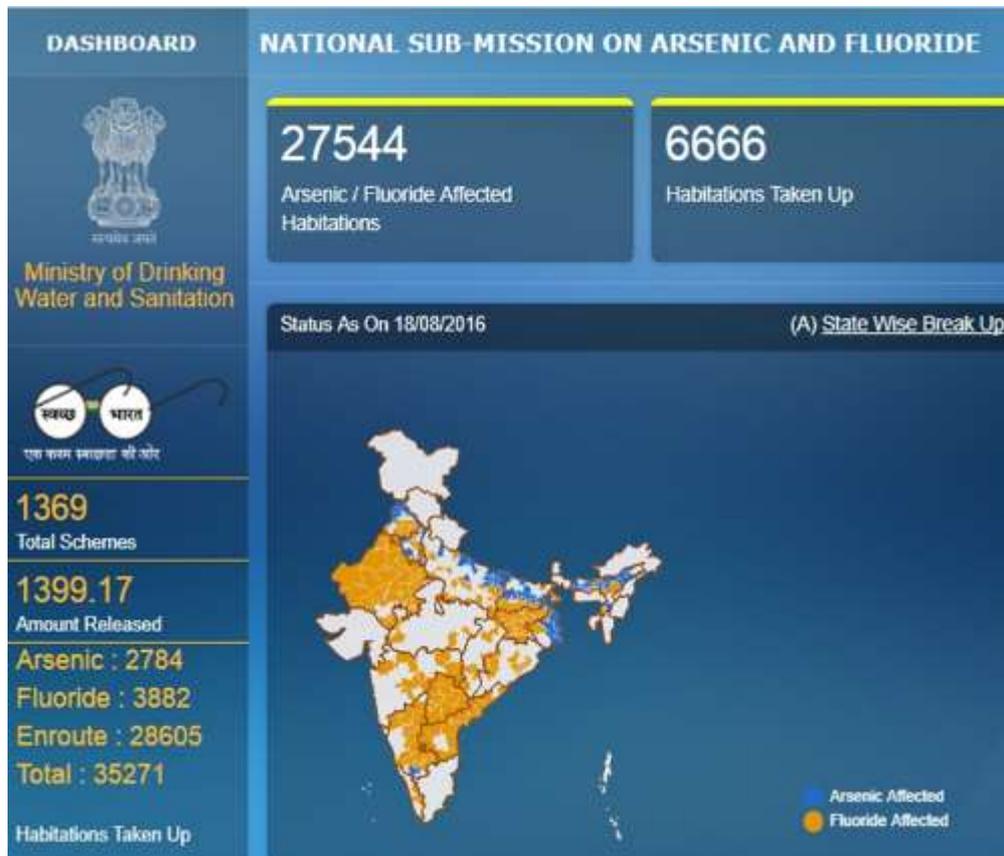

Map 4.

Now, if the same map is reviewed showcasing the distribution of the big corporate players in the rural drinking water market in these districts, there emerges interesting patterns and trends.

Source: Screenshot taken from www.indiawatertool.in

Map 5& Map6 : (left) Occurrence of Ground Water Levels below the ground (m) across India and the baseline Water stressed areas.

Source: Screenshot from www.indiawater.gov.in/submissiondashboard/dashboard.aspx

Encasing on the scarcity and quality issues

The map 5 shows the water stressed areas across India (measured as a ratio of amount of withdrawals to available supply in %) as given by WRI which shows that districts covering Western Rajasthan, North Western Gujarat , Western U.P, Marathwada, Vidarbha regions and parts of Andhra Pradesh and Telangana show high to extremely high water stress conditions which overlap with the districts under discussion. Moreover, the National Sub Mission on Water Quality offers

a map (Map 6) of habitations across India with Fluoride content greater than the permissible limits. These two correspond to the areas where the private players have emerged.

Some of the big names in the Indian industrial and commercial circle can be found to having an involvement in the profit-making efforts, in short making business through backdoor. Depending upon the rural demands and specificities of rural markets, the players have virtually customised their products and reduced the price to very low levels in order to cater to the rural customers. These include both home based solutions and community water solutions set up through partnerships and sponsorship of microfinance groups and NGOs. Interestingly, the state of the role is implicit in such models whereby the state ‘facilitates’ the access to land, water and electricity to the private water purification companies and the user charges come up as revenue in return. Also, in tune with the provisions of the National Water Policy, these business models ensure ‘community participation and engagement’ in the operations and maintenance of the systems.

Table 1 .Rural Water Supply Coverage in 'Open Defecation Free' declared Villages

State	Number of Habitations in ODF Declared Villages	Number of Fully covered Habitations with PWS	% of Fully Covered Habitations with PWS in ODF villages
HARYANA	7619	7147	93.80
TAMIL NADU	5743	5317	92.58
GUJARAT	35162	31372	89.22

The highlighted rows in the table refer to those states having the districts where these water players have reported to be operating their water ATMs or CPS in rural areas.

Home based solutions - water filters

In addition to these community based solutions, the companies have also found the opportunity lucrative enough to encash on this narrative of ‘safe drinking water consumption’ to penetrate the rural markets with their home based solutions in the form of low-priced water filters which are often non electric in nature and come with a decent amount of storage facilities.

Table 2: Major Market players for sale of Non-Electric Storage Filters customised for rural households with low purchasing power and lack of electricity facilities.

Brand Name/ Price	Mother Group	Corporate	Technology Used
Aquasure (rural specific brand) Rs. 1499 to 20,999/-	Eureka Group	Forbes; Shapoorji-Pallonji Group	Particulate, sediment filter, carbon block, UV,UF,RO Technology replaceable cartridge ‘Aquasure Amrit with Kitanu Magnet’ at 449/-
Pureit Rs. 2000/- (variants : 1200/- to 16000/-)	Hindustan Limited	Unilever	Chlorine discharger kit replaceable after 1500L at 365/-
Swach&Swach Smart (Rs. 999 & 749/- introductory prices, now 1349 to 3200/-) Takes off from Sujal	Tata	(Tata Chemicals, TCS, Titan Industries)	Silver Nano technology, Rice husk ash; replaceable cartridge with 3000L shelf life costs 299/-
Sujal (2000-2003) piloted among NGOs, Distributed in Tsunami affected rural districts of South India, 2004	Tata		Basic water filter
Other players include: Voltas Water Solutions, Kent UF Gravity water filters (Kent RO Systems Limited, Ion exchange India Ltd - ‘Srijal Purifier’ with Zero-B resin technology.			

Tables 3 and 4 in the following pages list out the details of some of the biggest names in the rural drinking water sector with their brand specifications and business models. A highly competitive market is mushrooming out there harnessing on this purification business. Combining modern technology with marketing strategies to promote their brands and building up 'water entrepreneurship' initiatives among the rural communities, these players have carved out a niche of their own leveraging on the scarcity and quality issues and paving the way for increased privatisation of the rural drinking water sector.

Mother group	Water ATM /CPS Brand Name	Districts	Technology	Funders/Sponsors	Partnerships	Business Model
Safe Water Network (SWN)	'iJAL Stations'; Rs 5 per 20 litres	Bhandara (Maharashtra), Karimnagar, Adilabad, Warangal Rural, Warangal Urban, Jayashankar, Mahabubabad, Jagtiyal, Peddapalli, Badradri, Mancherial, Suryapet, Khammam, Nalgonda, Medak (Telangana), Gautam Buddha Nagar , Mathura (U.P).	solar energy operated, 6 step water treatment process, RO,UV,UF technology used, access via prepaid RFID cards	Funders: BHEL, CISCO foundation,Honey wellIndia,MacquarieGroup,Merck Foundation, NABARD, Oracle , Pentair Foundation, Paul Newman's Own foundation, PepsiCo Foundation, Sir Ratan Tata Trust, USAID ; Solution partners - Accenture, IBM, IMRB , Tata Strategic Management Group,	with local governments and microfinance/NG Os	---

Piramal Piramal Healthcare Group	'Sarvajal'	Jhunjhunu initially. Now over 16 states	kiosks with UV, RO filtration systems; Sarvajal 'Soochak' - remote monitoring tool for real time monitoring of purity of product water, machine functionality and water output	Funders - Mercedes Benz, Adani, Cairn, DLF, Pratham, Lupin, Nestle, Michael and Susan Dell foundation, L&T Construction, HSBC, DJB, Honda	with local governments and microfinance/NG Os	social Entrepreneurship - Franchise Model/PPP/ Purchase Model
Supremus Group	Janajal -ATMs and 'Water on Wheels'-WOW-initiative ((500 litre tanks on e-rickshaws)	districts not specified but in areas of - Ghaziabad, Maharashtra, Gujarat, Andhra, Telangana, UP, Parts of NE	Areas where TDS < 500 PPM, Janajal relies on eco-friendly, low pressure, UF technology, patented for membrane design - 'SupremusAquaw ater Treatment System'. Payment via prepaid and digital wallets - BHIM app,Bharat QR Code, any UPI interface	---	with local governments and microfinance/NG Os	Cost of installing ATM - 8 lakhs, Franchise Model/PPP/ Purchase Model; keeps a profit margin of 20% at EDITDA level, after taxes 10% margin.

Mother group	Water ATM /CPS Brand Name	Districts	Technology	Funders/Sponsors	Partnerships	Business Model
Eureka Forbes	Aquasure Purifier/'Aquaguard Water	not specified but covers many of	many variants - UV, RO, UF	----	---	Forbes provide hardware,

	Shops' / Community centres ; 10-15p/litre	the Eastern and Western States	technologies			Panchayat - land, state- access to water. Business model : Govt. Subsidises plant cost, companies recover operational expenditure by running plants and selling water, promotes 'water entrepreneurship'
Naandi Community Water services Ltd	---	Bomminampadu Village, Krishna District of Andhra Pradesh	---	Danone Foundation and Water Health International		'social contract drinking water provision formula'
Aquakraft Projects Pvt. Ltd	AQUATM; Re1/ litre, cold drinking water -Rs 1.50/litre	some districts of Maharashtra, Karnataka, Rajasthan	green technology, unlike reverse osmosis, no wastage, 100% treatment of water, connected to a borewell or any other source of water, vends upto 5000l of water per day, card based prepaid system issued to customers	---	technological partnership with US based Aqueous Solutions LLC	local level engagement, SHGs managed by women, social Entrepreneurship Model - Franchise Model/PPP/ Purchase Model, Capital
Livinguard Technologies Pvt.Ltd	Livinguard Gravity filter; 1-6p/litre for community systems	some districts of Maharashtra, Gujarat	uses treated for microbial treatment, proprietary textile coating technology 100litres of water per hour	developed by Sanjeev swamy, as a 100% subsidiary of the Switzerland based investment firm Green Impact Holdings	NGOs like Swades foundation, Maharashtra, Jamnabaitrust , Gujarat , PHC-Jamsarvillage, Thane district	social Entrepreneurship - Franchise Model/PPP/ Purchase Model
Water Health International	Water Health Centres	districts in Rajasthan, Gujarat, Telangana	UV, RO technology; wastewater generated- discharged into the recharge soak pit after treatment - 'zero' wastage of water+ recharges aquifer.	Acumen Fund, International Finance Corporation, Tata Capital, Vital Capital Fund - investment contributors ;Sponsors - USAID, Tata Water Mission, The CocaCola Co.	SAIL Capital, The Dow Chemical Company	Panchayat provides land, water, electricity to set up Water Health Centres (WHCs), community initiatives for locals, Capacity building programs; eventual transfer to the community at the end of concession term.
Others include -Voltas Water Solutions (50:50 joint venture between Voltas Limited and Dow Chemical Pacific (Singapore) Pvt. Ltd. Payment coin/Smart card operated, 10-20 p/litre, 6 stages filtration, RO, 'Voltas Smart Monitoring app'; Aquasafi- started off in Gadag District of Karnataka, Waterlife,						

THE STRUCTURE OF THE MARKET

Types of Purification Models:

- a. Centralised water treatment facilities as the case of urban areas
- b. Point of use water purifiers
- c. Community water systems

Types of Business models

1. Outright Sale: Here the water company sells the water system to the government, NGO or CSR. Often the village panchayat (local government) owns and operates the plant either directly or through a jointly constituted committee. Revenue generated through the sale of purified water (typically at INR 2-5 for 20 litres) is used to fund operations. Often these systems are maintained poorly as the revenue does not cover the necessary operating costs.
2. Sale and Maintenance: This model is similar to the previous one in which the system is sold outright, usually to the government. However, in this case, the water company continues to service and maintain the system for a fee. Generally,

these continue to operate well although the price is higher (e.g. INR 4-7 for 20 litres) because the professional water company is being paid to properly maintain these units.

3. Franchise: Here the water company identifies a local entrepreneur who contributes part of the initial system cost. The entrepreneur operates the system and shares part of the profit with the water company. In this model too water is sold at a higher rate (INR 6-10 for 20 liters) to recover the initial capex cost (most of which is borne by the water company).

Microfinance and Water

- **Water-Credit**, an innovative program launched by Water.org which addresses this issue by providing small loans to households for the purchase of water filtration systems.
- In another such initiative, **Milaap**, a **Unitus Seed Fund** portfolio company has tied up with **Guardian**, a **microfinance institution** and **Yunus Social Business Fund**, to provide micro loans people in Tamil Nadu for building water connections and toilets in their homes.
- **SpandanaSphoorty** Financial Ltd. started off with this model in Neemuch and Ujjain district, MP involving a weekly repayment amount similar in both areas Rs 43 (\$0.95) per week for 25 weeks, Rs 39 (\$0.87) per week for 17 weeks.
- Monthly repayment plan Rs 250 (\$5.60) per month for 6 months, plus upfront payment of Rs 250 started by **Pragati Seva Sanstha under the umbrella org ACCESS in Andhra Pradesh**.

Investment firms in the water sector –

- **Aavishkar** – Mumbai based, equity investments in social enterprises. Investment in Waterlife.
- **Acumen** – Raises Charitable donations for investments, in India has invested in Water Health International, Guardian and Spring Health.
- **Avantage Ventures** – Asia based social investment company with offices in Hongkong and Beijing, invested in Piramal-Sarvajal which franchises their proprietary filtration equipment to local entrepreneurs who then operate the machines and sell water at a minimum cost.
- **Matrix Partners** – Investment in Waterlife.
- **Sandi group** – Washington based company investing in Aquakraft,

Unitus Seed Fund investing in many of the water projects operating in the districts shown in map.

4. CONCLUSION

Policies and international agreements have laid down targets and goals for the water and sanitation sector to achieve by 2030 and some even before that. However, some of the greatest barriers that the States face today are related to financing of development schemes and to bear the capital costs of increasing the coverage status in rural areas to ensure safe drinking water for all. Moreover the donor organisations backing such social sector programs have talked the language of neoliberal policies encouraging private players to take part in the service delivery mechanism and ensure cost recovery of it.

Although this study fails to validate the actual extent of privatization and the current size of the water market with details of its players and structural elements, the paper substantiates the fact that policy documents and the actions taken up by the supra national donor organisations have provided the incentive to the companies for seeking profit in this 'life- saving' business. The riveting fact is that the water business has set its strong footing in the rural drinking water sector taking advantage of the utopian imageries of 'safe water' created by policies so far and that too in areas which are official statistics wise found to be having pretty high treated water supply facilities by the State. The huge business potential given India's unmet demands by the State makes key themes - equipment supply, public private partnerships for water supply and distribution, water treatment plants and water EPC (engineering, procurement and construction) business and integrated water resource management for utilities – the building blocks of establishing increased private control in this sector.

1603 REDEFINITION OF REGIONAL DEVELOPMENT FACTORS OF THE EUROPEAN UNION IN THE LIGHT OF CONTEMPORARY SOCIO-ECONOMIC CHANGES

ABSTRACT

The contemporary socio-economic development process shows tendencies towards growing divergence. At the same time the limited effectiveness of present activities of regional policy is emphasized as well as the existence of barriers to achieve the differences in the level and standard of life socially accepted. External determinants of the development process, specific in various parts of the world including Western and East-Central Europe, are linked with long-term changes in economic systems (Naisbitt, 1982; Naisbitt, Naisbitt, 2016; Horváth, 2015; Salamin, 2016). The current state of these changes results from the transformation creating postmodern conditions for economic activity, characteristic of the present stage in the development of cognitive capitalism (Harvey, 1990; Boutang, 2012). They are strengthened by globalization manifested increasingly with advancing economic integration (Huwart, Verdier, 2013). In these difficult conditions, shaped by identified megatrends, a real challenge is a successful influence on regional development factors, which effectively tend to optimize the conditions of leading economic processes and consequently to improve the level of life (The Future of Cohesion Policy..., 2015; White Paper..., 2017; Seventh Report..., 2017; Schneider, 2017). This is so because these factors change the range, interpretation and mechanism of the interaction, and significantly differ in space, which leads to their redefinition. The analysis aims to determine the direction and range of the redefinition of development factors of the regions of the EU member states and to identify their current spatial differences. The research involves threestages. The first stage presents the results of the arrangements organizing the direction and range of the influence of contemporary megatrends in socio-economic development on the changes in regional development factors. The second stage involves an analysis and typology of differences in the level and dynamics of the development of the EU member states and their regions. The third stage of the analysis concerns the identification of differences in the factors of regional development in the set of all the investigated regions and in their sub-set representing the development types identified. This research also includes the organization of the obtained pattern of regional development factors in the three categories of cohesion: economic, social and territorial. This analysis seeks to identify the factors which significantly shape changes and the present state of regional socio-economic differences in Europe and their specific features in the pattern of regions: more developed – transitory – less developed. The study in question is implemented under the research project FORSED (<http://www.forsed.amu.edu.pl>) financed by the National Science Centre as part of the competition OPUS 10 - 2015/19/B/HS5/00012: New challenges of regional policy in shaping socio-economic development factors the less-developed regions.

1671 GROWING UP IN DIVERSITY: THE EFFECTS OF ENJIKAMPTHNIC DIVERSITY ON EDUCATIONAL OUTCOMES?⁵⁵²**Moh Agung Widodo, Budy P. Resosudarmo****(Work in progress)****ABSTRACT**

This paper examines empirically the effects of the exposure to ethnic diversity during school-age period on human capital outcome, measured mainly as year of schooling achievement. Combining three different data sets from Indonesia in 2000 and 2010, we link children's neighbourhood-ethnic diversity and the cohorts' average educational outcome at local level ten years later. The diversity is measured by the Herfindahl-based index constructed at sub district level from the full count 2000 Population Census. In addition, to net out the effect of diversity we control for neighbourhood characteristics that may be correlated with population density. Our OLS estimates tend to support the popular idea that diversity is harmful. More diverse communities are associated with lower mean year of schooling. However, when we employ instrumental variables to mitigate potential endogeneity issue in the neighbourhood ethnic mixture, the diversity effects become significantly positive. More diverse neighbourhoods tend to provide favourable educational environment for children so they are able to accumulate more year of schooling. The mechanism behind this is likely through an exposure to greater pool of talents.

Keywords: ethnic diversity, ethnic fractionalization, educational outcomes

JEL classification: C26, O15, Z13

1 INTRODUCTION

Interests on ethnic diversity has been increasing in the last decade for two reasons. Firstly, ethnic diversity is often associated with backwardness and one of the impediments of economic progresses in cross countries literature. Many developing countries with higher level of ethnic fractionalization, such as those in Sub-Saharan Africa, are predicted to have limited opportunity to catch up with more advanced economies (see Alesina & Ferrara 2005 for example). Secondly, population mix has been intensifying in many advanced countries because of international and internal migration, and this social heterogeneity is expected to become a common norm in the future (Putnam 2007). Policy responses to this change are also mixed, from immigration ban to affirmative programs for incoming migrants to help cultural assimilation. Scholars, therefore, are motivated to evaluate the benefits and costs of ethnic mixture on varied dimensions of economic development, as well as understand the underlying mechanisms behind it.

Findings on the net effect of ethnic diversity is still not conclusive. There are two competing hypotheses in the literature. On most cross-country analyses, diversity is generally seen as harmful (Alesina & Ferrara 2005, Collier 2000, Easterly 1997), a phenomenon that refers to a 'diversity debit' (Gerring et al. 2015). Ethnic fractionalization erodes trust and social capital (Putnam 2007), reduces investment and increases the probability of civil conflict (Montalvo & Reynal-Querol 2005). On the other hand, findings at sub-national and micro level have been a mixed, suggesting there exist the potential advantages of diversity. Firm-level analyses usually find positive impacts of workers' ethnic/racial mixture on firm's productivity and innovation. The mechanisms behind these benefits span from talent complementarity to greater product variation and better market understanding (Ozman & Erdil 2013, Ramasamy & Yeung 2016). Recent studies using class-level analyses also find evidence that students benefit from class' ethnic composition that help raise their educational performance (Hoogendorn and Van Praag 2012, Braster and Dronkers 2013).

Despite a large body of literature in the relationship between ethnic fractionalization and social economic development, the link between the former and the accumulation of human capital is still understudied, especially in two subtopics. Most of research are undertaken at national or state aggregate level, with only few use community or individual level analyses. Such macro-aggregate analyses are potentially omitting potential confounders, such as heterogeneous ability. Furthermore, most studies treat and assume ethnic diversity as exogenous, while in fact ethnic diversity and population mix are closely related with migration, which involves self-selection process. We attempt to contribute to the current literature by addressing these issues.

In this paper we focus our analysis on the potential effects of neighbourhood's ethnic diversity on children educational outcomes. Particularly, we observe whether there is an effect of ethnic composition during childhood to adolescence to children performance at formal education, tracked at primary, junior and high school, and finally at the accumulated year of schooling. We bring together two branches of the literature. Firstly, the literature on the determinants of human capital formation that includes theories on children development. Secondly, the literature on ethnic diversity and social formation. Our research question departs from the insights that if children social environment is influential to their subsequent development, then we would like to know the possible effects of diverse environment on children education outcomes.

We mainly use three datasets from Indonesia. Using the full count of the 2000 Population Census we construct ethnic diversity index as well as segregation index at subdistrict level (*kecamatan*), a level that we argue better reflect people interaction in most daily life. We then match the 2000 subdistricts with the corresponding subdistricts in the 2010

⁵⁵² Preliminary draft, not for citation.

Census. From the later we calculate average educational outcome for cohorts 16-22, 22-25, and 25-28 years. These cohort groups correspond to children and teenagers in the age group of 6-12, 12-15, and 15-18 respectively in the 2000 Census. The age groups represent common school age for primary, junior, and high school level in Indonesia. The main outcome that we analyse will be the subdistrict's mean year of schooling. We also use information from the 2000 Village Census (*Podes*) to control for region's characteristics. Instrumenting subdistricts' ethnic diversity, we find that ethnic diversity is significantly beneficial for educational attainment. Regions characterised with higher degree of ethnic mixture are associated with more year of schooling, as well as with higher rate of school completion. We propose the channels for this benefit are through greater pool of talent and complementarity which facilitate knowledge and skills spill over across ethnic groups.

The paper will proceed as follows. In the next section we discuss the theoretical framework on the importance of children social environment on their development. The following section elaborates data, research setting, and the empirical strategy. Finally we discuss results and offer possible mechanisms, and conclude.

2 WHY MAY ETHNIC DIVERSITY AFFECT EDUCATIONAL OUTCOMES?

We bring together insights from two different branches in the literature. The first branch is the literature on human capital formation, especially during the initial period of life. Including in this strand is the theory of child development. The second branch comprises literature on ethnic diversity, its origin and determinants, and its potential costs as well as benefits for human development.

Human capital formation at early life

Recent years witness the convergence of view among economists, education and health experts on the determinants of human capital. In general, human capital accumulation is a function of initial endowment including in-utero conditions, family background and investments on education and health, and environmental conditions which include natural, physical, and social environment (Barker 1990, Conti et al. 2010, Grossman 1972, Heckman et al. 2013). While the empirical evidence of the importance of health condition in early life on adult outcomes is well documented (Almond & Currie 2011, Currie & Vogl 2012, Glewee et al. 2001, Glewee & Miguel 2008, Hoddinott et al. 2011), evidence on the effect of social environment is still sparse and is dominated by class or school characteristics analysis. Children are exposed to social interaction not limited at school, but also at home and their neighbourhood.

Coleman (1988) conceptualizes the role of social capital in human capital formation. He combines two different perspectives, sociologists and economists views, on the actions made by individuals. While the former see the actor is dictated by her environment: social norms, rules and obligations, the latter see the actor as an independent agent with her self-interest. He then proposed the middle way, acknowledging rational action and use it in the analysis of social system. With respect to human capital formation, he sees two-way interaction: social capital as a kind of resources available to individual on the one hand, and on the other hand the functioning of social capital depends on social structure and social relation that may different from one place to another. Social capital here includes social capital in the family and the one in the community, both are important for children educational outcomes. Social capital in the family, in the form of interaction between children and parents, will enable family's financial capital and human capital (parents' education) to affect children learning process. Social capital outside family, in the form of mutual relationship, will facilitate children to reap benefit from the community.

Related to human capital framework is the theory of child development. There are many theoretical frameworks on this field, however we focus on theories that relevant to our studies. Jean Piaget's psychosocial theory divide children development into four stages: sensory-motor stage (up to 2 years), pre-operational stage when children are illogical thinkers (2-7 years), concrete operation stage when children develop their logical thinking (7-12), and the final stage of formal operation (12 years-over) when children develop abstract and complex thinking (NSW Office of Childcare 2002). The early adolescence (11-14 years old) is an important period when children cognitive development is occurring, and is characterised by strong peer effects (Stang and Story 2005). In addition, Ecological Theory of Bronfenbrenner proposes the balance between nature and nurture, suggesting heredity and environmental stimulation are both important for children development. In this framework, children are surrounded by four concentric circles that influence their development: family, preschool or school, wider network such as parents' network, and macro-system that includes values, customs and attitudes of the wider cultural group in which the children belong to.

Ethnic Diversity and Its Potential costs and Benefits

Ahlerup and Olsson (2012) suggest that ethnic diversity originate date back since prehistoric era, with geographic, diversity in vegetation, topography or the roughness of the earth surface, diseases, and the duration of human settlements determine the level of diversity in a country. More specifically, heterogeneity in land endowments has facilitated specific human capital to develop locally and coupled with mobility constraints have produced specific ethnicities and languages (Michalopoulos 2008). Later, in modern day ethnic diversity is affected by the duration of the modern state and human migration which has been intensifying in the last three centuries. This new development implies that ethnic diversity becomes more complex and challenging phenomena, and its exogeneity assumption becomes more difficult to hold in the contemporary analyses.

The negative effects of ethnic diversity on countries' performance identified in cross-country analyses (Alesina and Ferrara 2005, Allesina and Zuravskaya 2008, Collier 2000, Easterly 1997). Summarizing from these research, there are three mechanisms through which ethnic fractionalization produces detrimental effects. Firstly, ethnic diversity erodes

trust between group, thus country with high diversity will have thin social capital. This could increase the probability of civil conflict or at a lesser extent hampering common action and collaboration. Lower trust could also deviate budget spending away from public goods provision toward security spending. Secondly, community with higher level of diversity will find it difficult to agree with common public goods to be provided, since each group has strong aspiration for their own preferences. The worst is when the society failed to achieve consensus on important public goods to be provided, given private sectors will have no incentives to do so. Lack of public goods in turn hinder economic development and human capital formation. Thirdly, ethnic diversity is usually associated with diverse local languages used in the country. This could increase communication costs and slow down the diffusion of knowledge. At macro level, higher level of ethnic fractionalization could lead to lower level of investment and slower growth rate due to increased risks.

However, literature also provides another evidence suggesting the benefit of ethnic diversity. Analysis at sub national level in the US and Europe find that cities with higher level of ethnic mixture generally have higher level of innovation, productivity, and cultural capital. Similar results also found in firm-level analysis. Firms with greater variation in workers' cultural background are generally more productive. Economists suggest that diversity could have greater probability of talent complementarity. People from different cultural background bring with them specific skills that enrich stock of skills in their working place. People may also learn from other to equip them with new skills. Evidence on this mechanism is found by Hoogendorn and Van Praag (2012) who employ a randomized field experiment to 550 business students in the Netherlands and find that groups with high ethnic diversity perform better than those with homogeneous features. Similar positive effects also found in school/class level analyses, when diversity not only benefit the minority group and underperforming students but the high-achievers students also improve their understanding on the subjects they provide help to others.

Table 1 Summary of research and findings on the effects of ethnic diversity

Author/s	Methods and data	Main findings
Easterly and Levine (1997)	Cross-country analysis, OLS	Ethnic diversity explains cross-country differences in the quality of public policies, stability, and economic performance High ethnic fractionalization in Sub-Saharan Africa is associated with low economic growth, low schooling, political instability, underdeveloped financial systems, distorted foreign exchange markets, high government deficits, and inefficient infrastructure
Alesina et al (2003)	Cross country analysis, OLS, 190 countries Employs new measures of ethnic, linguistic and religious fractionalization Introducing ethnic polarization index	Ethnic fragmentation negatively affects economic growth Cross-correlation between ethnic fractionalization and legal origin, and its link with institutional quality Religious fractionalization has no association with economic outcomes
Lee et al (2016)	Panel data analysis of 600 municipalities and 1,286 school districts in the United States Time period: 2001, 2006, 2011 Pooled-OLS, Pooled-2SLS, Random effect 2SLS	Ethnic heterogeneity does not necessarily reduce local public spending (per capita) Low substitution between public goods in response to changes in ethnic diversity Ethnic diversity increases public spending on education, police, and fire
Sparber (2010)	Fixed effect analysis of US regions 1980-2000 Employ instrumental variable: a racial fractionalization index, predicted by shift-share approach	Diversity enhances productivity of cities Evidence is ambiguous at state level, find positive effect using Random Effect approach
Hoogendorn and Van Praag (2012)	Randomized field experiment involving 550 business students in Netherland, with 53 country origins Distribute students randomly into small groups, approximately consist of 10-12 persons, as part of a compulsory entrepreneurship program	Positive effects of larger minorities' share (implying more diverse) in group on business performance, higher sales and greater profits, when the share of minorities exceeds 55% More homogeneous team tend to experience less conflict Members of heterogeneous teams tend to learn more, suggesting greater variation of skills in groups
Parrotta et al. (2012)	Structural estimation of the firms' production function Firms data in Denmark	Diversity in education enhances firms' value added Diversity in ethnicity and demographics tend to harm firm productivity Communication and integration costs outweigh benefits from creativity and knowledge spillover
Braster and Dronkers (2013)	Classroom-level analysis of 905 students in	Ethnic diversity in the classrooms increases

	41 classes in 11 schools	educational performances of migrant pupils, but the effect is not significant for native students
Ramasamy and Yeung (2016)	Cross country analysis Evaluate the links between values diversity, ethnic diversity, and innovation Values diversity index is constructed based on 4 dimensions: self-enhancement, self-transcendence, openness to change, and conservatism	Ethnic diversity has a negative effect on innovation, while values diversity is beneficial The best innovators are countries with low diversity ethnically but heterogeneous in values orientation (eg. South Korea, Sweden)

3 DATA AND EMPIRICAL STRATEGY

The setting of this study is Indonesia. Our main variable in this analysis is ethnic diversity. We use Herfindahls based ethnic fractionalization index to represent the degree of ethnic composition in a neighbourhood as suggested by Alesina et al. (2003). The index ranges from 0, meaning an ethnically homogeneous society, to a maximum of 1 when everyone is different from another. Sometimes, the index is interpreted as the probability of randomly picking from the population two people who belong to different ethnic background. Mathematically the index is calculated using the following formula:

$$EF = 1 - \sum_1^N s_i^2$$

Where EF is ethnic fractionalization index, s is the share of ethnic group i in a unit of population, and N is the number of ethnic group. We calculate ethnic diversity index at subdistrict level. We argue that this administrative boundary better represents neighbourhood level in which people, particularly children, involve in daily interaction with others more intensively than in higher administrative unit. Based on the 2000 census we find the average population of subdistrict is 51,575⁵⁵³ with the average area is 379 kilometer square⁵⁵⁴.

We use the information on ethnicity in the 2000 Indonesian Population Census. Indonesia Statistics Office (BPS) collected information of ethnicity for the first time in the 2000 Census and continued in the subsequent census in 2010. Prior to 2000, ethnicity is considered as taboo in social and political discourse because of government concern on national unity. Government strongly encouraged a national identity and saw ethnicity, together with religion, race, and group identity (*Indonesian: Suku, Agama, Ras dan Antar-golongan*) as a threat to national harmony (Hugo in Ananta et al. 2015). Following the change in political regime, perception on ethnicity has also change and BPS collected ethnic identity using self-identification approach. By this approach, respondents are free to identify themselves to belong to particular ethnic groups, and these ethnic names would be added to the BPS lists if they were not identified beforehand. The result is 1030 ethnic identities identified throughout the country. It should be noted that some parts of Aceh Province were under identified due to security reasons and census officials found it difficult to collect information from the whole population.

In this paper we reclassify the ethnic group from 1300 into 31 bigger ethnic classification for the calculation of ethnic fractionalization index. The 31-group classification is used by BPS in its official report. There are two reasons to choose the 31-group classification. Firstly, the original ethnic classification does not necessarily provide equal classification because of self-identification process. Therefore, there is a mix between ethnic and sub-ethnic or even sub-sub-ethnic classification (Ananta et al 2015). Generally, among sub-ethnic groups under the same group share many similarities, thus less variation, and this will make the analysis less meaningful. The idea of estimating the effect of ethnic diversity is to identify the potential costs and benefits of the interaction between people from different culture, way of thinking, and importantly specific skills associated with ethnicity. Using the original classification is likely to overstate the actual diversity in the neighbourhoods. The other reason is practicality. The big classification is better matched with island and provincial unit, making it easier to improve the analysis with migration pattern.

Our calculation indicates that the level of ethnic diversity varies across country. On average, the ethnic diversity index of subdistrict is 0.23 with the minimum value is virtually zero 0.00011 (almost homogen) and the maximum one is 0.843. We use 31-group classification and exclude Aceh Province. One may ask whether the result will be different if we use the original ethnic classification or 630 classification proposed by Ananta et al. (2015). Our calculation indicates the correlation between indices calculated using 31 classification and original classification (1030) is 0.927, while the correlation between indices from 31classification and Ananta's 630 classification is 0.956.

⁵⁵³ We exclude Aceh Province from the calculation of national average due to incomplete census data collection.

⁵⁵⁴ Based on the 2000 Village Census (Podes)

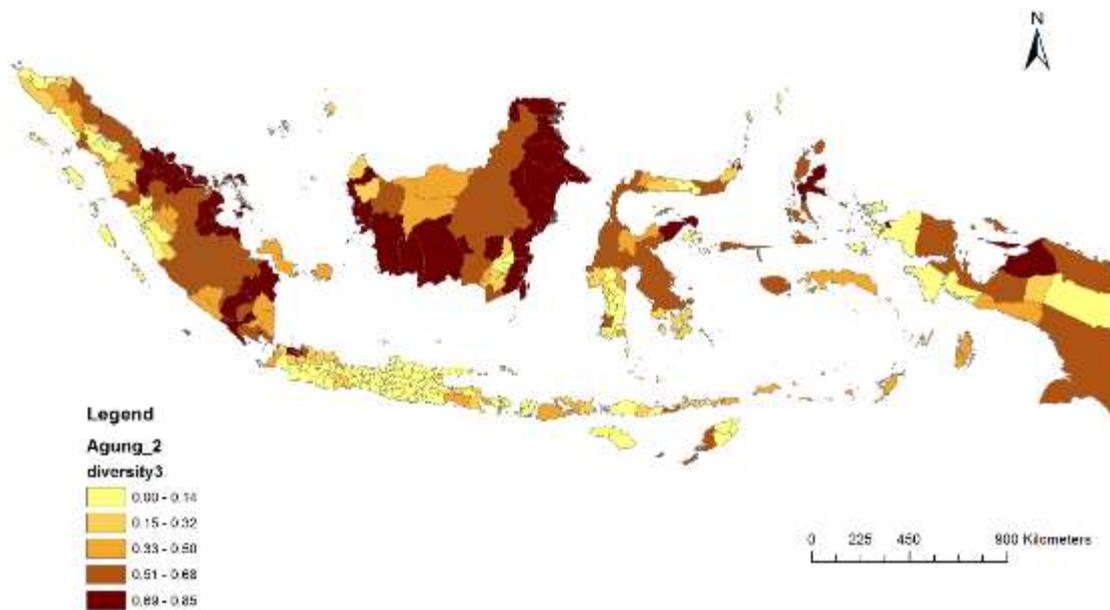

Figure 1 Ethnic Diversity Index by Province in Indonesia (2000)

In addition to ethnic diversity index, we also construct an alternative measure in the form of polarization index, as suggested by Reynal-Queroll (2005). The use of this measure is motivated mostly in social and political analyses, when ethnic diversity tends to be a less convincing predictor for social conflict and civil war. While ethnic fractionalization is increasing with the number of ethnic group, the maximum value of ethnic polarization is reached when there are two ethnic group with equal size in the community. The idea is the more the society is polarized, the greater the probability of diametric conflicts will be. The formula used to calculate ethnic polarization index is as follow:

$$RQ = 1 - \sum_{i=1}^N \left(\frac{1/2 - s_i}{1/2} \right)^2 s_i$$

Where RQ is Reynal-Queroll polarization index, N is total number of ethnic groups in a subdistrict, s is the population share of particular ethnic group in the society. As in ethnic diversity, the value of ethnic polarization ranges from 0 when there is only single ethnic group in the population to a maximum 1.

The origin of ethnic diversity in Indonesia

The cohabitation between different ethnic groups in the same place in Indonesia can be traced back from pre-modern era. There are three different waves of people mobility that affect ethnic composition across place in Indonesia. The marks of ethnic mix in Indonesia have been found far before the Dutch colonial era through interisland trades and slavery (Cribb 2000). The evidence is some similarities among traditional languages and the continuum of the physical appearance of Indonesian people. Through trade, people moved to look for more attractive resources and opportunities in more developed regions. People migration was also motivated by monopolistic trade imposed by local kingdoms or sultanates. As for slavery, the main victims were usually the population of small islands who lack of protection. Cribb (2000) also suggest the possibility that in the prehistoric era initially the people who first invaded the region spoke in the same language. Later, they spread to different places, settled and developed their own specific languages deviating or evolving from the original one.

The second wave was people migration during the Dutch Colonial. The Dutch Colonial Government launched transmigration policy for two purposes. First, along with the expansion of plantation in outer islands, especially Sumatera, the Colonial Government mobilised famers from populous Java island to outside islands. Up to 1930, around 443,000 people were moved from Java to North Sumatera (Cribb 2000). Furthermore, in the beginning of 20th Century the Colonial Government believed that Java had been over-populated, and they introduced a transmigration program supplemented with attractive incentives to resettle Javanese to the outer islands. The 1930 Population Census recorded that around 11.5 per cents of indigenous population lived outside their districts of birth (Volkstelling 1930 in van Lottum and Marks 2012).

The third wave of internal migration is post-independence modern era. The Government of Indonesia replicates the Dutch's transmigration program in an increasing scale. The main destination of transmigration from Java and Madura was initially southern parts of Sumatera in the 1970, and then shifted to Kalimantan and Irian Jaya in the 1980s and 1990s (Cribb 2000). While after 1990s the flow of government-led transmigration has been decreasing, the movement

of people attracted by economic opportunities has continued to increased since 1970, mostly towards developing metropolitan area in Java (van Lottum and Marks 2012). The share of population whose provincial birthplace are different from current residence increased from only 5 per cents in 1970 to 10 per cents in 2000.

