12th World Congress of the RSAI

The 12th Regional Science World Congress welcomes you to Goa, in India, a coastal location with breathtaking landscapes sculpted by the Konkan Coast and the Western Ghats.

On behalf of the Regional Science Association International and the Regional Science Association of India, we extend our warm greetings and cordially invite you to participate in the 12th Regional Science World Congress from May 29 to June 01, 2018, at Goa.

The conference is open to regional scientists, practitioners and researchers in the field of regional science. The Congress will include Keynote Lectures, Scientific Sessions, Poster Sessions, Workshops and Themed Sessions. Field trips will be organized in and around Goa. The theme of the 12th RSAI World Congress is Spatial Systems: Social Integration, Regional Development and Sustainability. The theme has been chosen to focus upon the development needs of regions as spatial entities, which is the subject matter of spatial science. We hope to provide an encouraging environment for researchers across the globe, to interact and learn from one another, and create a network that will be attractive and inspiring for young students and scholars. We hope to strengthen the community of regional scientists and achieve a better understanding of our future needs.

We wish you a good Conference!

Sumana Bandyopadhyay
Chair, Local Organising Committee
President, Regional Science Association, India

Themes

Umbrella Theme

Spatial Systems: Social Integration, Regional Development and Sustainability

Across the world, communities are striving to achieve an ecologically and socially secure future. The intricately linked ideas of sustainability and integration are the key to achieving our development goals. As regional scientists, our common pursuit of a sustainable future may be attained with more efficient understanding of the 'region' as a spatial unit. Keeping this objective in mind, the theme of the 2018 Congress highlights the importance of analyzing spatial systems as not just physical space or social space, but shared space. The sub-themes will be aimed at providing a platform for debates and discussions around the key issues of contemporary regional science and carve out the way to future research agenda.

General Themes

RS02 - Cooperation and Development
RS03 - Environmental Issues
RS04 - Infrastructure, Transportation and Accessibility
RS06 - Location of Economic Activity
RS07 - Methods in Regional Science and Urban Economics
RS08 - Migration and Labor Markets

RS09 - Real Estate and Housing
RS10 - Regional and Urban Policy and Governance
RS11 - Regional Finance, Investment or Capital Markets
RS12 - Rural Development
RS13 - Social Integration
RS14 - Spatial Planning
RS16 - Tourism

Special Sessions' Themes

SS00 – Sessions of RSPP on Forty under Forty
Editorial Team of RSPP (Chairs)
SS01 – Water management in South Asia: From conflict to cooperation
Paulo Casaca
SS02 – Smart Cities Initiatives for the 21st Century: Myth or Reality
Peter Nijkamp, Vijay Pandey and Sumana Bandyopadhyay
SS03 – Territorial Governance and Local Development in Developing Countries
Andre Torre and Habibullah Magsi
SS04 – Spatial Econometric Interaction Modelling
Manfred M. Fischer and Yee Leung
SS05 – Spatial Analysis: From Neural Computing to Deep Learning
Yee Leung and Manfred M. Fischer
SS07 – Economic Corridors, Development and Regional Cooperation in South Asia and Beyond
Siegfried O. Wolf
SS08 – Metropolitan Governance in a conflict, competition and cooperation contexts
Jorge Gonçalves
SS09 – Analytical Approaches to Climate Change at Multiple Scales
Gerrit-Jan Knaap
SS10 – Rural Transformation
Subrata Dutta

SS11 – The future of leisure: tourism, mobility and transportation
João Romão, Peter Nijkamp and Luca Zamparini
SS12 – Transforming Metropolitan Regions: Ideas and Examples
Amit Chatterjee
SS13 – Citizenry and Regional Planning
Subhra Chattopadhyay
SS14 - Revisiting rural-urban dichotomy for integrated regional development
Manisha Jain and Artem Korzhenevych
SS15 - Conflict, Migration, and Diaspora
Manas Chatterji
SS17 - Regional Science and Peace Science
Manas Chatterji
SS18 - Natural and Man-Made Disaster Management
Manas Chatterji
SS19 - Globalization and Regional Science
Manas Chatterji
SS20 - Gender and Social Justice
Saraswati Raju
SS21 - Innovation and Entrepreneurship
Rudra P. Pradhan
SS24 - Regional Issues in Economic growth and Development
Debasis Patnaik
SS 25 - Braille Mapping by NATMO & Its Utility to Visually Impaired People
Tapati Banerje

Organizing Committee

President, RSAI : Budy Resosudarmo
Executive Director, RSAI: Tomaz Ponce
Dentinho
Secretary, RSA India :

ABSTRACTS & PAPERS

INCLUDES ALL ABSTRACTS AND COMMUNICATIONS THAT WERE EFFECTIVELY PRESENTED AT THE CONGRESS.

Plenary Sessions

Spatial Systems: Social Integration, Regional Development and Sustainability

PLENARY SESSION **16:30-18:00** **Tue_ Auditorium**

Chair: Budy Resosudarmo, Australian National University, Australia

Keynote Presentations

Labor Force Diversity and Firm Survival

Janet E. Kohlhase, University of Houston, USA

The revenge of the places that don't matter

Andrés Rodríguez Pose, London School of Economics, UK

Regional Cooperation Policy

PLENARY SESSION **16:00-18:00** **Wed_ Lecture theatres A3**

Chair: Kingsley Haynes, George Mason University, USA

Keynote Presentations

Regional Integration and Cooperation: Quo Vadis?

Iwan Azis, Cornell University, USA and University of Indonesia, Indonesia

The Role of Government Behavior in Understanding the Relevance of Regions

Steven G. Craig, University of Houston, USA

Sachidanand Sinha, Centre for Studies in Regional Development at Jawaharlal Nehru University, India

Xue Ling (Paul Snow), School of Government, Peking University, China

Space Programm, Geoinformatics: Policy and Practice

PLENARY SESSION **15:00-16:30** **Fri_ Lecture theatres A3**

Chair: Debapriya Dutta, Department of Science and Technology, Government of India

Keynote Presentations

J. S. Rawat, Centre of Excellence for NRDMS in Uttarakhand Dept. of Geography, Kumaun University Almora, Uttarakhand

Marco Alves, WavEC Offshore Renewables, Portugal

Semi Plenary Sessions

Goa Government

SEMI PLENARY SESSION

11:00-12:30

Wed_ Lecture theatres A3

Chair: Tapati Banerjee, Director National Atlas & Thematic Mapping Organisation, India

Keynote Presentations

Evolution of the Regional Plan of Goa

S.T. Puttaraju, Chief Town Planner of Goa, India

Water-based Sports and Leisure Tourism in Goa

Seetharam Babu, Ministry of Tourism, Goa, India

Regional Science Policy and Practice (RSPP) & The Regional Science Academy (TRSA)

SEMI PLENARY SESSION

11:00-12:45

Thu_ Lecture theatres A3

Regional Science Academy Lecture Series: "The Voice of the Regional Science Academy"

Luc-Normand Tellier (University of Quebec, Canada) on:

Attraction, Repulsion and Gravity Fields: From Alfred Weber to an Urban Metric System

Inclusive City Planning

SEMI PLENARY SESSION

16:00-18:00

Thu_ Lecture theatres A3

Chair: M. Satish Kumar, Director Internationalisation, Queens University, Belfast and Faculty

Keynote Presentations

P. Jayapal, Executive Director of HUDCO, India

Banasree Banerjee, Urban Planner and Professor, IHS
Erasmus University Rotterdam

R. B. Bhagat, Indian Institute of Population Studies,
India

Round Table

Social and Spatial Integration and Global Citizenship

ROUND TABLE

11:00-12:30

Fri_Lecture theatres A3

Chair: Andrés Rodríguez Pose, London School of Economics, UK

Keynote Presentations

Ethnic Diversities and Social Integration in India

Abdul Shaban, Tata Institute of Social Sciences, India

Revisiting Gender Empowerment in India

Saraswati Raju, Jawaharlal Nehru University, India

Anindita Dutta, University of Delhi, India

Armida Alisjahbana, Padjadjaran University, Indonesia

Main Schools of Regional Science

MAIN SCHOOLS SESSION

14:00-15:30

Thu_Lecture theatres A3

Discussions about nature of Regional Science Academic Programs around the world

Chair: Roger R. Stough, George Mason University, Schar School of Policy and Government

Presenters and Programs

Henri de Groot, Department of Spatial Economics, Free University of Amsterdam, Netherlands

Vicente Royuela Mora, Department of Economics, University of Barcelona, Spain

Jouke van Dijk, Regional Science Program, Rijks University of Groningen, Netherlands

Eduardo Haddad, Department of Economics, University of Sao Paulo, Brazil

Poster Session

1212 MOBILITY PLANNING FOR AN INDIAN PILGRIMAGE CITY- A CASE OF UJJAIN CITY, MADHYA PRADESH, INDIA

Kakoli Saha, N.R. Mandal

Department of Planning, School of Planning and Architecture, Bhopal, M.P. -462030, kakolisaha@spabhopal.ac.in

ABSTRACT

Home to one of the twelve Jyotirlinga shrines to the god "Shiva" (Mahakaleshwar), Ujjain (also historically known as Ujjayini) is one of the seven sacred cities of the Hinduism (Sapta Puri - seven holy pilgrimage centres in India). About 3 million annual tourist visits, Ujjain is a prominent Pilgrimage Destination in India. Also, the city is one of the four locations of Kumbh Mela (the mass Hindu pilgrimage of faith in which Hindus gather to bathe in a sacred river), which is held once in every 12 years. During the last Kumbh in 2016 Ujjain registered visit of 80 million tourists. Since the city witness such huge flux of tourists, it requires to have an efficient mobility plan. Also, Since Ujjain is one of the identified cities for development as a Smart City under Smart City Mission launched by Government of India in 2015, it requires a sustainable mobility plan that promotes health and well-being of the city residents. Though a Comprehensive Mobility Plan (CMP) exist for Ujjain City, it fails to connect personal health and safety of residents of Ujjain City with its mobility pattern. This paper proposes an environment friendly transportation strategy, including enhancement of active mass public transit network and development of cycle routes. For the purpose of the study, the road network of Ujjain City is digitized in the GIS platform. Detailed door to door survey was conducted to gather information about modal choice, willingness to shift to bicycle for local travel. Integrity, level of preference and connectivity of each road is analyzed using the space syntax analysis tool. On the basis of the above analyses, proposals including the introduction of new bus routes, cycle track were formulated to enhance mobility of pilgrims within Ujjain City.