Population of ethnic group in Indonesia

Statistic Office of Indonesia (BPS 2010) reports the result of the 2010 Census for the population of ethnic group. The largest ethnic group is Java with more than 95 million population or accounted for 40.2 per cent of total population. The geographic origin of Javanese are in three provinces: Central Java, Yogyakarta, and East Java. Following in the second place is Sunda which is concentrated in West Java province with almost 37 million population (15.5 per cents). In the third place is Batak, originated from North Sumatera province, with 8.5 million people (3.6 per cents). Another ethnic group with size slightly above 3 per cents is Madura, whose origin is in Madura island in East Java province. The rest twenty-seven ethnic groups altogether constitute less than 40 per cent with Nias being the smallest group of 0.4 per cents of total population. Table 1 reports the population size of the 31 ethnic groups and its share to national population, as well as their historical geographic origin.

Table 1 Population of Ethnic Groups and Geographic Origin

Ethnic group	Population	Share (%)	Geographic origin
Aceh	4,091,451	1.73	Aceh province

Outcome variables and other covariates

Our second dataset is the 2010 Population Census. We calculate mean year of schooling at subdistrict as the main outcome indicators of knowledge accumulation for cohort groups 16-22, 22-25, and 25-28 year old. These groups correspond to children aged 6-12, 12-15, and 15-18 respectively ten years before, or in 2000. Basically we want to analyse the accumulation of knowledge for these cohort in year 2000 as a result of their exposure to ethnic mixture during their childhood. In addition we also analyse the completion rate of schooling at primary, junior, and high school levels.

We choose subdistrict (*kecamatan*) as unit of analysis instead of district or province levels. We argue that population and area size at subdistrict level will be better in representing people interaction in daily life. The provision of public school, health center, and local market is usually made at this level. The average population in subdistrict is 51,575 in 2000, with the average size of area is 379 km square. In 2010 the average population per subdistrict falls to 47,213 because some subdistricts have split into smaller ones. As we want to match the 2000 subdistricts with the corresponding one in 2010, we have to deal with the region proliferation issue. Our data shows that between 2000 and 2010, 1,336 out of 3,826 subdistricts (35 per cents) split into smaller size new subdistricts. For this analysis we merge the 2010 subdistricts based on the 2000 subdistrict boundaries.

In Indonesia's government system, subdistrict is the third tier of subnational administration after province and district (*kabupaten*). Each subdistrict consists of several villages (*desa* or *kelurahan*). As an administrative unit subdistrict is

unique in the sense that it does not have autonomous power. While the head of province, district, and village is directly elected, the subdistrict head is appointed by the district government. In short, the subdistrict is more of district representative at local level. This unique feature help us in controlling for potential unobserved confounders in the analysis of ethnic diversity and educational outcomes.

Finally, we use information from the 2000 Village Census (*Podes*) to extract regions' characteristics, such as geographic location, topographic features, and school availability at subdistrict level. Information in *Podes* is presented at village level, so we have to aggregate the data into subdistrict level. Furthermore, *Podes* also provides estimates of village population which we can sum up to get subdistrict population. However, for the analysis we use subdistrict population from the 2000 Census.

Empirical Strategy

We start our analysis by estimating the following equation:

$$EDU_i = \alpha + \beta EF_i + REG_i' \varphi + INFRA_i' \delta + SES_i' \rho + ADULT_YOS_i' \vartheta' + \partial_p + u_i \quad (1)$$

Where *EDU* represents educational outcomes of subdistrict *i*. *EF* is ethnic diversity index of subdistrict *i*. *INFRA* is a set of infrastructure indicators in subdistrict *i*, including the ratio of household electricity connection, school density at primary, junior and high school, and distance to nearest health center. *SES* represent a set of social-economic indicators of subdistrict *i*, comprises the share of households classified as poor (*pra-sejahtera*) and the year of schooling of the village head. *ADULT_YOS* represents average year of schooling for people aged 25 and above, which serve as a proxy for average parents' education and the stock of human capital in the subdistrict. We fix provincial effects by putting a set of provincial dummies ∂_p to control for potential unobservable at provincial level.

We adjust the standard errors by clustering at provincial level. The idea is to control for heteroscedasticity due to systemic correlation in the error term among regions within the same province.

Correlations

Estimating equation (1) by OLS we get the correlational relationship as depicted in Table 2. In column 1 gross correlation between ethnic diversity and year of schooling for cohort 16-22 year in 2010 (corresponds to cohort 6-12 in 2000) shows a positive value, suggesting that subdistrict with high diversity tends to have more year of schooling. The correlation becomes stronger if we fixed provincial effects. However, after controlling for regional characteristics, infrastructure, and education of village head the correlation becomes insignificant with the magnitude shrinking. Finally, when we add adults' year of schooling the direction of the correlation changes to negative, although remains insignificant, suggesting a harmful effect of ethnic diversity on educational attainment. In the column 7 and 8, the outcomes are mean year of schooling for cohort 22-25 and 25-28 respectively.

Causal Inference

We suspect that our OLS estimates in Table 2 biased because of two issues. Firstly, there may be a reverse causality between ethnic diversity and education. Regions that are relatively educated tend to be more favourable for ethnic mixture. Another issue is self-selection process, when family can choose where they live based on their preference on the neighbourhood characteristics, including the level of ethnic diversity and education level. There may be families who are convenient to live in diverse neighbourhoods, but other families may not. If their preference on ethnic diversity is correlated with unobservable characteristics of the family, which likely to be transmitted to their children, which also correlated with educational attainment, then the estimates in Table 2 will be biased.

We need instrumental variables for neighbourhood ethnic diversity to purge its correlation with unobservable confounders. Such instruments must meet two criteria. First, the instruments must be relevant, meaning they are good predictor for ethnic diversity index. The potential threat for this is if we get a weak instrument, which results in inefficient estimates. Technically, these instruments must be significant in the first stage estimation. The rule of thumb is the F-statistics from the first stage regression must not be less than 10. The second criterion is more challenging. The instruments must not have direct effect on the main outcome, educational attainment. In other words, the instrument should be excluded from the structural equation. Unfortunately, this criterion is not testable formally when we only have single instrument. If we can find more than one instruments and employ over-identified model, Hansen J-statistics and the p-value provide indication on the validity of our instruments under the null hypothesis that all instruments are valid. However, the results of the over-identification test must be evaluated with caution if all available instruments affect the endogenous variable by the same rationale (Murray 2006).

We propose topographic feature, in this case the share of village with flat topography, to instrument subdistricts’ ethnic diversity. We argue that flatness fits both criteria. Flat is expected to be positively correlated with ethnic diversity since this topographic feature can accommodate a wide range of skills and livelihoods. On the contrary, rugged surface and elevated topography may only be suitable for particular life skills embedded in fewer ethnic groups. There is also little to think that flat is correlated with unobserved characteristics, ability for example. More educated and skilled people may be expected to better able to locate near urban centres and main infrastructure. Once we control for infrastructure density and distance to district capital, flat will be virtually exogenous. In addition, our flat variable is expressed as the share of village within subdistrict with flat surface. Even if people with high ability prefer flat sites for their residence, they may not care with the rest of the villages in their subdistrict.

An alternative instrument for subdistrict ethnic diversity would be mean rainfall intensity, measured at district level, for the period 1978-1996. As part of tropical zones, Indonesia has a relatively wet climate. Our data shows the average district annual year is 2,336 mms, with the minimum and maximum values are 966.9 and 3575.9 mms respectively. The gross correlation between rainfall and ethnic diversity shows a relatively small positive value. However, when we control for the province dummies the correlation becomes negative, although the magnitude remains small, suggesting that lower rainfall associated with higher diversity within province. Given the high value of average rainfall, the correlation should be interpreted carefully as the less intensive rainfall provide more favourable environment for ethnic diversity. We argue that rainfall meets exclusion restriction criteria, meaning that regions with less intensive rainfall facilitate greater variation of skills and culture, but not necessarily correlated with unobservable confounders of education such as ability. In other words, controlling for infrastructure, distance to district capital, and other district’s characteristics, rainfall intensity affects educational outcomes only through ethnic diversity in the region.

4 RESULTS

Main findings

We start by estimating equation (1) by just identified 2SLS approach and later with over-identified model. In Table 3 we report the results of IV estimates in column 2-4, and column 1 provides OLS estimates as comparison. As in OLS model, we control for region’s characteristics (population, area size, share of village in coastal area), distance to district capital and distance from district to province capital, infrastructure (ratio of household with electricity connection, school density, distance to closest health center), and subdistrict social economic status (share of poor household and average education of village heads). We also fixed provincial effect to mitigate potential correlation between ethnic diversity and unobservable provincial characteristics. In the first stage estimations the value of F-statistics are above the rule of thumb 10 as well as Stock-Yogo critical value of 10% maximal IV size, suggesting our instruments are not weak. Compared to OLS, the IV estimates are significantly beneficial for educational outcomes. Using flat topography as an instrument, an increase in subdistrict ethnic diversity by 0.1 point leads to an increase in mean year of schooling by 0.6-0.7 years for three different cohorts. When we use rainfall to instrument ethnic diversity, the effect is between 0.4-0.5 years for the same increase in ethnic diversity. Employing all available instruments into an over-identified model, we find the effect of a 0.1 point increase in the index of ethnic diversity ranges from around 0.5 to 0.6 years more in the average schooling.

In over-identified model, Hansen's J statistics are below the critical value at 5% confidence level, suggesting that we failed to reject the null hypothesis that all instruments are valid. However, for cohort 16-22 the J statistics is bigger than the critical value at 10% level, casting a doubt about the validity of one of our instruments, although it is still unable to reject the null hypothesis at 5% level. This may be related with the fact that the mean year of schooling in younger cohort has less variation. Our data indicates that the average of subdistricts' mean year of schooling for younger cohort (16-22) is 8.7 years with standard deviation around 1.3, while the mean figures for older cohorts are 9.1 years (22-25) and 8.9 years (25-28) with standard deviation of 1.6 and 1.7.

Another indicator for educational outcomes is school-level completion. So we re-estimate the equation (1) with school-level completion as a dependent variable. We calculate the share of population who completed education at primary, junior, and high school level for the same cohorts as we have in the estimation of mean year of schooling. The report is in Table 4. Most of the estimates by IV/2SLS are significantly different from OLS estimates. However in the estimation of the effect of ethnic diversity on primary-school completion, the coefficients of IV are not significantly different from OLS when we use rainfall as the instrument. We suspect this because two things or a combination of the two. First is the low variation in the primary-school completion across subdistricts. It should be noted that primary education has been made compulsory by the Government of Indonesia since 1984 and in 2010 Census the figure of primary school completion has been relatively high. Our data indicates that the average percentage of subdistrict population who at least graduated from primary school are 93.3 per cent, 92.9, and 92.4 for cohort 16-22, 22-25, and 25-28 respectively. Second is the construction of the rainfall instrument at district level, meaning that all subdistricts within similar district are assigned with the same intensity of rainfall.

5 DISCUSSIONS

Specification test

We check whether using different ethnic measures will affect our results. First, we re-estimate our model with ethnic diversity calculated using 630 group classification. Then we also try ethnic diversity in logarithmic form. And finally, we estimate the model with polarization index substituting for diversity index.

Table 5 reports the results when ethnic diversity index is measured using 630 group classification, instead of 31 group. The gross correlation between the 630 and 31 indices is 0.96. Given this high correlation, we would expect that the main results are maintained. The coefficients of ethnic diversity across cohorts and instruments in the 630 group model have the same direction and significance as those in the 31 group model. In term of magnitude, the effect of ethnic diversity when topographic feature is used ranges from 0.6 to 0.7 more years of schooling for every 0.1 point increase. If the average rainfall is used the corresponding effect is between 0.3 and 0.4 more years. When both instruments are used, the effect is between 0.4 and 0.5 more years. The results of the endogeneity test suggest that the IV estimates are significantly different from OLS for all cohorts and instruments used. The first-stage F values are well above the critical values, so we confident enough that our instruments are not weak. However, the overidentified specification does not pass Hansen’s overidentification test for cohort 16-22, suggesting one of the instrument is not valid.

In table 6, we reports the result of the model with ethnic diversity, calculated by 31 group classification, is transformed into logarithmic form. The interpretation of the coefficient will be the effect on the year of schooling as a result of a percentage change in the ethnic mix in the subdistrict. In other word, the marginal effect will not be linear with the effect will diminish as the diversity keeps increasing. The direction and the significance of the main coefficient are maintained. For every 10 per cents increase in the level of ethnic diversity in the subdistrict will lead to an increase by 0.07-0.08, 0.08-0.10, and 0.07-0.09 when flat, rainfall, and both instruments are used, respectively. Interestingly, the log form model pass all the statistical tests.

When the polarization index is used instead of the diversity index, the inference is maintained, as shown in Table 7. The correlation between two index is high, around 0.93. However graphically the polarization index is a hump-shaped curve with the maximum is reached when the number of ethnic diversity is two, with both have equal group size, and the values get lower in either sides. This suggest an optimum level of diversity, with the extreme values of homogeneous and very fragmented society as detrimental to knowledge accumulation. Using different instruments, the schooling effect of ethnic polarization is positive with point estimates ranging between 0.34 and 0.47 more years of schooling for every 0.1 increase in ethnic polarization index. In terms of statistical tests, the first stage F values suggest that our instruments are not weak. The results of the endogeneity test also suggest that ethnic polarization should not be treated as exogenous. Furthermore, in the overidentification test, we cannot reject the null hypothesis that all instruments are valid.

Heterogenous effect

One may wonder if the ethnic diversity affects differently between migrants and residents. In this section we test this by estimating the model only for the stayers or those stay in their birth place. We identify this group in the census data as subpopulation whose birth place and current place are the same.

As reported in Table 8, the sign and the statistical significance of the coefficients of ethnic diversity for stayers subpopulation confirm our main results. However, compared to the main results, the magnitude of OLS coefficients are bigger while that of IV/2SLS one are smaller in the stayers estimation than the corresponding coefficients in the whole population. For causal inference we focus on the IV estimates. The analysis for stayers subpopulation suggests that the schooling effect of an increase in ethnic diversity by 0.1 point is between 0.3 and 0.6 more years of schooling for three different cohorts and across instruments. This results also suggest the effect in the main results (0.4-0.7) is magnified by the performance of the migrants.

Possible channels

We speculate that there might be two competing effects in play in the relationship between ethnic diversity and educational outcomes. As suggested in the literature, ethnic diversity may facilitate progressiveness through the assimilation process. Children learn from their peer and adults in their communities and families may have higher expectation because they are exposed to better and varied example than they would have in the homogeneous communities. It is likely that in diverse society the standard of achievement becomes higher due to competition among individuals with different talents. To see this, we regress the correlation between ethnic diversity and various indicators as proxies for talent diversity. Firstly, we use employment diversity and the availability of different life-skills training in the society to proxy talent variation among population. For employment diversity, we use information in the 2000 census on employment, classified in 9 industries. While for constructing training variation variable we use information in the 2000 Podes (Village Census) on the availability of the following training activities in the village: mechanics, electronics, typewriting, language, bookkeeping, culinary, sewing, agriculture, computer, carpentry, handicraft, and fashion. We expect these variables, after controlling for regions’ social economic conditions represent the pool of talents available in the communities. Simply put, comparing regions with the same level of social economic development, regions with more variation in employment and life-skills training would have greater pool of talents.

Secondly, we also check the correlation between subdistrict ethnic diversity and community’s facilities build in the village for hobbies or sport activities. In this case we use information on the availability of soccer and volley courts in subdistricts from the 2000 Podes.

As for the potential negative effects that commonly associated with ethnic diversity, we check its correlation with some indicators as proxies for cooperation and trust among subdistrict residents. We use information on the existence of *gotong-royong* (community-based self-help activities) and *karang-taruna* (youth organization) to represent cooperation. In addition, we use the incidence of fighting to represent trust. In most literature, ethnic diversity is expected to reduce the willingness to cooperate and erode trust among villagers.

The results are reported in Table 9. The coefficients of ethnic diversity are as expected for employment variation and soccer court. Subdistricts with higher degree of ethnic mixture tend to have greater variation in employment, controlling for infrastructure, adults' education and other regions' characteristics. This support the idea of talent complementarity. More heterogenous communities also tend to have facilities for hobby. Again this support our speculation about greater pool of talent. Interestingly, popular concerns about the erosion of the willingness to cooperate is not supported by our data. There is no correlation between ethnic diversity and the existence of community-based activities, and even more surprisingly more heterogenous subdistricts tend to have more village with active youth organization. On the other hand, the association between ethnic diversity and the incidence of fighting tend to support diversity debit hypothesis. The probability of fighting incidence increases with ethnic diversity.

Overall, the results in Table 9 suggest that the mechanism by which ethnic diversity benefits educational outcomes works through the availability of greater talent pool in the society. By exposing to many different types of skills children learn from other and help them in accumulating knowledge. Furthermore, the concern on lack of cooperation in diverse society is also not proved.

Regional features

Finally, we want to know whether the results are consistent if we limit the observation only for Outer Islands. It is reasonable to think that the results are driven by Java, given the size of the population and the level of development. Although Java only makes up around 6 per cent to total land area, the number of subdistrict in Java is 1,872, or about 49 per cent of total subdistrict (including Madura). As a results, our sample drop almost by half, from 3,826 to 1,954 subdistrict. This smaller sample size may affect the credibility of our estimate because of IV finite sample property. The biasness of IV estimate may also increase if our instruments are weak.

The results of Outer-Islands estimation in general maintain our main results, as shown in Table 10. The sign of the coefficients are consistent, but with the magnitude of the effect falls by around half of the magnitude in the main results. Attention should be given to the IV estimates using rainfall as instrument, which do not pass the endogeneity test. This is likely caused by weak instrument, as indicated by the low F value in the first stage estimation. Consequently, the standard errors become larger so the IV estimate is biased toward OLS. This is salient in the estimate of 16-22 cohort. On the other hand, the statistical tests for model with flat as instrument and overidentified model suggest that IV estimates are consistent. Overall, the results of subpopulation analysis confirm the main results that ethnic diversity, on average, is beneficial for subdistrict human capital formation.

6 CONCLUSION

Our analysis finds that ethnic diversity is beneficial for human capital accumulation. Using full-count data from two waves of Population Census and employing instrumental variable approach we correct the downward bias on the relationship between ethnic diversity and average year of schooling at subdistrict level. The results suggest that exposure to ethnic diversity during primary to high school age leads to more years of formal education in the subsequent stage, 10 years later.

The benefits are not only accrued to migrants, who are generally associated with more ability and agility, but also to stayers. The mechanism behind ethnic diversity benefit is likely through a greater pool of talent which in turn facilitate a spill over effects from the talented persons or groups to the rest of society. The concern that this process will be offset by eroded trust and willingness to cooperate among member of society is also not proved. In our research context, children in ethnically diverse communities are likely to reap more benefit through peer effects and their interaction with adults than children in homogeneous society. The results of our analysis provide supports for policies promoting multiculturalism and assimilation, especially in educational sector.

1089 REPRODUCTIVE LABOR AND COMMERCIAL SURROGACY: A CASE STUDY IN NEW DELHI, INDIA

ABSTRACT

Under the globally stratified biopolitical economy, the development of reproductive technologies and “outsourcing” of reproductive materials have led to the rise of reproductive industries in third world countries like India, and the involvement of women from the socio-economically disadvantaged background in the production process has been analyzed and critiqued in myriads of ways. This study aims to establish commercial surrogacy as a form of gendered labor practice in the Indian context. It examines how commercial surrogates are able to exercise their rights and agency in India’s surrogacy industry as reproductive laborers. Contemporary theoretical and empirical evidence clearly suggests that commercial surrogacy, empowering or not, provides employment for women from difficult backgrounds, and can be associated with the process of economic production in a market economy. The methodology primarily involves participant observation, including in-depth semi-structured interviews with the participants of commercial surrogacy, as well as workplace observations to gain insight of the surrogate’s day- to- day lives. The issues addressed here are empirically substantiated by field observation and case studies. The study involves a multiple case study set in the National Capital Region of Delhi (NCR) between October of 2016 and April of 2017. Given the present political scenario in India, with a proposed ban on commercial surrogacy; the economic activity today operates as undetected as possible. Due to the ethical aspects of the issue and the difficulty to locate informants for the study, snowball sampling method was adopted for the study. Surrogate mothers, fertility specialists, surrogacy agency owners, and surrogacy agents were interviewed in order to observe and understand the complexities of work and labor in surrogacy industry in India. This paper will present an illustration of the network through which surrogacy industry operates in India by identifying and mapping the segments of commercial surrogacy as an intertwining web of people and technology. The argument is based on the evidence derived from workplace and participant observations in the field and interviews with different stakeholders of surrogacy services, in order to understand the processes through which individuals operate and form a network within which power imbalances fuel the economic production. Further, the disposable nature of the labor in this highly commercialised process is alarming. Also, the disadvantaged socio-economic background that limits the surrogate’s decision-making capacity and their ability to exercise their agency as laborers in a production process reiterates the issue of commodification and exploitation. Commercial surrogacy in India has always been approached with a critical stance, owing to the traditional gender relations prevailing in Indian Society. As a result, surrogacy as a form of a labor practice is grossly undermined, something this paper attempts to address. The government’s abolitionist stance on surrogacy needs to be reconsidered and policies on surrogacy should be framed from a more pragmatic approach.

1295 GENDERED LANDSCAPE OF FEAR IN PUBLIC SPACE IN KOLKATA, INDIA

ABSTRACT

Existing research on fear of victimization in public spaces substantially pointed out its negative impact on women’s mobility, and corresponding restriction on their freedom and right to city space. Eminent scholars have argued that, albeit the apparent visibility of women in urban landscape, they do not possess equal access to public space with that of men. This produces gendered space, which increases and also gets reinforced through fear of violent crime, shaping geographies of spatial intervention by women. This paper focuses on fear induced production of gendered public spaces in otherwise acclaimed, one of the safest city scope for women in India - Kolkata. The city, has always been considered to be safe for women compared to other metropolis of the country. The robust social cohesion, neighbourhood appendage and its rich cultural heritage provided its women with secure social environment and (comparatively) fair command over public space. Nonetheless with the recent increase in the reporting of violent incidences in and around the city, the ‘being safe for its women’ image stands challenged and is questioned. The escalating rates of violent crime is perceived to have increased fear of victimization and reduced spatial confidence among the women of the city; restricting and reshaping their mobility and thus creating gendered spaces. Therefore an attempt is made to examine the real situation against the perceived notion; study the degree of change in the social environment of the city; the factors resulting in production of fear; and to what extent gendered spaces are being produced and (re)produced. The study is largely based on personal interviews nonetheless information from National Crime Records Bureau, Kolkata Police Station and newspaper reports are also used. The subjects for the study includes both men and women of various age cohort, however the lower range is kept at 16 years. It will therefore capture different perspectives and the varied gendered nuances that influence and also get influenced through the social process. The questionnaire used is extensively qualitative in nature along with necessary quantitative aspects. The choice of extensive usage of qualitative method is deliberately done as quantifying fear would reduce the importance of the study. A preliminary survey was conducted to get larger perspective of the people regarding their perception about the places unsafe in Kolkata and the rationale behind that. On the basis of that the sites are chosen to examine the real scenario. Having said that the study reveals (provisional) that the larger perception of people about a certain area being unsafe depends on the built area characteristics, social cohesion and feeling of “otherness”. Nonetheless the fear of victimization is very much present among women which modifies their mobility and accessibility of public spaces. Moreover, the slow alteration in the social dynamics from a cohesive society to one that is more egocentric and less empathetic towards the victim proves to be a major obstacle in creation of safer space for women. Key words: gendered space, urban landscape, social cohesion, fear, crime, restricting mobility, spatial confidence, otherness.

1381 CULTURE INDUSTRY AND GENDERED SPACES' STEREOTYPING IN HINDI CINEMA IN SELECT FILMS POST 1990

ABSTRACT

“Gender Bias Without Borders” (2014) reported of a high sexualisation of women in films made in India. The report identified media as an important tool shaping the development of nations and included ‘Women and Media’ as a section stating its objective as “Increase the participation and access of women to expression and decision- making in and through the media and new technologies of communication”. India’s report on implementation of the above gave a very vague description of the methods, intending practice particularly through media without any particular reference to women. Constant upheavals against various portrayals and the association with identity has cast serious doubts about any improvement in the continuing scenario. An attempt has been made to decipher the elements of ‘Bollywood’ that reinforce the application of the term ‘culture industry’, particularly the way commodified culture converts depictions of reality and appropriates, while defining and producing gendered spaces and stereotyping them in the process. Cinema thus as a form of entertainment based on fusion of amusement and knowledge, the way it combines the workings of pleasure and reality to form the industry producing meaning for the imagination of the viewers possesses great potential of bringing social change. Moreover, the cinema has the potential where identities are constructed and deconstructed with respect to the space by the manufacturers of the products of culture industry. The contents of Hindi cinema are examined in relation to the representations of identities as products of social and cultural interactions. The content analysed is of both mainstream and parallel cinema in select films post 1990 analysing the influence of the changes encountered under the Structural Adjustment in India post liberalisation, the major factor being increased influence of Global interaction through capital flow and culture flow, especially through the medium of mass media. The reach of cinema in India in terms of its effects is immense and thereby is looked at as an important tool of shaping the nation’s imagination. The movies selected are on the basis of their gross earnings and felicitation of awards of National recognition for both popular and critic appreciation. The parallel are also selected through an additional filter of being women centred. The movies are analysed on the basis of the portrayals of the male and female protagonists primarily, and the other lead roles as per the individual narratives. The perceptions are described and analysed as elaborated by the characters or as relatable to the referred literature. The main grounds identified for the production of commodified culture are i. The Regional / Location, ii. The Religion, and iii. The Gender. The gendered spaces are identified on the basis of the portrayals in the context of i. The Home, ii. The Workplace, and iii. The Marketplace / Street. The research overall succeeds in bringing out the properties of Hindi cinema as a mass producer of stereotyped images and spaces, serving its purpose as an industry aimed at profit maximisation by following the established “formulas”.

1412 WOMEN'S ACCESS TO HIGHER EDUCATION IN INDIA: AN ANALYSIS OF DISTRIBUTION AND QUALITY

ABSTRACT

In the post-economic reform period, there has been an unprecedented increase in growth of higher education system (HEIs) and enrolment in India. However, the presence of HEIs fails to guarantee equal access to all, especially in a society where gender is an important determinant of exclusion. The institutional- structural constraints regarding distribution and quality of HEIs are major factors to women’s participation in HE in India. This necessitates examining how much equitable and inclusive higher education system has become for women in the post-economic reform era. The study analyses the level of participation of women through GER and Eligible enrolment ratio in higher education at graduate and above level. Sopher’s disparity index measures the extent of gender disparity in enrolment among different social groups and rural-urban populations. The study tries to enquire how the distribution of HEIs affects the women’s accessibility to HE in India through an association between women’s access and college population density, the average size of enrolment per college across states and the nature of concentration of HEIs in a state. The rampant increase of private- aided HEIs has given rise to various levels of educational infrastructure which interfere with the affordability of HEIs and choices made. In the recent observations, we recognize an increase in women’s participation in HE, though the scheduled women suffer discrimination in access. The gender disparity is wider for rural women; however, in recent years, convergence is observing in its rural-urban differential. The study suggested that enrolment in local private colleges compromises the quality of education though offer better accessibility. At the same time, better quality of educational infrastructure in urban centers acts as motivation to women’s participation in HE through better access to hostels, common rooms, etc.

1504 FEMALE STREET VENDORS: A CASE STUDY FROM WEST BENGAL

ABSTRACT

At present a sizeable proportion of socio-economically poor women both from rural and urban areas are engaged in street vending in the urban areas. In the study areas these women mainly consists of Scheduled castes and 'Atraf' Muslim. Separated, widow and divorced women are forced to take part in such work due to absence of adult income able male persons in the family. Along with them very scanty income of some married women's husbands drove them in doing street vending. These women can easily engaged in such work, as these economic activities need nearly no education, very low skill and very small financial inputs. For these reasons illiterate or very low educated poor women from far off rural areas come to the road side areas of the city for selling mainly non- standardized and low priced raw vegetables and flowers. These women start to work nearly mid-night and go back home in the afternoon. These women could not have proper food during their long working period. Very few of them manage to arrange overhead shade to protect them from heavy rains and scorching sunrays. Even after doing very hard work these women earn very little amount of money that they used for family maintenance and can't save anything . They also could not look after their children properly, as a sizeable proportion of these women left their children abundantly at home. These women are forced to donate money for different local festivals and ceremonies. Though these women work for the whole life they do not have any old age financial security. The study area of this research work located on both side of Dum Dum station along Dum Dum Road. This study area is situated both in Kolkata and North Twenty-four Parganas districts of West Bengal. For this research work percentage and correlation matrix are used. Key Words : Street Vendors, socio-economically poor women, low priced selling objects, rural women, illiterate low skilled women.

1674 XENOPHOBIC VIOLENCE, TRAUMA, DISPLACEMENT AND REINTEGRATION: A CASE STUDY OF FEMALE MIGRANTS IN ISIPINGO, DURBAN, SOUTH AFRICA

ABSTRACT

Xenophobia has become a serious problem in South Africa since the dawn of democracy. South Africans have been accused of being “Afro-phobic”, as their xenophobia is mostly aimed at other African nationals in the country. Socio-economic conditions, relative deprivation and apartheid’s legacy foster xenophobia amongst South Africans. Female migrants have not been spared, and are especially vulnerable to xenophobic attacks due to their political status, and are exposed to human rights abuses, and experience of different forms of violence – physical, emotional, sexual, psychological and institutional. This paper focuses on the injustices that are inflicted on female refugees and undocumented migrants in South Africa. More specifically, this paper adopts a qualitative approach to investigate the trauma, displacement and reintegration of female migrants with reference to the 2015 xenophobic attacks in Isipingo, Durban, South Africa. A major concern was the health and safety conditions in displacement camps, and the challenges encountered by female migrants. The study revealed that prior to the xenophobic violence, the migrant women had received verbal threats to evacuate the area before they were attacked. However, the magnitude of the xenophobic attacks was unexpected. The displacement camps that were situated along the Isipingo Beach and the Chatsworth areas, had housed a massive population that deprived women of privacy and separate sanitation facilities. The purpose of the displacement camps was to provide a safe zone for migrants until the xenophobic violence had subsided. However, strategies to prevent violence and crime from occurring inside the confined camps were not considered. As the camp population increased, resource provisioning was inadequate. Re-integration of displaced women to their domiciles in Isipingo was a difficult process. Migrant women in Isipingo have been experiencing more insidious forms of xenophobic violence such as rape, ethnic discrimination and emotional abuse. Conceptually, this study was influenced by feminism and gendered migration perspectives. Women in Isipingo faced a ‘double jeopardy’ - being foreign and female. They encountered gender specific challenges during displacement and reintegration in specific localities. Females were more vulnerable to human rights abuses, making them one of the most helpless groups during xenophobic violence. Migrant women suffered the most injustices and trauma in displacement camps, and returning to their homes in Isipingo was deemed unsafe and risky. The hostility of local citizens poses a larger problem for the peaceful reintegration of migrant women back into their society in their original localities. Keywords: Female migration, displacement, xenophobia, trauma, violence, Isipingo, Durban, South Africa

ABSTRACT

The inclusive regional development can be based on the integration of marginalized stakeholders of the development process. In the marginalized section, major shares belong to women which constitutes half of the population. According to SDG 2030 of United Nations, gender and social justice are one of the 17 goals for achieving the target of sustainable development of any place or region. In most of the development programs for gender equality, women are treated as the target group which leads to the continuation of their subordinate role in socio-economic dimensions. It has been observed from the employment scenario of women in India, 53% of the working women are involved in the traditional knowledge-based industries followed by the 33% of the casual wage workers. Hence by tapping the potential of traditional knowledge-based industries can be resulted in the active inclusion of women in the development process of the region which is way more sustainable and inclusive in nature. In this paper, the role of traditional knowledge-based industries will be discussed as the potential tool for inclusive development of the region and as well achieving gender equality and social justice.

Keywords: Inclusive development, marginalized, sustainable, gender equality, social justice

1 INTRODUCTION

India is emerging as one of the fastest growing economies across the globe. With this growing economy, India has to ensure that its development path should be sustainable and inclusive. The inclusion of marginalized section based on gender, ethnicity, caste, etc. in the sustainable development process is need of the time. According to Sustainable Development Goal 2030 of United Nations, gender and social justice are one of the 17 goals for achieving the target of sustainable development of any place or region. The gender issue is one the major concern of sustainable or inclusive development of any place or region and inclusion of women in the development process will help in solving the gender issues. In the present scenario, most of the development program exclusively focussed on the women which resulted in the subordinate role of them in socio-economic dimensions.

It has been observed from the employment scenario of women in India, 53% of the working women are involved in the traditional knowledge-based industries followed by the 33% of the casual wage workers. Hence by tapping the potential of traditional knowledge-based industries can be resulted in the active inclusion of women in the development process of the region which is way more sustainable and inclusive in nature.

1.1 Role of Traditional knowledge-based industries

Traditional knowledge-based industries are living heritage of us. It is part of the cultural and ethnic identity of the region transferred from generations. The World Intellectual Property Office (WIPO) defines *traditional knowledge as indigenous knowledge related to categories such as agricultural knowledge, medicinal knowledge, biodiversity-related knowledge, and expressions of folklore in the form of music, dance, song, handicraft, designs, stories and artwork*. It contributes to the manufacturing sector of the micro and small industries of the economy. It is the labor-intensive sector and with the development of this sector, it can provide employment.

This paper discusses the role of the traditional knowledge-based industries in the inclusive development of the region by studying the case of West Mithila region, Bihar.

2 METHODOLOGY

The study was done majorly in two steps to understand the ecosystem of Traditional knowledge-based industries: (i.) assessment of the significance of traditional knowledge-based industries and scenario of women employment (ii.) Nesting of the Traditional knowledge-based industries in the region, and discussions on policy guidelines.

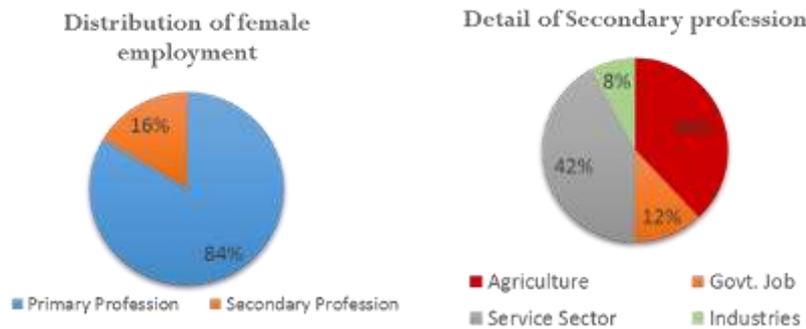

3 THE CASE OF WEST MITHILA REGION

3.1 Study area

Bihar has a variety of art & crafts like Mithila paintings, Patna Kalam, Tikuli art, Sikki grass Craft, Stone carving work, lac work, Khatwa work, Sujini work, etc. but the highest concentration of Traditional knowledge-based industries are in West Mithila region of the state. Basically, Mathili is a language of Bihar and Maithili speaking areas are known as Mithila region and western part of this region comprises of 7 districts- Sitamarhi, Madhubani, Sheohar, Darbhanga, Muzaffarpur, E. Champaran & W. Champaran. West Mithila is very rich in a variety of Art & Craft and about 20% of the total concentration of Art & Craft industries of the state is in these 7 districts of the region.

3.2 Assessment of Traditional knowledge-based industries

About 91% of the manufacturing in the region comprises of MSME industries (DCMSME). MSMEs have a large share of micro industries which is about 96% and in the micro industry sector, traditional knowledge-based industries have a share of 74%. It shows the clear domination of Traditional knowledge base industries in the region.

Source: DCMSME 2011, DC (Handicrafts & Weaving)

Figure 140 Nature of employment

84% of workers are solely dependent on the Traditional knowledge-based industries and other 16% are serving more as their secondary source of income. The maximum number of artisans which are serving traditional art & craft industry more as the secondary profession are involved in the service sector, than agriculture.

The spatial concentration of artisans is highest in Madhubani & Darbhanga districts. In West & East Champaran spatial concentration of craft is least.

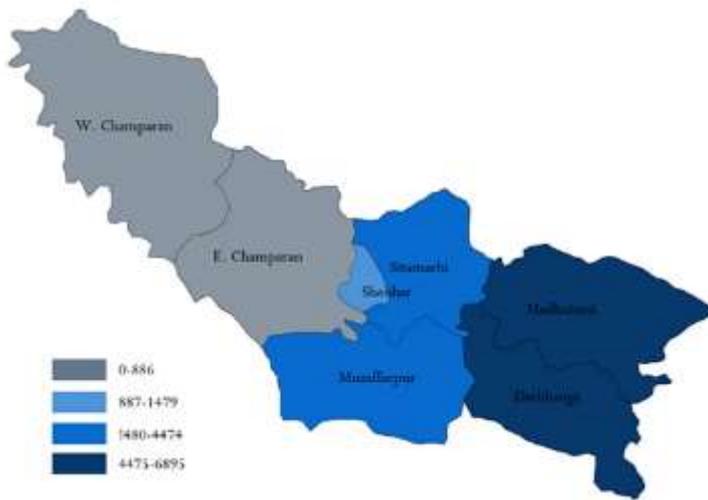

3.3 Nesting Analysis

For nesting analysis, location quotient of female workers in traditional knowledge-based industries is determined. Basically, location quotient of a district is the ratio of a number of female workers to the working population. Madhubani has the highest nesting of artisans in the whole region, preceded with Muzzafarpur and Darbhanga.

Source: Author

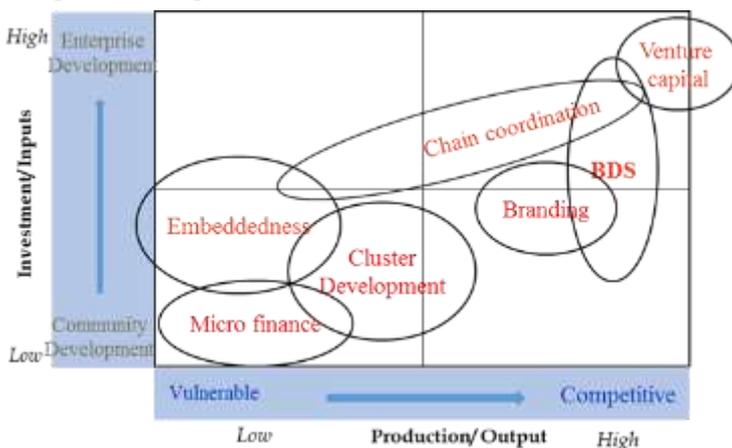

Figure 141 Spatial concentration of artisans in the region

Source: Author
Figure 142 Spatial Distribution of Location Quotient

3.4 Discussions

The West Mithila region is rich in traditional knowledge-based industries but on the other hand, it is one of the economically backward regions of India. The study of the ecosystem of Traditional Knowledge-based Industries is showing the dependency and involvement of female workers on it. In this region despite a high number of female employment, investment/ inputs, as well as production/ output, is very low. This situation is giving rise to the vulnerable condition of Traditional knowledge-based industries. Women-owned firms face multiple challenges. Although evidence shows they are as effective as men owner/managers, women often use their firms as part of household survival strategy and opt not to grow (Nichter, S. Goldmark, L.) and the strategy of community development is more suitable than the enterprise development.

(Source: Understanding micro and small enterprise growth, S Nichter, L Goldmark - Micro Report, 2005)
Figure 143 Investment Production Scenario

Hence tapping the potential of Traditional knowledge-based industries can play an important role in inclusive development by including women of West Mithila Region broadly by the following crucial factors: (i.) community development (ii.) social embeddedness (iii.) micro finance and (iv.) cluster development. Apart from the general business factors of micro- finance, capital, marketing, etc. this inclusive development path needs the more specific intervention of the community development, social embeddedness, and cluster development as women are the stakeholder.