Key words: Pilgrimage city, mobility plan, bicycle

1. INTRODUCTION

Most of the Indian cities have developed organically and earlier the process of city planning was never given priority in most of the development agendas. But however this random one sided demand, supply approach has disrupted the sequence of equitable development. The capitalistic nature of growth has so far addressed only the existing demand foregoing the actual need which is the basic right of every citizen within a democratic set up. Ujjain City of Madhya Pradesh is no exception to this.

In the Indian community, traditions are deeply rooted despite modern lifestyle. One such traditional practice is pilgrimage that almost all religions follow, in one form or the other. The ancient city of central India, Ujjain is situated in the Malwa region of Madhya Pradesh, on the eastern bank of river Kshipra. The religious importance of the town has made it one of the most prominent pilgrimage sites for Hindus with the divine presence of Mahakaleshwara Jyotirlinga and auspicious Mahakumbha mela that is held after every twelve years. With an annual pilgrimage volume of 75 million Ujjain needs a sustainable mobility plan for religious tourists.

For that purpose the study aims to explore the existing city transport network and propose sustainable, accessible and equitable movement strategies to enhance the living condition of the city.

2. BACKGROUND STUDY

Mobility forms one of the key functionalities in any urban area. Attempts to address mobility in Ujjain have been restricted to increasing capacity of existing roads (new flyover) and traffic management (one-way system). A holistic view to address the issue of mobility is lacking in the urban transport planning process in Ujjain. Ujjain has so far not formalized a comprehensive urban transport planning strategy, linked to an urban development strategy. What underlies the ensemble of actions, plans and proposals appears to be: negligent of pedestrians, non-motorized and local area travel; (lacking in engineering) supply-driven; overly accommodating to individual motor vehicles; severely lacking in provision & regulation of public transport services. This has led to a lack of comprehensive information on the issue of the different facets of mobility in the City.

To address the above mentioned issues, Ujjain Municipal Corporation took the initiative to formulate a Comprehensive Mobility Plan (CMP) for the city of Ujjain. Through this mobility plan, Ujjain Municipal Corporation and the supporting authorities aim to develop Ujjain as knowledge and pilgrim centre - maintaining its great religious, ancient and cultural image providing a better and sustainable environment & transport Infrastructure to all its citizens and visiting pilgrims.

Though the CMP proposed Traffic and Transportation plan for Ujjain, it's not linked with the environment and the health of the city. To fill the gap, this research proposed environment friendly transportation strategy, including enhancement of active mass public transit network and development of cycle routes.

3. STUDY AREA AND DATA USED

Ujjain city of Madhya Pradesh is selected as case study area because with more than 5000 years old history, Ujjain is one of the renowned Hindu places of pilgrimage in India (fig1A).

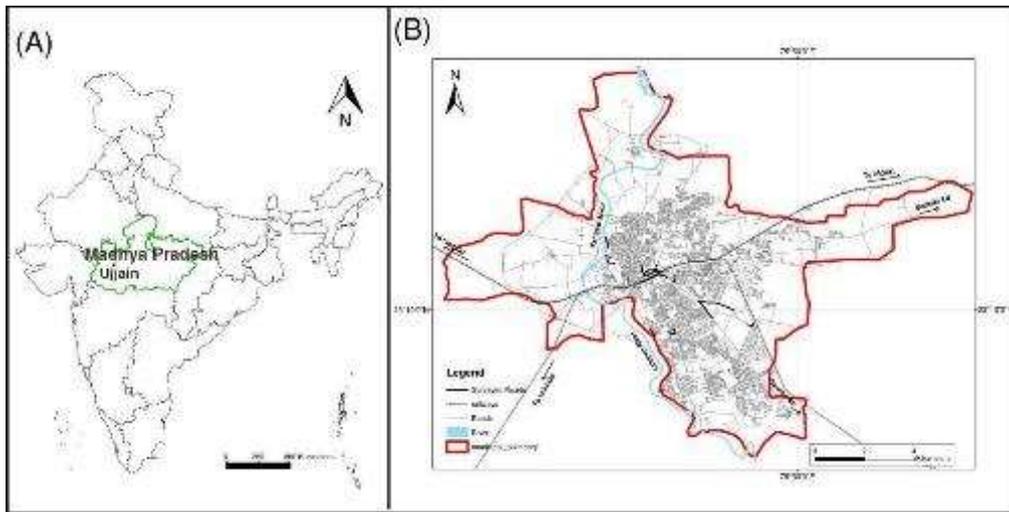

Figure 1: A. location of Ujjain city in India, B. Ujjain Municipal Boundary representing Ujjain city

For this study, data are collected through both primary and secondary sources. The road network of Ujjain City is digitized in the GIS platform. Information about modal choice, willingness to shift to bicycle for local travel was gathered through door to door survey.

4. METHODOLOGY

To propose sustainable, accessible and equitable movement strategies within Ujjain City, three steps were taken which are 1) Understanding existing city transport network, 2) To perform Travel Behaviour Assessment of Ujjain City residents, 3) City wide axial network analysis through Space Syntax.

4.1 Understanding existing city transport network

Information about existing city transport network was obtained through secondary data collection from concerned departments of Ujjain City. Table 1 summarizes the detail of the transport network of Ujjain City.

Table1: Existing City Transport Network

Total Municipal Area	102 sqkm
Total Road Length	883.80km
Public Transport Modes	Bus, Magic (ITP), Auto –rickshaw (three wheeler)
Total Bus within the City	36
Total no. of IPTs	7450

In Ujjain, the length of the road network is nearly 350 Km and there are maximum number of tar roads (86% of the total roads). Concrete road is almost 12% of total road. The per capita road length of Ujjain city comes out 0.81 meters.

4.2 To perform Travel Behaviour Assessment of Ujjain City residents

To perform Travel Behaviour Assessment of Ujjain City residents a detailed household level survey was conducted consisted of about 500 personal interviews within the delineated study area. The questionnaire format included components like modal choice, vehicle ownership and various other socio-economic detail that influences travel behavior. A willingness survey was also conducted along with the travel behavior questionnaire for deriving opinion regarding the preference to adopt bicycle as the major mode of transit within the city.

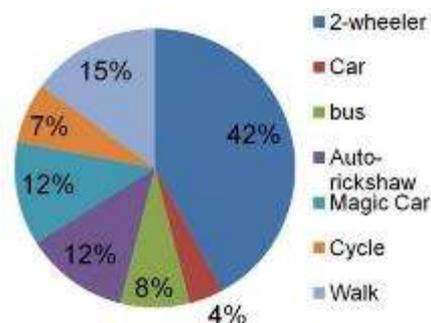

Figure2. Modal share of residents of Ujjain

The house hold data obtained from the primary survey exhibit that almost 22 percent of Ujjain traffic mix comprises of slow moving traffic among which 7 percent of people chose to cycle and 15 percent prefer walking over any other available mode of service. Hence a potential user group can be easily identified for the visionary goal of city health promotion through low carbon, equitable and accessible transport modes.

Figure 2 also shows that the majority of mobility demands are catered by two-wheelers especially among the higher income groups. The lower income population group uses magic and walk as their main mode of communication. The modal share of public transport within the city remains alarmingly low.

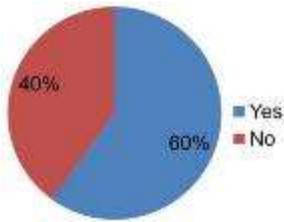

Figure3: willingness of people to accept bicycle as the major mode of travel

The household survey data in terms of acknowledging willingness of the urban residents summarized 60% positive inclination towards using cycle as an alternative modal choice over other motorized transport considering that supporting infrastructural needs are taken care of (fig.3). Also a large dominance of cycle users was identified for work related and education related trips. In addition to these, location that witnessed high slum population and chooses non-motorized systems for making their daily trips has the highest number cycle users.

4.3 City Wide Axial Network Analysis (Space Syntax)

Software based ‘Space Syntax’ is a technique which can help to analyze spatial layouts and network layouts in urban areas. Space Syntax makes us understand how people move, which the preferred routes are and how people adapt to city’s growth. Spatial form analysis is done by angular analysis. The method of angular analysis is applied on axial segment map. Analyzing axial map tells us the flow of movement in a given network. The most popular way to analyze an axial network is through Integration, Choice and Connectivity. In this research Space Syntax has been used to understand levels of ‘Choice’, ‘Integration’ and ‘connectivity’ of individual road stretches in the overall road layout pattern of Ujjain.

Choice measures movement flows through spaces. Spaces that record high global choice are located on the shortest paths from all origins to all destinations. Choice is a powerful measure at forecasting pedestrian and vehicular movement potentials. It literally shows how often a street happens to be on a shortest path between an origin and a destination.

Integration measures how many turns have to be made from a street segment to reach all other street segments using shortest paths. Integration is inversely related with depth. Depth tells how far away an element is from all the other elements.

Connectivity is a local property. It measures the number of nodes that are directly connected to a given node.

To perform Space Syntax analysis the road network of the Ujjain City is fed into depthmapX software. The software performed analysis and produced three separate maps for choice, integration and connectivity (fig.) in those maps, hotter colors (orange/red) represents higher values.

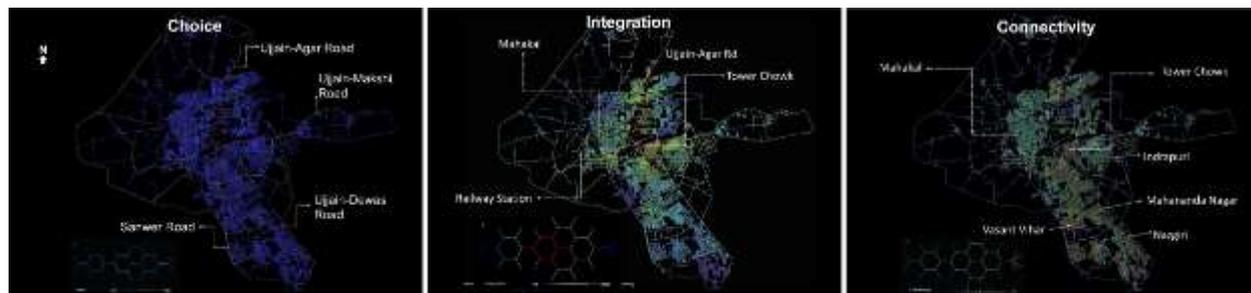

Figure 4. Maps showing results of Space Syntax Analysis.

According to choice analysis (fig.4), Ujjain-Agar road, Ujjain-Dewas road, Ujjain-Maksi road and the Sanwer road have the highest total values of accumulated flow resulting the highest choice values in Space Syntax. These roads also carry the highest through movement in Ujjain. According to “Integration” analysis (fig.4), Tower Chowk area, Mahakal temple area and the stretch along Ujjain Agar road up to the railway station are the most popular commercial and recreation areas in the city having nodes of highest integration levels. According to “Connectivity” analysis (fig.4), Vasant Vihar, Mahananda Nagar, Nazgiri and Indrapuri areas of the newer part of Ujjain have the most connected area. Because the newer part of Ujjain has planned road network, connectivity between roads is also high. From older part of Ujjain, Roads of Tower Chawk (fig.4) area show high connectivity.

Roads identified by space syntax analysis were further used to propose mass public transit network and development of bicycle routes.

5. DISCUSSION AND CONCLUSION

Detailed analysis of the city shows a greater opportunity to be evolved as a green, equitable, pedestrian friendly healthy city. Information gathered from detailed survey and space syntax analysis were used to formulate proposals related to bus and Magic services (Intermediate Para Transit or IPT).

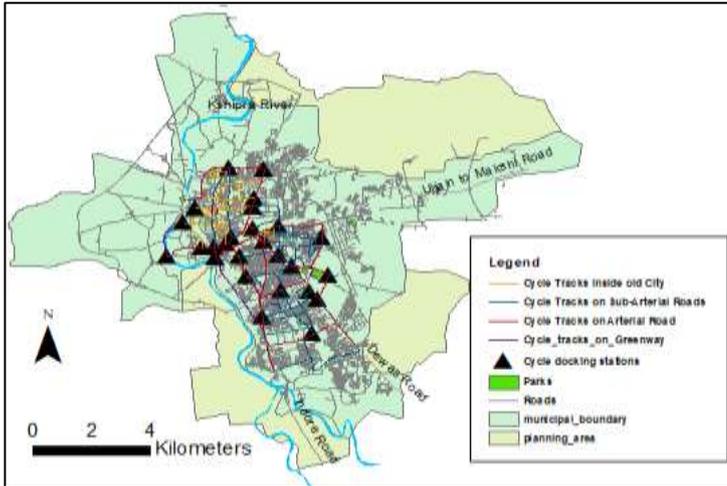

Figure 6. Proposed bicycle network

Table 2. Length of proposed bicycle routes

Proposed routes	lengths
Cycle tracks on Arterial roads	33km
Cycle tracks on Sub arterial roads	28.3km
Cycle tracks inside old city	15km
Cycle tracks on greenways	8km

The Proposed cycle route covers 10% of total road network promoting healthy city vision. Cycle docking stations are proposed in selected areas, according to the level of demand. The proposed docking system should accommodate automated locking systems with smart cards or QR codes. An automated system would ensure more security and would provide a better user experience. Twenty Five such Docking stations in Ujjain are placed near important origin and destinations, which includes heritage areas (Mahakal, Ram Ghat, Chakra Teerth ghat and Kothi palace) Commercial Areas (VK market, Freeganj, Tower Chowk) public transport hub (Ujjain railway station, Nanakheda Bus Stand) and residential areas. The uniqueness of these docking stations are that any user can lock their cycle using the smart cards.

To ensure user friendliness of the proposed cycle tracks and in order to maintain overall green cover of the city, high canopy trees like (Gulmohar, Neem, Maltus) will be planted along the major routes (fig.7).

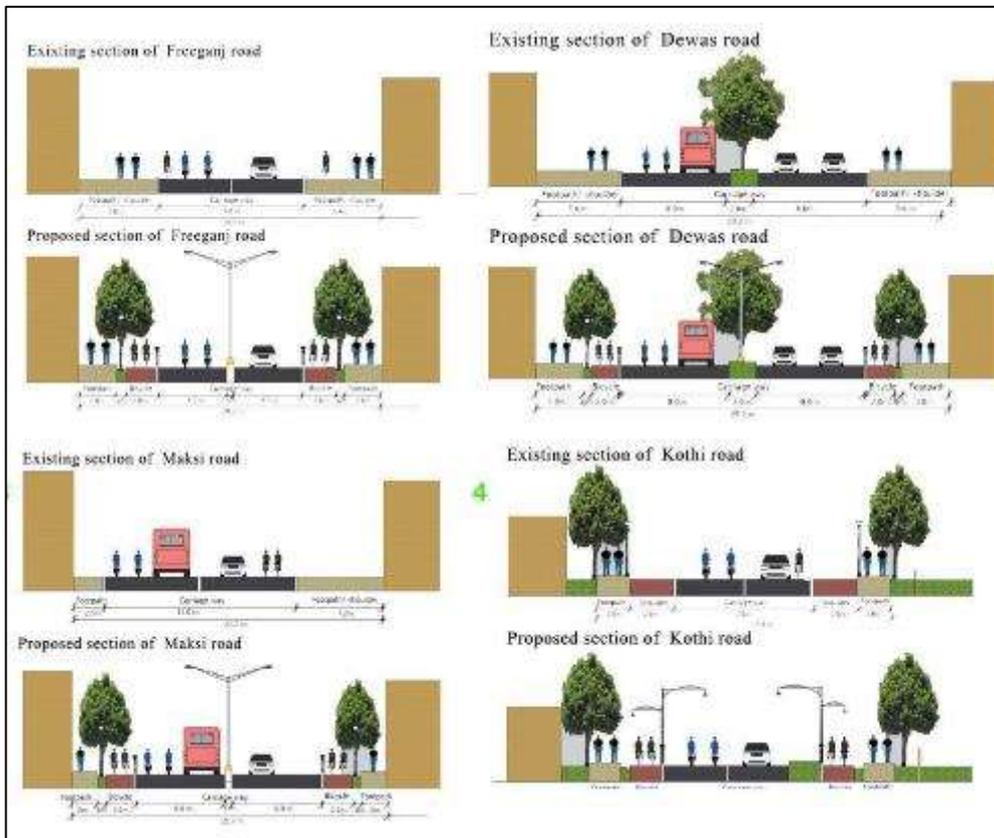

Figure 7. Proposed planned road cross sections

Since Ujjain is one of the identified cities for development as a Smart City under Smart City Mission launched by Government of India in 2015, substantial major urban investment in Ujjain City will happen through the Smart City

Mission (Smart City, 2015). As a result, the infrastructure proposed in this research for sustainable mobility may be implemented quickly and efficiently.

The proposed mobility plan would help local authorities to make Ujjain City more attractive to religious and other tourists ultimately increasing its revenue from tourism. Sustainable transport infrastructure will also improve the quality of life of the residents of the city. The proposed plan may be adopted by other such cities endowed with religious destinations.

ACKNOWLEDGEMENTS

The authors would like to thank and acknowledge all the students of Masters of Urban and Regional Planning Studio, SPA Bhopal for conducting the survey.

1257 A STUDY ON THE METROPOLITAN CITIES IN INDIA: PROCESSES, GROWTH AND INFRASTRUCTURAL FACILITIES

ABSTRACT

There has been a significant increase in the number of metropolitan (million plus) cities in India from one in 1901 to fifty three in 2011. The process of metropolitanization is a product of intense interaction between cities, and integration of the national economy and urban centres into a viable independent system (Ramachandran, 1989). The objectives of the study are: (i) to determine the various historical, economic, geographic, demographic, social, political factors that have played an extensive role in the metropolitanization of the cities, (ii) to analyze the status of infrastructural facilities in the metropolitan cities (iii) to capture the variation in growth, specifically the population growth and areal expansion of these cities. The study adopts a qualitative and quantitative measure to address the aforementioned objectives. The analysis has been made based on the data collected from The Census of India (District Census Handbook, All India Town Directory; H Series: Table on Houses, Household Amenities and Assets). A Composite Index has been developed to determine the urban infrastructural facilities (like the road density, banks, number of beds in the hospital, educational institutions, etc). Subsequently, the metropolitan cities were broadly categorized as high, medium and low level of urban infrastructural facilities. A descriptive statistical framework has been used to determine the variation in growth of the metropolitan cities. The analysis shows that there has been an incredible increase in the number of metropolitan cities from 23 in 1991 to 53 in 2011.