4 CONCLUSIONS

The discussion on the role of Traditional knowledge-based industries for inclusive development of region presented in this paper may raise more questions than it answers. It is evident from the study that female employment is higher in the Traditional knowledge-based industries and they often use their firms as part of a household survival strategy. Accordingly, policy should be framed for specific interventions in community development, social embeddedness and cluster development as women are the stakeholder of this inclusive regional development. Hence by tapping the potential of traditional knowledge-based industries can be resulted in the active inclusion of women in the development process of the region which is way more sustainable and inclusive in nature as well help in achieving gender equality and social justice.

RESEARCH HIGHLIGHTS

- This study examines the interaction among the entrepreneurship, innovation, and economic growth.
- The focus is on a sample of Eurozone countries over 2001-2016.
- A panel vector autoregressive model is used for the empirical investigation.
- The study demonstrates the existence of Granger causality, both short run and long run, among the variables.

GRAPHICAL ABSTRACT FOR REVIEW

Note:

H1A: Innovation Granger-causes economic growth.

H1B: Entrepreneurship Granger-causes economic growth.

H1C: Entrepreneurship Granger-causes innovation.

Subscript 2 (in place of 1) signifies Granger causality in reverse order.

ABSTRACT

Economic growth in the Eurozone has been lacklustre over the last two decades due to increased global competition from other economic players in other regions, economic and financial crisis, and political uncertainties within the Eurozone. To increase the global competitiveness of the region, the European Union launched the *Europe 2020 Strategy* to raise the level of entrepreneurship and innovation as key drivers of economic growth. This paper investigates the causal relationships among entrepreneurship development, innovation, and economic growth for a sample of Eurozone countries over 2001-2016. Using a vector error-correction model (VECM), the study finds that in the long run, both entrepreneurship and innovation stimulate economic growth. In the short run, however, the causal links are not always uniform and depend on the specific proxies that are used for innovation and entrepreneurship. The results provide valuable insights on the types of policies and strategies that would sustain economic growth in Eurozone countries.

Keywords: Entrepreneurship, innovation, economic growth, VECM, Eurozone countries

1 INTRODUCTION

A vibrant entrepreneurial culture and a strong national innovation ecosystem are seen as key catalysts for enhancing global economic competitiveness. There is an extensive literature that has examined the inter-relationships between entrepreneurship, innovation and economic growth. While there is a strong understanding of the theoretical foundations on the relationships between these three variables, it is clear from the literature that the causal relationships among them

are rather complex and are underpinned by forces that simultaneously impact all three. The literature on micro-foundations (entrepreneurial activities) of the macro-economy (innovation and economic growth) is still evolving, and the forces that define the underlying structure of the economy are still sources of debate and research among policy-makers, researchers, and industry analysts.

It is widely accepted in the literature that economic growth is determined by factors of production and entrepreneurial activities which spur innovation; by innovation which spurs entrepreneurial activities; and by entrepreneurship and innovation in efficiently allocating resources to deepen the impact of traditional factors of production on economic growth (Schumpeter, 1934; von Hayek, 1945; and Baumol, 1968, 1990). These studies and others have shown that entrepreneurs contribute to the economy via several channels, including: investing resources to produce products and services that meet the needs of the markets; creating new employment; reinvigorating industrial clusters, innovation accelerators and special economic regions; nurturing and sustaining regional trade and cooperation; investing in research and development activities; introducing new innovations to the markets; undertaking social and philanthropic activities; increasing competition in the market that lead to better service quality and cost structures; and continuously undertaking product and process improvements (Romer, 1986 and 1990; Porter, 2008 and Warsh, 2006).

Due to the positive spill-over benefits of entrepreneurial activities, governments across the globe have invested significant resources to nurture entrepreneurial activities and enhance the innovation ecosystems in their respective countries. For example, the European Union introduced a 10-year plan called the *Europe Strategy 2020* in 2010 to foster smart, sustainable and inclusive economic growth in the Eurozone (World Economic Forum, 2014). Smart growth is defined as “developing an economy based on knowledge and innovation”; sustainable growth is defined as “promoting a more resource efficient, greener and more competitive economy”; and inclusive growth is defined as “fostering a high-employment economy delivering social and territorial cohesion” (European Commission, 2010). Under this plan, entrepreneurship and innovation are key drivers for ensuring sustainable economic development, job creation and improvement of the quality of life in Europe. This plan was put in place to help countries in Europe slow economic growth due to the following reasons: financial crisis the plague some countries and its contagion effect on other Eurozone countries; increasing government debts; gloomy economic prediction due to potential fragmentation of the European Union; increasing wealth gap between member countries; and loss of competitiveness to countries from North America and Asia (World Economic Forum, 2014).

Key targets were set under *Europe Strategy 2020* for employment, R&D, increasing green energy and reducing emissions, improving education rates, and reducing poverty. The European Commission recognized that the targets are interrelated and critical to overall success. As such, each initiative has both an EU-level action plan and a national level (member state) action plan (European Commission, 2010). As of 2015, key outcomes achieved under this plan include the following: employment increased from a low of 68.4% to 70.1% from 2012 to 2015; R&D increased from 1.85% of GDP in 2008 to 2.03% in 2014; greenhouse gas emission reduced from 90.3 in 2008 to 77.1 in 2014 (index 1990 = 100); early leavers (population aged 18 years to 24 years) from education and training fell from 14.7% in 2008 to 11% in 2015; tertiary enrolments increased from 31.1% in 2008 to 38.7% in 2015; and people at risk of poverty or social exclusion reduced from a peak of 122.5 million in 2012 to 120.9 million in 2014 (Eurostat, 2016).

The primary objectives of this paper are to shed additional light on the roles that innovation and entrepreneurs play in nurturing and sustaining a vibrant economy in Eurozone countries. This paper is structured as follows. In Section 2, a brief background of the literature and theoretical underpinning of the paper are provided. In Section 3, the methodology used to capture the complex relationship between entrepreneurship, innovation and economic growth is outlined. In Section 4, the empirical results are presented. In Section 5, a discussion of the results, including policy implications is provided.

2 LITERATURE REVIEW

The literature demonstrates that there is a wide range of definitions for “innovation” and “entrepreneurship”. Schumpeter characterized five different types of innovation: introducing new products and services; incorporating new methods that lead to process improvements; expanding to new and diverse markets; acquiring new sources of inputs for the production of goods and services; and introducing new business models and industrial systems that hinder monopolistic market structures (Schumpeter, 1934). While the characterization by Schumpeter covers a number of types of innovation, the definition of innovation has not changed much over time. Consider Du Plessis (2007) who describes innovation as “the creation of new knowledge and ideas to facilitate new business outcomes aimed at improving internal business processes and structures and to create market-driven products and services”. Thus, while specific innovations change over time due to the very nature of innovation, the idea of innovation has not necessarily changed. There is also a wide range of definitions and descriptions of entrepreneurs in the literature. Schumpeter (1934) describes an entrepreneur as someone who undertakes production processes by using different possible combinations that gives them a strategic market advantage and acquire a decent entrepreneurial profit. Knight (1921) describes an entrepreneur as someone who takes ‘calculated risks’ and transforms uncertain endeavors into productive outcomes. Liebenstein (1968) characterize entrepreneurs as creating a vibrant firm culture that reduces organizational entropy and inefficiencies. According to Liebenstein, there are two classes of entrepreneurs that enhance the competitiveness of a firm by 1) allocating resources to enhance the efficiency of the production process and 2) identifying opportunities in the current market and introducing new products that meet the needs of the market.

There have also been several studies that have linked the micro-foundations (entrepreneurial activity) to the state of the macro-economy. For example, studies by Baumol (1990) and Holcombe (1998) argue that entrepreneurs promote an innovation-driven economy by investing in both incremental and radical innovation that spawn new products, services and industries. The entrepreneurial acumen needed to create value for the economy is due to the unique abilities of entrepreneurs to identify profitable arbitrage from uncertain endeavors (Kirzner, 1973 and 1997). These studies show that entrepreneurial activities are key drivers for continuously moving the economy to a new and higher equilibrium by enhancing the richness and reach of the factors of production. There have been numerous empirical studies that have examined the role of innovation in economic growth as well as the role of entrepreneurship in economic growth. Given that there are strong links between entrepreneurship and innovation, this study will examine the trivariate relationship between innovation, entrepreneurship and economic growth. This section addresses three strands of literature pertaining to the possible causal relationship between entrepreneurship, innovation, and economic growth.

2.1 Links between innovation and economic growth

The relationship between innovation and economic growth has received considerable attention in the literature, as discussed above. The relationship between innovation and economic growth can be captured by four different schools of thought. The first school of thought supports a *supply-leading hypothesis* (SLHA), which suggests that innovation Granger causes economic growth. Proponents of this school argue that research and development (R&D) and other new innovations contribute to new products, services, processes, product improvements, and new business models, all of which have the potential to increase economic growth (Kirchhoff et al. (2007), Guloglu and Tekin (2012), and Pradhan et al. (2016)).

The second school of thought promotes a *demand-following hypothesis* (DFHA); which argues that economic growth Granger causes innovation. Proponents of DFHA argue that as economies become more affluent, they invest in innovation to strengthen their economic growth strategies so as to ensure that they remain globally competitive (Sinha (2008), Sadraoui et al. (2014), and Pradhan et al. (2016)).

The third school of thought posits a *feedback hypothesis* (FBHA), which suggests that innovation and economic growth Granger cause and reinforce each other (Hasan and Tucci (2010), Galindo and Mendez (2014), and Pradhan et al. (2016)). Interestingly, some studies such as Pradhan et al. (2017) and Pradhan et al. (2016) support the validity of all three hypotheses, depending on the choice of variables and samples that are used.

Finally, the fourth school of thought presents a *neutrality hypothesis* (NEHA) and argues that innovation and economic growth do not Granger cause each other (Cetin, 2013 and Maradana et al., 2017). The economic rationale is that innovation may be at an infant stage in many of these economies and therefore has a negligible impact on economic growth. Economic growth in many of these economies is due to traditional factors of production.

Hence, the following hypotheses are tested in this study:

H1A: Innovation Granger-causes economic growth H2A: Economic growth Granger-causes innovation

2.2 Links between entrepreneurship and economic growth

The second strand of literature examines the relationship between entrepreneurship and economic growth. Similar to the link between innovation and economic growth, the Granger causality between entrepreneurship and growth can be presented by four different schools of thought. First, a *supply-leading hypothesis* (SLHB) claims that entrepreneurship Granger causes economic growth. The economic rationale for the proponents of SLHB is that entrepreneurs play a key role in investing in R&D and other resources that will lead to new products, services, processes, product improvements, and new business models, all of which will contribute to economic growth. Studies that support SLHB are Urbano and Aparicio (2016), and Li et al. (2012).

Second, are the proponents of a *demand-following hypothesis* (DFHB) who argue that economic growth Granger causes entrepreneurship. The rationale for this line of argument is that as an economy grows, governments have adequate resources to create a vibrant entrepreneurial ecosystem by introducing and establishing new institutions, sophisticated regulatory architecture, and both iscal and non-fiscal incentives to foster entrepreneurship. Improving business support systems should enhance entrepreneurial activities and innovations. Studies that support DFHB are Castano et al. (2015) and Fuentelsaz et al. (2015).

Third, are the proponents of a *feedback hypothesis* (FBHB) who claim both entrepreneurship and economic growth Granger cause and reinforce one another. For example, improving the entrepreneurial culture will stimulate economic growth and a buoyant economy will further encourage higher entrepreneurial investment and activities. The studies that support the FBHB are Huggins and Thompson (2015) and Wennekers and Thurik (1999).

The fourth school of thought supports a *neutrality hypothesis* (NEHB) which argues that entrepreneurship and economic growth do not Granger cause each other. The rationale for this line of argument is that weak entrepreneurial ecosystems, plagued by overregulation, bureaucracy and rent-seeking behaviour, tend to hinder productive endeavours and economic growth. Further, unclear business rules of engagement and opaque regulations may lead entrepreneurs to veer towards unproductive activities, resulting in high failure rates of firms (Bowen, and De Clercq, 2008 and Helmers and Rogers, 2010). All of these factors, including migration of successful entrepreneurs to other business-friendly countries support the NEH hypothesis.

Therefore, the following hypotheses are tested in the study:

H1B: Entrepreneurship Granger-causes economic growth H2B: Economic growth Granger-causes entrepreneurship

2.3 Links between entrepreneurship and innovation

The third strand of literature considers the link between entrepreneurship and innovation where the possible Granger causality between entrepreneurship and innovation can be summarized in four different ways. The proponents of a *supply-leading hypothesis* (SLHC) argue that entrepreneurship Granger causes innovation. The economic rationale for SLHC is that entrepreneurs take calculated risks to invest in R&D and innovation to create value for their portfolio of investments. These entrepreneurs are savvy at identifying firms that have the potential to enhance their return on investment. In many of the developed economies, much of the venture capital industry is led by entrepreneurs who promote both incremental and radical innovations. For example, studies by Popov and Roosenboom (2012) and Kortum and Learner (2000) show that VC funding led by entrepreneurs are a major contributor to industrial innovation in 21 EU economies and US.

The proponents of a *demand-following hypothesis* (DFHC) argue that innovation Granger causes entrepreneurship. Their rationale is that new innovations, especially many of the technology innovations, have resulted in the development of new business models. These new innovations have reduced the entry cost into various market segments and spawned new 'open innovation' platforms. The latter has further reinforced greater access to information, knowledge, market intelligence and other resources – all of which have intensified entrepreneurial activities. For example, Uber's investment in an online user- friendly platform to connect taxi drivers has opened opportunities for every driver to be an entrepreneur. Hall and Kruegger (2016) show that the number of active Uber driver- partners has increased exponentially from the middle of 2012 to December 2015 (from zero to more than 450,000 active Uber Driver-Partners). Other studies such as Audretsch et al. (2002) shows that U.S. government programs such as the *Small Business Innovation Research (SBIR)* program, produce several spillover benefits. The SBIR program provides small businesses access to R&D and innovation support; and, has encouraged new startup firms and commercialization activities among these firms.

There are other studies that support a *feedback hypothesis* (FBHC) of entrepreneurship-innovation nexus, where both entrepreneurship and innovation diffusion Granger cause each other. The economic rationale for FBHC is that, as entrepreneurs invest in new innovations, these new innovations increase the reach and richness of existing products and services, and in some instances, reduce barriers to entry. These lead to more new entrepreneurs entering the market. Studies that focus on the relationship between entrepreneurship and innovation include Capello and Lenzi (2016) and Galindo and Mendez-Picazo (2013).

The fourth school of thought is the proponents of a *neutrality hypothesis* (NEHC); who argue that entrepreneurship and innovation do not Granger-cause one another. The economic rationale for proponents of NEHC is that in some countries, the entrepreneurial and the innovation ecosystems are weak or dysfunctional. This is primarily evident in countries that are plagued by over-regulation, unfriendly business practices, rent-seeking behaviour, low investments in R&D, and lengthy time to register patents and business licences/permits – all of which can stifle innovation and entrepreneurial activities (Kritikos, 2014).

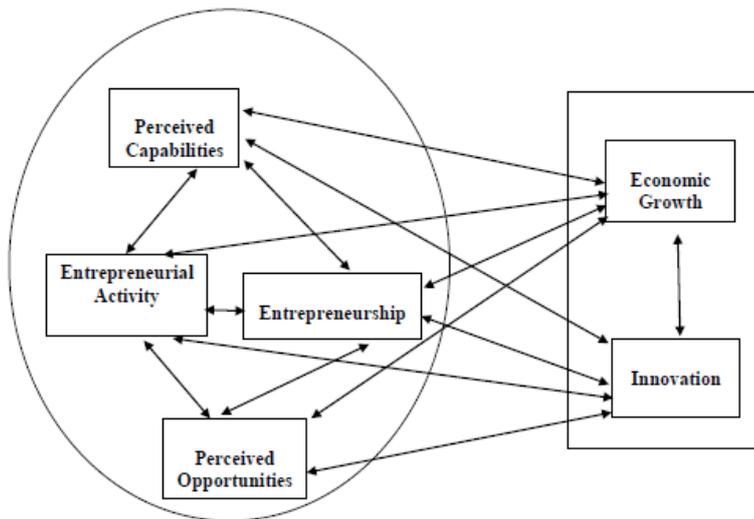

Based on the four schools of thought, the following hypotheses are tested in the study:

H1C: Entrepreneurship Granger-causes innovation H2C: Innovation Granger-causes entrepreneurship

3 DATA, VARIABLES, AND ESTIMATION PROCEDURES

As noted above, while the relationships between economic growth, innovation, and entrepreneurship have been studied, there is no real consensus on the causal direction of these relationships. Additionally, empirical studies on these relationships typically use a bivariate framework and therefore consider only two of these variables at any given time.

Figure 1 provides the possible set of links between economic growth, innovation, and entrepreneurship, based on the discussion in Huggins and Thompson (2015) and Wennekers and Thurik (1999).

Note 1: As will become clear in the text, entrepreneurship can be defined in terms of perceived capabilities and opportunities, as well as entrepreneurial activity.
 Note 2: The figure is developed using Huggins and Thompson (2015) and Wennekers and Thurik (1999).

Figure 1: The Conceptual Framework on the Possible Causal Relations between Entrepreneurship, Innovation, and Economic Growth

Extending the bivariate empirical literature on this subject, the present study uses a Granger causality approach to understand the dynamics among all *three* variables, namely innovation, entrepreneurship, and economic growth. Our study is on a broad scale for 19 Eurozone countries⁵⁵⁵ during the period 2001-2016. We use annual time series data obtained from *World Development Indicators* and the *Global Entrepreneurship Monitor* (see below).⁵⁵⁶

We deploy real per capita economic growth (PEG) and seven different indicators for innovation (INO): the number of patents by both residents and non-residents measured per thousand of population (PAT); trademark applications measured per thousand of population (TRA), researchers in research and development activities measured per thousand of population (RRD); scientific and technical journal articles measured per thousand of population (STJ); research and development expenditure measured as a percentage of gross domestic product (RDE); high-technology exports measured as a percentage of gross domestic product (HTX); and a composite index of innovation (INN), which is weighted average of all six innovation indicators (PAT, TRA, RRD, STJ, RDE and HTX).

It should be noted that we have no direct variables that can represent the status of innovation in a country at a particular period of time. The inclusion of these seven indicators can give a representative approximation for innovation status, particularly with reference to examining the Granger-causal relationship between entrepreneurship and per capita economic growth. However, the importance of a particular innovation indicator varies from study to study. For example, the study by Guloglu and Tekin (2012) places high value on both patents (an output-type innovation) and R & D expenditure (an input-type innovation) for regulating the long-run economic growth in high-income OECD countries, while the study by Kaneva and Untura (2016) looks to both R & D expenditure and R & D staff (an input-type innovation) for regulating long-run economic growth in the Russian Federation. Brenner (2014) places more emphasis on both scientific and technical publications (an output-type innovation) and R&D expenditure for regulating the long-run economic growth in a group of developed and developing countries.

This study uses three indicators as proxies for entrepreneurship. The data was accessed through the World Bank TCdata 360 which obtains the data from the *Global Entrepreneurship Monitor* (an adult population survey). All three indicators are expressed as the percentage of the population between 18–64. Total early-stage entrepreneurial activity (TEA) considers the percentage of the population who are either nascent entrepreneurs or owner-managers of a new business. Perceived capabilities (PEC) considers the percentage of the population who believe that they have the required skills and knowledge to start a business. Finally, perceived opportunities (PEO) considers the percentage of the population who believe that there are good opportunities to start a business in the area where they live.

The present study considers three samples and seven cases on the basis of the three entrepreneurship indicators and the seven innovation indicators.⁵⁵⁷ All the monetary variables are measured in constant US dollars. The variables are converted into their natural logarithms for our estimation in order to normalize the data.

555 The countries are Austria, Belgium, Cyprus, Estonia, Finland, France, Germany, Greece, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Portugal, Slovakia, Slovenia, and Spain.

556 We have an unbalanced panel since data on the variables is not uniformly available for all the countries and for all the years over the period of our investigation.

557 The subset of countries and the years covered under each of these set ups and cases are on the basis of data availability for the selected variables; we have an unbalanced panel.

We estimate a set of dynamic panel regressions, as given by the following equations:

$$\Delta PEG_{it} = \eta_{1j} + \sum_{k=1}^p \beta_{1ik} \Delta PEG_{it-k} + \sum_{k=1}^q \lambda_{1ik} \Delta INO_{it-k} + \sum_{k=1}^r \mu_{1ik} \Delta ENT_{it-k} + \delta_{1i} ECT_{it-1} + \varepsilon_{1it} \quad (1)$$

$$H_0^A: \beta_{1ik} = 0; \lambda_{1ik} = 0; \mu_{1ik} = 0; \delta_{1ik} = 0 \quad \text{for } k = 1, \dots, p, q \text{ and } r$$

$$H_1^A: \beta_{1ik} \neq 0; \lambda_{1ik} \neq 0; \mu_{1ik} \neq 0; \delta_{1ik} \neq 0 \quad \text{for at least one } k$$

$$\Delta INO_{it} = \eta_{2j} + \sum_{k=1}^p \beta_{2ik} \Delta INO_{it-k} + \sum_{k=1}^q \lambda_{2ik} \Delta PEG_{it-k} + \sum_{k=1}^r \mu_{2ik} \Delta ENT_{it-k} + \delta_{2i} ECT_{it-1} + \varepsilon_{2it} \quad (2)$$

$$H_0^B: \beta_{2ik} = 0; \lambda_{2ik} = 0; \mu_{2ik} = 0; \delta_{2ik} = 0 \quad \text{for } k = 1, \dots, p, q \text{ and } r$$

$$H_1^B: \beta_{2ik} \neq 0; \lambda_{2ik} \neq 0; \mu_{2ik} \neq 0; \delta_{2ik} \neq 0 \quad \text{for at least one } k$$

$$\Delta ENT_{it} = \eta_{3j} + \sum_{k=1}^p \beta_{3ik} \Delta ENT_{it-k} + \sum_{k=1}^q \lambda_{3ik} \Delta INO_{it-k} + \sum_{k=1}^r \mu_{3ik} \Delta PEG_{it-k} + \delta_{3i} ECT_{it-1} + \varepsilon_{3it} \quad (3)$$

$$H_0^C: \beta_{3ik} = 0; \lambda_{3ik} = 0; \mu_{3ik} = 0; \delta_{3ik} = 0 \quad \text{for } k = 1, \dots, p, q \text{ and } r$$

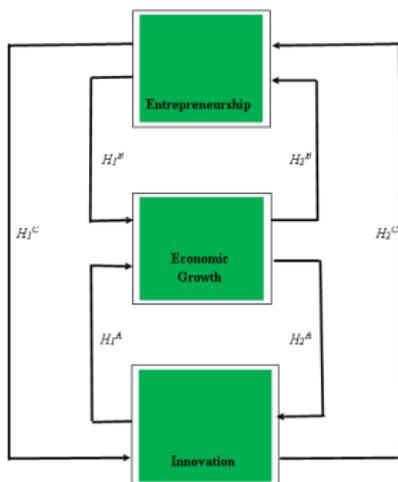

$$H_1^C: \beta_{3ik} \neq 0; \lambda_{3ik} \neq 0; \mu_{3ik} \neq 0; \delta_{3ik} \neq 0 \quad \text{for at least one } k$$

where Δ is the first difference operator, i is country and t is year in the panel, and ε is the error term. *Innovation (INO)* is defined as PAT, TRA, RRD, STJ, RDE, HTX or INN; and *entrepreneurship (ENT)* is defined as TEA, PEC, or PEO.

Additionally, p, q and r are the lag lengths for the differenced variables of the respective equations and can be determined by the Engle-Granger approach. The lagged error-correction terms (ECT-1) are derived from the long-run equilibrium properties inherent in equations (1) to (3). The ECTs represent long-run dynamics, while differenced variables represent short-run dynamics between the variables.

For short-run causal relationships, if the null hypothesis $\lambda_{1ik} = 0$ (or $\lambda_{2ik} = 0$) is rejected, there is Granger causality running from INO to PEG (or PEG to INO). If the joint null hypothesis $\mu_{1ik} = 0$ (or $\mu_{2ik} = 0$) is rejected, there is Granger causality from ENT to PEG (or ENT to PEG). For long-run causal relationships, the null hypothesis ($\delta_{1i} = 0, \delta_{2i} = 0,$ and $\delta_{3i} = 0$) needs to be rejected. The above tests are performed through a Wald test.

Figure 2 presents a synopsis of the hypotheses that are tested in this empirical investigation.

Note:

H1A: Innovation Granger-causes economic growth.

H1B: Entrepreneurship Granger-causes economic growth.

H1C: Entrepreneurship Granger-causes innovation.

Subscript 2 (in place of 1) signifies Granger causality in reverse order.

Figure 2: A Summary of the Possible Causal Links among the Three Sets of Variables

4 ESTIMATION RESULTS

The vector error-correction model (VECM) is used to examine the possible Granger causal relationships among innovation, entrepreneurship, and per capita economic growth. The first step of this framework is to determine the order of integration and presence/absence of cointegration⁵⁵⁸ among the three sets of variables.

We use three panel unit root tests, namely the Levin-Lin-Chu (LLC) test, the Augmented Dickey-Fuller (ADF) test, and the Philipps-Perron (PP) test to identify the order of integration of the variables in our panel setting. The tests establish that all the variables are integrated of order one (see Table 1). These results suggest the likelihood of cointegration among innovation, entrepreneurship, and per capita economic growth. The Johansen panel cointegration test (see Larsson et al., 2001) is then used to test the hypothesis that there is a long-run relationship among these three sets of variables. The results from this test validate the existence of a long-run equilibrium relationship among innovation, entrepreneurship, and per capita economic growth in our three samples and seven cases under each sample (see Table 2).

Table 1. Empirical Results of Panel Unit Root Test

Variable	Test Statics					
	Level Data			First Difference data		
	LLC	ADF	PP	LLC	ADF	PP
TEA	0.611	10.8	20.3	-12.9*	140.4*	217.5*
PEC	-0.49	13.9	16.3	-14.2*	142.9*	209.9*
PEO	0.68	11.97	12.99	-10.4*	106.5*	154.1*
PAT	0.889	24.3	24.9	-10.3*	125.7*	191.3*
TRA	-0.80	16.3	86.9	-8.00*	116.1*	168.1*
RRD	-0.38	19.2	137.8	-6.21*	84.90*	148.8*
STJ	-0.86	10.6	127.6	-3.98*	48.70*	83.88*
RDE	1.28	16.9	46.2	-6.68*	85.80*	147.9*
HTX	0.54	16.6	60.2	-9.32*	133.7*	181.3*
INN	1.17	15.8	10.7	-4.91*	72.50*	43.31*
PEG	0.73	20.6	28.1	-18.4*	278.7*	383.4*

Note 1: TEA is total early-stage entrepreneurial activity, PEC is perceived capabilities, PEO perceived opportunities, PAT is patents filled by both residents and non-residents, TRM is trademark applications, STJ is scientific and technical articles, RDE is research and development expenditure, RRD is researchers in research and development activities, HTX is high-technology exports, INN is composite index of innovation, and PEG is per capita economic growth.

Note 2: INN is the weighted average of PAT, TRA, RRD, STJ, RDE, and HTX.

Note 3: LLC is Levin-Lin-Chu statistics, ADF is Augmented Dickey-Fuller Test statistics, and PP is Philipps-Perron statistics.

Note 4: * indicate that parameter estimates are significant at the 1% level.

558 Cointegration entails a long-run equilibrium relationship that ties the three-time series variables even though short-term departures from equilibrium may exist (Engle and Granger, 1987).

Note 1: PEG is per capita economic growth; INO denotes innovation. TEA is total early-stage entrepreneurial activity, PEC is perceived capabilities, and PEO is perceived opportunities. There are seven measures of INO: PAT is patents filled by both residents and non-residents, TRM is trademark applications, STJ is scientific and technical articles, RDE is research and development expenditure, RRD is researchers in research and development activities, HTX is high-technology exports, and INN is composite index of innovation.

Note 2: NOC is number of cointegrating vectors (1/2/3).

Note 3: Tra is trace statistics; Max is maximum Eigenvalue statistics; and NOC is number of cointegrating vectors.

Note 4: * and ** indicate that parameter estimates are significant at the 1% and 5% levels, respectively.

The above findings justify the use of the VECM approach to determine possible Granger causal relationships among innovation, entrepreneurship, and per capita economic growth. The results are presented in Tables 3 and 4.

We first report the long-run Granger causality results, which are established by examining the statistical significance of the ECT-1 coefficients. We find that when Δ PEG is the dependent variable, the coefficients for lagged ECT terms are statistically significant at the 1% level. This implies that per capita economic growth converges to its long-run equilibrium path in response to changes in both innovation and entrepreneurship.

This is true for all of the cases that we considered (see Table 3). Subsequently, we conclude that per capita economic growth in Eurozone countries is significantly influenced by both innovation and entrepreneurship. The implication of this finding is that, in order to stimulate long-run economic growth, it is imperative to facilitate both innovation and entrepreneurship in the Eurozone countries.

Note 1: PEG is per capita economic growth. TEA is total early-stage entrepreneurial activity, PEC is perceived capabilities, and PEO is perceived opportunities. PAT is patents filled by both residents and non-residents, TRM is trademark applications, STJ is scientific and technical articles, RDE is research and development expenditure, RRD is researchers in research and development activities, HTX is high-technology exports, and INN is composite index of innovation.

Note 2: INO denotes innovation and is used for PAT, TRA, RRD, STJ, RDE, HTX, and INN.

Note 3: ECT₋₁ is the lagged error-correction term.

Note 4: *, **, and *** indicate that parameter estimates are significant at the 1%, 5%, and 10% levels, respectively.

The short-run results, however, are mostly non-uniform. A summary of the non-uniform short-run Granger causality results is provided in Table 4 and demonstrates that the short-run adjustment dynamics vary across the three samples and seven cases.

Table 4. Summary of Short-run Granger Causality Results

Setups	Cases	Possible Causalities		
		PEG and ENT	PEG and INO	ENT and INO
1	1	PEG \Leftrightarrow TEA	PEG \Leftrightarrow PAT	TEA \Leftrightarrow PAT
	2	PEG \Leftrightarrow TEA	PEG \Leftrightarrow TRA	TEA \Leftrightarrow TRA
	3	PEG \Leftrightarrow TEA	PEG \Leftrightarrow RRD	TEA \Rightarrow RRD
	4	PEG \Leftrightarrow TEA	PEG \Leftrightarrow STJ	TEA \Rightarrow STJ
	5	PEG \Leftrightarrow TEA	PEG \Leftrightarrow RDE	TEA \Leftrightarrow RDE
	6	PEG \Leftrightarrow TEA	PEG \Leftrightarrow HTX	TEA \Leftrightarrow HTX
	7	PEG \Leftrightarrow TEA	PEG \Leftrightarrow INN	TEA \Leftrightarrow INN
2	1	PEG \Leftrightarrow PEC	PEG \Leftrightarrow PAT	PEC \Rightarrow PAT
	2	PEG \Leftrightarrow PEC	PEG \nleftrightarrow TRA	PEC \nleftrightarrow TRA
	3	PEG \Leftrightarrow PEC	PEG \Leftrightarrow RRD	PEC \Leftrightarrow RRD
	4	PEG \Leftrightarrow PEC	PEG \Leftrightarrow STJ	PEC \Leftrightarrow STJ
	5	PEG \Leftrightarrow PEC	PEG \Leftrightarrow RDE	PEC \Rightarrow RDE
	6	PEG \Leftrightarrow PEC	PEG \Leftrightarrow HTX	PEC \Rightarrow HTX
	7	PEG \Leftrightarrow PEC	PEG \Leftrightarrow INN	PEC \Rightarrow INN
3	1	PEG \Rightarrow PEO	PEG \Leftrightarrow PAT	PEO \Rightarrow PAT
	2	PEG \Rightarrow PEO	PEG \Leftrightarrow TRA	PEO \Leftrightarrow TRA
	3	PEG \Rightarrow PEO	PEG \Leftrightarrow RRD	PEO \Rightarrow RRD
	4	PEG \Leftrightarrow PEO	PEG \Leftrightarrow STJ	PEO \Leftrightarrow STJ
	5	PEG \Rightarrow PEO	PEG \Leftrightarrow RDE	PEO \Leftrightarrow RDE
	6	PEG \Rightarrow PEO	PEG \Leftrightarrow HTX	PEO \nleftrightarrow HTX
	7	PEG \Rightarrow PEO	PEG \Leftrightarrow INN	PEO \Leftrightarrow INN

Note 1: PEG is per capita economic growth. TEA is total early-stage entrepreneurial activity, PEC is perceived capabilities, and PEO is perceived opportunities. PAT is patents filled by both residents and non-residents, TRM is trademark applications, STJ is scientific and technical articles, RDE is research and development expenditure, RRD is researchers in research and development activities, HTX is high-technology exports, and INN is a composite index of innovation.

Note 2: INO is used for PAT, TRA, RRD, STJ, RDE, HTX, and INN. ENT is used for TEA, PEC, and PEO.

Note 3: \Leftrightarrow , \Rightarrow , \Leftrightarrow stands for direction of Granger causality; and \nleftrightarrow stands for non-Granger causality.

We also performed some additional tests in order to check the validity of our results. First, we obtained FMOLS⁵⁵⁹ and DOLS⁵⁶⁰ estimates, which show that both innovation and entrepreneurship have positive impacts on per capita economic growth, congruent with the findings of Urbano and Aparicio (2016)⁵⁶¹ and Galindo and Mendez-Picazo (2013).⁵⁶² The results from these estimation approaches are not reported due to space constraints and are available from the authors on request.

Second, we changed the order of the VECM. There were no significant changes to the earlier results reported in Tables 3 and 4. These results are not reported for the sake of brevity, but are available from the authors on request.

Third, we utilized generalized impulse response functions (GIRFs) to trace the effect of a one-standard deviation shock on the current and future values of all the endogenous variables through the dynamic structure of VECM. The GIRFs offered additional insight into how shocks to per capita economic growth can affect and be affected by both innovation and entrepreneurship. The results of GIRFs are not reported here due to space constraints and are available upon request. In short, they provide additional support for the argument that there is causality among innovation entrepreneurship and per capita economic growth, as outlined above.

5 DISCUSSION OF RESULTS AND CONCLUSIONS

Our study examines the causal relationships among innovation, entrepreneurship, and per capita economic growth in Eurozone countries over the period 2001-2016. We find that these three indicators are integrated of order one and cointegrated, irrespective of the particular innovation and entrepreneurship indicators that are used. Most importantly, there is clear evidence that both innovation and entrepreneurship matter in the determination of long-run per capita economic growth.

In the short run, however, there is a myriad of relationships between the three variables. From Table 4, on the nexus between economic growth and innovation, 16 out of 21 cases support the feedback hypothesis, while 4 support the supply-led hypothesis, and 1 supports the neutrality hypothesis. When we examine the link between economic growth and entrepreneurship, 11 out of 21 cases support the supply-led hypothesis, 5 support the demand-led hypotheses, and 4 support the feedback hypothesis. Finally, the relationship between entrepreneurship and innovation shows that 6 out of 21 cases support the demand-led hypothesis, 8 support the supply-led hypothesis, 5 support the feedback hypothesis, and 2 support the neutrality hypothesis. Unlike the long-run results, which are homogenous, the short-run results depend on the types of innovation and entrepreneurship we incorporate in the estimation process. On the whole, a rich set of short-run dynamics exist among the variables. However, in the long run they all produce the same result, namely that entrepreneurship and innovation are key drivers of economic growth.

Our empirical results clearly suggest that to sustain long-term economic growth in the Eurozone countries, priority should be given to strengthening the innovation and entrepreneurship ecosystems in the region. Furthermore, the results show that there are strong endogenous links between entrepreneurship, innovation and economic growth even in the short run. In this context, entrepreneurs play a key role in not only creating jobs, but undertaking risky endeavours that lead to incremental and radical innovations. Many entrepreneurs invest in R&D and innovation that lead to new product development and process improvements. Hence, it is important that countries in the Eurozone strengthen their national innovation ecosystems, as envisioned under the Europe Strategy 2020 Plan, which promotes a culture of innovation and entrepreneurship by undertaking the following steps across the region (Braunerhjelm, 2010; World Economic Forum, 2014; and Kritikos, 2014):

- enhance public sector efficiency and business-friendly policies, including reducing bureaucratic practices that will lower the time and cost of setting up a business;
- put in place economic growth promoting strategies, including identifying key economic priority regions, corridor development plans and inclusive development policies with a sound investment strategy that will foster strong and competitive industrial and economic clusters across the region;
- develop a favourable taxation system and vibrant financial system (e.g., venture capital and angel funding) that encourages investment in R&D and innovation;
- have a clearly articulated intellectual property right framework, implementation strategy and enforcement mechanism;
- put in place R&D grants and subsidies that enable entrepreneurs to undertake innovation, product development and process improvement to enhance the competitiveness of the firms;
- provide entrepreneurs access to state-of-the-art scientific technology, expertise and business support programs to continuously undertake translational R&D and innovation that will enable them to move up

559 FMOLS is fully modified ordinary least squares (OLS), a non-parametric estimation approach, taking into account the possible correlation between the error term and the first differences of regressor as well as the presence of a constant term to deal with corrections for serial correlation (Pedroni, 2000).

560 DOLS is dynamic OLS, a parametric estimation approach that adjusts the errors by augmenting the static regression with leads, lags, and contemporaneous values of the regressor in first differences (Kao and Chiang, 2000).

561 This study relates to 43 countries in the period from 2002 to 2012.

562 This study relates to ten countries, namely, Denmark, Finland, France, Germany, Italy, Japan, the Netherlands, Spain, Sweden and the USA for the period 2001-2009.

the global innovation value chain (key best practices include the Small Business Innovation Research – SBIR program and Small Business Technology Transfer – STTR program in the [US \(https://www.sbir.gov/\)](https://www.sbir.gov/)); and,

- promote a culture of risk-taking by enabling entrepreneurs who have failed to still gain access to funding, mentorship and other business support to transform and reinvent their businesses.

In summary, the empirical analysis from this paper suggests that long-term economic growth within the Eurozone will depend on a carefully curated and orchestrated national innovation ecosystem that promotes a vibrant entrepreneurial culture and innovative climate across the region, as envisioned by *Europe Strategy 2020*. Strong support for entrepreneurship and innovation will strengthen the competitiveness of existing sectors of the economy and will lead to new sources of economic growth in the Eurozone. Needless to say, the lessons from our Eurozone case study may be valuable for policy-makers from other economic regions who may be designing policies and strategies to elevate their economic growth.

1159 IMPACTS OF ENTREPRENEURSHIP AND SOCIAL CAPITAL ON THE PROCESS OF NEW FIRM FORMATION IN JAPAN

Akira Kiminami¹, Lily Kiminami², Shinichi Furuzawa²

1 The University of Tokyo

2 Niigata University

1. INTRODUCTION

Recently, researches on entrepreneurship have shed new light on the importance of new firm formation to economic growth. However, new firm formation in Japan is stagnating and its rate is consistently from 4 to 5%, which is at a very low level compared with other developed countries such as that of rate is 14.3% in the UK and 12.4% in France in the year of 2015 (National Association of Trade Promotion for Small and Medium Enterprises 2017).

The factors promoting new firm formation can be roughly divided into entrepreneurship and entrepreneurial environment. Entrepreneurial environment consists of economic factors, institutional factors, and social factors (such as social capital), it affects entrepreneurship as well.