Historical factors have played an imperative role in the evolution of cities like Delhi, Kolkata, Varanasi, Madurai, Mumbai, Patna and Hyderabad. Additionally, in cities like Kanpur, Lucknow, Surat, Asansol, Dhanbad, Jamshedpur, Jabalpur, Kozhikode, Thrissur, Malappuram, Thiruvananthapuram, etc., economic factors played a vital role in its growth. Cities like Vasai-Virar, Meerut and Ghaziabad have grown under the ambit of the megacities of Mumbai and Delhi. Adoption of the development plan by Kerala has been one of the reasons for an increase in the number of metropolitan cities in the state. An observation on the status of the infrastructural facilities calls for its future development especially in the improvement of the road, industries, increase in the number of beds in the hospital, educational institutions, street lighting. Keywords: Metropolitan Cities, Composite Index, Urbanization, Infrastructural facilities.

1286 UNDERSTANDING THE PRESENT SOCIAL STATUS OF THE ANGLO-INDIAN COMMUNITY OF KOLKATA

Puja Banerjee

M.Sc., Presidency University 2014-2016, Ph.D Scholar, University of Mumbai -bannerjeeputa@gmail.com

ABSTRACT

The fusion of diverse cultures and races lead to a formation of unique socio-cultural community, of which Anglo-Indians are the best example. The Anglo-Indians are the mixed descendants of the cross-cultural union between Indian and British. The largest numbers of Anglo-Indians are found in different parts of Kolkata among all the cities of India, who still reflects their unique imprint of cultural traditions. But from Independence, the community started losing their grip in the multi-cultured society of the city. Though their presence can still be observed when one visit Bow Barrack and Park Street during Christmas or Halloween yet they are getting socially intermingled with other communities and thus are unable to retain their own specific identity with the help of unique cultural imprints, unlike the earlier days in Kolkata. This research paper has dealt with some Anglo-Indians from different parts of the city where they are considered as the dominant residents. The results from structured questionnaire surveys with open-ended questions as well as close-ended questions and in-depth interviews revealed that not only their numbers are diminishing but also in terms of social status the structure of the community has undergone modifications and changes, their occupational distinctness (the first generation of Anglo-Indians were mainly involved in jobs of railway departments) is eventually getting extinct and their indifference to retain their society through cultural and social activities result in the intermingling of the community to a great extent with the other communities residing in Kolkata. Further they were also asked to comment on their social status as a cultural group and it was found from the survey, where they were asked to ascertain a scale of their opinion in 1-5, the results reflects that in spite of their responsiveness of being a faint cultural group most of them are not that much involved in reclamation of their social entity and that is a very pertinent reason which in future will result in acculturation of Anglo-Indians and socially integrating themselves with other communities which will make their cultural imprints merely a history.

Keywords: Anglo-Indian, Cultural group, Social status, Acculturation, Bow Barrack, Kolkata

1. INTRODUCTION

The intermingling of diverse culture and racial background has often led to acculturation, of which Anglo-Indian is a perfect example. British in the hope of indigenous support encouraged the growth of the community of Anglo Indian, who was the mixed descendant of the cross-cultural union between Indian mother and European father ([Bhowmick 2009](#)). Anglo-Indian community gradually developed its distinct culture and unique lifestyle which were the blended version of both Indian and European traditions, but the prevalence of latter one is remarkable ([Procida 2002](#)). British were the dominant contributor to form such assimilated community rather than any other Europeans like Portuguese and French ([Debi and Nandan 2006](#)).

In the nineteenth century, Anglo-Indians numbering 100,000 represents a small minority group having a sound authoritative knowledge of Indian cultures and complete believe in British Raj ([Walsh 2006](#)). During the freedom movements in India, many Anglo-Indians were found to be with the British and thus, it resulted in a deep feeling of distrust among the then Indian people which in turn reduced the potential acceptance from the native country people in favor of them ([Masters 2012](#)). Most of the Anglo Indians had already left India during its independence in 1947 intending to settle down in UK, Australia, New Zealand and Canada. The exodus continued till late nineteenth century when most of the Anglo-Indians left the country and those who could not, still aspire to leave ([Anthony 1969](#); [Mills 1997](#)). They followed British customs and tradition and thought themselves as British. Melvyn Brown, known as the “chronicler of Anglo-Indian community” says that most Anglo-Indian who left for western shores were affluent enough but those who left behind could not afford to move. Since 1961 Anglo-Indians have not been counted separately in the census ([Caplan 2003](#)). Presently as per as the Indian constitution, Anglo-Indians forms the only minority group in the arena of the social, cultural and political level, with English as their mother tongue and are most urbanized in terms of residence. Though being a marginalized community, the socio-cultural uniqueness of the community has a noteworthy impact in India and in Kolkata as well, where they constitute the largest number of the population compared to the other place of residence.

The Anglo-Indian community after 1970 faced a challenging phase of their existence. The job reservations in certain public sectors like railways, post and telegraphs and customs for the community ceased to exist, the social survival situation becomes difficult (Dhavle, 2010 & Sen, 2014). The separation of the community from the mainstream society forces them in the formation of their own association, incorporated themselves into a new avenue of work and developments of the schools. The community lacks the solidarity and collaborative power which have created political backwardness for themselves which has impinged upon the educational backwardness as well, as exemplified in the study by Lobo in 1996. The Anglo-Indians soon after independence faced identity crisis and their social position and existence become endangered which has forced the community into endogamous marriage. The women who go out of this tradition and marry non-Anglo-Indian men are excluded from being a member of the community (Sen, 2014). This leads more to the decrement of the Anglo-Indians population also.

The paper specifically deals with the cultural and social aspect of Anglo-Indians of Kolkata city. It also attempts to find out the imprints of remarkable cultural aspects of the community and at the same time, the work analyses the social

entity and status of such cultural group in Kolkata city, especially in those places which are significantly characterized by their habitat and working environment. The work is very pertinent from the social dimension as in different studies of society it has been found that culture really matters in the society. The culture of a group helps to shape its social process and this is why culture is considered as work; and work itself is a social process ([Smith 2000](#)).

2. OBJECTIVES AND RESEARCH QUESTIONS

The objectives of the research work are:

1. To understand the remarkable cultural imprint of the Anglo-Indians in Kolkata

Research questions:

- What are the unique cultural traits they follow?
- How are they different from rest of the community in terms of housing, food style, eating habit and dress code?

2. To unveil the present social entity and status of the Anglo-Indian community.

Research questions:

- What is the present social crisis that the community is undergoing?
- How is the community overcoming the crisis?

3. METHODOLOGY

The research work is based on literature studies and primary survey via interviews and questionnaire survey. The work has undergone through reviews of literature which are available in different texts, libraries and some exclusive sources in Kolkata city, like National Library, Asiatic Society and Young Men Christian Association. The literature background analysis through bibliographic research, provide the base for the understanding of the cultural traits of the community. The Map has been prepared under the GIS environment which demonstrates the evolution of the habitat of Anglo-Indian in West Bengal and it is self-explanatory in the study of socio-cultural dimensions of a particular cultural group. The map is important in the socio-cultural evolutionary studies as it helps us to understand the spatial and temporal pattern of the community and its location along with tracing of its migration paths ([Calkins 2012](#); [Edelson 2012](#)). Primary data has been collected by conducting the survey which includes interviewing of Anglo-Indians in Kolkata, questionnaire survey with open-ended as well as option based questions. Such questionnaires have been framed on the basis of perception which is guided by the detailed literature studies about cultural and social aspects of Anglo-Indians. The sample size of seventy Anglo-Indian persons is considered keeping in mind the time constraints and research objectives and moreover, such sample has been chosen very carefully so that it can represent the whole community and different aspects under study. In addition, the respondents are chosen through snowball sampling as their population counting was stopped recorded in the census since 1961.

4. CULTURAL IMPRINTS OF ANGLO-INDIANS IN KOLKATA

Kolkata can be considered as the habitat of a considerably largest number of Anglo-Indians in the world ([Andrews 2014](#)). They have a lasting impact on the culture and tradition of Kolkata city and have developed their own cultural uniqueness. In all dimensions from distinct Churches like St. Andrew's, St. Mary's to vibrant educational institutes like St. Xavier's College, Assembly of God Church to typical cake shops like Flurys, Saldanhas bakery Anglo-Indians have a strong cultural imprint. Their clothing, foods, traditions, customs highly resemble their significant inclination towards the European culture ([Bönisch-Brednich and Trundle 2012](#)) and their reluctant nature to adopt Indian culture that lacks western essence ([Procida 2002](#)). Their cultural attributes such as following Christianity and western style and considering English as their mother tongue resulted in a cultural gap between them and other Indian cultures ([Gist and Wright 1973](#)). Thus, Anglo-Indians are considered as an amalgamation of two cultures and two races ([Padua 2005](#)).