As for the situation of entrepreneurial environment, World Bank (2018) made the index of “Starting a business” from the measurement of procedures, time, cost and paid-in minimum capital to start a limited liability company by comparing 11 areas of business regulations in 190 countries. This index means how easy to start a business for each country and the rank of Japan is at 106th in 190 countries and at 32th in 35 OECD countries in 2017, though many regulations on firm formation in Japan have been mitigated in recent years (see table 1).

Table 1 Regulation measurements for starting a limited company in Japan

	Procedures (number)	Time (days)	Cost (% of income per capita)	Minimum capital (% of income per capita)
2017	9	12.2	7.5	0.0
2003	11	31.0	10.5	71.3

Source: *Doing Business 2018, Doing Business 2004*, World Bank.

As for the entrepreneurship, Global Entrepreneurship Monitor (GEM) (2017) reported “Entrepreneurial Spirit Index” as the composite index of entrepreneurship and ranked Japan at the lowest of all 54 countries in 2017, in which “Perceived opportunities” and “Perceived capabilities” ranked at the 51th, “Entrepreneurship for a good career choice”, “Entrepreneurial intentions”, “Total Early-stage Entrepreneurial Activity (TEA)”, “Female/Male TEA Ratio” at the 50th, and “High status to entrepreneurs” at the 48th.

Furthermore, Employment Status Survey (Ministry of Internal Affairs and Communications of Japan) investigated the working situation of population of 15 years old and over. Figure 1 shows that the number of “Business starter” in 1979 was 323 thousand and it has been constant 300 thousand, despite recent deregulation on startup. During the period of 1979-2012, the number of “People hoping to startup business” decreased from 3.05 million to 1.52 million and the number of “People making startup preparations” decreased from 1.28 million to 0.74 million. Therefore, it is supposed that the decreasing of entrepreneurship is the one of the major causes for low new firm formation rate in Japan.

As the results of such changes, the ratio of “Business starters” to “People hoping startup” and “People making startup preparations” has been increased rapidly after late 1990s (Figure 2). Mitigation of regulation on starting business has effects on promoting new firm formation and contribute to the regional employment, but there is also the risk of increase in easy business starters with low entrepreneurship.

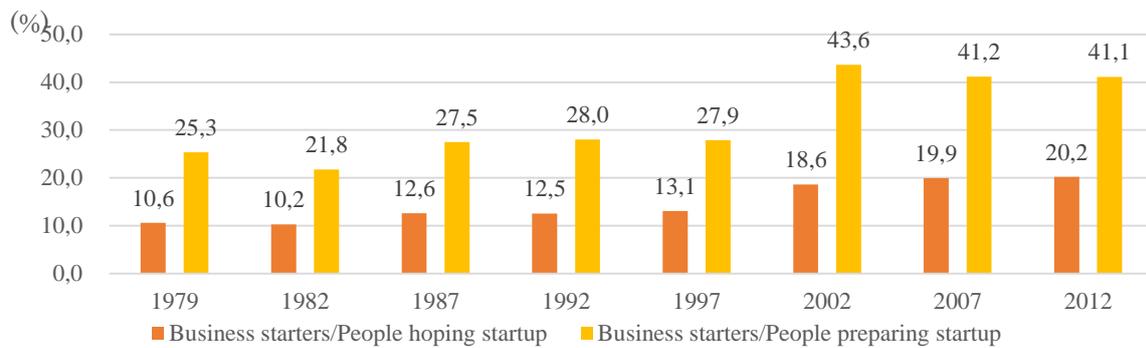

Source: Employment Status Survey issued in each year, Ministry of Internal Affairs and Communications of Japan.

Figure 1 People responsible for business startups

“People hoping startup” are those who responded that they are looking to change jobs and “wish to start their own business”, or unemployed persons who responded that they “wish to start their own business”.

“People preparing startup” are those who responded that they are “preparing to start a business”.

“Business starters” are those who have changed jobs or found a new job within the last year and who have become officer of a company, etc. or self-employed persons.

Source: Employment Status Survey issued in each year, Ministry of Internal Affairs and Communications of Japan.

Figure 2 Ratio of business starters to people hoping startup and preparing startup

Therefore, in this study, we will clarify the mechanism of new firm formation and derive policy implications through analyzing the relationships among economic factors, social capital and entrepreneurship in Japan because not only entrepreneurship but also the actual process from entrepreneurship to business startup are usually influenced by various factors in each country and region.

2. SURVEY OF EXISTING STUDIES

2.1 New firm formation

In general, there are disparities in the ratio of new firm formation among regions, and many studies tried to reveal their factors. Most of studies measured the relationship between regional economic variables and the ratio of new firm formation.

By using multiple regression analysis, Armington and Acs (2002) clarified that the number of new firm formation per labor force was influenced by company size, industry concentration, income growth rate, population growth, managerial proportion (number of executers / labor force), unemployment rate, educational background in the United States. However, Parajuli and Haynes (2017) revealed that population density, deposit balance, company size, income growth rate, public school, unemployment rate influenced new firm formation rate using panel and spatial econometric analysis in New England of the United States. Piacentino et al. (2017) also showed that population growth, innovation (patent), population density, age structure, withdrawal rate, unemployment rate, industrial specialization, number of commuting workers, number of referendum voters affect the firm formation rate per capita by the estimation of a Spatial Durbin Model in Italy.

As for Japan, Komoto (2007) clarified that the business closure rate, unemployment rate, household increase rate, taxable income growth rate, population aged 65 or over, commercial land price, wage, service industry ratio, and the ratio of professional and technical workers affect the new firm formation rate.

Although, the above-mentioned studies revealed the impact factors of regional economy towards new firm formation, their relationship is not a such simple. Taking a high unemployment rate as an example for a region, the new firm formation rate could be high due to the unemployed choose new business to get employed, or it might be easier to secure workers when starting new business on one side, but might be the result that people have lower willingness to start new business on the other due to the a high unemployment rate reflected a bad economic situation in the region. Audretsch et al. (2015) revealed that the impact of unemployment rate on new firm formation depends on the structure of labor market in the region and the nature of new business from study in Germany. For example, the unemployment rate of highly educated people only positively influences the knowledge-intensive new firm formation without affecting the new firm formation of business in general. Furthermore, the high proportion of unemployment in a long term such as one year or more might suppress new business formation.

Since new firm formation is considered as the result of entrepreneurial activity and entrepreneurs play a major role in starting new business, it is necessary to consider the influence of regional economic and social factors on the entrepreneurial activity.

2.2 Studies on Entrepreneurship based on GEM data

Although, there have been tremendous researches on entrepreneurship both from theoretical and empirical aspects, studies on Japan to clarify the entrepreneurial consciousness and activities and the factors that influence them based on GEM data are scarce. Using GEM data of the European region, Bosma and Schutjens (2011) clarified the variables for impact of entrepreneurial environmental on entrepreneurial attitudes and entrepreneurial activities while Hundt and Sternberg (2016) showed that mutual relationship between personal attributes and regional factors is important to explain entrepreneurial activity at individual level and regional level.

2.3 Social capital

Social capital has multiple definitions and one of the representative definition is “features of social organization, such as trust, norms, and networks that can improve the efficiency of society by facilitating coordinated actions.” (Puttnam,

1993). It is categorized into bonding social capital and bridging social capital by the differences in function of connecting actors.

Knack and Keefer (1997) showed that social capital has significantly positive impact on economic growth from studies on 29 countries. As for Japan, Yodo (2005) clarified that trust and norm in the community influence the growth rate of per capita GDP by multiple regression analysis at prefectural level. Furthermore, the studies focusing on the relationship between information and starting new business clarified that information from others is important as well as information held by entrepreneurs themselves (Aldrich and Martinez, 2001; Newbert and Tornikoski, 2007). However, the mechanism that social capital influences economic growth has not been analyzed so far.

Therefore, this research will analyze the mechanism of new firm formation, not only on economic factors but also on social factors represented by social capital, and how they affect the situation of people's entrepreneurship and how they lead to startup new business.

3. ANALYTICAL METHODS AND FRAMEWORK

3.1 Analytical framework and hypothesis

In order to reach our objectives in this study, we built an analytical framework as shown in Figure 3 and set the hypotheses as follows.

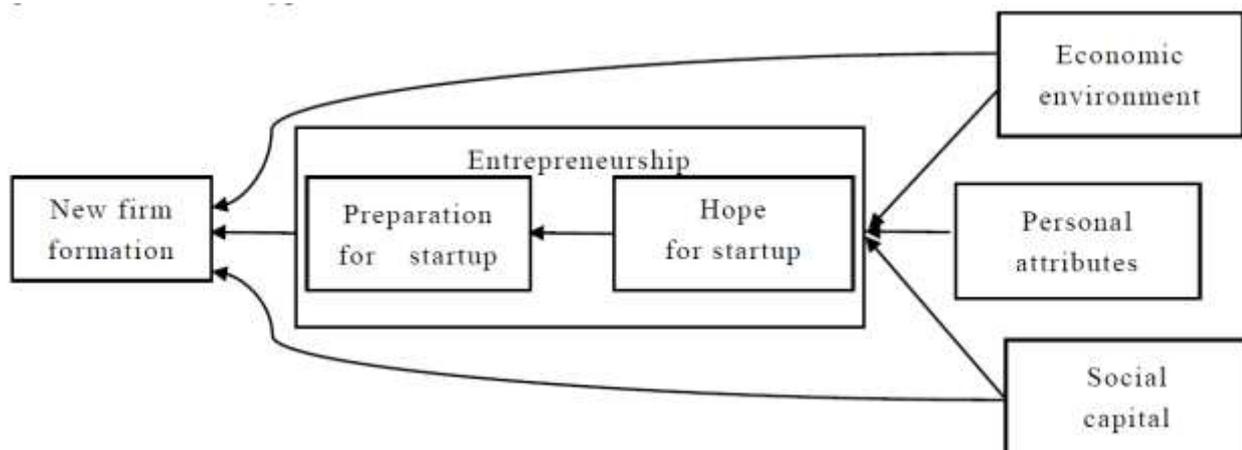

Figure 3 Framework of analysis in this study

Hypothesis 1: Economic environment, social capital, personal attributes affect entrepreneurship.

Hypothesis 2: Economic environment, social capital, entrepreneurship affect new firm formation.

3.2 Data and methodology

For introducing structural equation modeling (SEM), following data of new firm formation, economic environment, social capital, personal attributes are collected at prefectural level. Table 2 shows the summary of variables.

1) New firm formation rate

Number of new firm formation from 2009 to 2014, Number of enterprise: Economic Census for Business Frame in 2014.

2) Economic environment

Population density: Population / Land, Census in 2012.

Income: Per capita Prefectural Income, Prefectural Accounts in 2012

Unemployment rate: Jobseeker / Labor force, Survey on Employment Status in 2012

3) Social capital (Japan Research Institute, 2008)

Index of bonding social capital, Index of bridging social capital

4) Personal attribute (Employment Status Survey in 2012)

Sex : Male=1; Female=2

Age: 15-24=1, 25-34=2, 35-44=3, 45-54=4, 55-64=5, 65-74=6

5) Entrepreneurship (Employment Status Survey 2012)

Hope for startup: Ratio of people hoping startup

Preparation for startup: Ratio of people preparing startup

Table 2 Summary of variables

Variables		Unit	Min.	Max.	Average	S.D.
PopDen	Population density	person/km ²	70.20	6015.70	655.66	1165.73
Income	Income	Thousand	2030.00	4442.00	2733.74	381.67

		yen/person				
<i>Unemploy</i>	Unemployment rate	%	1.30	25.00	7.36	4.11
<i>Bonding</i>	Index of bonding social capital		-0.96	1.78	-0.01	0.55
<i>Bridging</i>	Index of bridging social capital		-1.52	2.01	0.00	0.80
<i>Gender</i>	Male=1, Female=2		1.00	2.00	1.50	0.50
<i>Age</i>	Age structure (1-6)		1.00	6.00	3.50	1.71
<i>StartHope</i>	Ratio of “people hoping startup”	%	0.00	6.23	1.35	1.14
<i>StartPre</i>	Ratio of “people preparing startup”	%	0.00	3.71	0.63	0.58
<i>NewFirm</i>	New firm formation rate	%	2.20	4.01	2.84	0.41

Note: Data source is explained in the text.

3.3 Description of variables

3.3.1 New firm formation rate and related factors

Usually, there are regional disparity in new firm formation rate. Table 3 reported that the top 5 prefectures of high rate of new firm formation were Tokyo, Miyagi, Fukuoka, Okinawa, and Kanagawa in the period of 2009-2014. It seems that there have been different factors promoting new firm formation in these prefectures because Tokyo, Fukuoka, and Kanagawa are the most developed industrial regions and have high population density, but the economy of Okinawa is stagnated and Miyagi had severe damage from Great East Japan Earthquake in 2011.

Table 3 New firm formation rate in 47 prefectures (2009-2014)(%)

Hokkaido	3.07	Ishikawa	2.63	Okayama	2.70
Aomori	2.73	Fukui	2.44	Hiroshima	3.04
Iwate	3.13	Yamanashi	2.41	Yamaguchi	2.73
Miyagi	3.82	Nagano	2.66	Tokushima	2.43
Akita	2.42	Gifu	2.54	Kagawa	2.75
Yamagata	2.22	Shizuoka	2.85	Ehime	2.39
Fukushima	2.66	Aichi	3.13	Kochi	2.53
Ibaraki	2.55	Mie	2.58	Fukuoka	3.56
Tochigi	2.59	Shiga	2.95	Saga	2.84
Gunma	2.61	Kyoto	2.90	Nagasaki	2.69
Saitama	3.13	Osaka	3.40	Kumamoto	2.95
Chiba	3.19	Hyogo	3.28	Oita	2.90
Tokyo	4.01	Nara	3.03	Miyazaki	2.76
Kanagawa	3.47	Wakayama	2.20	Kagoshima	2.80
Niigata	2.40	Tottori	2.79	Okinawa	3.55
Toyama	2.44	Shimane	2.50

Table 4 shows the correlation coefficients of variables with new firm formation at prefectural level in which population density, unemployment, hoping startup, and preparation for startup have highly positive effects on new firm formation. However, variables of social capital are not highly correlated with new firm formation rate.

Table 4 Correlation coefficients of variables with new firm formation

	<i>PopDen</i>	<i>Income</i>	<i>Unemploy</i>	<i>Bonding</i>	<i>Bridging</i>	<i>StartHope</i>	<i>StartPre</i>	<i>NewFirm</i>
<i>PopDen</i>	1.000	0.629	0.320	-0.249	-0.120	0.666	0.646	0.635
<i>Income</i>	0.629	1.000	-0.157	-0.131	-0.117	0.391	0.328	0.315
<i>Unemploy</i>	0.320	-0.157	1.000	-0.180	0.151	0.619	0.652	0.639
<i>Bonding</i>	-0.249	-0.131	-0.180	1.000	0.822	-0.269	-0.233	-0.158

<i>StartPre</i>	0.646	0.328	0.652	-0.233	-0.033	0.888	1.000	0.727
<i>NewFirm</i>	0.635	0.315	0.639	-0.158	0.025	0.799	0.727	1.000

3.3.2. Entrepreneurship in different labor force status and personal attributes

Entrepreneurship is also thought to be related to labor force status which is “engaged in work” or not and personal attributes. As shown by table 5, entrepreneurship is reflected by the ratio of hoping and preparing startup as below.

- 1) Entrepreneurship of “engaged in work” is lower than that of “not engaged in work” for labor force between ages of 25 and 64.
- 2) Labor force engaged in work choose more startup business as additional job than that of as changing job.
- 3) Entrepreneurship is lower in female than male in all labor force status and ages.
- 4) Entrepreneurship is high for labor force between ages of 25 and 45 in both gender.

Table 5 Entrepreneurship by types of working and personal attribute

	Gender	Age	Labor force status				
			Total	Engaged in work (by job status)			Not engaged in work
				Subtotal	Additional	Changing	
Ratio of person hoping startup	Male	15-24	1.03	1.67	0.86	0.81	0.62
		25-34	3.51	3.43	2.00	1.43	4.23
		35-44	3.48	3.34	2.07	1.27	5.38
		45-54	2.75	2.56	1.61	0.95	5.27
		55-64	1.56	1.37	0.75	0.63	2.31
		65-	0.53	0.60	0.38	0.21	0.51
		Subtotal	2.04	2.41	1.44	0.96	1.23

		25-34	0.70	0.70	0.36	0.34	0.69
		35-44	0.67	0.61	0.40	0.21	0.80
		45-54	0.58	0.50	0.32	0.18	0.82
		55-64	0.29	0.27	0.18	0.10	0.31
		65-	0.05	0.12	0.07	0.05	0.04
		Subtotal	0.36	0.47	0.28	0.19	0.27
Total		0.67	0.85	0.51	0.34	0.42	

Source: Calculation of data from Employment Status Survey 2012, Ministry of Internal Affairs and Communications of Japan.

Table 6 clarified the correlation coefficients of each variable with entrepreneurship. The variables for personal attributes used in the research are gender, age, and unemployment rate. The result shows that there are negative correlations between personal attributes with entrepreneurship, although a positive correlation between unemployment rate and entrepreneurship at regional level was found in Table 4. These results are consistent with the discussion in the above section 2 that the impact of unemployment rate on new firm formation depends on the structure of labor market in the region and the nature of new business, and the high proportion of unemployment in a long term such as one year or more might suppress new business formation. Furthermore, as showed by Table 5 that the first case (for additional job) is the most popular in Japan for startup business could be added as a new finding to the discussion and support for the policy of “Work style reform” as well.

Table 6 Correlation of variables with entrepreneurship

	<i>Unemploy</i>	<i>Gender</i>	<i>Age</i>	<i>StartHope</i>	<i>StartPre</i>
<i>Unemploy</i>	1.000	0.249	-0.556	-0.394	-0.359
<i>Gender</i>	0.249	1.000	0.000	-0.539	-0.483
<i>Age</i>	-0.556	0.000	1.000	-0.242	-0.208
<i>StartHope</i>	-0.394	-0.539	-0.242	1.000	0.936
<i>StartPre</i>	-0.359	-0.483	-0.208	0.936	1.000

4. RESULTS OF STRUCTURAL EQUATION MODELING

Table 7 and Figure 4 show the results of structural equation modeling (SEM), and table 8 summarizes the effects of factors on new firm formation.

Regarding social capital, each has the opposite effect while bridging social capital has a positive but bonding social capital has a negative effect on new firm formation. It is considered that bridging social capital has the positive effects on promoting startup business and expanding new business directly through the increase of entrepreneurship. Bonding social capital, on the other hand, has the negative effects not only on startup new business but also on startup hoping and startup preparation through the decrease of entrepreneurship.

Although, unemployment rate has a direct effect on the new firm formation rate which is thought to be the reflection of both demand and supply for new business, it has negative effects on the entrepreneurship which is thought to have indirectly influence on the new firm formation rate, its effect on new firm formation is small as a total.

On the other hand, population density has the largest positive influence on new firm formation rate among the variables. Besides direct effects on startup hoping, indirect effect on startup preparation as entrepreneurship are both positive.

However, income has a negative impact on the new firm formation rate which is considered that the necessity for starting new business is comparatively low in the regions with high income.

5. CONCLUSION

The above-mentioned results showed that entrepreneurship is activated by population density and bridging social capital but deactivated by income, unemployment rate, and bonding social capital.

As for promoting new firm formation, population density had a large influence on new firm formation rates, but unemployment rate does not simply affect new firm formation due to the cross-interaction among regional and individual factors.

In addition, social capital does not simply promote new firm formations, since the effects on new firm formation are negative for bonding SC and positive for bridging SC by contrast. Furthermore, gender and age affect entrepreneurship as economic and social factors in Japan but their indirect effects on new firm formation are limited.

There have been several measures to promote new firm formation in Japan, such as financial support, improvement of economic environment, providing of information. However, these measures are considered to make contribution to the decrease in the cost of startup but not to stimulate and enhance entrepreneurship and may have negative effects on actual new firm formation through interaction among factors.

The findings on the relationship between entrepreneurship and working status suggested that measures should be designed according to the types of working status. For instance, the measures of deregulating side business and decreasing risk of job transfer are thought to be effective for the people who are engaged in working. On the other side, the support for the cultivation of entrepreneurship is needed for the people who are not engaged in working. Finally, it is requested to facilitate the social condition for encouraging the female and aged people to participate in business activities.

However, our discussions in this paper are closely related to the issues on regional disparity and vitalization, because population density is not only one of the important factors for entrepreneurship and new firm formation but also a result of them. In this context, the study from the aspect of regional sustainability is needed.

Furthermore, there exists a bit of room for improvement this study through including more economic and social factors, time series analysis, analysis by industry, and international comparison. These will be our future challenges.

1334 THE ROLE OF TECHNO PARKS ON REGIONAL INNOVATION IN TURKEY**Ferhan Gezici¹, Burcu Müderrisoğlu², Güliz Salihoğlu³, Gülay Başarır⁴**¹ Corresponding author: Istanbul Technical University, Urban and Regional Planning Department, gezicif@itu.edu.tr² Ondokuz Mayıs University, Burcu.muderrisoglu@omu.edu.tr³ Gebze Technical University, gozturk@gtu.edu.tr⁴ Mimar Sinan Fine Arts University, gulaybasarir@msgsu.edu.tr**ABSTRACT**

Innovation and its capacity in the regions have become the most interesting topic for academia and policy makers, not only for developed countries but developing countries as well in the knowledge economy. The determinants of the innovation process are introduced as providing existing knowledge stock along with national and regional policies that ensure necessary environments and conditions for innovation creation, having firms with a vision and aim to create innovation, adoption of an innovation mission by universities and supporting entrepreneurship (Sternberg, 2000; Asheim and Gertler, 2005; Castells and Hall, 1994; Etzkowitz, 2002; Malecki, 2011). Most of the studies have been focus on patents for the main determinant of knowledge production and innovation (Griliches, 1990; Jaffe, 1989; Siegel, 2003; O'hualachian, 1999; Anselin, 1997). Since it is realized that the innovation process has been non-linear and more complex, the scope of studies on the innovation process has become broader considering the role of universities and other regional actors, networks and the impact of proximities (Florax, 1992; Cooke, 2005; Rallet and Torre, 1998; Boschma, 2005; Arnkil et al., 2010). On the other hand, within the literature of innovation, techno parks/science parks took their place in many developing countries' agenda with the successful performances that developed countries put forth (Saxenien and Hsu, 2001; Benneworth and Hospers, 2007; Lee and Yang, 2000). Techno parks that emerged as a result of university-industry and government cooperation encourage R&D firms to be located close to the university, contribute to knowledge production, develop centers of technology and knowledge spill-over and support national and regional economic growth. Techno parks in Turkey were founded initially in industrialized cities with well-established universities, skilled labor and knowledge production dynamics since 2001, and the numbers of techno parks increased to 64 in 44 provinces of Turkey in 2016. The roles and efficiency of the increasing number of techno parks that also have the goal of regional development is a subject of debate. The aim of this paper is to discuss the role of techno parks on regional innovation in Turkey. First, the policies on innovation in Turkey will be evaluated. Secondly, the performance of regions based on the patent data is analyzed related to techno parks as a base of geographically localized networks and cooperation with the universities and other endogenous characteristics by two multiple regression models.

Key words: Innovation, science parks, regional development**INTRODUCTION**

The significance of innovation has been relatively neglected after Schumpeter by theoreticians' on local development. According to Schumpeter, growth would occur throughout the changes and inventions on production, consumption and behavior of entrepreneurships. Neo-Schumpeterian perspective points out that innovation is an outcome of commodification of new knowledge (Wolfe, 2011). It is known that outcomes of technological innovation are very much related with the attempts of capital to increase its own profits within the capitalist process. In the new economic system, firms have to develop new products to be more competitive and productive, while economic development has to be seen as a process of qualitative change driven by innovation (Fagerberg, 2003). Investments on research and development as a cumulative process of existing knowledge stock have been essential for innovation (Cantner and Graf, 2010). Most of the studies examining the relationship between the innovation and regional dynamics at both macro and micro levels have used patent data. As the study of Pakes and Griliches (1984) points out, there is a strong relationship between research and development and the number of patents across firms and industries. Therefore, patents have long been significant indicators of economic analysis (Schmookler, 1966; Griliches et al., 1980; Griliches, 1998; Siegel, 2003), while the study of Jaffe (1989) on academic research emphasizes that knowledge spillovers are facilitated by geographic coincidence of university and research labs within the states in the US. Furthermore, patents have been used by economic historians to study regional patterns of economic growth and agglomeration (Kelley, 1972; Sokoloff, 1988). Therefore, the importance of space for innovation has become one of the most interesting research topics. According to Simmie (2006), local agglomeration economies are still important, city size provides assets which are required by innovative firms. O'hualachian (1999) found that the largest metropolitan areas in the US were the most innovative, although rank size relationships vary by regions. However, Carrincazeaux and Gaschet (2007) emphasize that regional concentration of resources in innovation does not necessarily lead to superior economic performance. The study of Qi and Lui (2011) indicates that education, foreign capital, concentration of physical and human capital, international networks and institutional supports have a positive impact on innovation performance of regions in China using patent data. Porter and Stern (2000) point out that national knowledge stock and the R&D sector employment induced the innovation capacity in 17 OECD countries during the 20-year period. Moreover, most of the studies from different geographies prove that especially R&D activities and incentives induce the number of patents (Cincera, 1997; Zachariades, 2003; Bosch, 2005; Yanhui, 2015). Kaygalak and Reid (2016) indicate that spatial and organizational proximity among the firms enhances the innovation capacity of different geographies and sectors in Turkey using the patent data.

In the 1990s, the National Innovation System took place and innovation was identified as a process of interactions and networking among all components considering the proximities, path dependency and capacity within the system

(Nelson,1993; Freeman,1998; Cooke, 1998; Audretsch, 2001; Cohen and Levinthal, 1994; Moulert and Seika, 2001; OECD, 1997).

Since innovation is not linear, rather it is a dynamic and complex system, and geographically localized, the new approach with the concept of a regional innovation system has become significant. It is expected that RIS should be conducted regarding the regional characteristics and needs, contrary to a national innovation system. Asheim and Gertler (2005) identify RIS as the culture of networking considering the role of local actors. It requires region-specific policies in innovation to achieve collective learning among the actors (Lundvall, Borrás, 1997). The importance of localized networks and cooperation for innovation has mostly been related to the success story of Silicon Valley. Saxenian (1994) explains that innovation was a must for firm competitiveness, while a dynamic innovation system should require cooperation among firms and other related actors. Cooke (2005) identifies a regional innovation system with five key concepts: the concept of the region as a meso political unit, the concept of innovation as the process of new knowledge, the concept of network, the concept of learning, and the concept of interactions. The efficiency of RIS depends on the density and power of interactions among the actors. It is known that RIS does not only concentrate on firms and factor conditions, but more on localized public-private networks (Bellini et al., 2012).

Regional aspects of innovation could be realized as converging the experiences of clusters regarding the benefits of agglomeration economies and a regional innovation system as localized networks. Technology clusters have been identified as clusters which include the sectors/firms that are research based and their knowledge as the main outcomes. The triple helix approach is grounded on the idea that innovation is the outcome of an interactive process involving different spheres of actors such as public and private sectors and universities. Meanwhile the role of universities in the new economy has been evolving beyond the knowledge production and providing human capital to the entrepreneurial university that supports the start-ups (Benneworth and Charles, 2005). Although as Florax (1992) points to the role of universities as engines of growth, it is not uniformly confirmed by empirical studies. Several studies indicate a significant and positive effect of the presence of universities on the location of high-tech production, new start-ups and R&D facilities (Malecki, 1986; Nelson, 1982; Lund, 1986; Anselin et al., 1997). On the other hand, Howels (1984), Florax and Folmer (1992) find a weak relationship between the university research activities and location of high tech production.

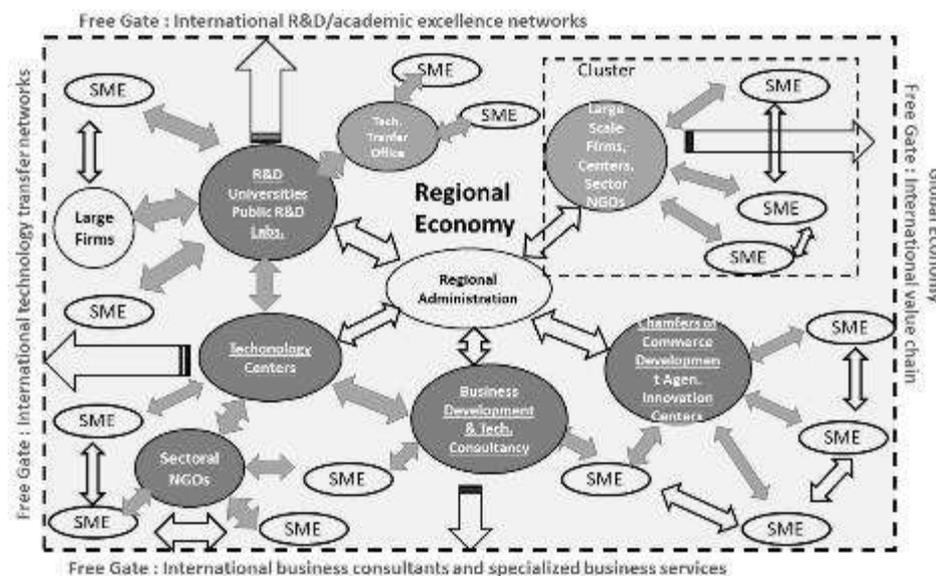

Figure 1: Regional Innovation Systems, European Commission, 2004.

However, technoparks (science parks) are mostly regarded as key elements of the research based regional development policy. The success stories of the developed countries would not be always valid for other countries and regions especially regarding the role of entrepreneurial universities. Castells and Hall (1994) point out that there have been three main motivations for the establishment of technoparks: reindustrialization, regional development and the creation of synergies. Existing knowledge stock, engagement on innovation of the firms, entrepreneurial mission of the universities and supports for start-ups, national and regional innovation policies for cooperation among the actors are the determinants of innovation (Sternberg, 2000; Asheim and Gertler, 2005; Castells and Hall, 1994; Etzkowitz, 2002; Malecki, 2011).

However spatial proximity matters for innovation, as a debate has been going on about to what extent (Brecsh and Lissoni, 2001; Johnson et al., 2006; Carrincazeaux and Coris, 2011; Lung et al., 1999; Rallet and Torre, 2005; Boschma and Frenken, 2011). Massey et al. (1992) argue that spatial proximity between the university and firms has a weak impact on technology transfer. The study on thirty-five techoparks in the UK, Westhead and Storey (1995), denote that firms would be more competitive if there is a strong relation with the university, and the firms in the technoparks have more opportunity to do that. In the case of Western Australian Technology Park, Phillimore (1999) points out that the role of technoparks is significant especially for the technology based small firms. Bakouros et al. (2002) emphasize that science parks in Greece have not been established by pioneering universities, but with government support, and initial investments have been solely made by government.

Technoparks include both the firm clusters and the research institutions, and the interactions among them, having the advantages of spatial proximities. Although, there have been several studies on innovation using the patent data or analyzing the performance of technoparks, studies looking at the role of technoparks on innovation performance of the regions have been limited. Therefore the aim of this paper is to examine the innovation capacity of the regions (provinces) in Turkey. Using the patent data as the indicator of innovation, it is intended to explore mainly the impact of technoparks (as one of the important tools in Turkey since 2001) and other determinants of local characteristics.

FACTS AND FIGURES: INNOVATION POLICIES AND TECHNOPARKS IN TURKEY

National innovation capacities and policies play a dominant role in the adaptation of countries to the global system, competitiveness and the production of new technologies today. Castells and Hall (1994, 1996) refer to the role of states in the beginning of the "information age" by forming innovation politics, strategies and pioneering institutions. In this context, national innovation systems have become an important part of science and technology policies.

Regional potentials related to key innovation actors as well as national policies and strategies are also important. Actors such as firms and networks, R&D institutions and supportive institutions shape "national innovation capacities" in the process. One of the key innovation indicators used to measure national innovation capacities and cross-country comparisons is patents. The patent statistics for 2016 show that 65% of the total patent applications and 57% of total patent grants are made in Asia (2,019,100-77,1000), 20.9%-24% in the USA (640,300-329,500) and 11.6%-14% in the European countries (354,900-195,900). It is observed that in Asia, China (1,338,503-404,208), Japan (318,381-203,087), Republic of Korea (208,830-108,875) and in Europe, the United Kingdom (22,059-5,602) are leading countries of total patent grant distribution. Turkey ranks 128th in the Global Innovation Index 2016, while the number of patents (6,848-1,764) is lagging.

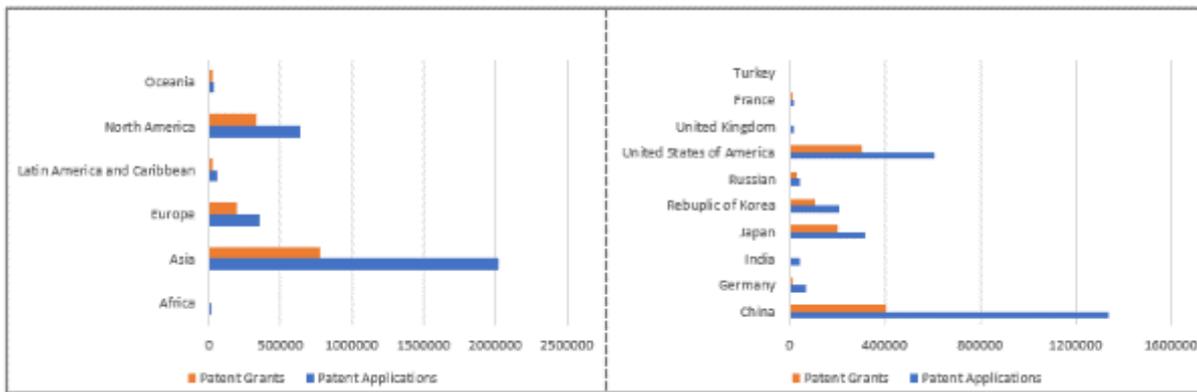

Figure 2: Patent Application & Grant Numbers, 2016, WIPO (World Intellectual Property Organization), <https://www3.wipo.int/ipstats/ipsPiechart>

In Turkey, the science and technology policies have gone back to the 1960s in accordance with the planned period. The steps to establish national innovation capacity were initially taken during these periods. The increase in the importance given to regional capacities and institutions in the 1990s also provided positive outcomes after the 2000s. The increasing trend of patent numbers supports the contribution of policies in development.

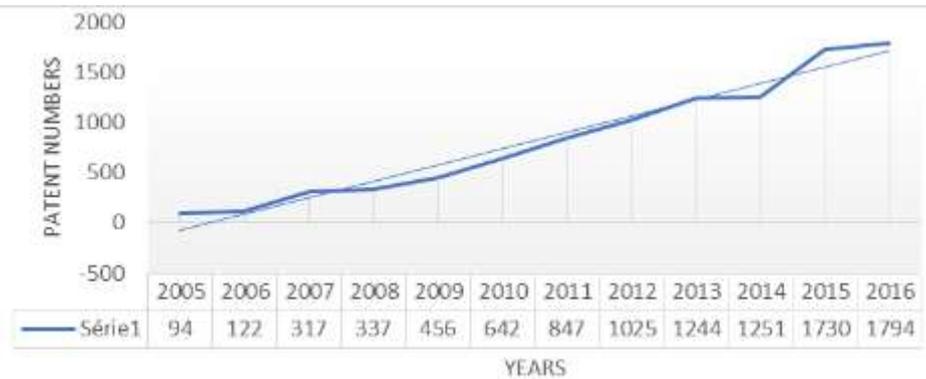

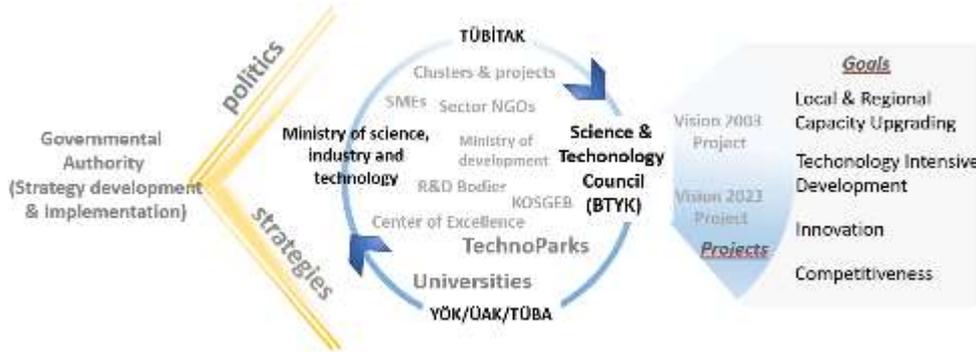

Figure 3: Number of Patents, 2005-2016, TPO (Turkey Patent Organization).

Throughout this process, TÜBİTAK (1963), YÖK and ÜAK (1980) and TÜBA⁵⁶³ (1993) were established to direct National Innovation Policies and support innovation capacity. These institutions especially support the production and spillovers of knowledge at the regional level by encouraging cooperation between universities and industry. In 1983, the "Supreme Council for Science and Technology (BYTK)" was established. Today, it is the supreme institution that leads the national innovation system. In the post-1990s' development policies, the focus shifted to R&D, innovation and technology. As the first organizations in the implementation of this process were established in 1992 in relation to "TEKMER" the Middle

⁵⁶³ TÜBİTAK: The Scientific and Technological Research Council of Turkey, YÖK: Council of Higher Education, ÜAK: Council of Universities, TÜBA: Turkish Academy of Sciences,

East Technical University and transformed into Turkey's first technopark in 2000. Science and Technology Development projects were prepared as *Vision 2003* and *Vision 2023* under the coordination of BYTK in the 2000s (Figure 4). In parallel to the development goals of the country, "*motivation of local resources, regional development and support of research and development institutions*" are among the strategies of these projects. In this context, support has also been important for establishing R&D centers for the private sector on a sectoral basis. In this period, MAR-TEK technopark was established as a research center affiliated to TÜBİTAK. Science and Technology strategies implemented in Turkey play a significant role in the formation of *technoparks*, R&D activities, knowledge spillovers, new products/services - similar to international practice.

Figure 4: National Innovation System of Turkey and Actors.

The technoparks started to be established in the 2000s in the cities/regions where industrial production, deep-rooted universities, human capital are concentrated. According to MSIT (2016), there are 64 technoparks in 44 provinces in Turkey. Istanbul, Ankara, İzmir and Kocaeli have high regional potentials and have emerged as the most established technoparks (Figure 5). Numerous research on the roles and activities of technoparks, which are increasing in number in a widespread geography, has been lacking in studies that take local/regional characteristics into consideration. Eyyüboğlu and Aktaş (2016) indicate that technoparks in Turkey are seen as a public policy tool for contributing to economic growth, especially in developing regions, and this situation brings together various opportunities and problems in terms of the selection of the technoparks and the performance of the firms. Pekol and Erbaş (2011) indicate that spatial proximity, being the university supported structures and a high concentration of R&D activities, increase the production of innovation by examining 4 technoparks with the highest number of patents. In this context, regional distribution of technoparks as an important regional tool of the National Innovation System indicates a concentration in the provinces having relatively a high number of patent, high middle-high technology employment and high performance universities (Figure 5). The total number of technoparks in 2005 was 28 within 13 provinces, and the number increased to 64 within 44 provinces in 2016.