4.1 Habitat imprints in the city

In the earlier times the city was divided into two main sections: "the Black Town" for natives and "the White Town" for the British administrators, businessmen and Anglo-Indians. The central Kolkata is largely influenced by British as reflected from its architecture than any other part of the city. This is the area where Anglo-Indians first made their home ([Andrews 2005](#)). They mainly avoided the wards that were dominated by the then Hindu population. Since the Anglo-Indians were the result of the mixed union between British and Hindu, they were denied of a recognizable status within Hindu caste system and thus were excluded from the Hindu society. But to the contrary, European community welcomed them wholeheartedly as the addition to their numbers ([Dover 1943](#); [Glorney 1935](#); [Stark 1987](#)). It was in the late eighteenth century when they got recognized as a separate cultural group ([Grimshaw 1959](#)) and by 1750 in Kolkata Fort Williams, St. Anne's church, freemason's society were built and the first theater was opened. After the Mutiny in 1857, the gap between Anglo-Indian and Indians became wider due to their assistance and support to British for controlling the transport and communication means ([Grimshaw 1959](#)). Later in the last decades of the nineteenth century, under the pressure of 'Indianization' the British started to seclude them and denied their preferential right ([Craddock 1930](#)). Thus, the social contact between the British and Anglo-Indian community started declining. Such decline caused a strong unity among the Anglo-Indian members and they started acting in a group as an exclusive community and ultimately acquired a cultural identity which is a blended version of both East and West. They started considering India as their Motherland and British as their Fatherland ([Blunt 2002](#); [Grimshaw 1959](#)).

Basically, the Anglo-Indians indigenously settled in small railway colonies (Figure 1) like Kharagpur, Santragachi and Asansol ([Roychowdhury 2000](#); [Schermerhorn 1975](#)). They were mostly engaged in the jobs offered by the then railway departments ([Cressey 1935](#)). Slowly the second generation of Anglo-Indian started moving towards Kolkata (Figure 2); mostly settling in areas around Elliot Road, Bow Barrack, Rippon Street, Park Street, the area between Circular Road and Chowringhee, Park Circus in their own mansions ([Sen and Goswami 1988](#)). But the scenario in case of the Bow Barrack (oldest building of central Kolkata) is completely different. The Anglo-Indians of Barracks are born and brought up in Kolkata. They at heart are Kolkatans. This has also been revealed from the interviews. Now Anglo- Indians are known for their typical big families. Later on, when India got independence, they had a choice either to leave or stay in India. Frank Anthony, their political leader and historian made a decision to stay on ([Anthony 1969](#)). Since then they have imbibed the Indian culture into their lifestyle.

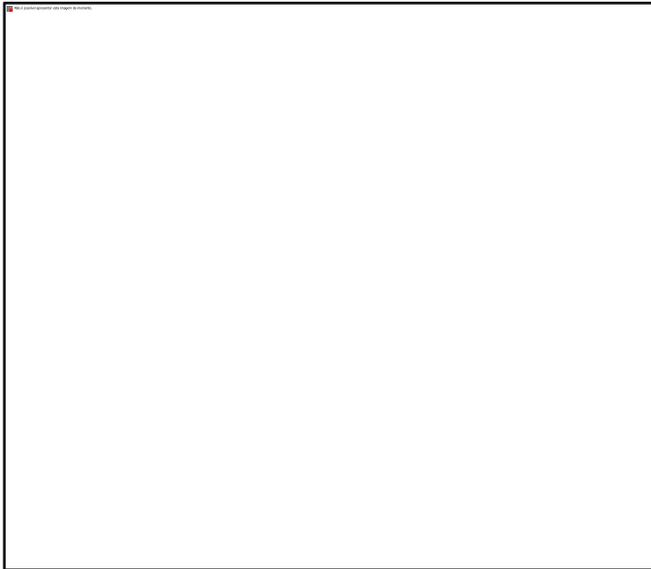

Figure 1. Railway Colonies of West Bengal from where the Anglo-Indians migrated to Kolkata

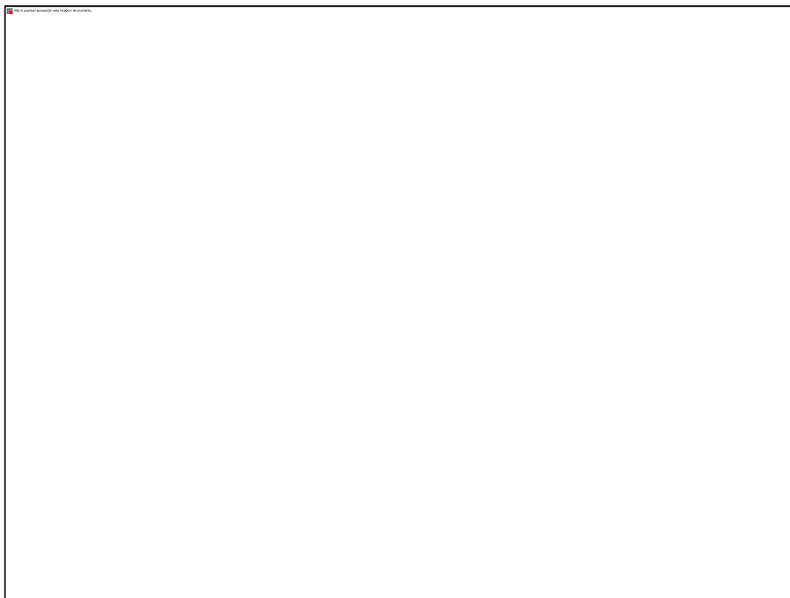

Figure 2. Places in Kolkata city where to the Anglo-Indians migrated

4.2 Anglo-Indian Associations

Anglo-Indians have formed an association known as All-India Anglo-Indian Association (AIAIA). It is the direct progeny of Eurasian and Anglo-Indian Association, founded in 1876 in Calcutta ([Moreno 1923](#)). The Association has over 62 branches in India. In Kolkata, the Anglo-Indians have developed the club culture where there are clubs like the Ranger Club, Grail Club, Calcutta Anglo Indian service society (CAISS), Dalhousie Institute and Anglo-Indian Catholic federation. In Bow Barack, they have formed their own Bow Barack Association where they take initiatives to organize special days for sports, Easters, New Year and Christmas (revealed through interviews). They get together mostly on Sundays and whenever they are free to have a drink or play some pool and party. Mostly the club members come together and celebrate the day by playing guitar and singing a country song. All together, they consider themselves as socially well-coordinated community and certainly love to have parties and also need lots of get-togethers which may be exemplified by the IXth International Anglo-Indian that was held in Kolkata from 6th to 12th January 2013 where the Anglo-Indians all over the world gathered at the same place.

4.3 Anglo-Indians' typical cultural imprint on Kolkata

Anglo-Indians' cultural identity in terms of their customs and traditions are more of the European type. They have adopted English as their mother tongue and attire as of western kind. Their family planning, house structure, housing furniture, lifestyle, food habits and accepting Christianity as their religion, associate them more with the Western culture rather than of East. They have put a little effort in understanding of other Indian cultures like Hinduism, Islam or any other else. They also have a faint knowledge about Indian mythological heroes, Indian's art, dance forms and literature than that of the British's form of society, western folk protagonist and literature. It is highly evident that the Anglo-Indian members of India belong mainly to two most powerful and conservative Christian sects ([Hedin 1934](#)). Most of the Anglo-Indians are Roman Catholic and so, in every church like St. Thomas in Middleton Row or St. Mary's in Rippon Street they can be mostly found, though one-third is Anglican and remaining are of Protestant faith ([Cressey 1935](#)). Anglo-Indians with Catholic and Protestant beliefs differ from each other in the services they do and prayer they perform. Protestants believe they can directly pray to Jesus instead of praying to the saints' intercession while the Catholics believe in the saints. Catholics have an Order of Mass while Protestants just have Sermons, Protestants have Pastors who can marry but Catholics have Priests and Nuns who completely devote their lives to Jesus. Anglo-Indians have a convention of visiting churches on every Sunday. Christ with the sacred heart is the common image that is present in almost every Anglo Indian's house in Kolkata. Apart from the holy images and idols, the altar and showcase are common too. Most of them don't know the reason but they believe that the altar and showcase have to be there. And this tradition is passed through every generation. The altar and the showcase are mainly present in the living room but those who have large mansion they have them in a separate room ([Andrews 2005](#)).

At a very scheduled time at 7.15 in every evening, the Roman Catholics of Bow Barracks recite the rosary at a grotto, built in 1999, against the wall separating two blocks of Barrack. Held once a year is the Feast day of Lady of Lourdes (title given to Blessed Virgin Mary) in Barrack which is the celebration of the anniversary of the grotto with a rosary, procession, supper, drink and merriment ([Andrews 2005](#)). Anglo-Indians are the culturally rich community with members having a sound knowledge about their customs and traditions. Anglo-Indian culture is completely different than that of the Converted Christian. They have a sense of superiority over the Converted Christian ([Caplan 2003](#)). Moreover, in Kolkata, the Anglo-Indian Christianity is the milieu of Hinduism. Thus it is termed as "Hindu Christianity". This is reflected through the change in the seating arrangements in the church that is made on the floor, use of agarbatti (incense sticks), garland and arti (prayer with candle), which enlighten the shift of expression or the assimilation of culture ([Robinson 2003](#)). The seating arrangements are made on the floor especially during a marriage.

Among the festivals celebrated by Anglo-Indians, Ash Wednesday marked as the beginning of the season of lent where they burn the Palms of the previous years' Sunday Palm for ash which is blessed. They considered ash as the symbol of the transience of life; it is from dust humans are created and to dust, they shall return. After forty days of lent which is the period of prayer, fasting and self- introspection they celebrate Maundy Thursday. Maundy Thursday is the ceremony of washing the feet and reciting the story of Jesus' last supper ([Bower 2003](#)). Maundy Thursday is followed by Good Friday, which commemorates the final hours of Jesus life which is in turn followed by the celebration of Easter, which is the resurrection of Jesus Christ, the old and most important Christian feast ([Trawicky 2009](#)). Christmas is their main festival of merriment when they celebrate the birth of Jesus. They have a tradition of making their own Christmas cake which is the distinct Anglo-Indian custom. Each family has a secret cake recipe, handed down by their grandmother. During Christmas Anglo-Indians as well as other community of Kolkata celebrate the day by eating cakes. They mostly buy cakes from Flurys, famous Anglo-Indian cake shop and others include Nahoums and Saldanhas Bakery. Nearly three weeks prior to the holy eve of Christmas every church like St. Paul's cathedral, St. Mary's, Auxillium, St. Anthony's , St. Thomas, St. Anne's including the whole Park Street and Bow Barracks get dressed with lights. And on the eve the whole Kolkata along with the people from neighboring districts gathered around Park Street, St. Paul's cathedral and other notable places to enjoy the Christmas celebration, which is celebrated with singing carols, bursting of crackers and all people wear Christmas caps. And the Anglo-Indians of Barracks donate and help the poor Anglo-Indians' as well as other communities' children on the Eve of Christmas. Next to Christmas, Baptism, first Holy Communion is celebrated by the community with a big bash. They consider Baptism as a bond which binds the community together. Marriages, engagements and birthdays are the other celebrations which they are heavily into.

Anglo Indians are highly gregarious and convivial community who love to feast. They are a connoisseur in eating and drinking and are crazily into sports and music lovers. Music, movies and socializing were high on their agenda. From jazz to tango; from swings, cabaret songs to Hollywood film songs, their styles in music are varied. Sheet music i.e. handwritten or printed form of musical notations was first organized out of Kolkata which was later available throughout most cities of India ([Shope 2004](#)). The famous jazz singer of Kolkata Pam Crain, on whose song the whole Park Street swings, is the Anglo Indian whose contribution is widely known. She is India's first and only jazz diva. She was the voice of the legendary Blue Fox in Calcutta. In 1971 Pam Crain, saxophonist Braz Gonsalves and Louis Banks together form a band known as "The Louis Banks Brotherhood". They began performing at the Hindustan Hotel which led to an invitation to play at the famous nightclub of the then Calcutta, The Blue Fox Restaurant ([Atkins 2003](#)). Among Anglo-Indian bands, Sonny Lobo's band and Don Saigal's band are the well-known bands of 1930s Calcutta. They love to dance. Jam attracts mostly the Anglo Indian teenagers while all other loved jive, jitterbug, foxtrot, waltz, swing dance which embellishes on the two-step pattern and frequently incorporates acrobatic style swing steps. Annual Christmas dance, wedding dance, regular club dance; they would find excuses for music and dance ([Brown 2010](#)). All the Anglo-Indians are crazily into sports. Leslie Claudius and Vece Paes are the recognized personnel who have made a huge contribution in the Indian Hockey; Jennifer Paes in volleyball and Leander Paes, the son of Vece Paes and Jennifer Paes, in lawn tennis are the Anglo-

Indians of Kolkata, nowadays here lies huge difference between the new generation Anglo-Indian and Kolkata's Anglo-Indian. Today Anglo-Indian refers them more towards India than towards Kolkata of which the best examples will be of Leander Paes and Derek O'Brien whose own excellences gave them the limelight in India.

4.4 Culinary imprint of Anglo-Indian community

Anglo-Indians have adopted a unique cuisine style which is a mixer of both East and West, combination of the European and Indian percent. The intermingling of the two cultures has resulted in an assimilated food recipes in the Anglo-Indian kitchen. They are non-vegetarians and thus have a strong affection towards the western dishes for meats and eggs and Indian dishes for rice, vegetables, curds, papads, pickles and chutney. Anglo-Indian cuisines have a great deal of innovation and variety in soups, entrees, side dishes, sauces, salads and desserts. They liberally use coconut, yogurt and almonds in their recipes with a tinge of Indian spices ([Brown 1998](#)). Of all the cuisines "mulligatawny" is the world-renowned soup, which is the anglicized version of the Tamil word for "pepper broth". Even though their food resembles the amalgamation of British and Indian, the Christmas dinner is uncompromisingly the British. For Christmas dinner, Anglo-Indian of Kolkata consume mostly chicken roast, pork vindaloo, mashed potatoes and spiced ribs and for lunch, pulao chicken curry is commonly preferred. And the dessert includes Palm cake, Apple pie and pudding. They normally consume yellow rice and ball curry which is actually pulao and kofta. Most of them cooked yellow rice and ball curry on Sundays. Other Anglo-Indian recipes include boiled eggs and capsicum curry; devilled beef mince balls, caramel custard, pork or lamb chops, chicken jalfrezi, kushka rice, pea's pulao and others. Anglo-Indians in Kolkata have opened their own cake shops known as Flurys and Saldanhas bakery which are famous for cakes and desserts. At the time of Christmas, the hotels and restaurants at Park Street mainly serve Anglo Indian cuisines. They are frequent visitors of Nahuoms and Trincas. Fairlawn is the only Anglo-Indian hotel in the heart of Kolkata established at 1783, stood on the junction of Madge Lane and Sudder Street. Six National awards were awarded to the Hotel by The Ministry of Tourism which contributed to the pride of the hotel itself and to the city, Kolkata. Famous actors like Sashi Kapoor and Jennifer Kendall have stayed in the hotel, whose pictures are still hanging on the wall of Fairlawn Hotel ([Bhattacharya 2014](#)).

4.5 Exclusive dress code

During pre-Independence, the apparel styles included organza, taffeta and fluffy skirts. It was till the 1970s when women wear only western attires- dresses, skirts and pan-suits and gowns; both at works and houses. Anglo-Indians have clothes for different occasions ([Vimala 2013](#)). Usually, twelve dresses they have in total besides four wrappers, which include two afternoon dresses, two plain white dresses, one cold weather wear, one ball dress, two dinner dresses, one waterproof dress, two evening dresses, one black silk, with two skirts and two bodices ([Anglo-Indian 1882](#)). But in recent times, to blend with others they wear salwar and kameez at work. Clothing for men includes long tailored trousers and open-necked business shirts ([Andrews 2005](#)). Even now during marriages, engagements and funerals they prefer to wear dresses and suits. Anglo-Indian women could be identified by the Holy Cross on a necklace they wore with any clothing. English is the mother tongue of all Anglo-Indians in Kolkata. The language which they use is quite unique. They have funny phrases like "Chutney Mary", for a girl who dresses up a lot; when aunties wear dresses and petticoat shows, they call it "Sunday is longer than Monday"; they call a girl "Wallflower" when she is without a partner at a dance.

4.6 Community imprint in educational sector

In the first half of nineteenth century in the urge to provide education to their children many educational institutes were established with the aid of influential men and societies La Martiniere College was established in 1836, St. Xavier's College in 1834 and the other institutions include St. Thomas, Calcutta Boys', St. Paul's' Mission School, St. Michael Anglo-Indian School, Frank Anthony Junior School, Pratt Memorial, Scottish Church, St. Bernabas' High School ([Kaminsky and Long 2011](#)). The Anglo-Indian organization in Kolkata by taking subscription fee from their members which varies from 15-45 rupees a month provides scholarship to students in every year. And they have an educational institution like Frank Anthony Public School which provides free education for Anglo-Indians. In fact the ICSE board (Indian Certificate of Secondary Examination) is an Anglo-Indian board for education. In fact in Kolkata during recent post Independent era for proper pronunciation and accent of English, the English Missionary Schools appointed Anglo "Miss". They have contributed a lot to the educational system of which mention could be made of Miss O'Connor, Mrs. Brackstar, Miss White and Miss Martindale who were the teachers of Loreto Day School, Sealdah. Other includes the principal of Calcutta Boys' Mr. Hicks and Prof. Pinto of St. Xavier's College ([Bhattacharya 2014](#)).

4.7 Typical occupational pattern

Anglo-Indians have never adopted the traditional joint family system of India. They are believer of equalitarianism of nuclear family. They never imposed any restrictions upon their women in fields of marriage, education and work unlike caste system in Hinduism, which they regard as undemocratic System ([Gist and Wright 1973](#)). In Kolkata, Anglo-Indian women play the dominant role in service sectors during the British Rule, as Hindu women due to their orthodox traditions and customs forbid them to work outside. During British Rule, in occupations like nursing, teaching and secretarial work, mostly the Anglo-Indian women were involved. Eventually, after Independence such involvement was replaced by Indian Christians as Indian Christians have fluency in local languages other than English whereas Anglo-Indians only have proficiency in English on as they were reluctant to learn other local languages. But slowly due to their command upon English they were appointed in number of office works likes airhostess, receptionist, sales personnel, nightclub entertainers, models. So unlike other Hindu women, Anglo-Indian women are independent, self-reliant, hard worker, who have the ability to support themselves and their family ([Schermerhorn 1975](#)). By virtue of the lifestyle, the Anglo-

Indian women were quite habituated in attending nightclubs, drinking liquors and the dresses they wore were considered indecent by the Indian women. Their free and liberated western style of living was considered cheap by other people (Lyons 2005). Very significantly in the present day situation, their lifestyle has a strong imprint upon the women of Kolkata for which they were neglected and considered indecent and cheap before.

The twentieth century was the modern period of Anglo-Indians when they were able to make a rapid progress in every direction. The availability of well standard educational institutes helps them to hold post in different departments of Government. Various Bills and Reforms of the Government like Morley-Minto Reform in 1909, the Montague- Chelmsford in 1919, and the Indian Bill in 1935 recognized Anglo-Indian as a minority group and provided separate electorate for them, where two seats were reserved for them in Lok Sabha. In Kolkata also one seat is reserved for them in the Vidhan Sabha (legislative assembly) (Gangopadhyay 2012).

5. PRESENT CRISIS OF UNIQUENESS IN THE COMMUNITY

The primary survey exemplifies the changing character of the three hundred years old community. The structure of the community has undergone modifications and changes not only in terms of number but also in terms of the social entity.