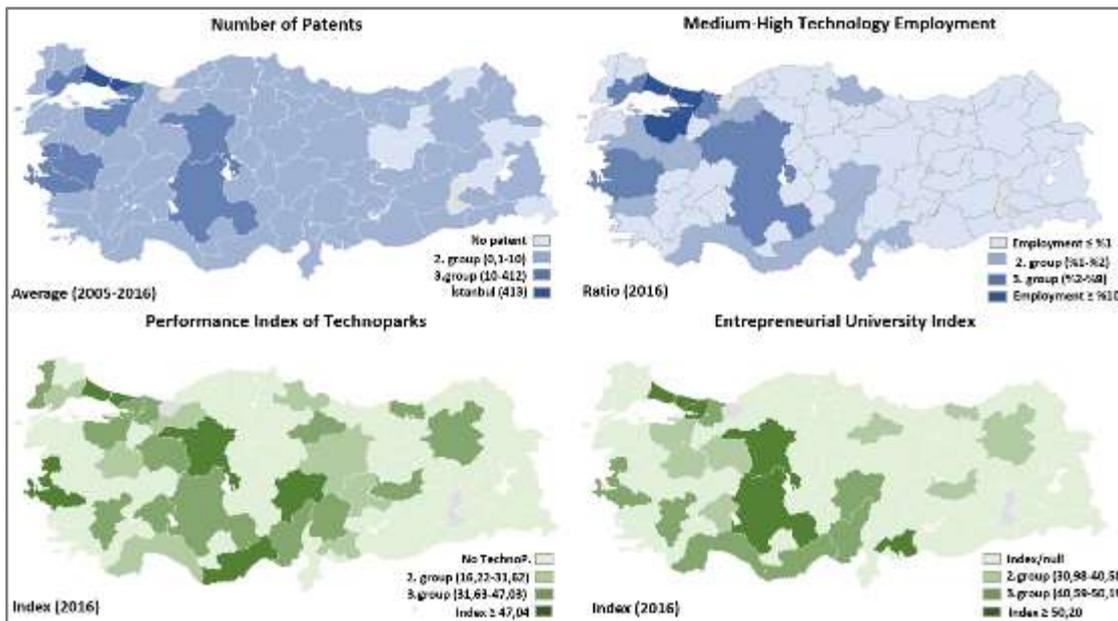

Figure 5: Main indicators of regional innovation potentials

The maps (Figure 5) indicate that there has been a similar pattern when the performance of technoparks, the performance of universities and a concentration of medium-high technology employment are considered. Ankara, Istanbul, and Izmir have many public and private universities, research institutes and organizations having the highest values for entrepreneurial university indices. The patent dominance of the first four provinces at national level remained in the same order between 2005-2016. These provinces also take top rank because of the concentration of medium-high

technology employment and production. Although new technoparks have been established in the eastern part of the country, all indicators show that eastern provinces have still remained behind.

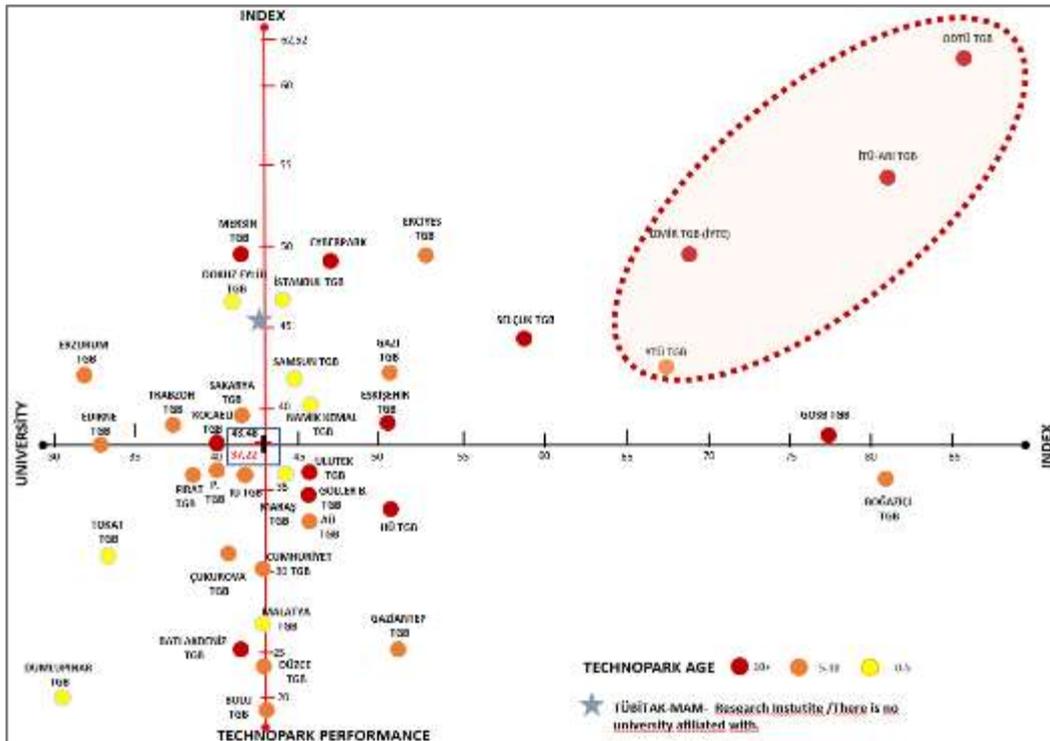

Figure 6: TechnoPark Performance Index (TPERIN) & Entrepreneurial University Index by the Age of TechnoParks, 2016

The analysis on the technoparks that are included the performance index of the Ministry of Science, Technology and Industry (BTSB) provides some insights about the relationship between the technopark and university performance. Among the 39 technoparks, Ankara (METU Technopark), Istanbul (İTÜ-ARI, YTÜ) and Izmir (İYTE) technoparks are seen as outliers with their high performance (Figure 6). The universities that these technoparks are established in connection with them are the oldest universities with the highest entrepreneurship index value along with these technoparks: especially ODTÜ technopark (Ankara) and MAR-TEK (Kocaeli) established in the scope of the national innovation initiatives. It is assumed that the year of technopark establishment is important for their performance, therefore the life cycle of technoparks is defined as 0-5 years - establishment process, 5-10 years - development process and 10+ years - maturity process. Most of the technoparks have been established less than 5 years and less than 10 years and indicating low performance are located in the eastern part of the country.

METHODOLOGY AND DATA

Patent data have been utilized as economic indicators, whereas Griliches (1990) and Anselin et al. (1997) identified patent as output of knowledge production function, and Jaffe (2000) focus on academic researches. Griliches (1998) pointed out that in spite of difficulties, patent statistics remain a unique resource for the analysis of the process of technological change. Since firms and industries vary in their technology regimes (Iammarino and McCann, 2007), micro-level analysis would give more detailed information about the innovation process. However, in this paper the innovation performance of regions in Turkey due to their endogenous local characteristics, as displaying stylized facts is the concern. Furthermore, the role of technoparks on innovation, as a base of geographically localized networks and cooperation with the universities would be the main interest of this research.

With respect to the conceptual framework of the research, we identified patent data as a dependent variable, however considering the number of patents, the data of utility model and trademark have been decided to be taken into account as well. Finally the dependent variable is identified as a combination of those three variables and mean values between 2005 and 2016 for each province. Thus, the analysis prevents the instabilities which might occur during this period. Since the range of the data (values of patents) is big, logarithm transformation is applied.

Two different models are estimated; first to find out the relations between the dependent and exogenous variables in 81 provinces of Turkey. Secondly, since each province does not have a technopark, the model is constructed just for the provinces which have technoparks (28 provinces). Thus, cross-sectional analyses have been conducted by using data for 81 provinces and in the second stage for 28 provinces.

However, most of the studies from different geographies prove that especially R&D activities and incentives induce the number of patents, there is a data limitation on R&D expenditures and employees in Turkey. Therefore, considering the literature on knowledge production function and a regional innovation system, the exogenous variables are identified due to the data limitations.

Since one of the main interests of research is to find out the role of technoparks on innovation performance of the regions, the Technopark Performance Index (TPERIN) is utilized. This index has been developed by Ministry of Science,

Technology and Industry (BTSB) based on different criteria. For the provinces, which have more than one technopark, the value of the technopark which displays the highest performance has been taken into account. The performance of the technopark is considered a proxy for mainly industrial R&D activities (Anselin et al., 1997). In addition to this, the Entrepreneurial University Index (ENTUNI) has been identified to examine the role of universities (Benneworth and Hospers, 2007).

$$\log(pat) = a + b_0 TPERIN + b_1 ENTUNI + e_{i,t} \tag{1}$$

The variables for exogenous local characteristics are identified as followings:

The ratio of university graduates and academic staff (UNIAC) is considered as proxy for human capital following the studies of O’huallachain (1999); Wolfe (2011); Qi and Lui (2011). The ratio of medium-high tech employment within total employment (MHTEMP) and new firms/ start-ups (NFIRM) is identified as proxy to capture agglomeration economies (Feldman and Florida, 1994; Anselin et al., 1997). The number of the first 1000 large firms (1000LARGE) as proxy to access the effect of firm scale (Acs et al., 1994; Anselin et al., 1997). The ratio of import/export: IMEX has identified as proxy for external linkages of the regional production, since empirical studies and theory have increasingly emphasized the importance of global networks (Qi and Lui, 2011). In equation 2, LOCENDO represents all local endogenous variables of the model.

$$\log(pat) = a + b_0 TPERIN + b_1 ENTUNI + b_2 LOCENDO + e_{i,t} \tag{2}$$

RESULTS OF THE ANALYSIS

Two models are conducted with the same variables, however the number of observations as provinces is different. In the first model, observations are 81 provinces and the model examines which factors have significant impact on innovation performance (the number of patents+ utility model+ trademark) of the regions. Therefore, innovation performance is identified as a combination of three variables and the mean values.

Multiple regression analysis is applied and the model 1 is significant ($\alpha=0.05$), with 67% explanatory power (&math>R^2 = 0.67</math>). No assumption violation exists.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.819 ^a	.671	.640	.44108	2,156

ANOVA (a)

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	28,981	7	4,140	21,280	.000 ^b
	Residual	14,202	73	.195		
	Total	43,183	80			

a: Dependent Variable: log(pat)

Figure 7: Model Summary and ANOVA

Afterwards, stepwise regression is applied to find the most effective variables on innovation performance of the regions. R^2 is 0.668 and the model is significant ($\alpha=0.05$). As shown in the coefficients table, the ratio of medium-high tech employment, technopark performance, university performance and the first 1000 large firms are significant independent variables and have a positive effect on the number of patents in the regions. According to a standardized coefficient, the most effective variables are technopark performance, first 1000 large firms, university performance and the ratio of medium and high tech employment, respectively. The result enhances our assumption about the role of technoparks and universities on innovation performance of the regions. Moreover, the power of the manufacturing industry and structural changes in the manufacturing industry and leading firms in Turkey make significant contribution to the innovation process. Gezici et al. (2017) put forward that high- and medium-high technology sectors are mainly concentrated in the western part of Turkey and prefer to locate where there is already an existing concentration of industrial activity. Thus, agglomeration economies are still very important not only for productivity but for innovation as well.

Coefficients^a

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics

Figure 10: Regression results for log (patent) in 28 provinces

The second model excludes the provinces that do not have technoparks. Meanwhile the role of universities and leading firms has become more obvious for these provinces. The findings prove the evidence from the earlier studies which emphasize the positive impact of dynamic manufacturing industry and efficient cooperation networks between the firms and universities on regional innovation.

CONCLUSION

In the new economic system, innovation has become an outcome of commodification of knowledge. Not only as outcome but the process of innovation is significant since it is realized that it is not linear but more complex system. On the one hand, there have been studies using patent data as indicator of innovation, on the other hand a literature has been emerged on regional innovation system covering the local actors, co-operations and networks. Conceptual framework of this research is constructed based on the role of techno parks on innovation performance of the regions in Turkey. Techno parks has been developed with respect to the success of technological clusters, which are not focus only the co-operations between firms but other related sectors, whereas techno parks are mainly identified as tool for co-operation between the firms and universities.

In Turkey techno parks have become one of the significant policy tools regarding the development strategies as, "motivation of local resources, regional development and support of research and development institutions". Therefore, the number of techno parks has been increased to 64 in 44 of 81 provinces since 2001. With reference to the number of patents, medium-high technology employment ratio and entrepreneurial university index value, the location of techno parks indicates more dispersed pattern. However, to establish techno parks in the provinces, which do not indicate sufficient endogenous dynamics, would not be an efficient policy in a developing country. Therefore, further research will be conducted to realize the dynamics of techno parks and endogenous local characteristics, which are located in, by considering the strengths and weaknesses.

Evidences on importance of agglomeration economies are quite obvious for the innovating firms in literature. The findings of our research on Turkey support it as well, since the number of patents is concentrated on the most developed metropolitan cities/provinces. Furthermore, according to two models in this research, we have got the similar results with earlier findings that both dynamic manufacturing industry and related activities; and efficient cooperation between the firms and research institutions/universities are the main determinants of innovation for the regional success.

1713 SUPPLY NETWORKS IN THE AUTOMOTIVE INDUSTRY REVISITED: HOW DO MULTIPLE CLUSTERS IN TURKEY REACT TO RIVET EFFECTS? ⁵⁶⁴**Adem Sakarya***, **Yiğit Evren***** PhD candidate, Research Assistant at Yıldız Technical University, ademsakarya@yahoo.com.tr** Assoc.Prof.Dr. at Yıldız Technical University, yigitevren@gmail.com**1. INTRODUCTION**

Supply networks in the automotive industry continues to be a complex and fruitful field at the intersection of economic geography and regional development. In Turkey, various scholars have researched different aspects of this issue by bringing empirical evidence from the local industry (Evren, 2002; Wasti et.al, 2006; Özatağan, 2010 and 2011). In this paper, we revisit the Turkish automotive industry to reach a better understanding of supplier customer linkages and their geographies. Our investigation is based on the concept of *rivet effect* (Martin and Sunley, 2015) and its impact on the first tier supplier network of Turkish automotive production. We focus on the automotive supplier firms in the Marmara Region –the industrial heartland of the country- and their forward linkages with OEMs in Turkey. In this context, we seek answers to below-listed questions. How did the automotive industry in Marmara react to positive and negative rivet effects during the last decade? Did the density and composition of the supply networks change, and, if so, what are the spatial outcomes of this process? We will address these issues by conducting a quantitative research.

2. RIVET EFFECT AND PRODUCTION CHAINS

Rivet effect, as described by Martin and Sunley, refers to the idea that “...the more a region’s economic structure is dominated by and dependent on a particular sector or major firm, then the failure or decline of that sector or firm in response to a shock could lead to widespread collapse or decline of the region’s economy as a whole. Conversely, high-growth ‘new economy’ sectors may act as drivers of resilience...” (2015: 28). This is the very idea of the hub-and-spoke industrial district model as Ann Markusen (1996) described some twenty years ago that means that, a number of key (or rivet) firms act as anchors or hubs to the regional economy, with suppliers revolve around them like spokes of a wheel. Although, Markusen did not use the word “rivet” directly, she was one of the first authors who conceptualized this notion within a typology of industrial districts.

The hub-and-spoke industrial district model is typical for the automotive industry. Toyota City, where Toyota’s main plant is located in Japan (Park, 1996), and Detroit, the historical capital of the US automotive industry, are among the well-known examples for this spatial pattern (Klepper, 2002). The literature postulates two issues as major reasons for the emergence of an economic landscape as such. The first issue is closely related to the implementation of just-in-time stock inventory system (JIT). In this system, the speed and the frequency of deliveries are of primary importance. In most cases, suppliers are required to make more than one delivery per day to meet the relatively small and significantly more frequent orders of their customers. Therefore, for transportation cost advantages the close proximity between suppliers and customers is almost essential.⁵⁶⁵

In addition to JIT, it is also argued that R&D grounded innovative activity increases the pressure for proximity between suppliers and customers. Contemporary subcontracting in automotive industry is often associated with the notions of technology sharing and detailed financial negotiations. From this point of view, the delivery of high technology component systems, in particular, implies the spatial agglomeration of transactions. Furthermore, for more cost-efficient linkages, OEMs and their suppliers are expected to be in close proximity to each other, especially when the relations include prototype-work and design activity.

From an organizational point of view, one of the most important developments in the automotive industry is customers increasingly seeking for key first tier suppliers to supply complete systems rather than individual parts (Sadler, 1999; Humphrey and Memedovic, 2003; Maurer et. all., 2004; Pires and Neto, 2008; Dicken, 2011). This trend has caused significant changes in the hub-and-spoke production organization, reducing the number of first tier suppliers on the one hand and reinforcing the pyramidal structure especially within the second and below tier supply chains on the other.

3. METHODOLOGY

Most of the literature on geographic linkage studies that bring empirical evidence from the automotive industry tend to adopt a *parent firm centered* analysis (Klepper, 2002; Ivarsson and Alvstam, 2005; Boschma and Wenting, 2007; Price and Wang, 2012). While backward linkages that link assembly firms to their suppliers have been widely studied, multiple forward linkages which stem from these suppliers have not been fully investigated. In this paper, we focused on the latter and used Evren’s (2009) typology of suppliers.

In this typology, he presented three distinctive supplier types based on the geography of their forward linkages. Type 1 suppliers solely work with assembly firms co-located in the same locality or cluster. Type 2 suppliers are comprised of firms with forward linkages that occur both within and without the cluster boundaries. Type 3 suppliers, on the other

⁵⁶⁴ This paper reveals some of the findings of the first author’s ongoing PhD research under the supervision of the second author at Yıldız Technical University, Department of City and Regional Planning.

⁵⁶⁵ We should, however, we need to emphasize that the locational aspects of JIT may differ from one case to another and thus the ‘JIT=proximity’ thesis is difficult to generalize (Evren, 2002).

hand, serve solely to outer-cluster customers. Schematic visual models of each are illustrated in Figure 1. Here, forward linkages within the cluster are depicted inside the circle versus those outside of it.

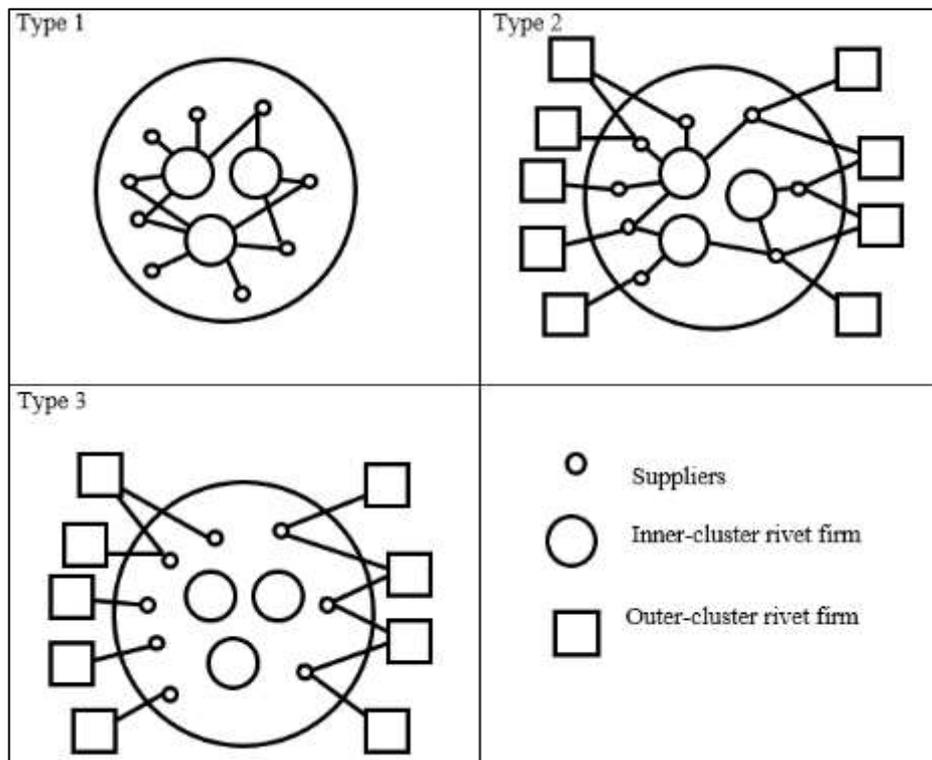

Figure 1. A Classification of Supply Networks (Evren, 2009)

Our analyses were two-fold. The first stage was dedicated to explore the past 15-year performance of the automotive industry in the Marmara Region. For this purpose, we conducted a multivariate time series analysis of employment, revenues, production and exports, by using index. This has provided us to capture the occurrence of a V-shaped pattern in the sector and relate it to rivet hypothesis. At the second stage, we produced the supplier typology for each cluster within the Marmara Region. Supplier classification was made using the OSD lists published by the Automotive Manufacturers Association in 2006 and 2013. These lists comprised over 1300 first-tier supplier firms having direct contact with assembly firms and provide suppliers' address information as well as their multiple forward linkages.

4. AUTOMOTIVE INDUSTRY IN THE MARMARA REGION

The automotive industry in Turkey is mainly clustered at the North-Eastern quadrant of the country, namely the Marmara Region, where 11 out of 17 vehicle manufacturing plants are located. This mega-city region is the ultimate centre for the local sector, in which 81% of total employment by OEMs is created, 89% of vehicle exports are generated and 94% of Turkey's vehicle production is realised. The Marmara Region is also an important hub for the supplying industry; 74% of all first tier suppliers of the Turkish automotive industry and their densely interwoven network of forward linkages with OEMs are situated here (Ökten *et al.*, 1998).

When we look at the Marmara Region closely, we can observe a pattern of multiple clusters (Bursa, Istanbul, Kocaeli and Sakarya) each of which has different characteristics (Erkut and Albayrak, 2010) (Figure 2). Among these four clusters Bursa has a very distinguished position. The establishments of Tofas (the joint venture of Fiat), Oyak-Renault and later Karsan (operating under the licence of Peugeot) throughout the 1970s have attracted a considerable number of suppliers into this city and paved the way for the emergence of a hub-and-spoke automotive cluster at the South-Eastern corner of the Marmara Region. As of 2015, Bursa holds 49% (815.000 vehicle/year) of the total established capacity of vehicle production in Turkey. In 2013 Oyak-Renault, Tofaş and Karsan produced more than 588.000 vehicles, 70% of which were passenger cars and mainly exported to the EU countries (OSD, 2013; OSD, 2015). Same year, there were about 208 (20%) first-tier supplier firms in Bursa.

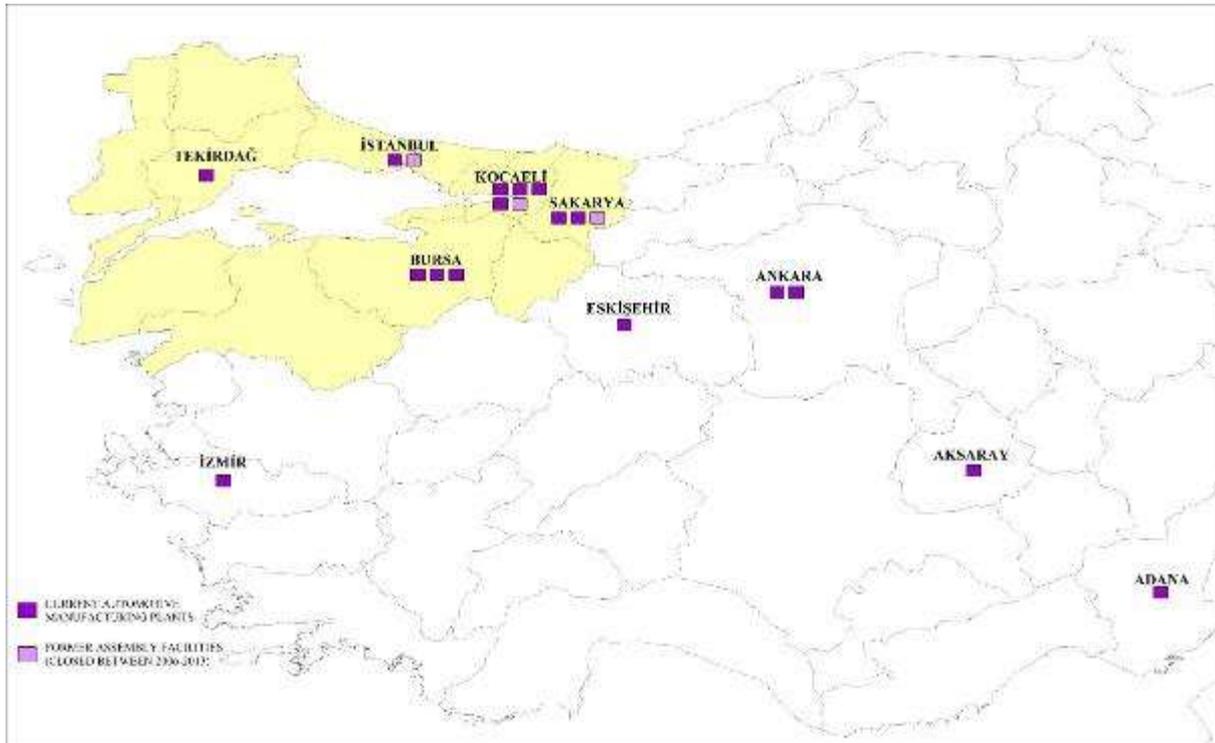

Figure 2. The Spatial Distribution of the Automotive Industry in Turkey (2013)

With its four parent firms (Hyundai-Assan, Honda-Turkey, Ford-Otosan and Anadolu-Isuzu) and 121 first-tier suppliers Kocaeli is the second most important automotive cluster in the region. These four OEMs realized 34% of Turkey’s total vehicle production. Like Bursa, Kocaeli has a strong export base too; despite the closure of Askam-Chrysler in 2007, this cluster can generate 28% of Turkey’s vehicle exports. The third cluster is Sakarya, where two parent firms (Otokar and Toyota) are located. These two firms realized approximately Turkey’s 16% passenger car production in 2013. Compared to the other clusters in the region, Sakarya has shown a relatively slow pace of growth in terms of supplying industry. There are only 24 first-tier automotive supplier firms. The fourth cluster is İstanbul. Different from all others İstanbul (which used to be a major hub for this sector) has significantly lost its previous stickiness since the mid-1990s, partly because of the ongoing twin processes of deindustrialization and rapid urbanisation. Today, there is only one OEM in İstanbul (Mercedes Benz Turk) and there are 379 small scale first-tier suppliers.

5. FINDINGS

Since the beginning of the new millennium, the automotive industry in the Marmara Region has been exposed to two major shocks. The first shock was in 2001. The severe political crisis in February which triggered the worst ever banking crisis in the recent history of the Turkish economy, later turned out to be a major shock that severely affected almost all industrial sectors including the automotive industry. The local sector tried to remain resilient by successfully adopting an export-based strategy, resulting a sharp increase in vehicle exports by 65% just in three years (Figure 3). Between 2005 and 2008 employment and production were also increased by 17% and 20% respectively.

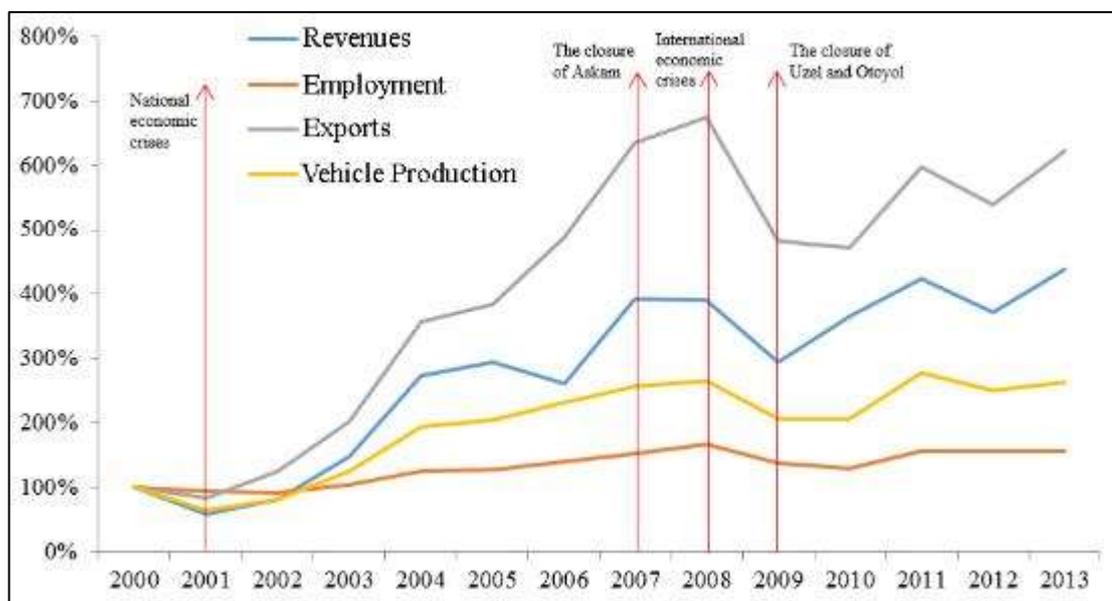

Figure 3. The Performance of the Automotive Industry in the Marmara Region (2000-2013)

The second shock was the global financial crisis in 2008, the impacts of which was very serious on the local automotive industry. December 2008, year-over-year production, sales, and exports were all down 50% or more (Berzin, 2010). Under these poor conditions, Askam in Kocaeli, Uzel in Istanbul and Otoyoil in Sakarya went out of business, while others scaled back. This situation has created a negative rivet effect on the supplying industry. Two years later, the sector has started to witness some signs of recovery. With the support of a stronger domestic market and the expanding export market, some OEMs have courageously taken some actions, most of which had positive rivet effects on the local sector. The opening of a new R&D center of Tofas, Renault’s shifting the production of the new Clio model to Turkey, and Otosan’s winning the *North American Truck of the Year* award at the 2010 Detroit Auto Show with its transit van have somehow made the industry better positioned for long-term growth and success.

Having mentioned the co-emergence of major events that created positive and negative rivet effects in the region, we can now turn our attention to the impact of them on the first-tier supplier network. We have two findings. The first one is about the suppliers’ organizational response to changes. Despite the closure of three assembly firms in the region, there was no significant change in the number of first-tier suppliers. In 2006 there were 769 first-tier suppliers; this figure in 2013 was 732. There was, however, some structural changes within the local network of supplier customer relations. By 2013, the number of total forward linkages had decreased by 17% compared to that of 2006. Throughout the same period, average forward linkages per supplier had also been decreased from 2,8 to 2,4. Furthermore, some significant shifts among supplier groups (Types) had occurred. Except the third group (Type 3), the shares of all other supplier groups had decreased, indicating a tendency of supplier firms to find outer-cluster customers (Table 1-3).

Table 1. Supplier Typology in the Turkish Automotive Industry (2006) (Compiled by the authors from OSD statistics)

	Type1		Type2		Type3		Total	Total Network	Network per Supplier
	Number	(%)	Number	(%)	Number	(%)			
Bursa	29	13	93	43	93	43	215	651	3.0
Istanbul	74	17	143	33	212	50	429	1065	2.5
Kocaeli	10	11	44	46	41	43	95	363	3.8
Sakarya	11	37	12	40	7	23	30	59	2.0
Total (4 centers)	124	16	292	38	353	46	769	2138	2.8
Turkey	221	21	359	34	482	45	1062	2805	2.6
4 Centers / Turkey (%)	56		81		73		72	76	

Table 2. Supplier Typology in the Turkish Automotive Industry (2013) (Compiled by the authors from OSD statistics)

	Type1		Type2		Type3		Total	Total Network	Network per Supplier
	Number	(%)	Number	(%)	Number	(%)			
Bursa	44	21	71	34	93	45	208	586	2.82
Istanbul	22	6	62	16	295	78	379	782	2.06
Kocaeli	18	15	47	39	56	46	121	356	2.94
Sakarya	13	54	6	25	5	21	24	44	1.83
Total (4 centers)	97	13	186	26	449	61	732	1768	2.42
Turkey	218	21	230	22	581	57	1029	2365	2.3
4 Centers / Turkey (%)	44		81		77		71	75	

Table 3. Supplier Typology in the Turkish Automotive Industry: A comparison of 2006 and 2013

	Type1	Type2	Type3	Total	Total Network	Network per Supplier
Bursa	52	-24	0	-3	-10	-7
Istanbul	-70	-57	39	-12	-27	-18
Kocaeli	80	7	37	27	-2	-23
Sakarya	18	-50	-29	-20	-25	-8
Total (4 centers)	-22	-36	27	-5	-17	-13
Turkey	-1	-26	21	-3	-16	-13

Our second finding indicates a spatially uneven impact of the rivet hypothesis in the Marmara Region. From the perspective of economic geography and regional planning, Bursa, Kocaeli, Sakarya and Istanbul do not only differ from each other with respect to production organization, size and historical evolution, but also with reference to the density and spatial composition of their supplier customer linkages. The supply networks that stem from these co-located automotive clusters within Marmara Region and across country also display different features in response to positive or negative rivet effects. Take, for instance, Bursa which had increased its type1 suppliers approximately 1.5 times. Conversely, in Istanbul we observe a sharp decline in the number of type1 suppliers. In Kocaeli, however, there was a different story; it was the only local cluster that had increased the number of its first-tier suppliers. As a matter of fact, Istanbul’s decline and Kocaeli’s growth are interrelated processes. Significant increase in land prices in Istanbul over the past two decades forced several supplier firms to seek alternative locations in the region. In this context, Kocaeli has gained new competitive advantages for industrial investments and become an attractive cluster.

6. CONCLUSION

This study has revealed that both the organizational and locational structures of supply networks are context specific. Even within the same industry and/or region, there is a wide spectrum of strategic responses to positive and negative rivet effects from supplier firms in different localities. The comparison of the four automotive clusters in the Marmara Region of Turkey supports this contention, indicating that each industrial district has its own unique story. This assessment is also in line with the contemporary writings in economic geography, most of which acknowledge that there is no single deterministic relationship between particular forms of the organization of production and their spatial patterns (Martin and Sunley, 2015; Bathelt and Glückler, 2011; Boschma, 2015).

As far as the policy implications are concerned, it should be strongly emphasized that policies which concern the future of the Turkish automotive industry should not ignore the multi-directional development patterns of local clusters in the Marmara Region. Based on our findings, we can confidently forecast that Kocaeli and Sakarya (and even Bursa though it seems to have reached a saturation point) will sustain their attractiveness to supplying industry. Conversely, the production space in Istanbul will become increasingly slippery for the sector, as the decentralization of the industry continues and as new competing clusters are set up elsewhere.

1726 TEXTILES AS A TOOL FOR SOCIAL IDENTIFICATION

Maria João Delgado, Gianni Montagna, Cristina Carvalho

CIAUD, Lisbon School of Architecture, Universidade de Lisboa, Lisbon, Portugal

ABSTRACT

Dating back to human's memory, textile materials have always accompanied men and women on an intimate and personal journey and represent them in all its dimensions throughout life. From birth until his death on earth, textiles represent the interface between intimate body and the outside world and his closest element of communication with the society in which he lives and interacts.

Innovations in the materials themselves and in the technologies used for their production have always been allies that together allow great versatility of production, but also of adaptation and use in situations so different and diverse.

The social representation of textiles and their communication functions are probably their most important characteristics, and they can assume such special characteristics that can represent peoples as in the case of regional costumes, political propaganda to represent cultures or unique social moments, allowing our personnel to constantly communicate different messages that present and define us as people but also as elements of a society that welcomes us.

This paper intends to trace a path that allows the recognition of the textile material as an element of communication and social identity to the different cultures and social codes. The methodology is based on a social and historical review of the textile literature, selected due to their representativeness in certain social contexts. The aim will amplify the understanding practices and social representativeness in textile production as a material culture that represents a utilitarian tool to communicates social and political patterns that allow ordering and guiding entire societies.

Keywords: Social Textiles; Textile Communication; Material Culture; Textile Innovation; Textile Material.

INTRODUCTION

The social representation of textiles and its power of communication can take on such special characteristics as individual representation or belonging to a group, a region, a civilization, as in the case of regional costumes or political propaganda (Japan, England, USSR, etc.) to represent cultures or unique social moments, allowing each individual to communicate different messages that present and define them as people, but also as elements of a society that welcomes us. For Barnard (2003) clothes are not ideologically neutral in that they are used to constitute and communicate a position of social order but also to challenge and challenge positions of relative power within it.

If the history of clothing goes back to the age of prehistory, as a result of man's need to cover himself and protect himself from climatic variations (Laver, 1989), it is only in the Middle Ages in the West that the clothing simultaneously assumed the function of social identification with certain groups (Lipovetsky, 1989). According to this author, materials and colours were used to characterize the various costumes, namely the representative robes of each feud with a symbol and bicolour patterns in the clothes of the nobles. But, if clothing was for a long time a privilege of upper classes, globalization and its social importance increased considerably, becoming increasingly complex and demanding, in response to different lifestyles, identities, and social groups.

a textile's surface is more than just a façade — it's a curious layer of aesthetics and identities and a contentious site of exploration and resistance. (...) Surfaces are also manifestations of social norms and moral codes, (...) [and] have perceptual qualities, their mutability enabling the body to take on chameleon-like characteristics. Because surfaces are interpreted by sight and touch, physical contact with the surface initiates a complex multisensory, emotional and cognitive experience that provides a uniquely individual interpretation of the world (Quinn, 2010).

During many centuries, for the production of textile materials, only natural fibres such as linen and cotton were used, or, as happened later, wool and silk, allowing the individual to satisfy his personal and social needs. Nowadays, considering the possibility of creation with the use of textile fibres with very varied origin, as in the case of the new functional fibres and the intelligent materials, more and more we can perceive the connection and the influence of the textile design in the creation of a plural clothing, without physical, social, economic and even emotional borders. Innovation and entrepreneurship are characteristics that accompany textiles, innovations in the materials themselves and the technologies used for their production have always been allies that together allow great versatility of production, but also of adaptation and use in diversified contexts.

In this way, the present work aimed to establish a parallel between textile materials associated with the production of clothing and its recognition, as elements of identification of different cultures and social codes over time. As a methodology, a documentary research was carried out, aiming to broaden the understanding of the nature, practices and social representativeness of textile design in its different aspects. The textile material culture represents a tool that, intrinsically, communicates social and political patterns that guide whole societies.

TEXTILE MATERIALS AND CLOTHING

Going back to the memory of man, the textile materials always accompanied him in an intimate and personal journey, representing it in all its dimensions throughout life. These textile materials form an integral part of the history of clothing and signify an expression of personal, social, cultural, religious and gender identity in all civilizations. If the skins, along with the leaves and the bark of the trees, were the first material to be used by man, the fibres of vegetal origin began to

be cultivated and manipulated for the creation of the first pieces of clothing. Textile fibres are the central element in the production of any substrate and either used in their most primitive form or spun and twisted in yarn form give rise to textile surfaces which are responsible for all the production of the textile object.

In the prehistoric period, the humankind begins to make the first fabrics, although in a very primitive way, appearing not only as a user of clothing products but also as a manufacturer, craftsman, and artist of these pieces. "Textiles are always present in any culture and geography because from the highest antiquity man needed to protect himself and to dress." (Teixeira, 2008, p.356). Until the 19th century, textiles were mainly made from the artisanal work of natural fibres, such as flax, cotton, wool, and silk, and were later replaced with artificial and synthetic fibres when these natural materials began to scarce and industry gradually mechanized, allowing mass production. The use of textiles in clothing has always been related to technological advances and to the needs and trends of society in the field of fashion.

THE GOLD OF THE NILE

Flax is one of the oldest cultures used in textiles and food. It is known that the linen began to be cultivated and used for the production of clothing in the Neolithic period, as a result of the people fixation to a specific place. Being one of the oldest textile fibres much appreciated for dressmaking, it has become, in many civilizations, as in Greece, Crete or Egypt, as a social differentiator, when it was considered a luxury fibre.

The Egyptian civilization, which maintained unchanged attire for about 3000 years, resorted to the best linen cloth, known as the luxurious "gold of the Nile", as an expression of class distinctions, to produce its pieces and refusing the use of animal fibre for religious reasons. The dead were wrapped in linen robes that accompanied them on their journey to eternity. The Greeks and Romans wore the linen mantle wrapped around the body, with drapes and belts tied around their waist (Steele, 2005).

Also, in the West, linen was, during old times as in the Middle Ages considered a luxury fabric. Various types of fabrics were made with this fibre, depending on the thinner or thicker yarn used for the confection of pieces with different requirements, such as shirts, scarves, lace or embroidery.

"In ancient societies and the Middle Ages, the difference between rich and poor is more pronounced than in modern western and democratic societies, even because in a society with trade based on commodity exchanges, devastated by endemic pests and droughts, power finds itself its exemplary manifestation in arms, armour and the magnificence of clothing "(Eco, 2004, p. 105).

In Medieval society, as Medieval society explains, the dying of fabrics with vivid, bright, artificial colours derived from minerals or vegetables, worn in the green or red girdled coats, embroidered with gold and adorned with semiprecious stones of the powerful lords, represented wealth, while the poor wore robes with natural colours, dull and dark. (Eco, 2004).

During the eighteenth and nineteenth centuries, the production of flax and hemp fabrics accompanied population growth, providing an essential response to social needs throughout the human life cycle, from baby diapers to shrouds for the Jewish people (Steele, 2005). Their physical properties were decisive for the making of different types of clothes with fabrics of different structures: men's and women's underwear, wedding dresses and children's clothing, which both plebs and elites used, valuing the use of white over white and transparency (Steele, 2005).

Natural colours for linen fibres include buff and grey while white and pure colours are obtained through bleaching. The shirts, which emerged in the seventeenth century in Europe, are of great importance as pieces of clothing in the early eighteenth century, made of white linen for gentlemen who had the possibility to buy, change and wash them regularly, which was not possible for the working class to do. Also, the bodices included a strip of embroidered linen cloth, known as a "fichu", to cover a woman's chest. (Steele, 2005, 193).

The manufacture of luxury linen textiles continued to occur during the Industrial Revolution but began to lose its place in the luxury hierarchy and market share by being replaced by petroleum-based fibres, produced in large quantities and at lower prices accessible.

Flax, because of its specific characteristics, namely, resistance to heat and sunlight, its ability to absorb moisture rapidly returning to the environment (Malichenko, 2017) continued to be the appropriate fabric for clothing hot and humid countries, as it helps regulate the body's normal temperature.

Due to its environmental and emotional potential, associated with its physical characteristics, linen has been rediscovered in recent decades by fashion design and science and engineering. Men's designer John Alexander Skelton recently presented a suit made of the century, which proves the longevity of linen, contrary to the concept of "fast fashion". Currently, the main producers of linen for the global market are Europe and Asia, mainly the countries and regions of China, where flax is used for the production of high-quality clothing. Because of its specific characteristics of being a product of natural origin, as opposed to synthetic materials, it reaches high market prices and is considered a luxury material. It is a fabric that holds its social claim in Western fashion.

Cotton began to be mass produced in the nineteenth century, replacing linen in the confection of some clothing products.

TRENDY COTTON FROM TIME TO TIME

In ancient times, cotton has been present in western and eastern cultures and is currently one of the most widely used natural fibres in the world. India, Ethiopia, and Egypt are associated with the early days of cultivation and production of

cotton pieces, and their planting has expanded mainly in countries of Africa, America, and Asia, where the climate was decisive for their cultivation. The best qualities of cotton grow in climates with a dry and hot harvest season with high rainfall in the growing season.

Cotton production has played an important role in the trade and economy of many countries worldwide. During the Roman Empire, cotton textiles were widely traded, with cotton beginning to be imported from India around 190 BC. This and other fibres were woven by women workers on large estates or by men and women in companies located throughout the empire. (Steele, 2005).

The cotton industry had a great expansion in the nineteenth century, during which the use of cotton fabrics became popular for garments of all kinds. The production of cotton fabrics was greatly facilitated by the invention of the Cotton Engine machine, which separated the cotton seeds from the fibres, invented by the American Ely Whitney (1765-1825), and validated in 1807 (Callan, 1999). Cotton spinning and weaving, largely mechanized and centralized in factories, led to major economic and social changes. However, handicrafts and the industrial production of clothing for men and women coexisted until the beginning of the 20th century. Cotton, woven by weavers, remained in many homes, as did the system of exchanging and buying used clothing. One of the best examples of this is the production of knitted socks that were still being made by hand while spinning and weaving cotton was already largely mechanized and factory-centered.

In the thirteenth century, Barcelona became a thriving centre of the cotton industry specializing in producing a cotton canvas for candles (Steele, 2005). In the USA, for example, in 1859, two-thirds of the world's cotton fibre production originated in the United States. This production in large quantities demanded the increase of slave labour, associating it with the "controversial role in the slave trade; cotton, produced by slaves in America, was among the commercial goods used to procure other slaves in Africa "who could work on the cotton plantations (Parker, 1998).

In Europe, the use of cotton diffused in the seventeenth century when significant amounts of crude fibre began to be imported into Britain from the expanding British colonies.

Cotton has a number of characteristics that keep it very competitive in the market. It gives rise to a fabric highly valued for its softness, so it is considered a comfortable fibre for daily use, ease of maintenance, resistance to heat and sunlight and easily accepts dyeing. Because of its comfort characteristics in everyday wear, when associated with design, it has become a differentiating element, not only between social classes but also between cultures and peoples. Not only the quality of the cotton fabrics but also the colours, the texture, the varied patterns and the design of the pieces that distinguish the clothing of different peoples.

In the 16th and 17th centuries, thanks to large imports of this fibre by England from its Indian colony, cotton has become one of the most popular fabrics for everyday use. The first Indian kinds of cotton were so fine and soft that they competed with the silk and wool fabrics, making it a commercially very valuable and competitive commodity in the fabric market. At the end of the 18th century, along with white linen, cotton was the basis of fabrics for the clothing of children and young people.

Cotton fabrics were originally only available to the rich, as they reached high prices as a result of the intensive manual labour required by the transformation of fibre into yarns. In the West, in the second half of the nineteenth century, the use of cotton was already widespread, not only for the making of underwear but also for the fresh dresses of summer. The cotton used in dresses could be plain or printed with flowers, stripes or squares. Undergarments could be made from various materials such as wool, cotton linen, cambric/linen or chanvre (Callan, 1999). Besides the quality of the material, these pieces were manufactured on a small scale, reaching very high prices, which, however, the bourgeoisie could pay, differing from the working classes.

Cotton textiles have been widely used in many civilizations. For example, in Central America, since pre-Columbian times, cotton has become the fibre most used by weavers. With the European colonization of the Americas, cotton has become an established culture in this territory, forming part of the masculine and feminine clothing of this people. The Kogis and the Incas wore cotton tunics, tightened with a belt, on tights, while women wrapped strips of cotton cloth around their bodies, tied around their shoulders and fastened at the waist with a belt. After Chinese Revolution in 1949, the Mao blue cotton suit was imposed for the use of men and women. Some minority groups in China, Burma, Laos or Vietnam, though conservative, albeit with some variations, still wear black-tinged cotton robes, worn with skirts or trousers and ornamented with coloured embroidery and coins or sewn silver beads. Bangladeshi women often wear cotton saris over blouses (Steele, 2005).

WOOL AND ITS SOCIAL DIMENSION

With regard to the use of wool, this fibre has been used since prehistory, assuming great importance in the production of textiles in antiquity, for example in the Assyrian civilization where artisan corporations were created to manufacture wool, or the Greek robes, made from unbleached wool. The production of fabrics with different types of wool yarn, applied in the production of different pieces of clothing, happened only in century XIX.

The wool fibre used in countries with cold climates for the production of clothing uses its insulation properties, which make the wool fibre and its derivatives do not warm the body but maintain its physiological temperature, in a constant way allowing the creation of a microclimate within the pieces and the body. In view of the fact that in very hot countries such as the Arab countries there are large desert areas with high thermal excursions, the use of wool fibre covers, for the protection of individuals, allows the maintenance of constant body temperature even when its exterior can reach several degrees above that. These characteristics make it a superior fibre because of its adaptability to different contexts. It can

be found in most wool fibres, be it sheep, goats or other animals, such as camels, rabbits, etc. For this type of textile, it cannot be neglected that it is a material that grows and develops in perfect harmony with the environment where the animals live and adapting its characteristics to the habitat that it finds. Thus, wool produced in Australia will have different specificities from that produced in Ireland or Tibet, each of which is used for the development of products with specific social and cultural reflexes and an added value for the community and the local economy.

Many are the collective images of groups of women sitting in the candlelight spinning their yarns. This social image, where the community meets around a craft, not only for the production of yarns for the production of knits or for weaving but also for the sharing of experiences between individuals who share the same symbolic and metaphorical culture, is very recognizable in the trade related to this fibre. In the spring, after the long winter, shearing comes: the longest days are spent outside the house to wash and dry the wool, after carding the fibres are spun on a spindle and the wires are wrapped in skeins, ready to be stored. On the colder winter days, when outside is only allowed for the most urgent tasks, it is time to weave woollen fabrics, in the comfort of the home and in a more comfortable space.

THE CULTURAL PREFERENCE OF SILK

In the 16th century, with the arrival in the West of large quantities of silk for clothing, linen was used only in the production of underwear, shirts and household linen.

The silk, produced in China from 1700 BC, only in the year 300 AD is known in India and only comes to Europe in the sixth century, brought by the Arabs and Byzantines. The cultural preference for the use of silk has spread from China to the rest of the world, as well as production technology.

With maritime expansion in the Modern Age, new fabrics began to be developed from the use of different natural fibres and vegetables, initiating a transfer and sharing of materials and weaving techniques, influencing trade and fashion. Through the Silk Road which was the most important commercial and cultural link between East and West for hundreds of years, the trade of silks, skins, porcelains, gold and silver, spices, among others, was especially destined for wealthy people.

In the West, the greatest technical and technological developments related to the production of silk yarn and the weaving process were developed especially in the Italic Peninsula, in the south of France and in Spain, where mulberry cultivation presented favourable climatic conditions. (Tolaini, 1997). Currently, Italy and France continue to produce high-quality silk textiles from imported fibres from China, Japan, India, and Thailand "Silk has long been considered the ultimate in luxurious feel on the skin. Many synthetic fibres are engineered to emulate the look and feel of silk" (Steele, 2005, p.183).

Since 1860, the city of Lyon has become one of the largest silk-weaving centres in the world, where the flowering of haute couture and the luxury of the court make this industry a centre of development in textiles and fashion in Europe. The notion of fashion existed only in the nobility, where dress and beauty represented more a form of power and glory than an aesthetic subject (Kawamura, 2005).

The silk was still associated with high status and becomes a symbol of luxury and power. The taste of royalty for garments made of bright taffeta, heavy silk, moiré, and velvet make Lyon factories make them, in addition to the French "à la Jacquard" silk fabrics (BOUCHER, 1965). It was the fabric of election of the wealthy bourgeoisie for the costumes of weddings, feasts, and other events in Western society.

"The silk velvet is suitable for receptions given in the European courts but also places under private living rooms, at social balls and Parisian shows" (Fauque, 1994).

In ancient China, too, silk was worn in high-class robes, while commoners wore hemp-cloth clothing, and in Eastern countries, the best-quality silk was reserved for the royal family, both for the emperor and his wives. Consequently, weavers had a high status.

The motifs and patterns selected to print or wave the silks were heavily influenced by the Orient. As Albuquerque says, "there was a predilection in Europe for the preciousness of materials and the great attraction for the exoticism of the Persian, Indian and Turkish decorative motifs that will create a real fashion phenomenon and the consequent demand for these consumer goods. However, the industry will often combine European tradition with oriental motifs, thus creating very original textile motifs" (2011, p.236).

THE INDUSTRIAL SOCIETY

Textiles begin to become elements of social differentiation when fabrics of silks, wool or cotton produced on a small scale, at very high prices was designated exclusively to the bourgeoisie. These materials, which differed from those produced on a large scale for other social classes, had great quality, different patterns, and exclusive colours (Forty, 2005).

In the West the history of textiles was linked to the industrial revolution, with the transition from artisanal production to industrial production as a result of the transformations that steam machines and mechanical looms provided, allowing a significant increase in the quality and quantity of textile production.

From the spinning wheel invented by John Kay in 1733 that doubled the speed of weaving (Barbosa, 2011) to the mechanical loom of Edmund Cartwright in 1787 and later improved by Jacquard in 1808, which applied to the weaving of both silk and cotton, to the steam engine of the mechanic James Watt, in 1769 that the textile industry became a mark of the industrial revolution, producing fabrics of great quality and very varied destined to different publics.

At the end of the eighteenth-century factories specialized in the production of cotton fabrics began to appear in England and their use was generalized in clothing and all types of clothing of different social classes (Forty, 2005). The British administration of India allowed the importation into England of large quantities of this fibre with consequent development of technical and productive capacity at more affordable prices

At the same time, the development of chemistry has revolutionized the printing of fabrics, making possible the diversified creation of prints. From 1802 onwards the mechanized printing of fabrics with copper rolls for the printing of the multiple colours, which greatly boosted the commercialization of printed textile materials at a more affordable price (Boucher, 1965). In 1856 the English chemist William Perkin (1838-1907) discovered the first synthetic dye, "mauve", mauve, and by the early twentieth century, it was possible to obtain about 700 synthetic colours. Many companies were challenged to produce cotton fabrics with prints of different colours and patterns, intended for a distinct socio-economic audience.

"Many of the materials, techniques, and forms used in ancient times remain in use today, both the essential aspects of production in many regions of the world and the ingredients of textile arts. Such continuity makes textile unique among all artefacts "(Shoeser, 2003).

Whether hand-made or industrial lace or embroidery, both made with silk or cotton thread, were often used in the second half of the 19th century to make various garments or to adorn them, wrists, cuffs or even as intermixtures and frills on the blouses, dresses or skirts or underwear (Boucher,1965). There is a wide variety of combination of various lace-associated fabrics for the making of the same garment (Harris, 1999).

The well-known Nylon yarn, created in 1935, had important repercussions on textile design, such as acrylic, which appeared in 1947 and began to be produced on a large scale beginning in 1950. This material gave rise to the production of resistant fabrics were used in the knitting and lining of boots, gloves and men's suits.

Lycra was another important fabric, which began to be used in 1958 in the United States. Endowed with distinctive features it is particularly used in the confection of lingerie and beachwear.

Synthetic fibres, initially used in the aerospace, military and sporting industries, only entered post-war textile production for garments (Menegucci, et al, 2012). The new textile materials allow associating with textiles new functions that until a few years ago would have been impossible to imagine. The combination of these materials with areas such as electronics, chemistry, engineering, biology, and design, allow the production of new textile materials associated with the development of new fibres and fabrics. Daily wear clothes use new technologies capable of generating ultra-light, breathable, quick-drying and supportive clothing that can provide UV protection and excellent fit to different body shapes (Sinclair, 2015).

This has definitely marked a new technological and social dimension associated with textiles, maximizing its characteristics in terms of comfort, appearance, and performance. The use of these materials has also changed, allowing wider specific uses, giving rise to new requirements and uses. This is the case with sports materials that, since the 70's, increasingly influence those used on a day-to-day basis, associating them with greater levels of freedom and comfort.

This democratization of access to most textiles, taking into account their new features and functionalities, transform them into objects of desire and can improve the quality of life of citizens: "Recent advances have been truly innovative where aesthetic is the important ones". (Braddock & O'Mahony, 2005, p.12). These features can be easily found in projects such as "SpaceBra", which is based on a vital function monitoring system that can detect changes in body shape that can indicate a health (medical) problem, monitor heart rate (sports), and change a way to provide varying levels support (fashion). Another interesting design is the Oricalo shirt, whose fabric used for the sleeves can be programmed to shorten immediately as the ambient temperature gets a few degrees warmer (Fig. 3) (Seymour, 2008). Bioswim is a project that provides for the application of biometric and biomechanical signal monitoring systems in order to help high-performance swimmers improve their performance, but also enable a full monitoring of the signs of impaired patients in their motor and its most efficient recovery (Montagna, 2012)

Nowadays, clothing tends to give a better response to the needs of users, reinforcing all their levels of comfort. As Lipovetsky (1989) points out, "consumption, in essence, is no longer an activity regulated by the search for social recognition, rather it is carried out for the sake of well-being, functionality, and pleasure itself" (p.232).

CONCLUSION

Textile materials, which are the genesis of the production of clothing, have appeared since the earliest civilizations as a social, cultural, economic and technological phenomenon. Interacting in the relations of individuals with society, textiles have an important social representation that expands through cultural and economic sectors and can be affirmed as one of the main elements of meaning and distinction of individuals. Considered as a proper communication system it is possible through it to identify a historical period, a behaviour or the patterns of beauty established in society. The textile materials used by man in his garments represent the interface between his inner world and the exterior context, assuming himself as the most immediate element of communication of man with the society in which he lives and interacts and using the body as a medium of expression and non-verbal communication. These have a great capacity to adapt to the users through the inclusion of concepts related to ergonomics and the different dimensions of comfort, extending the social concept of utility and beauty, providing wellness and comfort and social integration for all the people who make up society contemporary art.

The evolution of the textile materials in the search for new solutions and functionalities, mixing traditions, art, technology, and science, has emerged a textile potential based on the use of new fibres and new structures, applying new finishes and integrating electronic systems. In the era of so-called intelligent fabrics, in which research in the fields of biotechnology, ergonomics, robotics, nanotechnology, and computing, among others, for the application in traditional clothing, or in clothing for new-borns or the elderly, the integration of intelligent interactive structures with added functionality for the user is a great development. The type of consumption and the consumer is changing, and it is essential that the textile industry produces clothing and textiles that satisfy the consumer as well as the ethical and environmental requirements. The close relationship we have with clothes raises our expectations of what they can do for us in relation to the needs of our daily lives.

ABSTRACT

The discipline of design is proposed as a fundamental discipline in the production and dissemination of traditional techniques and materials. It can help to promote socio-cultural integration needs, promoting a privileged mediation due to its own nature, promoting original identity and cultural characteristics.

Textile handicrafts belong to this collective memory of an inheritance that reveals the identity and culture of each population and can be observed as one of the most revealing and spontaneous elements of this identity.

Textile material is an object of preferential communication that has always been used throughout the world as a social statement belonging to different social strata adapting the use of more or less noble materials such as loom textiles, knits, lace, needlepoints, embroidery, jewellery, leather crafts, among others.

The analysis of the tradition of a population through its costumes allows us to adopt an interdisciplinary approach in the areas of design and craftsmanship, taking advantage of the potential of the handicraft for reinvention to meet modern needs.

The methodology used for the development of this paper is based on case studies based on projects that present approaches used by different stakeholders to develop innovative products that promote regional cultural identity.

We found a great source of inspiration in Craft, which challenged designers to develop innovative projects in the field of fashion and textiles, with the goal of promoting national cultural identity, meeting the economic and social sustainability needs of the regions.

Keywords: Fashion, Craft, Textile Design, Tradition, Co-design.

INTRODUCTION

Handicrafts stand as a collective memory of the cultural and social heritage of a country, of a people, but also of ethnic groups. Used as an agglutinating element, handicraft, it is responsible for the traditional collective memory that has its origins in the beginning of the history of the mankind himself and in the objects of craftsmanship of that same time. They are very varied objects of daily use that reveal a high level of utility, but from the beginning they also bring together the construction of an aesthetic oriented to the creation of an imaginary that goes far beyond the utilitarian and functional. Knowing handicrafts is not limited to knowledge of the past, its traditions and customs, but above all, it is a contact with its ancestral cultural values that identify and characterize the enjoyment of these objects, allowing it to be recognized as belonging to a certain group and territory and enabling the design of elements of innovation, creativity, technique and design, inspired by this same identity. The cultural product, says Ahmad, 2006, covers tangible and intangible values and dimensions embodied in a product that has economic utility as a cultural reference for the society or community that produces them. The users' interest in crafts and their products as elements of material culture is related to the ability of these objects to incorporate personal meanings, to communicate emotions, to facilitate interpersonal relations and to achieve a mediation between the individual's perception and self-identity and also between him and the social space (Woodward, 2007; Berger, 2009).

Miller (2009) refers that, for being a cultural product of the intangible heritage and vernacular traditions, crafts are seen to carry meanings for the makers and for the users of the products.

The concept of craft or "ancient techniques" Heidegger (1988) appears for the 1st time in the Italian Renaissance, to distinguish the manual work created and produced by an artisan who uses natural raw materials, those who design artefacts that would be produced by others. Most of the studies on this theme, according to Ko (2013), deal with the study of handicrafts with emphasis on their folk values, emphasizing traditional motifs, specific structures or still worrying about the implications of the globalization of the values of a traditional culture. According to the same author, there are still few studies that attempt to study and understand the perceptions of consumers that allow us to deepen and work the dimensions of the market and the strategic positioning of this type of products.

CRAFTS AND TEXTILES

Traditional textiles, together with other objects that make up the artisanal panorama of any country or region, have always been one of the main elements of communication, either for the extensive daily use of this material or for its versatility in being able to present itself as an element of dissemination (printed, embroidered, structured, felted, etc.). If it is true that any object has the capacity to appropriate symbolic values and to communicate them when displayed, textiles, given the privileged relationship they have with the body of the users, could mean to their users much more than any other object. Textiles in general, be they traditional or not, are elements of interface between the individual and the world and can function as a filter that can regulate the amount of information to be transmitted and to be observed, becoming a true element of bidirectional communication.

The communicational power of textiles has been used since the beginning of the use of textiles by mankind, always been privileged elements of social and class distinction and used as a differentiating and aggregating element to social groups or to an identity specific.

The craftsman produces objects that fit a particular public, works the material alone and transforms it into an object for the user, adapting the final object to the different possibilities that form, function, manuality and technique can allow, producing an object imbued with meanings and memory. In this sense, the researcher and author Martina Margetts, through her essay "Action not Words" (Margetts, 2011), refers, considering the role of know-how in the creative process, that it adapts and gives rise to new ways of thinking, seen to aggregate in a single moment the materials, the techniques and the ideas, implied in the production of the object.

Design is a discipline that by nature brings together different areas of action and knowledge in order to gather consensus in the creation of design objects. Being the design a discipline that aggregates different scientific areas, it enjoys this to be able to develop the object of study in its different levels, material and immaterial.

The tools available to the design to create objects adapted to its user are varied, and some of them are already widely used by designers in their relationship with the end user and entail some facilities in terms of methodology. The collaborative design tool (Co-Design) allows the shared realization of design objects, both at the level of idea production and at the level of process development, between the designer and the end user or, as is often the case in the case of craftsmanship, between the designer and craftsman. "Co-Design is a general term that involves Participatory Design, Metadesign, Social Design and other design approaches that encourage participation. [...] the term Co-Design is used to designate - make Design with [others]" refers Faud-Luke. (2009, 147-148). If the designer has the ability to develop a product that respects user's needs and is prepared to be industrially produced, the artisan masters the technique and the different possibilities that the material can offer for the aesthetic and communicational expression of the object itself. This know-how that the craftsman possesses due to years of development of the technique and the inclusion of cultural elements in the objects he produces daily is an added value that enriches the new design products and a cultural vehicle that can and should be used in the design and textile design. We seek to approach user-centred design, with criteria for success being consumer satisfaction (Bonsiepe, 1992) and socio-cultural innovation (Bonsiepe, 1999) to cover not only concerns about social context and sustainability, but also the participatory process in each intervention.

Currently, the market is looking for products that are more exclusive and different, while at the same time privileging an aesthetic and formal personalization that is ever increasing. In this sense, the use of these participatory design tools among artisans and designers presents a great value and an important strategy in the redefinition of the cultural and aesthetic identifiers in which the users can recognize themselves.

Talking about the know-how and experience of individuals in the production of handicraft textile objects, Jill Riley (2008) argues that the production of textiles increases the identities of individuals, increasing the sense of personal belonging and belonging to the collectivity. Other authors, such as Pöllänen (2011), defend this argument with regard to the manufacture of textiles, where experiments are used as sources of inspiration for the production of the textile object itself.

Recognition by users of a product that is perceived as being an authentic product is a key issue in the craft and production of design articles that are inspired by them.

It is not only a question of working with objects from the past, with specific traditions or habits, it is mainly about knowing the values of our culture and its techniques to create a space of creativity, innovation, design and tradition that associates the technical knowledge and the construction of a national identity.

The concept of Co-design appears in this context as a strategy that suggests the inclusion of the user as an active participant from the beginning of the Project, collaborating with all the professional team involved in the process. It is, in fact, a co-creation and production partnership between handcrafters and designers, whose main objective is innovation and economic and social sustainability at a local and regional level.

This article intends to understand how the regional tradition contributed to the establishment of textile products in Portugal through partnerships based on the work of co-creation, transparency and complicity of all interested parties - designers, handcrafters, users, promoters, among others.

The redesign methodology is also a collaborative tool frequently used for the production of artisanal-inspired textile objects but with the application of a more modern know-how, more focused on the needs of the users and often with the aid of more modern tools and ergonomically better adapted to the way of working of the modern craftsmen. Redesign is concerned with the reproduction of objects taking into account the adaptation of some variables that may meet the needs of more specific users or better respond to requests of production methods. In textile and in relation to traditional textile objects some blankets can be made with different weights (square meter weight) taking into account different uses of modern life; textile objects can meet an updated aesthetics regarding the same traditional object; the finishes will be able to meet the sensory needs to which the new consumers are already accustomed, etc.

As pointed out in earlier studies (Aakko 2015, apud Aakko 2014, Bettiol & Micelli 2013, Sandino 2004), "central to the artisanal approach [to fashion and textiles] is the integrated role of designer, which makes possible a high level of craftsmanship, skill, and quality".

In traditional terms, handicrafts are considered as an area where a high level of technical execution and personal knowledge should be applied, enabling the creator to manage the technology involved, the design and the materials used to produce "a well-made object" (Fariello, 2011, Dormer 1997, Adamson, 2007).

All products created for a traditional use, using traditional techniques and that adapts to traditional forms, says Cornet (1975), can be considered an authentic product. According to Littrell (1993), the main identifying characteristics of a

product are five and are based on qualitative parameters: uniqueness and originality, artisanal work, cultural and historical integrity, aesthetics and to possess functions of use.

Craft objects are, of course, tremendously important as objects designed to fulfil different expressive, functional, material, aesthetic, experiential, multisensory, collaborative, and narrative meanings. (Kouhia, 2016)

During the very defunct age of Fordism - dominated by a sense of powerlessness in the shadow of mechanization - to enjoy craft was to resist the homogeneity of face-less industry, say Rafael Cardoso (2010) in his "The persistence of craft in the age of mass production".

Peter Dormer (2010) refers to the apparent ease with which textile craftspeople and de-signers use remarkable new materials. It is a tradition within the craft that contradictory or complementary materials be woven together. Haute couture has a freedom of action that can be considered unique but that is envied by many: the total design provided by an army of craftsmen and technicians specialized in the most different techniques of textile art and garment construction, which allow the realization of any type of stylistic vision for fashion. (Montagna & al., 2017)

CASE STUDIES

As indicated by Mattoso (1993), in his *Historia de Portugal*, the country had its origin in an administrative structure, not an ethnicity, bringing together regions with their own cultural characteristics and, therefore, without an identity common to all of them. In this sense, and taking into account these regional distinctions, the specific costumes and textiles of each region are very important for the communication between the different regions of a specific regional identity, but also in the relation with the other regions in the identification and construction of an identity. The costumes and textiles of each region of Portugal recall a specific identity adapted to the social and cultural needs of its people and can be proposed as an essential starting point in the question of the factual identity that is presented as an essential factor for cultural recognition and identity (Jorge & Silva, 1992, 12).

Nowadays, activities related to handicrafts and crafts are losing importance in general terms. With the needs of the increasingly global international market of the last decades and the development of products in a perspective of controlled industrial production in all its elements and the increasingly urgent need for a just-in-time product, set aside, for a long time, craft production of objects. The last years have been marked by a revival of artisanal production and its know-how especially for markets in luxury products and those which, in order to distinguish themselves from those produced on a large scale, not only add greater elements of identity and culture, but are a demonstration of a know-how and techniques that the mass production industry has forgotten or, for economic reasons, never wanted to assume as their own.

The discipline of Design, always attentive to the needs of the market and its users in constant change, was charged very early to accompany the integration of the techniques and the artisanal know-how with those of the industry, for the production of objects that incorporate a socio-cultural dimension where the user recognizes him selves and promotes sustainability between society, culture and industry that was not previously possible in Portugal.

Nowadays there are several cases of collaboration between designers and craftsmen and craftsmen who incorporate in the objects of their production elements of design, at the service of the user, and where traditional textiles are used as a source of inspiration for the production of objects that effectively respond to the cultural identification needs of the users. From the use of specific and traditional materials to the use of different techniques of weaving and traditional embroidery, there are examples of production of traditional pieces in renewed materials and developed with dyes and finishes of the typical national costume.

Among the different case studies presented here we can mention the Portuguese textile artist Guida Fonseca who makes a renewed use of weaving techniques and traditional national materials such as flax and wool and develops their products with the application of traditional natural dyeing, in their technical and colour range, dyeing these, which by their organicity can change their appearance over time, creating new possibilities.

The renovation of the traditional textile patterns executed by the weaver Fernando Rei is a modern response to the requests for the renewal of a traditional image by those who, through textile materials, recognize themselves in a century-old culture and find in these materials a renewed expression of design. They are in many cases traditional objects that are developed in a modern key and whose use is adapted to the new times and spaces of the XXI century or that serve as a vehicle of cultural transmission in social and ethnographic presentations.

The Portuguese "Save the Portuguese Wool" project is a project that is concerned with the use of wool produced in national territory and which, because it is produced on a small scale, loses its commercial value and, in most cases, is disposed of in landfills so as to be quickly destroyed. Along with trying to recover and not allow the destruction of this type of raw material, the project is concerned with safeguarding the biodiversity of this type of material through the study and safeguard of the different qualities of the Portuguese national territory. The production of small quantities of wool yarn from different micro-herds was the first output of this applied research project linked to textile fibres of animal origin and that can be acquired for the development of pieces produced by hand.

In a process of revaluation of traditional Portuguese textile materials and with the idea of producing contemporary clothing that can encompass different traditional cultural values, the Capuchinhas cooperative seasonally develops a set of traditional and timeless flavoured pieces that they trade through fairs and sales in specific stores. They are objects created in collaboration with designers and who want to maintain a balance between past and future, using traditional

textile substrates such as “Burel” which is a woollen fabric that after being beaten and felted, its protect from the cold and become water repellent. This material, which does not slip when it is cut, offers numerous creation possibilities for clothing, but also for architecture and interior decoration.

The Bilros’ Lace from Peniche is another example of Portuguese craftsmanship that has become a model for redesign and collaborative design. Present in the national territory since about 400 years ago through commercial relations with the Flemish, this type of weaving, which produces lace of very high quality, is nowadays adapted to the different aesthetic needs so that it can still have a commercial value that allows keep alive its cultural worth and its technique that gradually was disappearing. Different designers developed diverse objects with alternative materials so that this lace not only continued to be used as “napperon” but also as income for dresses and household linen, or used in jewellery or other decorative objects. “The focus on product innovation and attracting new niche markets is an important part of all the strategy around sustainability of Peniche bobbin-lace” (Silva, 1992).

As Ko, Chun & Lee (2011) refer to the possibility of communication of the cultural product as the craft, a product that is considered to be traditionally genuine, can produce a large number of variations that may have a high value in economic terms. In this sense, the cultural exposition that a product of artisanal inspiration design can be a fundamental element of development and sustainability of the very companies that produce these objects.

CONCLUSIONS

In an age of globalization and the predominance of some cultures, the need for recognition of cultural values where individuals can recognize themselves is growing stronger. In this millennial culture, community recognition of its origin and roots strengthens the survival of many communities and social groups. If, on the one hand, craftsmanship needs to learn to create more balance with the needs of the market and its end users, in order to produce products that are more suited to the needs of those who want to acquire them, on the other hand, industry, through designers and actors in the production process, needs to adapt some production techniques so that it has the capacity to produce differentiated products and less standardized, allowing a greater personalization of the final product.

The alliance between craft and industry is still embryonic, but it must go a long way so that the reciprocal advantages can be many and varied, always taking into account the best user satisfaction in their different levels of need.

The techniques and work methodologies applied to textile materials are constantly being updated and the know-how of craftsmen and designers are fundamental elements for a transformation and adaptation to the user of a product that entails an age-old symbology of culture and identity as few of other materials can do. Nowadays, crafts are particularly important and relevant in different areas and associated with the production of high quality products that are increasingly exclusive and unique.

As can be seen from the examples described in this article, the interventions introduced in the production of textiles can be multiple, from the raw material, to the use of specific finishes, through the creation of structures that contribute to the sustainability of many craft enterprises, through interventions based on the concept of co-design and redesign.

In sum, these renewed collaborative interpretations are presented as a way to promote the cultural approximation of individuals and the recognition of a sense of identity, allowing users to be satisfied in their tangible and intangible dimensions.

1741 MODEL CHANGE IN THE HUNGARIAN HIGHER EDUCATION – ISRAELI EXAMPLE

Ákos Országh, Dávid Nagy

ABSTRACT

Higher education, as one of the most important resources of a country, determinates its competitiveness, capital-retaining ability and the success of R&D. In spite of some changes in the system and operation of the Hungarian higher education in the last 25 years, the basic elements – such as legal environment, organizational structure, budgeting principles and mechanisms – are permanent. For the renewing of the Hungarian higher education and for an international competitiveness, the reconsideration of the whole model of operation, and – if it is necessary – some fundamental changes are necessary. For the reconsideration of the model, the study of international best practices can serve as input. Firstly, we examined the higher education of Israel. When studying the financing and the operational model, we put special emphasis on the proprietorial model and the system and predictability of the allocation of state fundings. The financing cycles of five years, the clear aims of the government and power of the owners enable the Israeli higher education to be effective and marketable.

Key words: Israel, Hungary, higher education, financing, model change

THE COMPARISON OF ISRAEL AND HUNGARY

	Hungary	Israel
Surface	93 011 km ²	20 770 km ²
Population	9 855 571	8 463 400
Number of HEIs	66	63
<i>of which university</i> ⁵⁶⁶	36	9
<i>of which state funded</i> ⁵⁶⁷	29	50
Number of students in higher education		310.000
Budget for higher education ⁵⁶⁸	170 Mrd Ft	775 Mrd Ft
Number of Nobel-prize winners	10	12
GDP per capita	11 800 USD	28 365 USD
R&D expenditure of the state as a percentage of GDP	0,48%	4,00%
number of R&D stuff of research and development organizations as a percentage of all employees	0,88%	16,50%

THE ISRAELI HIGHER EDUCATIONAL SYSTEM

Sector management

Education and research – most significantly higher education and the researcher developer work in HEIs – have an important role in the everyday life of Israel. There are 4000 high-tech and 250 R&D and innovation enterprises in the country. According to the conclusions of the World Economic Forum in Davos, there is a strong rapport between research collaborations, the quality of research, the proportion of innovations and the number of R&D and innovation collaborations.

The minister responsible for education is at the same time leader of the Council of Higher Education – CHE founded in 1958. The chairing of this body is mostly a representative task that comes with the ministerial assignment.

The operational management of CHE is carried out by a Vice Chairman and a Board of 25 members. The body has 100 employee and several sub commissions, the most important one among them is the Planning and Budgeting Committee (PBC, founded in 1977).

The task of this latter (PBC) is to plan the (professional) system of higher education, to prepare decisions on the extent of the usable resources and the manner of its usage. The seven-member committee consists of five academic and two non-academic members. During the operation of tasks, they collect data by themselves for each planning tasks, especially from the Statistical Office, higher educational institutions and other (unbiased) experts and they carry out researches by themselves as well.

Israeli higher education in a nutshell

The oldest Israeli university can pride itself on having a longer history than the country. The participation in higher education was the privilege of only a few people in Israel as well up until the 1990's, when a sudden boost happened in the number of institutions as well as in that of students of higher education. As long as in 1990, 8 state universities, 1 state college, 5 private colleges and 7 state teachers' training colleges operated in the country, this number has increased to 63 until today: 9 state universities, 20 state colleges, 13 private colleges and 21 teachers' training colleges. In parallel, the number of students has increased from 80.000 to 310.000.

⁵⁶⁶ Together with the universities of applied sciences (29 universities, 7 universities of applied sciences)

⁵⁶⁷ All together (out of 66 and 63 institutions)

⁵⁶⁸ Source: Annual Budget of Hungary for 2016 (besides the allocations of beneficiaries);

At the moment, there are two Israeli universities ranked in the top 100 universities: the Technion – Israel Institute of Technology in Haifa and the Hebrew University of Jerusalem. What is more, Israel is the first state in citations in the field of information technology, third in the field of technology and fifth in the field of chemistry and biomechanics.

Although the institutions operate as civilian organizations/budgetary authorities, the framework of their operation and the majority of their budget are given by the state. Their operation is of a non-profit approach, they can and have to use up the profit in the next year(s). The long-distance predictability is secured by the six-year plans compiled by the PBC and approved by the government. These plans determine in a transparent way – beside the amount of money dedicated to higher education – the exact resources for each fields.

The budget planned by the PBC for the past six-year cycle increased the amount of sources by 43% (roughly at an even degree) for the institutions, and this increase will be of the same degree in the next six-year cycle as well. Infrastructural developments (BigData), international mobility and the improvement of the quality of higher education are constant objectives. Incubators and the improvement of digital learning (MOOCs in Arabic and Hebrew languages) are also focal areas.

THE CHE

The duty of the Council of Higher Education – founded in 1958 – is to manage all areas connected to higher education. At the moment, the committee is of about 100 members and it operates on 9 big fields with several commissions. The main decision-making body is the Composition of the Council of 25 members. It is chaired by the Minister of Education and the members are the chairman of PBC and two student representatives. At least two third of all members have to be persons with experience in the field of higher education, the other members are private actors. All members are appointed by the head of state for a period of five years.

THE PBC ⁵⁶⁹

It is a sub-commission of the Council of Higher Education created by the government. It was set up on 6 June 1977 by the government on the proposition of the Ministry of Education. The PBC consists of 7 members, out of which there are 5 academic members (4 coming from state institutions and 1 from a private institution) and 2 members from market actors.

The duties of PBC:

- a) It is a mediator between the HEIs and the government or governmental institutions about all matters concerning higher education. The government does not take comments, proposals or demands directly from the HEIs or other actors, and only allocates resources on the recommendation of the PBC.
- b) It makes proposals on the main and developmental budgets of higher education, taking the social and national necessities of the country into account, while respecting academic freedom and promoting the development of researches and education.
- c) It has the exclusive right to allocate resources among the HEIs.
- d) It makes proposals for the Council of Higher Education and the government concerning the development of higher education (programs) and their financing.
- e) It motivates the HEIs for a more efficient work and mediates between them in order to avoid parallelisms and to take the needs of the market into consideration.
- f) It supervises the usage of resources continuously in order to avoid outage or misuse.
- g) It expresses its opinion to the Council of Higher Education when a new institution or a new unit of an existing institution is established and the action has financial consequences. In these cases, it examines if the establishment of a new institution or that of a unit is necessary and what kind of financial consequences it may have.

FINANCING

The financing of the institutions is diversified. Although there were some differences between the institutions we managed to visit, but on the whole, they showed a similar pattern.

Primarily, the state funds the 9 universities and the state colleges. The resource distributed by the PBC gives 50-70% of the total budget of these institutions. The universities got 63% of the total budget directly (775 milliard Ft in 2016), the colleges got 17% and the remaining 11% was used for research funds. If you look at it from a different perspective, 51% of the budget was spent directly on education, 32 % on research and 17% on other purposes.