5.1 Change in habitat distinctness

It is evident that groups of the Anglo-Indian population who are living in the Bow Barrack area are original habitants of Kolkata city and other groups who have migrated into the city are living in some other specific places like Rippon Street, Park Street, Picnic Garden and Behala (Figure 2). Still now, internal migration within the Kolkata city is taking place. The Anglo-Indians from Bow Barracks, Rippon and Park Street are migrating to Picnic Garden and Behala (Andrews 2005). The reasons of migration when asked, they replied in favor of wider place, less congested area. Few among most of the Anglo-Indians of Barracks are still willing to migrate to the other parts of the city. In the context of migration from India, most of the Anglo-Indian surveyed are aspire to go and settle down abroad if they would get chance in the future. Though they the love city and the place they live yet they have the desire to move to places outside India specifically to European, American and Australian countries. But however, their wish to migrate is more imaginative than physical (Gangopadhyay 2012). As revealed from the survey, the Anglo-Indians staying in Kolkata have social communication, links and network with the Anglo-Indian staying in abroad. This is the reason for keeping the flame of desire alive to migrate out (Kandel and Massey 2002).

5.2 Changing occupational uniqueness

Changes have taken place in the family occupation of the individual household when it is compared with the present generation occupation. A Negative correlation (-0.09) exists between the past and present occupational pattern (Table 1). The present generation is not motivated enough to stick with the occupation in which their predecessors were engaged. This highlights the transformation and change in the occupational pattern of the household which in turn reflects the unwillingness to carry on the traditionally typical Anglo-Indian occupations by the present generation. Thus the occupational distinctness is also getting extinct eventually which is quite inevitable.

Table 1. Correlation matrix for family occupation history and present occupation trend

	Family Occupation history	Present Occupation trend
Family Occupation history	1	
Present Occupation trend	-0.097590007	1

5.3 Change in ancestral exclusiveness

In context to the relationship with other community members as revealed from the survey throw light on the fact that they are very sociable and friendly. They have got assimilated with different other communities of Kolkata. In fact, in Bow Barracks they exist side by side with other communities like Muslims, Bengalis, Chinese and Goans. When asked about the relationship and whether they face any discrimination in the city of Kolkata, their reply was like – “No, we work with them, celebrate with them and stay with them within the same compound”, but another aspect has also come out of the survey that within the community there is a little bit of lack of co-operation, mainly among the high and low class Anglo-Indian people. This difference is subdued within their mental set up and generally is not reflected outwardly. The customs, traditions and rituals of this community are the essence of binding the whole community together, otherwise, the sense of commonness and feeling of togetherness would have been lacking among the Anglo-Indians (Cressey 1935).

As far as the inter-community marriage is concerned it is found that once believing in extreme endogamy this community in the present day is characterized by some exogamous marriage practices. It generally leads to acculturation at the cost of exclusive and conspicuous cultural traits. Therefore, the Anglo-Indians who are accepting the exogamy practices are basically accelerating the process of acculturation. The community encourages its people not to accept the exogamy. The analysis of primary data represents that the correlation between ‘intercommunity marriage’ and ‘financial assistance from Associations’ (Table 2) is a little bit positive (0.22) there is a relationship between these two components. It is because of the fact that the persons, who have done inter-community marriage, are not getting financial incentives provided by the Anglo-Indian Associations, even the children of those parents do not get any scholarship for their study. Inter-community marriage is the only eligibility criteria to avail the financial support from such Associations. This is why the community people are encouraged to get married not only with the Christians but also within their community to keep their cultural entity intact in the form of a typical social group.

Table 2. Correlation matrix for inter-community marriage and financial assistance from Associations

	Inter-community marriage	Financial assistance from Associations
Inter-community marriage	1	
Financial assistance from Associations	0.224345482	1

5.4 Inactiveness in reclamation of entity

Positive correlation between awareness of Anglo-Indian about social entity and ‘feeling of getting socially faint’ is coming out with a value of 0.25 (Table 3). A five point scale has been effectively used during the survey to assess the awareness of the Anglo-Indian about their social entity (Table 4). The result represents that about 87% respondents (considering point 4 and 5) are well aware of the gradual faintness of their entity in society, but when they were asked about their involvement in the social activities to revive and to improve their social status, the replies mostly represent their inactiveness. That is why a negative correlation is found (-0.12) between awareness of Anglo-Indian about their social entity and ‘activity to reclaim social status’ (Table 3) which means there is no link between awareness and activeness. The turmoil of association between their fatherland (Europe) and motherland (India) created a dichotomy in their mind; physically they are in their motherland but their mind wants to be in their fatherland. This duality resulted in the loss of their identity ([Gangopadhyay 2012](#)). The value of 0.15 in the correlation matrix (Table 3) between ‘Anglo-Indian Associations involved in’ and ‘aware of their social entity’ depicts that few of the Anglo-Indians are attached with some Anglo-Indian Associations because of their strong feelings of keeping their society intact. A moderately strong correlation (0.42) has been found (Table 3) among the two components viz. ‘performing cultural activity to reclaim the society’ and ‘activity to reclaim social status’. The value is indicating the fact that those Anglo-Indians who are involved in reclaiming the community entity in the society have focused on reviving the cultural aspects of the community. The associations are trying to bring back their former social entity into the present era of cultural assimilation and acculturation.

Table 3. Correlation matrix showing relationships between awareness and activeness of Anglo-Indians

	Aware of their social entity	Activity to reclaim social status	Feeling of getting socially faint	Anglo-Indian Associations involved in	Performing cultural activity to reclaim society
Aware of their social entity	1				
Activity to reclaim social status	-0.126523004	1			
Feeling of getting socially faint	0.25361705	-0.137620471	1		
Anglo-Indian Associations involved in	0.150750041	-0.578444773	-0.029368607	1	
Performing cultural activity to reclaim society	-0.378991874	0.429772247	-0.032530002	-0.2766475	1

Table 4. Individual's community awareness in 5 point scale

Points	No. of respondents	% of respondents
1 (No idea)	1	1.42857143
2 (Not aware)	0	0
3 (Neutral)	8	11.4285714
4 (Aware to some extent)	16	22.8571429
5 (Fully aware)	45	64.2857143

This glimpse of getting socially pale and their unwillingness to retain their society through cultural and social activity results in the break in their cultural solidarity. They lack strong leadership who may amalgamate the whole community into one. This leads to the cessation of the autochthonous Anglo-Indian institutions. Social work is mainly done by the Anglo-Indians of the outside country, they on an annual basis send fund to the Institutions in the hope of keeping the community alive as a unique social group ([Cressey 1935](#)).

CONCLUSION

This study of Anglo-Indian community is done to assess their strong cultural imprint and eventual faint social entity in Kolkata city. The study reveals that culturally, the community has a distinct and unique position in Kolkata city since its inception. The celebration of Christmas, the birth of Jesus is as grandeur as the celebration of Durga Puja (worship of Goddess Durga) of Bengali community which is a dominant one in the city. The Christmas without Anglo-Indian would not have been so lively. The Park Street Cemetery and St. Paul’s Cathedral occupy important historical positions in Kolkata. These places are being promoted as the tourist destinations as large number of people are visiting regularly. The present day Kolkata is significantly experiencing the Anglo-Indian imprints in different dimensions of the city life like dress codes, cakes and educational institutions.

In spite of holding a strong cultural position, this community is at the verge of getting faint. The population of Anglo-Indian, which was estimated to be the largest in Kolkata, is presently decreasing day by day. People are migrating out from the city to other countries to settle down permanently. Thus is rightly termed by Caplan ([1995](#)) as “culture of

"emigration" visualizing the stream of out flow of Anglo-Indians from India. The Primary Survey discloses the fact that the community is well aware of their faint social entity, but the magnitude of socio-cultural activities to reclaim that by them is not significant. The Associations to some extent are trying to revive their social entity. A small percentage of people who are associated with the society are involved in cultural activities to rekindle their social existence. Though they have feeling social faintness yet their unwillingness to retain their social status will slowly result into the break in their cultural flow.

The decreasing number of people, weak social entity and gaining more importance of western culture will lead to their migration outside Kolkata as well as India. Andrew (2008) has thrown some light on the situation that though the Anglo-Indian political leaders are trying to persuade these people to stay in India they are willing to migrate out because of their strong belief that they will get more social benefits outside India. There is an increasing trend of inter-community marriage and their awareness of becoming socially faint have created little or no stir in the society which points out the fact that as a whole the community is not that much interested to carry on their cultural distinctness with faint social status and thus in the span of time the community will disappear from the heart of Kolkata. Younger (1987) thus has significantly stated –

"After twenty or thirty years, one will not hear of an Anglo-Indian as such. The few that are left in India will marry Indians and become Indians. The Community that was born 300 years ago will eventually disintegrate"

1411 INDIA'S URBAN GROWTH WITH SOCIO-DEMOGRAPHIC ASPECTS ON GENDER SCANNER

IIT Bombay

**India's Urban Growth With Socio-demographic Aspects
On Gender Scanner**

Rathin Biswas, Naveen Krishna & Kamlesh Kumar

Centre for Urban Science and
Engineering
Indian Institute of Technology Bombay

RSAI 2018, GOA
Abstract ID: 01411

MOTIVATION

- Population is the primary component for any urban expansion. So demographic analysis can help us to prepare for societal issue.
- Demographics insights may help in planning and development

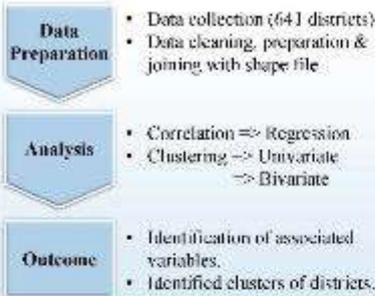

GOAL

- To find out the nexus among socio-demographic variables in India mostly on gender-point of view.