It is important to note that for the funding of research, the government adds one shekel to each shekel coming from the R&D actors of the market.

Although, the fair and objective allocation is an objective, there are 3 main aspects of financing (the planning of financing):

- a) outcome based financing
- b) transparency
- c) competition over excellence

⁵⁶⁹ http://lang.che.org.il/en/?page_id=3945

The government finances the institutions through three channels:

- a) PBC's teaching model
- b) PBC's research model
- c) other fundings (these need to be applied)

PBC's teaching model

The teaching component of the block grant is calculated as the sum of the number of students in each field of study multiplied by a tariff (per field of study) and by an efficiency factor parameter (calculated by the proportion of graduates to students). Data on students and graduates comes from the Central Bureau of Statistics (CBS).

PBC's research model

Competitive Grants 34%, Scientific public grants 34%, Other grants 15%, PhD 15%, Masters 2%

The inconvenience of the PBC's research model is that the size of the cake is of a unit, in other words, *ceteris paribus*: if all the institutions raise the number of their students or the excellence of their researchers equally, they will get the same amount of money, but will have more expenses.

Knowledge transfer companies

All the HEIs have knowledge transfer companies. As long as the bigger universities have their own ones (since the end of the 1950s), the smaller ones can market the results of their researches with the help of a common knowledge transfer company.

INSTITUTIONAL EXPERIENCES

Hebrew University of Jerusalem

The application of the six-year plan ensures the stability of the university. They are the main beneficiary of the state subvention (24%). The number of academics is 941. The number of students is 22,000.

Motivating employees to obtain funding for research: the professors of the university have the opportunity to gain complements to their basic salary from research grants (about 20-25% of the total research funding). The salary of the teachers cannot exceed 190%, given that they teach exclusively on the university, obtain funding for research, and get paid after Master and PhD students. Working at their private business is strictly prohibited; they are only allowed to work at the university's own technology transfer company.

The students are required to pay a flat school fee (2,500 EUR/year for BSc students, 3,500 EUR/year for MSc students) that is determined centrally by the PCB. The differences in the budget are compensated by a teaching model which uses different multipliers for the different fields of studies.

The university is represented on the market by their own TT company. The purpose is to motivate the teachers to engage in international collaboration. The entire budget of the university is 880 million U.S. dollars (64% comes from PBC, 18% from research grants, and 10% from subventions). The payroll expenses consist 37% of the total amount. Another important and considerable part of the budget (33,9%) covers the pensions. In 2000, it was 19,8% of the total amount.

Tel Aviv University

The university was founded in 1956. They have 1040 university programs in 28 fields of study on nine different faculties. There are currently 29,200 students at the university of which 1,200 are from abroad. 55% of the students are female. With 173,000 members, they have a notable alumni program.

There are 1,040 senior academics, 3,000 junior academics, and 1,600 administrative staff members at the university. The challenging task is to pay the pension of the 1,500 retired academics (of which 500 are still active).

The entire budget of the institution is around 750 million euros. 60% of the total amount is used to cover operational expenses, 125 million euros are spent on research, while 60 million euros cover investments and another 60 million euros are paid as scholarship. The sources of the income of the university is the following: 60% comes from PBC models, 18% from school fees, 10% from the income of projects and services, and 12% from the yield on investments, and from direct donations.

Their finances are calculated based on the academic year (1 October to 30 September). They present an annual report to the PBC and a quarterly report to the leadership.

Organization

The institution is directed by the President (5+5 years), who is the boss of the Rector (academic, 4+4 years). The university is led by the Board of Governors of 170 members, who elect the President. Their task is decision making. The operational tasks are carried out by the 13-membered Executive Council. The leaders are eligible for a special bonus.

Ben Gurion University

Ber Sheva is the capital of cyber technology.

Their continuous investments are primarily paid by subventions. The north campus is currently under construction; it costs 200 million U.S. dollars. The price per m² there is 4,000 U.S. dollars. 50% of the development costs are covered by

donations, 1% comes from the state. The number of students is 17,414. The number of academics is 820. As the budget for higher education decreased by 26% between 2003 and 2010, a number of PhD students were unable to enter the universities, and migrated abroad, mainly to the US. The tenth Israeli university is there.

They recently received a 400-million-U.S. dollar donation from the Marcus Family.

The total budget is 464.9 million U.S. dollars.

Income

a, PBC	70%
b, School fees	19%
c, Donations	1%
d, Yield on investments	4%
e, Other incomes	6%

Expenses

a, Wages	74%
b, Scholarships, student allowances	6%
c, Educational expenses	4%
d, Educational and research units	3%
e, IT expenses	1%
f, Library expenses	2%
g, Administration and Finance	3%
h, Utilities and maintenance	7%

Division of PBC resources:

a, Teaching model	54%
b, Research model	39%
c, Other research fundings	7%

They get 14,46% of the research budget, which is not too much, and can hardly increase.

The questions of adaptation in Hungary:

1. Approach - the status of the institutions: is it possible to quit public finances and if so, how and in which area? Will the State then become only a procurer or will it maintain its controlling-coordinating function? Another important question is the future of the assets of the institutions (which is funded by the state, as of today), as well as the future status of the students currently being part of the system, and the continuous employment of the teachers, researchers and other colleagues.
2. Planning: with a long term and predictable financing model it is possible to plan for the HEIs. A question of high priority is, for example: when employing a well-known professor, what kind of resources the university can plan with to be sustainable? The launch of a new field of study, the development of the infrastructure or the human resources, the expansion of the services, or the injection in their own technology transfer companies, to state some specific examples also represent a similar situation.
3. Creating a legislative environment: thanks to the numerous international agreements and the European Higher Education Area, the described operational and administrative/managing questions, after the required preparations, can quickly be integrated in the Hungarian law.

1777 WHY WEALTH INEQUALITY MATTERS? EVIDENCE FROM INDIA

ABSTRACT

According to the World Wealth report 2017, India is now the sixth wealthiest nation in the world. India’s wealth has grown tremendously in the past few years, but was this growth distributed fairly amongst the population? This paper tries to look at this aspect of wealth distribution at household level and tries to compute the social welfare loss due to wealth inequality present. The paper uses AIDIS data (All India debt and Investment survey data) for 48th (1991), 59th (2002), and 70th (2012) round to look at the wealth growth and distribution at household level. In this paper, we compute the total asset value and total wealth per household by sector (rural versus urban) and for different social, religious groups and occupational groups. We found that total assets value per household in real terms in rural area was less than that of urban areas and this gap widened over years and by 70th round it was found that total asset value per household level at urban area was more than double that of rural areas. The growth rate of total asset per household for urban areas increased at almost double rate than that of rural areas. Same trends are seen for the wealth values at household level. We found that the share of land in total asset was largest for rural areas for all the rounds and share of building in total asset was largest for urban are for 59th and 70th round while share of land was largest for 48th round for urban areas. TheGini coefficient at national level has remained constant for 48th and 59th round while has increased drastically for 70th round and main contributor to this wealth inequality for all three rounds was the value of land owned by different households. Further, the study examinesspatial variation in wealth distribution and concentration among social, religious and occupational groups.Finally, the paper quantifies the welfare loss that that the country India has experienced over the last two decades as a consequence of the segregation of the various demographic groups that encompass it.

1778 EFFECT OF QUALITY COMPOSITION OF HUMAN CAPITAL ON ECONOMIC GROWTH. A STUDY OF THE INDIAN STATES

ABSTRACT

There are contrary views in the literature regarding the relationship between education and economic growth. Some argue, it the accumulation of human capital which is important, others argue it the stock and some say it the stock of human capital employed in the R

1779 DEVELOPMENT AND GROWTH DRIVERS IN LATIN AMERICAN COUNTRIES- VIOLENCE IMPACTS EMPLOYMENT AND HDI – POSSIBLE WAY OUT THROUGH AGRICULTURAL TRANSFORMATION

ABSTRACT

This paper attempts to study development and growth drivers in Latin American countries. Lack of employment planning was taken as base leading to revelation of lawlessness in various forms in different countries. A counterfactual approach reveals that mitigating violence leads to increase in life expectancy and boost Human Development Index. Correlation figures showed positive between 2000-2015 between high growth phase and increase in HDI. Various data sources were employed to study diverse parameters like crime, HDI parameters, employment, agriculture, etc. The UN Office on Drugs and Crime's International Homicide Statistics database, about intentional homicides for the years 1995-2015 is used along with data from reports of UN, WHO and Penn world tables. Another way of calculating the costs of violence is to estimate the years of life lost due to homicide; that is to say, the impact of lethal violence on life expectancy. Measurement of the Human Development Index in fifteen Latin American countries showed that in 2009 the region lost 331 million years of life due the homicides. The relationship between homicides, employment and HDI is explored. A linear regression model was used for the analysis with number of Employees in a country as the independent variable and the dependent variable was used as the HDI value of the respective country. The data used was for the years 1991-2015 and the regression analysis was done for each of the four countries (Argentina, Brazil, Mexico and Colombia) separately. In most of the countries, employment comes from largely from three sectors of the economy, agriculture, industry and the services sector. Hence all employment was divided into these three sectors and their contribution to the total employment in a year on year format was analyzed. While a Cobb-Douglas production function is used for capturing the effect of two or more variables on the total production quantity, the effect of total area under cultivation on the total agricultural produce through an exponential function is done.

SS24.2. Regional Issues in Economic growth and Development

1780 ASSESSMENT OF GROWTH FACTORS IN AFRICAN GROWTH STORY

ABSTRACT

This paper selects twenty countries of Africa based on income heterogeneity and representative of the diversity of geographical regions. An Input Output approach in a multi regional framework is used to test the show the progress of economic variables over two time periods 2005 to 2015 and sufficient to reveal sectoral trends for possible interpretations. A robust approach demand prediction of overall employment parameters across regions and across sectors differentiated by geographically homogenized regions. Subsequently, a decentralized approach to each of the country’s sectoral data set driven sectoral growth rate would enable identification of ‘meso’ for forecasting development outcomes. The identifiable meso factors are taken as rules translated into policies and practices, education-skill-IT variables and the tangible historical factors like roads, ports airways along with its historically density factors and the projected features based on economic data. The third stage of the paper relates to commercial banks lending for products and services, C/D ratio and aid amount disbursed across country-sector-product. This would reveal the relevance of aid induced growth or endogeneity of the growth processes necessary for long- termish development.. Spillover effects, terms of trade effects across neighboring countries and ‘distant’ countries are factors to show trade effects of growth in Africa, neighborhood policies for trade or aid conditionality. Whether meso leads to interconnected-ness for trade in Africa is a research outcome given the distribution of resources leading to change in regional income and employment.

1781 DEVELOPMENT AND REGIONAL INEQUALITY: A STUDY OF GOA

ABSTRACT

The income inequality is on an increase across and within the countries over the past two decades. This is true for both in developed and developing countries. It has emerged as a great challenge for the economic policy makers. Since 1980s most developing countries are getting integrated into the World Trading System and the inequality is also rising during the same period giving the feeling that trade leads to inequality. Trade is considered as an engine of growth. However, the capacity of international trade to enhance economic growth depends on many factors. International trade, in some countries, may result in job loss than job creation. It is also possible that skilled workers benefit more from international trade than unskilled workers. All these may contribute to inequality in some regions or some countries. Besides, the existing studies show that trade generally promotes growth and high inequality retards growth. The link between trade, growth and inequality is not very straight forward and there are enough empirical evidence to establish this link. There are reasons to believe that the last two decades witnessed trade integration more through Regional Trade Agreements (RTAs) and Bilateral Trade Agreements than through multilateral trading system. This gives another dimension to the trade, growth and inequality. The main objective of the study is to establish the link between trade, growth and inequality among different countries within the selected RTAs. The paper will try to establish the above link among countries belonging to different RTAs. Study would also like to look into few selected Bilateral Agreements to understand how trade affects growth and inequality.

1782 ECONOMIC GROWTH ANALYSIS OF FOUR WEST AFRICAN COUNTRIES NAMELY GHANA, NIGERIA, NIGER AND TOGO

Vedant Bhardwaj, David Botchway, Sartaj Singh Sandhu, Rijul Arora, Debasis Patnaik

ABSTRACT

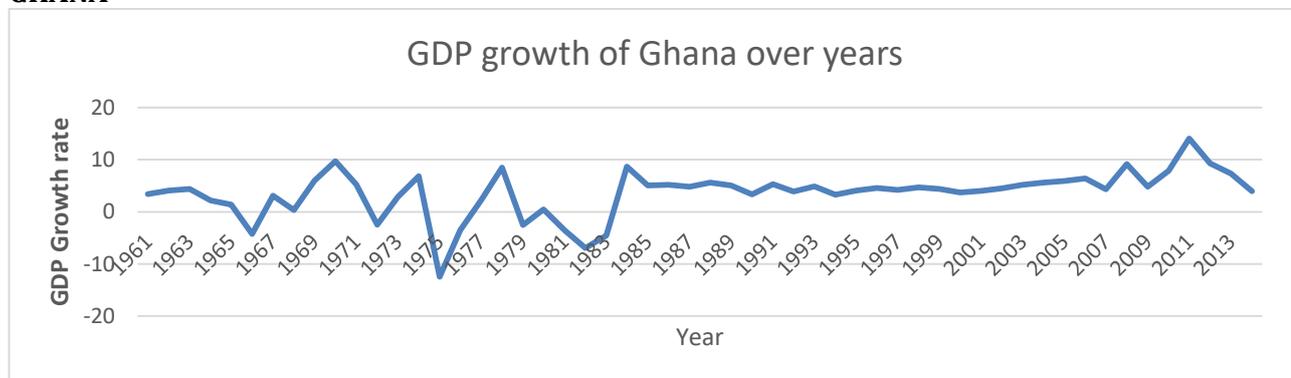

In this paper, we have analyzed the general growth trend of various parameters for major African countries namely Ghana, Niger, Nigeria and Togo. The parameters that we have analyzed include gross capital formation, GDP, FDI (here Foreign Direct Investment is the direct investment equity flow in the reporting economy. It is the sum of equity capital, reinvestment of earnings and other capital), imports, exports, unemployment and inflation. Also we have seen the implications of FDI, imports and exports on the GDP of the host country. The results show that, along with model being significant, there is a significant effect of FDI on GDP for Ghana and Nigeria. Imports on the other hand had a significant impact on the GDP of Ghana, Niger and Togo.

Keyword: GDP, FDI, Import, Export, Unemployment, Inflation, Gross Capital Formation

INTRODUCTION

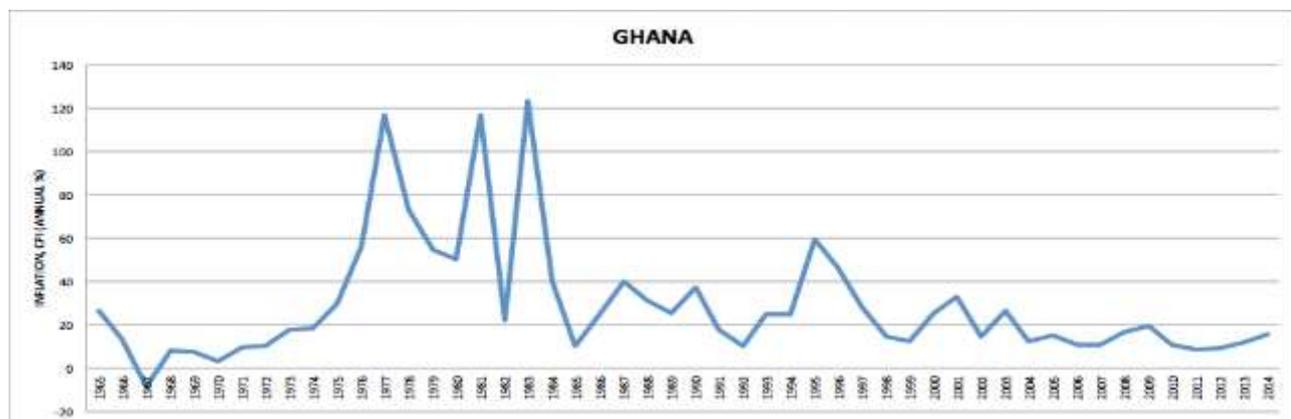

This paper looks into growth determinants of 4 African countries differentiated by size. While Niger is land locked, the rest three are coastal.

GHANA

Source : data.worldbank.org

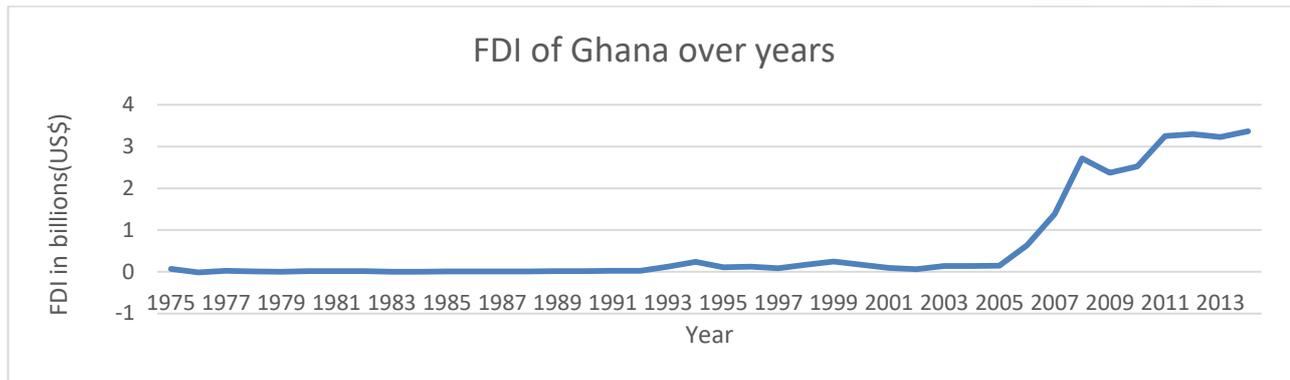

Graph 1

Source : data.worldbank.org

Graph 2

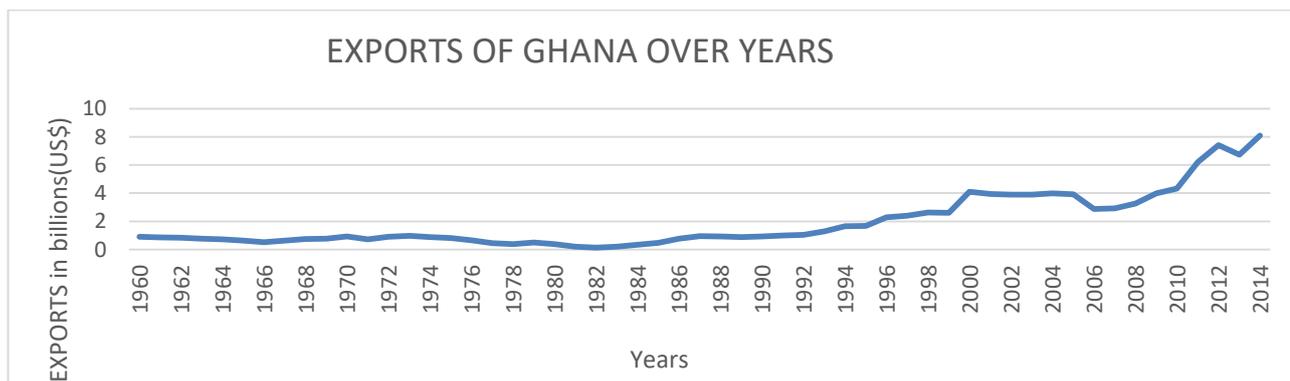

Its been more than 50 years since Ghana has attained independence, yet the Ghanaian economy is still at the same level as it was in the earlier period (Aryeetey, Harrigan and Nissanke, 2000). Ghana had a high growth rate in the early 1960s, but it soon began to experience a slowdown in its GDP in the mid 1960's. It continued to deteriorate throughout the 1970s. The entire decade was characterized by high inflation, declined exports, increase in illegal activities and political instability. The economic recovery program (ERP) that the government of Ghana launched, were a series of reform initiatives from 1983 to 1986, helped the GDP of Ghana to grow to 8 percent in 1984 and helped to keep the GDP growth at 5.3 an average from the year 1983 to 1986. Another program, named Structural Adjustment Program (SAP) was introduced from 1986 to 1990 which enabled Ghana to continue its high growth path with an average growth of 5.4%. During the December 2007 recession, Ghana saw a decline of growth from 7.2% in 2008 to 4.1% in 2009. In 2011 GDP rebasement was done which made Ghana the fastest growing economy in the world at that time.

Source : data.worldbank.org

Graph 3

From 1957 to 1966 Ghana’s decision makers chose a socialist path for its economy, the then president Nkrumah allowed FDI but with conditions as he inveighed against neo-colonialism, this policy attracted very less FDI. The next government National liberty council (1966-69) and Busia government(1969-1972) claimed to pursue more open economics but didn’t decrease the participation of government in economics. The next three governments The National Redemption Council, Supreme Military Council and Limann government expanded the government interference in economy in response to political instability. In 1982 Jerry Rawling came to power and they introduced many liberal policies and Ghana opened up its economy to world economy but government attitude remained somewhat hostile towards private enterprises. The next President John Agyekum Kufuor in his inaugural speech stated that Ghana is open for business and he welcomed foreign investors. John Agyekum Kufuor and following presidents followed the same policy and formed Bilateral relations with many countries and allowed FDI in different sectors which encouraged investors and increased FDI.

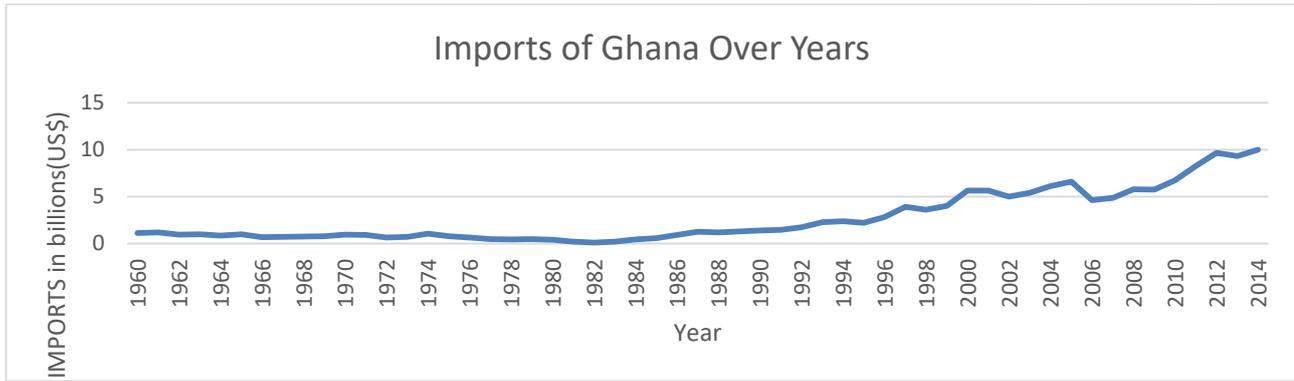

Source : data.worldbank.org

Graph 4

The major exports of Ghana include pearls, precious stones, metals, coins, cocoa and cocoa preparations, wood, articles of wood, wood charcoal, edible fruits, peels of citrus fruit, melons, machinery, boilers and nuclear reactors.

Ghana’s agricultural exports have declined by about 4.6 percent during the 1960-to 1987 period. Various reasons have been adduced for the decline of real agricultural exports, either in the aggregate or with reference to specific export commodities(see Okyere(1989), Killick(1978), for instance). The domestic factors behind this were the inadequate infrastructure and supply of inputs, smuggling of cocoa beans to border countries like Togo, labour shortages, low and declining export commodity prices and competition from other crops.(see Okyere(1989), Robertson(1997), Ghana Cocoa Board(1974,1987), Nyanteng(1997,1980), Dapaah(1982), Kotey, Okali and Rourke(1974), Manu(1974), Adomako-Sarfoh(1974), Bateman(1973,1974), La-Anyane(1972), Stern(1965) and Atsu(1965)). The external factors originate in the structure of international commodity market like eternal terms of trade, have tended to limit Ghana’s exports. Such challenges were overcome by Ghana, further opening of the economy (liberalization in 1983), allowing FDI in different sectors like mining, oil and gas exploration and increase in the commodity prices, resulted in the increase in exports from 1987 onwards.

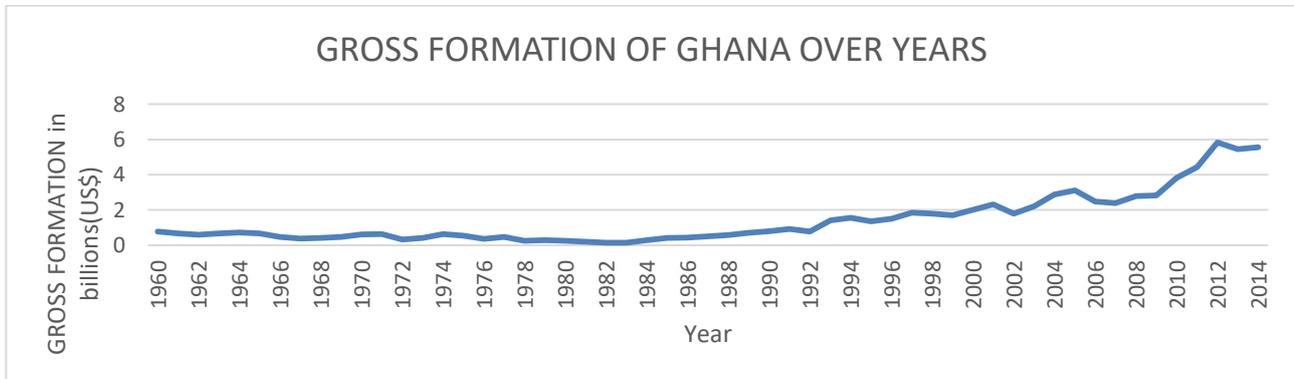

Source : data.worldbank.org

Graph 5

The major imports of Ghana are vehicles other than railways,boilers, machinery, nuclear reactors, electrical and electronic equipment, cereals, mineral fuels, oil, distillation products.

Ghana liberalized in 1983, before which it was almost like a closed economy. After 1983 liberalization, the imports increased dramatically over the years. During 1990s the major import of Ghana was rice because there was a huge difference in the quality of the local and foreign rice. Hence there was a poor substitutability between the domestically produced good and the good imported.

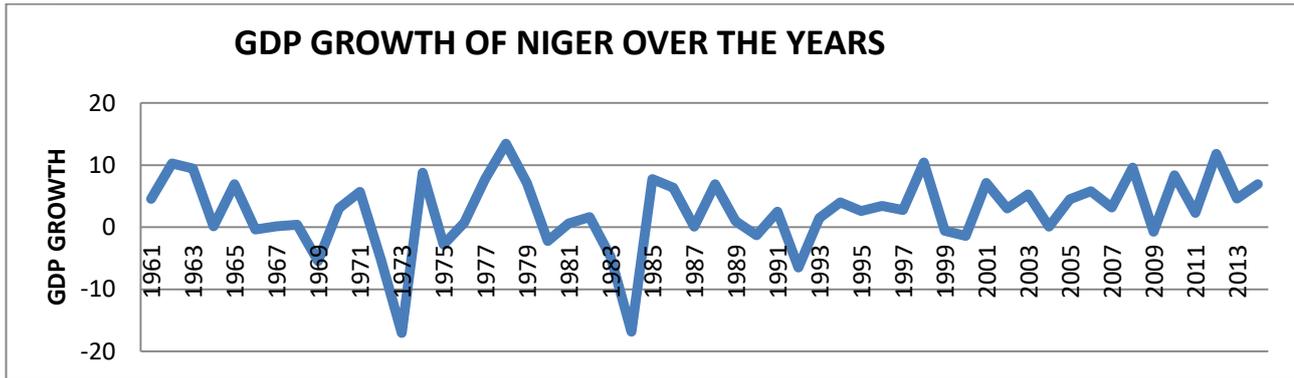

Source : data.worldbank.org

Graph 6

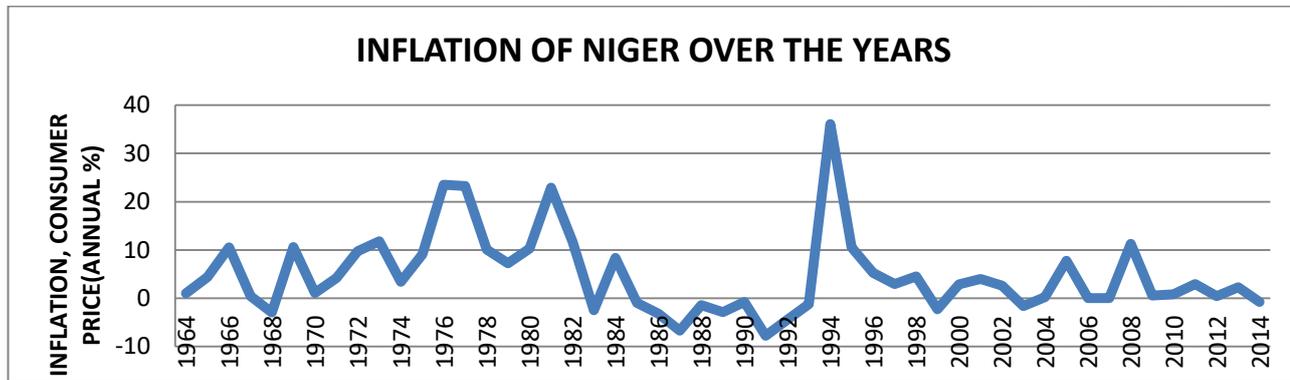

From the above graph we can also infer that after liberalization, the gross capital formation of the Ghanaian economy also increased significantly over the years.

NIGER

Source : data.worldbank.org

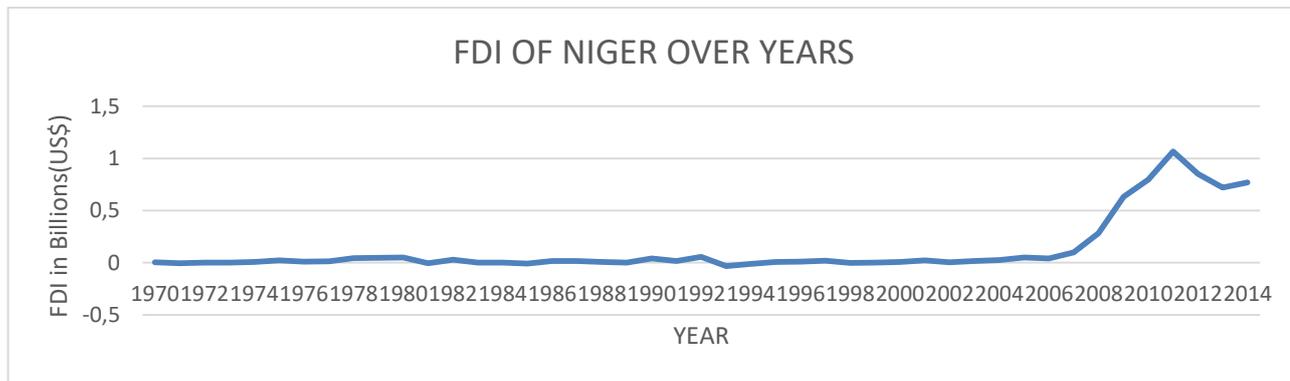

Graph 7

Source : data.worldbank.org

Graph 8

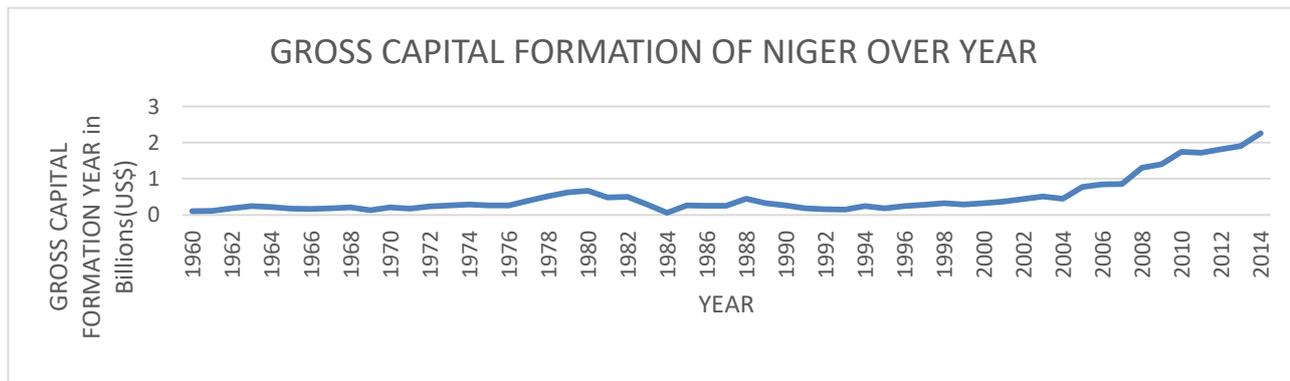

Niger is a landlocked country with two-thirds of its landmass as desert. It mainly relies on agriculture. Its economy centers on subsistence crops, livestock, and some of the world’s largest uranium deposits. Hence the economy faces extremely high variability inflation and GDA growth. One of the most severe droughts on record had hit Niger’s economy, beginning in the late 1960s and lasting well into the 1980’s. Hence since the independence in 1963, Niger has faced many droughts that caused food shortages and famines. The main source of Niger’s exports is mining, in which uranium has the largest share. In 1980’s, the uranium-led boom ended leading to the stagnation of the economy in 1980’s. The devaluation of the (CFA) franc contributed to a 3.5 percent average annual economic growth in the mid 1990’s. But again the economy slacked in 1999 due to sharp decrease in foreign aid. Reflecting the importance of the agricultural sector, good rains led to a growth of 5.1 percent, 3.1 percent, 6 percent and 3 percent in the years 2000, 2001, 2002 and 2003 respectively.

Source : data.worldbank.org

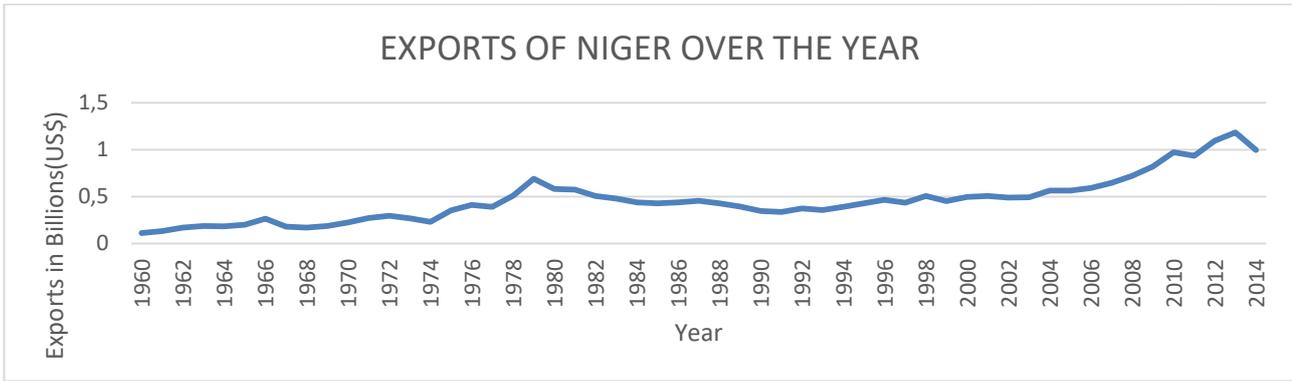

Graph 9

In recent years, particularly 2000 toward, the government of Niger has revised its investment code(1997 and 2000), petroleum code(1992), and mining code (1993), with attractive terms for investors. Hence the FDI inflows have increased exponentially which has also led to the increase in gross capital formation. It can be seen from the graph above.

Source : data.worldbank.org

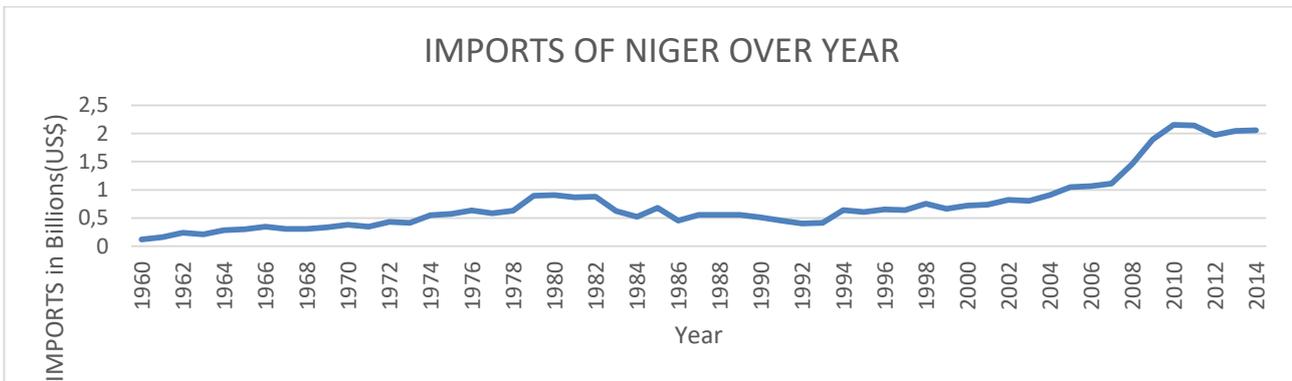

Graph 10

Source : data.worldbank.org

Graph 11

Niger had substantial export earnings and rapid economic growth during the 1960s and 1970s when it opened up two huge uranium mines near the northern town of Arlit, but soon the uranium boom ended in the early 1980s that left the economy stagnated. Since 1992, several oil companies explored oil in areas of Niger that led to a substantial increase in exports in the years succeeding 1990s.

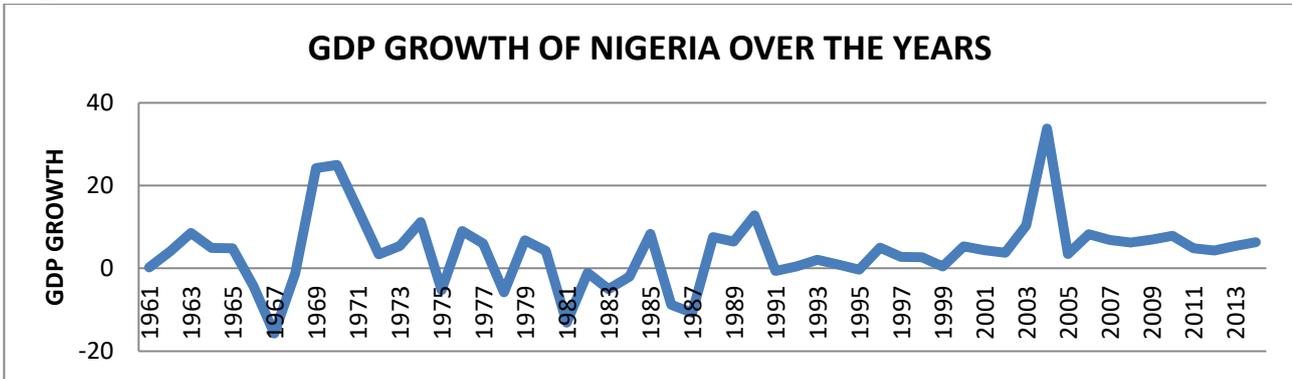

Source : data.worldbank.org

Graph 12

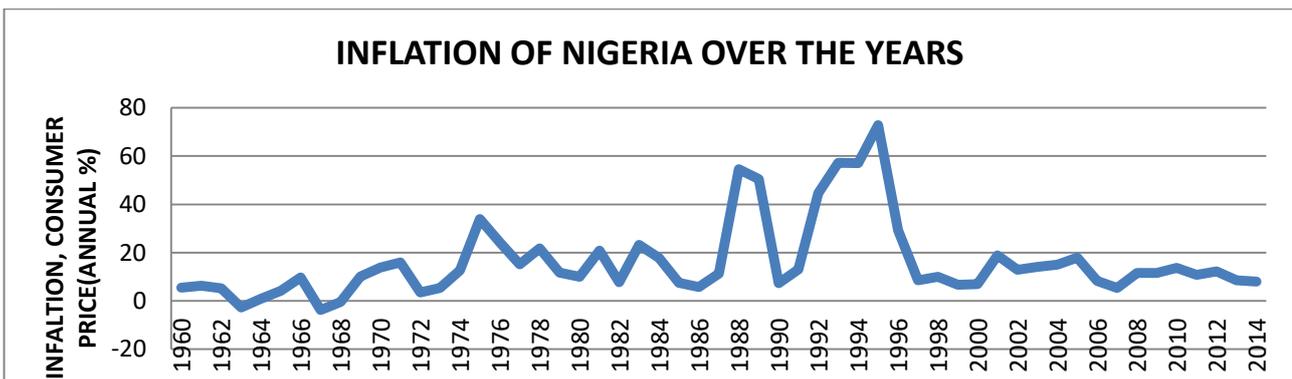

From the graph above it can be seen that the imports into Niger have increased substantially from 2000s onwards.

NIGERIA

Source : data.worldbank.org

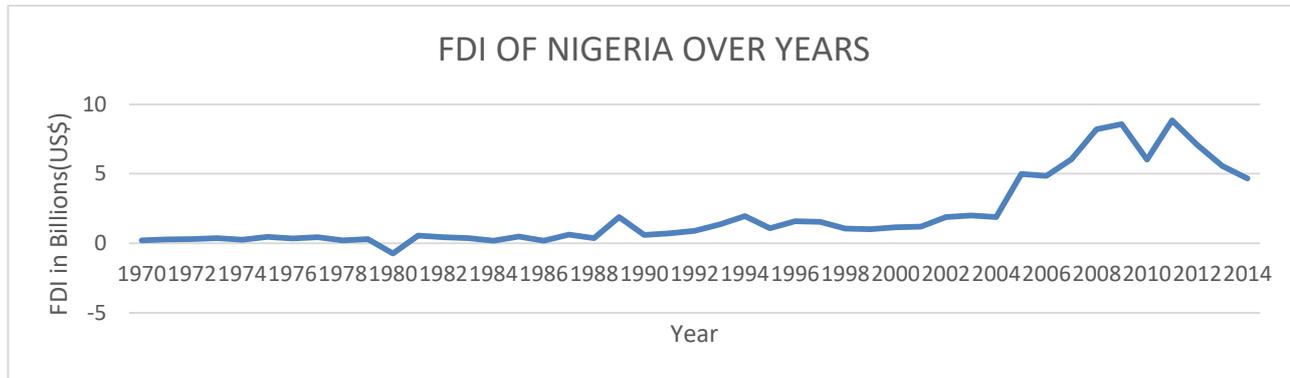

Graph 13

Source : data.worldbank.org

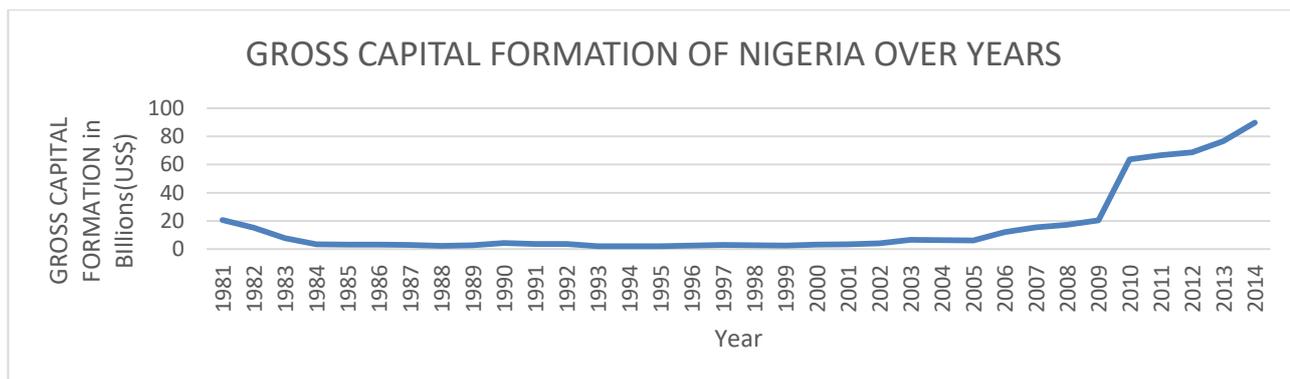

Graph 14

In terms of farm output, Nigeria stands first in Africa and sixth worldwide. But agriculture has suffered dramatically in Nigeria due to inconsistent and poorly delivered government policies, neglect, mismanagement and lack of optimal infrastructure. Yet for Nigeria, this sector accounts for about 26.8percent of GDP and two thirds of employment. Due to the oil boom during the 1970s, Nigeria neglected its strong agriculture and light manufacturing bases and highly depended on the exports of crude oil. According to 2000, 98 percent of Nigeria’s exports are due to oil exports. Hence in the early 1980’s, there was a collapse of the basic infrastructure. The decline in oil prices, mismanagement of the economy and continued military rule defined Nigeria in the 1980s. In other words, oil dependency spawned other economic distortions. Another aspect that affected the Nigeria’s economy was mining. In 1967, the Nigerian civil war broke out which continued till early 1970. This had a derailing effect on the mining industry, thus ultimately affecting the growth of the country.

Source : data.worldbank.org

Graph 15

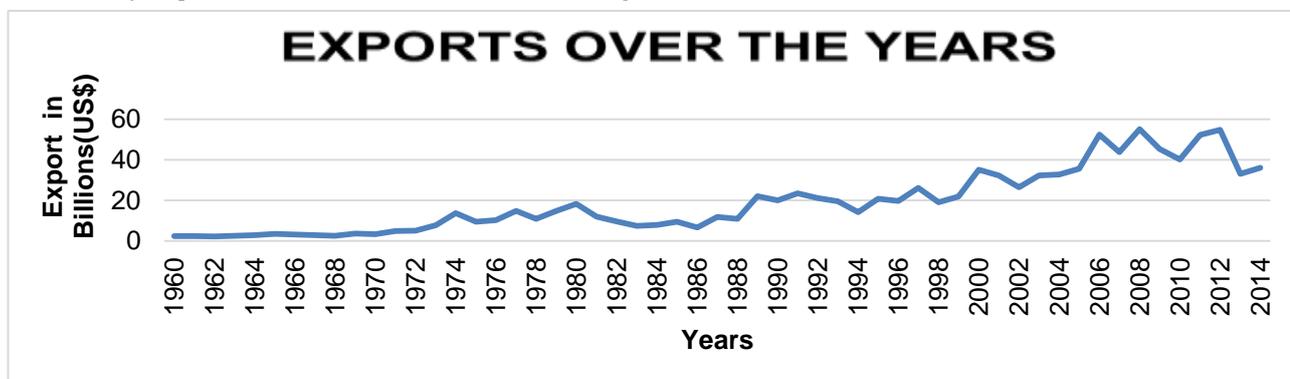

Source : data.worldbank.org

Graph 16

The Nigerian Enterprises Promotion(NEP) Decree of 1972(revised in 1977) was implemented in order to curb the foreign direct investment into the Nigerian economy. This was the prime reason as to why Nigeria had low FDI until 1990s.

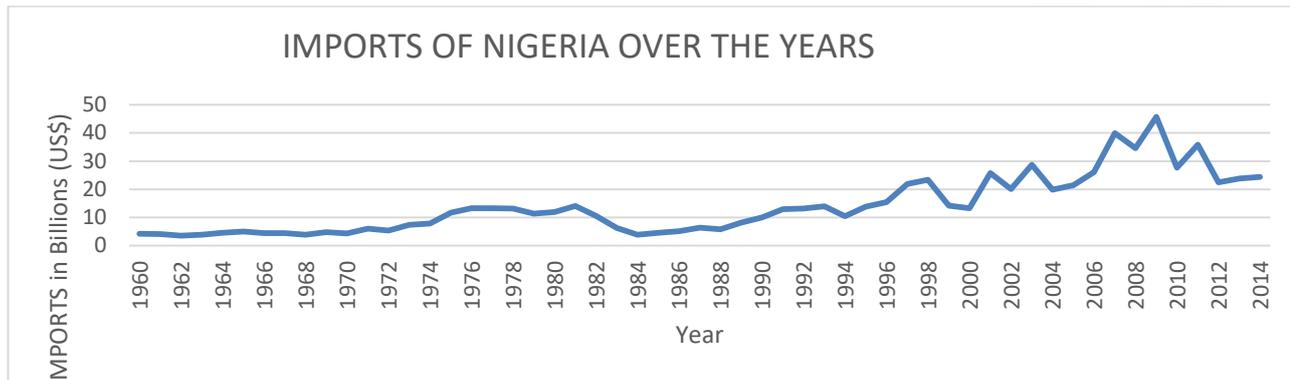

Another reason for low levels of FDI was Nigeria’s political instability. Multiple coups and counter coups since 1966 and politically motivated riots created an environment not suitable for foreign investment. From the 1990s, the increase in the stability of political and economic structures in Nigeria led to an increase in FDI into the nation.

Source : data.worldbank.org

Graph 17

Nigeria is a major exporter for oil and natural gas. The oil boom of the 1970’s led to a high increase in Nigeria’s export sector. The exponential growth of exports was primarily due to the increase in the demand of oil over the years.

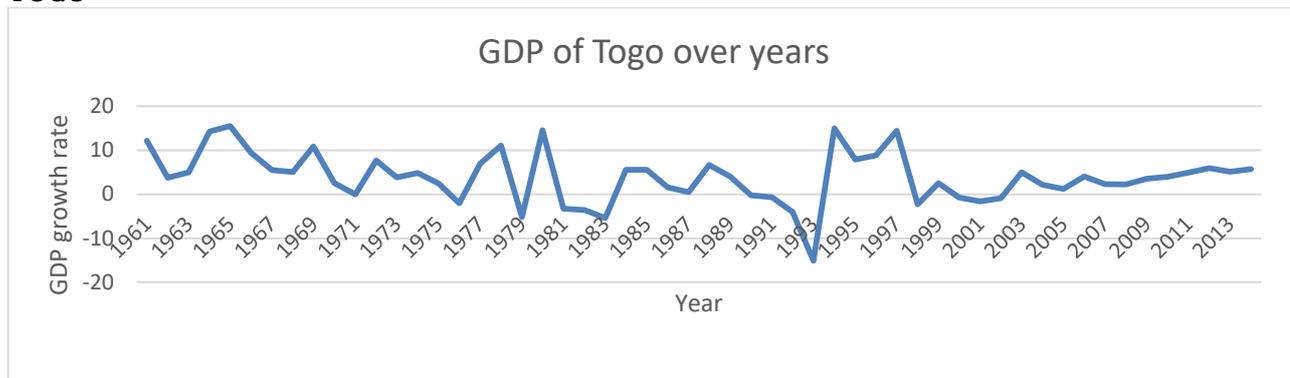

Source : data.worldbank.org

Graph 18

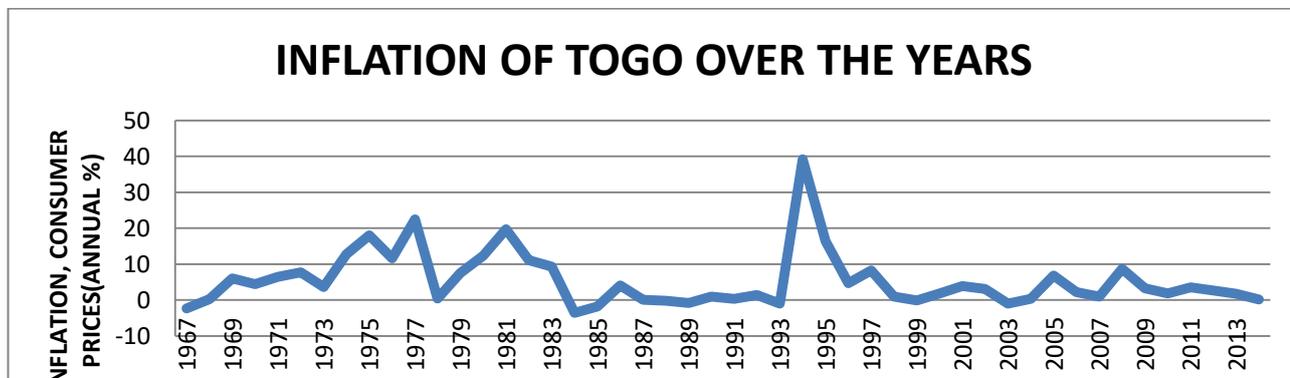

The major imports of Nigeria include industrial supplies, capital goods, fuel and lubricants, food and beverage, transport equipment and parts and consumer goods.

TOGO

Source : data.worldbank.org

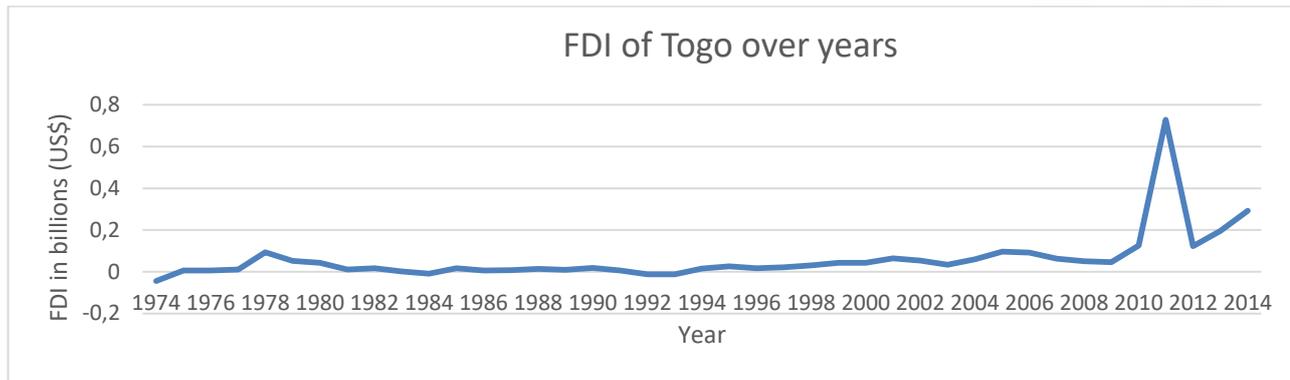

Graph 19

Source : data.worldbank.org

Graph 20

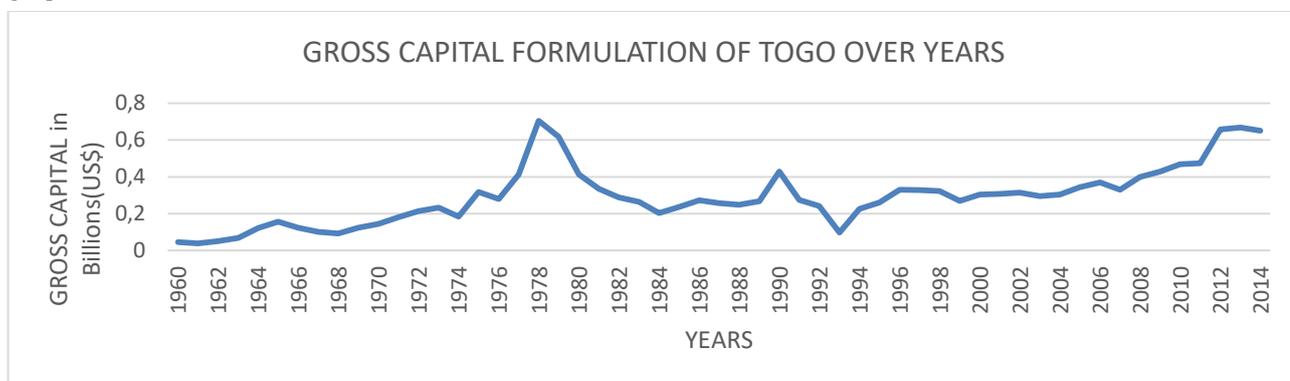

Subsistence agriculture is the major economic activity in Togo. Food and cash crops account for about 42 percent of the GDP. Major cash crops produced in Togo are coffee, cocoa and cotton. In 2001, due to a disastrous harvest, the country suffered significantly in terms of growth. In the industrial sector, Togo's one of the most important commodity is phosphate. Due to the commodity boom in mid-1970s, Togo increased its prices which had a positive impact on the economy. However later decline in the commodity prices resulted in the Togo's fiscal imbalances, heavy borrowings and loss making state enterprises. In 1979, international monetary fund(IMF) gave assistance to the Togolese economy, helping it to improvise on its economic position. Togo had a lot of political ups and downs as well which affected its economic growth throughout the years. Togo got its independence in 1960, but the provisional constitution gave monopoly of executive power to the president Sylvanus Olympio. In 1963 the Olympio was assassinated in a coup and opposition leader Nicolas Grunitzk became president. He was overthrown by the military in 1967 and Colonel Etienne Gnassingbé Eyadema takes control. Till 1991 he ruled Togo as a dictator, then allowed a multiparty election where Kokou Joseph Koffigoh is selected as prime minister, in 1992 the people feared that Eyadema will not voluntarily give up the power, so trade unions and opposition parties launched a general strike, which lasted for 9 months and decimated Togo's economy that is the reason for highly negative GDP growth rate in 1993 and in 1994 the peak in GDP growth is due to devaluation of CFA franc. Eyadema was president till his death in 2005. Eyadema death resulted in political crisis which lead to fair elections in 2007 in which ruling party came back to power this political stability, this is the reason of stable growth rate after 2007.

Source : data.worldbank.org

Graph 21

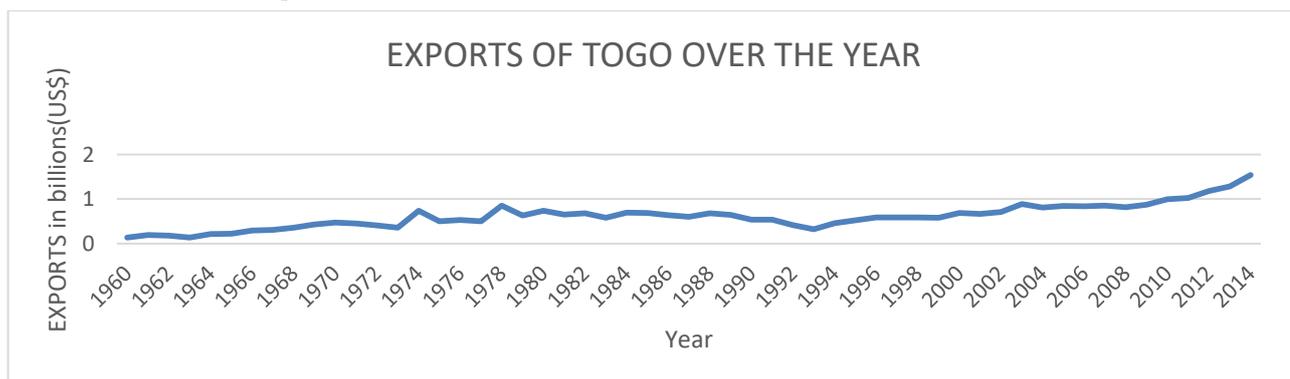

Lack of transparency, poor infrastructure and political instability discouraged the investors to invest in Togo till 2007. In 2007 largely free and fair legislative elections were held which led to the formation of new government. This was followed by presidential elections in 2010 which was recognized by international community as free and fair despite some irregularities. In 2012 the national assembly adopted a new investment code which according to Ministry of Commerce of Togo provides equal treatment of Togolese and a foreign investor this is the reason for such a large spike in the above graph.

Source : data.worldbank.org

Graph 22

The abrupt increase in the gross capital formation in 1973 to 1979 was due to the increase in government spending. In other words, this spike occurred due to the fiscal policy of the Togolese government. Government expenditure rose sharply, leading to large budget deficits. It increased from 13.4 percent of GDP in 1977 to 39.6% of GDP in 1979. The stable increase in the capital formation after 2009 is attributed to the increase in FDI.

Source : data.worldbank.org

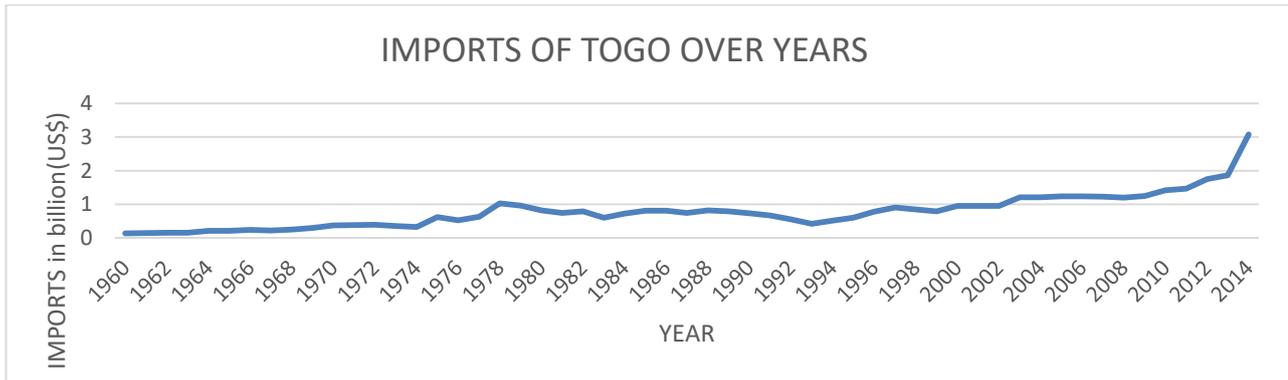

Graph 23

The major commodities that Togo exports include phosphate rocks, coffee and cocoa. The phosphate boom of 1974 and 1975, along with the rise in coffee price in 1997 led to a substantial increase in the exports. Also we can see from the graph above, that during the 1990s, exports started to decline. The cause behind this decline was the unstable economic environment, public authority dysfunction and strikes. People of Togo were fighting for democracy.(Collins and Bosworth(1999) and O'Connell and Ndulu(2000) and Hoeffer's(1999))

Togo faced from 1990 to 1993, a complete social and political crisis that resulted in breakup of cooperation within the country. Togo has huge imports of rice. Nearly half of the consumption of rice is imported. The first major policy related to the production of rice was designed in 1993. It focused on three major goals:

1. Intensification and diversification of agricultural production

2. Reducing poverty by improving rural incomes
3. Sustainable environment for agricultural growth

Source : data.worldbank.org

Graph 24

Unfortunately, there were very few gains in terms of staple food production because of poor social and political environment. Hence as the demand grew, the domestic production could not cope up, leading to exponential increase in imports for the commodity.

LITERATURE REVIEW

(Ousseini Hamadou) 2011

The motive of this paper is to study the impact of FDI on economic growth in Niger. This paper explores the relationship between FDI and economic growth for the period 1970-2008 in Niger using VAR (Vector Autoregressive) model. This model is established from World Development Indicators (WDI, 2010) online databases of the world bank (2010) and transparency International database online (2010). This study finds a long-term relationship between FDI and economic growth. This finding is a long-term relationship between variables but failed to establish the direct correlation between each variable. This can be explained by the fact that low volume flows of FDI in Niger have major consequences on the economic system, particularly on employment, inflation and GDP.

(Azeez, B A, Dada, S O, Aluko, O A) 2014

The study analyses the effect of international trade on the economic growth of Nigeria in the 21st century. The model in this paper takes GDP as a dependent variable which is dependent on Import, Export and trade openness. The paper uses Ordinary Least Square (OLS) estimation technique from 2000-2012 on annual timeseries data. The source of data is from the Central Bank of Nigeria (CBN) Statistical Bulletin. The result showed that international trade has a significant positive impact on economic growth. This study recommends that government should reduce over-dependence on oil exports and increase and diversify its export base to earn more revenue.

(Assiobo Komlan Mawugnon, Fang Qiang) 2011

This study investigated the relationship between Foreign Direct Investment (FDI) and Economic Growth in Togo from the period 1991-2009 using time series data. The paper used the Granger-causality test to determine the relationship between FDI and Economic Growth in Togo. The data has been collected from World Development Indicator Website. The paper found out that there was a unidirectional relationship between FDI and GDP. The direction of causation ran from FDI to GDP enables to conclude that FDI cause GDP and not vice-versa. The study recommended improvement in the investment climate for foreign capital to enhance competitiveness and strengthen the bargaining position of the country in the emerging globalized economy.

(ANTHONY CHIARAHAH & PAUL KWAME NKEGBE) 2014

This paper aims to analyse the implications of exchange rate, GDP growth and monetary policies for inflation in Ghana. This paper uses the Engle-Granger (1987) method to test for the possibility of cointegration and least square method of regression. Data was collected from the WDI online database. This paper is unable to prove a significant long-run relationship between exchange rate and inflation in Ghana. The results confirm a long-run equilibrium relationship between inflation, money supply, foreign price and the real income. In line with theoretical assumptions, the findings demonstrate that in the long run, inflation in Ghana is positively related to the money supply while it is negatively related to real income and foreign price level.

(Adeleke Kunle M., Olowe S.O, Fasesin Oladipo Oluwafolakemi) 2014

The paper aims to analyze the impact of foreign direct investment on the economic growth of Nigeria over the period of 1999- 2013. OLS (ordinary least square) regression analysis has been employed to find impact of the Foreign Direct Investment on economic growth. The main type of data used in this study is secondary; sourced from various publications of Central Bank of Nigeria, such as; Statistical Bulletin, Annual Reports and Statement of Accounts. The findings revealed that economic growth is directly related to inflow of foreign direct investment and it is also statistically significant at 5% level which implies that a good performance of the economy is a positive signal for inflow of foreign direct investment. So the paper implies that foreign direct investment is an engine of economic growth. The paper recommended that

government should liberalize the foreign sector in Nigeria so that all barriers to trade such as arbitrary tariffs; import and export duties and other levies should be reduced so as to encourage investors.

METHODOLOGY

This study has employed time series data from 1960 to 2014. The data was collected from the world bank online database. The major variables that were analyzed are: GDP, FDI, gross capital formation, imports and exports.

We used the following methods in order to find the growth rates:

β =beta

Y=parameter into consideration

t=time

1. OLS method:

$$r_{ols} = e^{\hat{\beta}} - 1$$

Where,

$$\hat{\beta} = \sum_{s=2}^T \times \frac{6(T - S + 1)(S - 1)}{T(T + 1)(T - 1)} \times \Delta \ln Y_s$$

2. Log difference regression:

$$r_{LD} = e^{\hat{\beta}} - 1$$

Where,

$$\hat{\beta} = \frac{1}{T - 1} \times \sum_{t=2}^T \Delta \ln Y_t$$

3. Average annual growth rate:

$$r_{AAGR} = \frac{1}{T - 1} \times \sum_{t=2}^T \frac{Y_t - Y_{t-1}}{Y_{t-1}}$$

4. Geometric average:

$$r_{Geo} = \left(\frac{Y_t}{Y_1} \right)^{\frac{1}{T-1}} - 1$$

For OLS regression analysis we use the following model,

$$GDPG = \alpha + \beta_1 FDI + \beta_2 EXP + \beta_3 IM + \epsilon$$

Where

GDPG= GPD growth

FDI = Foreign Direct Investment

IM= Imports

EX= Exports

The results of the above four growth formulas suggest that:

GHANA

1. On an average, the growth in exports is 4.53%
2. On an average, the growth in imports is 5.35%
3. On an average, the growth in GDP is 3.3%
4. On an average, the growth in FDI is 9.78%
5. On an average, the growth in gross capital formation is 4.23%

NIGER

1. On an average, the growth in exports is 3.38%
2. On an average, the growth in imports is 4.85%
3. On an average, the growth in GDP is 2.12%
4. On an average, the growth in FDI is 8.66%
5. On an average, the growth in gross capital formation is 4.62%

NIGERIA

1. On an average, the growth in exports is 5.54%
2. On an average, the growth in imports is 3.70%
3. On an average, the growth in GDP is 3.74%
4. On an average, the growth in FDI is 6.76%
5. On an average, the growth in gross capital formation is 2.85%

TOGO

1. On an average, the growth in exports is 4.51%
2. On an average, the growth in imports is 5.75%
3. On an average, the growth in GDP is 3.4%
4. On an average, the growth in FDI is 3.83%
5. On an average, the growth in gross capital formation is 4.19%

The results of the regression analysis:

GHANA

Residuals:

Min	1Q	Median	3Q	Max
-1.344e+09	-2.121e+08	1.018e+06	1.966e+08	1.888e+09

Coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	3.850e+09	1.605e+08	23.987	< 2e-16 ***
FDI	1.703e+00	1.464e-01	11.635	9.36e-14 ***
EX	4.256e-02	3.029e-01	0.141	0.889
IM	9.621e-01	2.143e-01	4.489	7.07e-05 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 6.12e+08 on 36 degrees of freedom
Multiple R-squared: 0.9839, Adjusted R-squared: 0.9825
F-statistic: 731.2 on 3 and 36 DF, p-value: < 2.2e-16

The adjusted R squared value for Ghana is 0.9825 which tells us the fact that 98.25% of the variation in the GDP growth is explained by FDI, Exports and Imports while the rest of 1.75% variation is explained by some other factors not included in the model and is given by the residual or the error term in the model.

The p value for the regressed model for Ghana is 2.2×10^{-16} . Since the p value is very less therefore the model is significant. The value of F statistic is very high i.e 731.2 on 3 parameters and 36 degrees of freedom which signifies that the model is statistically significant. The individual 't' statistic values show that the impact of FDI and Imports are significant while Exports is insignificant in the model.

NIGER

Residuals:

CONCLUSIONS

From the above analysis we have seen that, how, over the years, FDI, gross capital formation, inflation, GDP, imports and exports have varied for four major West African countries, which include Ghana, Niger, Nigeria and Togo.

After analyzing the graphs, we saw the growth trends in parameters for the four countries in consideration.

We applied four different growth formulas to analyze the parameters:

1. OLS regression
2. Log difference regression
3. Average annual growth rate
4. Geometric Average

Further, we regressed GDP with FDI, imports and exports. The following were the findings:

1. For Ghana, FDI and imports had a significant impact on the GDP while exports was insignificant. Overall, the model explained 98.25% of the variation in the GDP.
2. For Niger, imports had a significant impact on GDP while FDI and exports were insignificant. Overall, the model explained 85.97% variation in the GDP.
3. For Nigeria, FDI had a significant impact on the GDP (**our finding is consistent with the findings in the research paper International Journal of Academic Research in Business and Social Sciences August 2014, Vol. 4, No. 8 and Adeolu B. Ayanwale (2007) "FDI and economic growth: Evidence from Nigeria") while imports and exports were insignificant. Overall, the model explained 80.7% variation in GDP.**
4. For Togo, imports had a significant impact on the GDP while FDI and exports were insignificant. Overall, the model explained 72.79% variation in GDP.

Lastly we made a correlation matrix between GDP, FDI, imports and exports. The results were:

GHANA

Correlation between:

1. GDP and FDI is 89.77%

2. GDP and exports is 95.01%
3. GDP and imports is 94.72%
4. FDI and imports is 79.58%
5. FDI and exports is 80.21%
6. Imports and exports is 98.67%

NIGER

Correlation between:

1. GDP and FDI is 84.61%
2. GDP and exports is 91.28%
3. GDP and imports is 92.66%
4. FDI and imports is 93.34%
5. FDI and exports is 87.26%
6. Imports and exports is 95.38%

NIGERIA

Correlation between:

1. GDP and FDI is 90.03%
2. GDP and exports is 84.02%%
3. GDP and imports is 77.44%%
4. FDI and imports is 84.65%
5. FDI and exports is 88.37%
6. Imports and exports is 86.37%

TOGO

Correlation between:

1. GDP and FDI is 60.23%
2. GDP and imports is 85.82%
3. GDP and exports is 80.42%
4. FDI and imports is 60.09%
5. FDI and exports is 60.10%
6. Imports and exports was 93.14%

SS25. Braille Mapping by NATMO & Its Utility to Visually Impaired People

BRaille MAPPING BY NATMO & ITS UTILITY TO VISUALLY IMPAIRED PEOPLE

By Tapati Banerjee, Director, NATMO

National Atlas and Thematic Mapping Organisation (NATMO) is an organization of applied Geo-Spatial technology and pioneer in Thematic Mapping and Atlas Cartography under Department of Science & Technology (Ministry of Science & Technology), Govt. of India. The Organization publishes different thematic maps and atlases on national, state, district, block level besides many other monographs. NATMO recently has walked ahead to prepare Braille Atlases for visually impaired persons. Visually Impairment is one of the Disabilities as per PWD Act 1995, like Mental, Hearing, Speech, and Locomotors & Leprosy Cured. The provisions contained in the Full Participation of every Disabled Citizen in all walks of life. Braille Language which is based on Tactile Codes developed by Mr. Louis Braille French on 1824 is an important tool to visually handicapped persons and is universally applied for blind disabled to read and write.

ORGANISATIONAL SET UP

National Atlas & Thematic mapping Organisation (NATMO) since its inception (1956) located at Kolkata. With a passage of time it grew into a highest ranked organization as one & single largest maps and atlases production unit in Asia where highest number of geographers work under a single roof. It has its own map production unit with latest technology. Besides main printing unit it has a separate printing set up for Braille mapping too.

As an endeavour to disperse practical knowledge of maps to the visually impaired persons, NATMO applied Braille system in thematic mapping to facilitate visually impaired persons, who were left behind the knowledge of geographical features of the country. After continuous efforts and experiment, NATMO has published **Atlas for Visually Impaired (India), Special edition 2017**, in English Braille script. This publication has received a huge response from the users of all over the country. Hon'ble Prime Minister, Shri N.D. Modi conferred **National Award on "S & T Intervention for Physically Challenged"** to NATMO for this publication. Hon'ble Union Minister of Science & Technology and Earth Sciences, Dr. Harshvardhan, officially released this Atlas on 10th February, 2017 in a gathering of about 200 visually impaired students in INSA, New Delhi. Indian National Cartographic Association (INCA) has included **"National Map Quiz for Visually Impaired Students"** as a part of its annual activity.

Receiving such overwhelming response, NATMO has taken up the preparation of Braille Atlases for different states of India in concerned regional languages as well. The Technical Advisory Committee (TAC) of NATMO has advised to prepare Braille maps/atlasses of the SARC countries also in its last meeting.

BEGINNING OF BRAILLE MAPPING IN NATMO

Exploratory beginning with the preparation of a Tactile Map (Braille mapping) was first done on "India-Physical" on a Zinc plate in order to display and demonstrate at the first **Technology Conference for Visually Handicapped** organized by **All India Confederation of the Blind, New Delhi in the year 1997**.

Initially metal plate was taken as a medium of production but this proved to be danger for the visually handicapped students. Later on many other mediums were used to print the tactile maps as detailed below;

- Metal Tactile: 1997
- Fiber Glass: 1997
- Braillion Paper: 1998
- Plastic Sheet: 1998
- Screen Printing Art Paper: 2000 & onwards

Afterwards numbers of Braille atlases have been published by NATMO with the existing organizational setup. The first volume of Braille atlas was brought out in collaboration with the Blind Boy's Academy, Ramakrishna Mission Ashram Narendrapur, South 24 Parganas, West Bengal, and Society for Visually Handicapped, Kolkata.

BRAILLE ATLASES PUBLISHED BY NATMO

1. SCHOOL ATLAS FOR THE VISUALLY IMPAIRED VOL - I, ENGLISH VERSION
2. SCHOOL ATLAS FOR THE VISUALLY IMPAIRED VOL -II, ENGLISH VERSION (ADMINISTRATIVE AND PHYSICAL MAPS)
3. DRISHTIVADITARTH SCHOOL ATLAS VOL -I (HINDI)
4. DRISHTIVADITARTH SCHOOL ATLAS VOL -II (HINDI): - WITH MAPS OF SIX CONTINENTS (ADMINISTRATIVE AND PHYSICAL MAPS)
5. DRISHTIHIN CHHATRA CHHATRIDER MANCHITRAVALI (BENGALI):- 14 MAPS ON WEST BENGAL AND 7 MAPS ON INDIA
6. BRAILLE ATLAS OF MEGHALAYA (ENGLISH):- 19 MAPS ON MEGHALAYA AND 7 MAPS ON INDIA: COMPLETED AND SUPPLIED TO THE GOVERNMENT OF MEGHALAYA
7. SCHOOL ATLAS FOR THE VISUALLY IMPAIRED VOL - I, ENGLISH (SECOND EDITION 2013)
8. SCHOOL ATLAS FOR THE VISUALLY IMPAIRED VOL - I, ENGLISH (THIRD EDITION 2016)

9. ATLAS FOR THE VISUALLY IMPAIRED (INDIA)- SPECIAL EDITION 2017

Till 1998 our experiments of preparing the Braille maps were found to be ineffective for the blind as they were not so user-friendly. Hence the preparation of patterns and locations were experimented in such a way that will be appreciated by the users. Towards this requirement the GIS and Digital mapping technology have been adopted. As a result NATMO achieved the mixture of Digital maps with Windows Braille Software in different languages.

ONGOING PROJECT OF BRAILLE ATLASES:-

1. ATLAS FOR VISUALLY IMPAIRED (INDIA), HINDI
2. BRAILLE ATLAS OF ASSAM IN ENGLISH AND ASSAMEESE LANGUAGES:- 14 MAPS ON ASSAM AND 7 MAPS ON INDIA
3. BRAILLE ATLAS OF TELANGANA IN ENGLISH AND TELUGU LANGUAGES: 15 MAPS ON ASSAM AND 7 MAPS ON INDIA
4. BRAILLE ATLAS OF ANDHRA PRADESH IN ENGLISH AND TELUGU LANGUAGES: 15 MAPS ON ANDHRA PRADESH AND 7 MAPS ON INDIA
5. BRAILLE ATLAS OF GUJARAT IN ENGLISH AND GUJARATI LANGUAGES

WHY BRAILLE MAPPING

Developments on the use of Braille system for providing maximum utilization in national and international level are still being done. Computer or electronic devices have been introduced such as Text to Speech, Screen magnifying Software, OCR and Scanners to provide maximum benefit to the visually impaired people all over the globe. But such devices still have limitations and not viable to reach conveniently deep to the grass root level of the beneficiaries as those are costlier. Maps on the other hand with nominal cost can be easily reachable to the users and can be used without fear of damages. While attending national conferences/seminars/book fairs, the organization has received unmet demands of Braille atlases from the number of the organizations. The statistics of visually challenged persons in India at present are detailed below;

Table - 1

Sl. No.	State	Total numbers of Disabled persons by 2011 Census			<i>In seeing/Visually Disabled persons by 2011 Census</i>		
		Persons	Males	Females	Persons	Males	Females
1	Jammu & Kashmir	3,61,153	2,04,834	1,56,319	66,448	35,656	30,792

The statistics shows that India is having more than 50 lakhs persons with visually impairment. There are about 395 blind schools in India spreading over different states. The highest number of schools are in Uttar Pradesh (51), followed by Maharashtra (49) and Gujarat (38). Considering the demand of Braille Atlases from different schools as well as from different states, NATMO has taken up some of the projects on regional languages viz. Marathi, Gujarati, Bengali and Telugu apart from English and Hindi.