OBJECTIVES

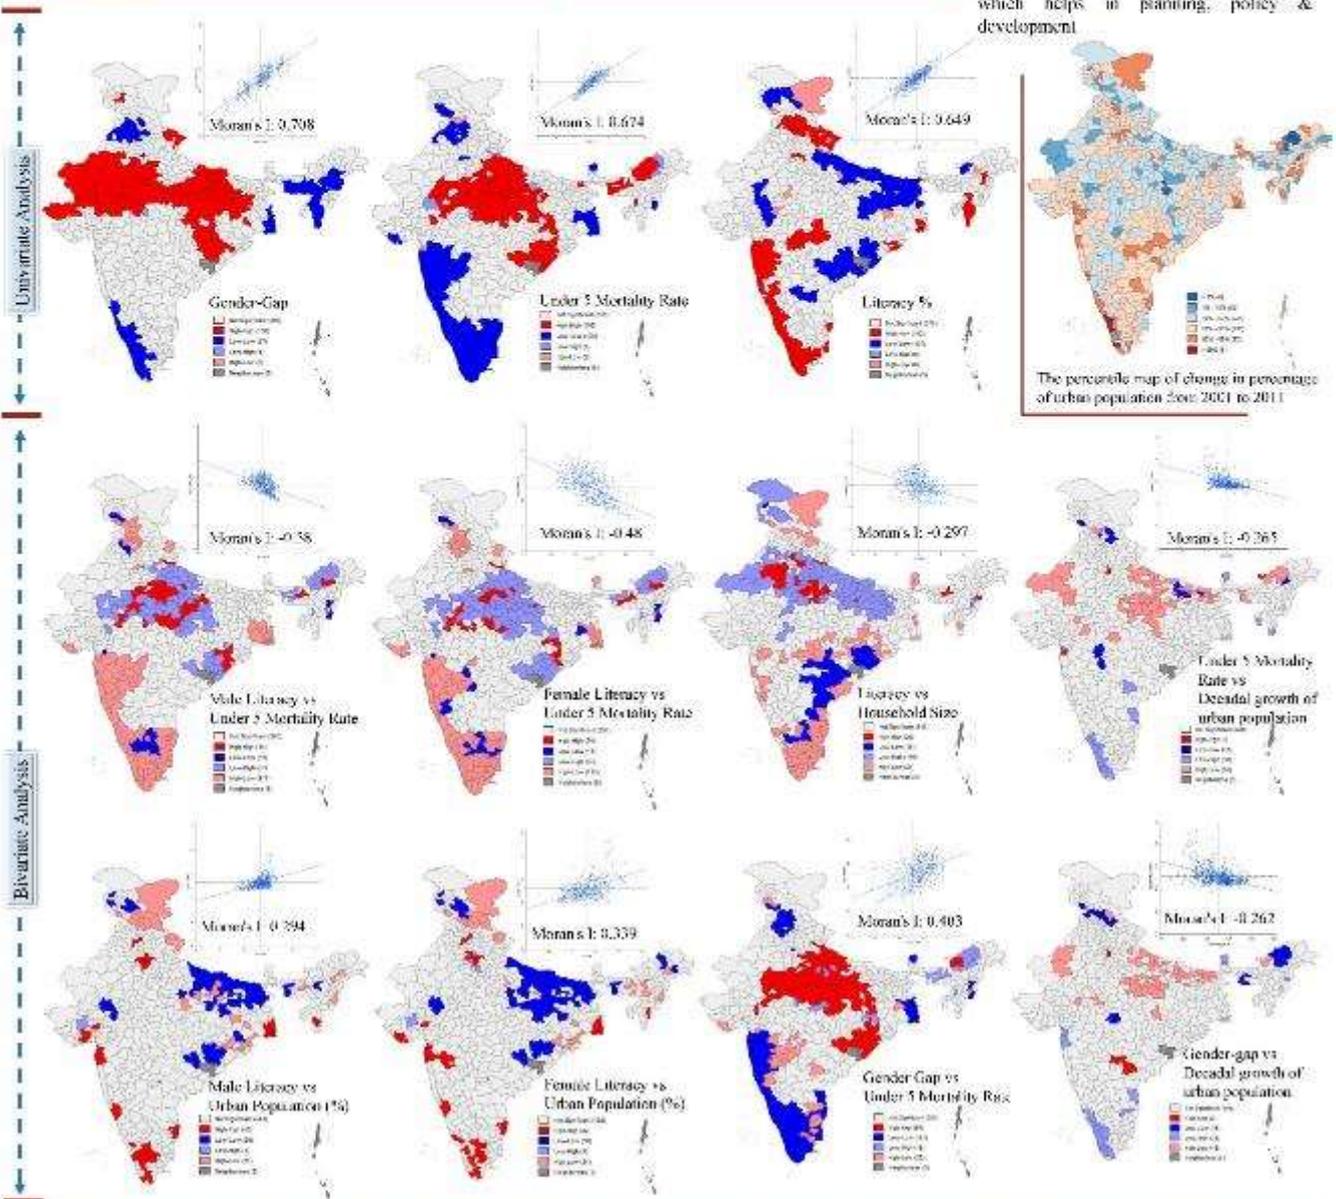

- To find out the correlated variables with Urban population growth
- To identify the clusters of districts for associated socio-demographic concerns (Under 5 Mortality Rate, Gender Gap, Literacy, etc.)

APPROACH

OUTCOMES

- Literacy-Percentage, Infant-Death, and Gender-Gap, are strongly associated with decadal growth of urban population [R^2 (0.551140), Adjusted R^2 (0.547317), Multi-Collinearity Number (10.832944)]
- High Gender-Gap with high Under-5-Mortality-Rate, are clustered mostly in Rajasthan, Uttar Pradesh, Madhya Pradesh & Chhattisgarh.
- As compared to "Male-Literacy", "Female-Literacy" has strong negative association with "Under-5-Mortality-Rate".
- This analysis shows which districts need to improve in certain demographic profiles, which helps in planning, policy & development

At C-USE, We combine science and technology with sustainable, equitable and human-friendly design to deliver innovative and holistic services to improve the life of the rapidly urbanizing population in the developing world

1528 ALLOTING LAND FOR PUBLIC PROJECTS USING LAND-USE SUITABILITY MATRIX: CASE STUDY OF MULTI-MODAL LOGISTICS HUB PROJECT IN THE CITY OF ROURKELA

ABSTRACT

Complex decisions in land use planning include the feasibility of a portion of land to tolerate the allocated activities in a sustainable way. Objective of this study is to forecast the land-use suitability of all vacant, reclaimed and waste land parcels in the administrative area of Rourkela city. This required devising a simple analytical relationship between the land-use suitability and land use influencing factors, like terrain, landscape, land price, residential density, accessibility (to CBD, major roads), existing infrastructure (water supply, drain age, sewerage, solid waste management, public utilities and functions). This allows quantification of spatial units of land available for development, in strategic order of priority. Once analytical relationship factors are established, this matrix can be upgraded as a decision-making tool for strategic allocation of infrastructure and other services. Results from this matrix in our study also show overlaps of different land-use suitability in same land parcels. Prioritization of the development order is done by incorporating public opinion, thereby making the planning process inclusive. This analytical relationship matrix is then used to allocate space for a much-required logistics hub. This strategic model functions as a tool for land-use planning and setting development control and guidelines.

GRADUATE SCHOOL OF POLICY SCIENCE
RITSUMEIKAN UNIVERSITY

ACKNOWLEDGMENT

This activity of the research was conducted during author's master degree study (2013/2014) in Institute Technology of Bandung (ITS) under supervision of Dr. Sri Pujiatni Sitjupriatni and Ritsumeikan University under supervision of Prof. Soekoto Doko, which was funded by the Center for Process Development, Creation and Training (Pusat Penelitian, Pembinaan dan Pelatihan/P3P) Ritsumeikan University, the National Sustainable Planning Agency (Badan Perencanaan Pembangunan Nasional) Republik of Indonesia, Etnopluri (Etnopluri Forests Initiative), Development Project II (EPIP II), Green Leaf and an access to ITS online journal website.

BACKGROUND

- CBFM with a land sharing and simple coffee cultivation scheme (CBFM Coffee) has been implemented in Simpang Village, Garut Regency, Indonesia since year 2001 and takes place of several plots of protection forest (Hutan Lindung) under Peraturan KPM Garut (please refer to Figure 1). This scheme re-enables the community to utilize forest land through coffee cultivation and helps Perhutani to reforest their area since the community should also participate in rehabilitating the forest. Thus, it is predicted that more sustainable uses of forest resources as well as more improved livelihood of the community will be obtained [5].
- Community-based Forest Management (CBFM) or Pengelolaan Hutan Bersama Masyarakat (PHBM) is shown as:
 - forest-based poverty alleviation strategy in Indonesia, especially in Java Island [1].
 - solution to solve deforestation, illegal logging and agricultural invasion to forest, particularly after the Reformation Era [1].
 - forest conflict resolution since it was implemented to reduce conflicts between forest manager and surrounding forest farmers that happened due to the shift of forest status from production forest (Hutan Produksi) to protection forest [5].
- However, after years of implementation, CBFM Coffee in Simpang Village is sought fail to reforest the protection forest either to deliver economic benefits for the adjacent community.
 - deforestation has been worse,
 - surrounding villagers keep continuing their vegetable farming on their CBFM Coffee area,
 - community (forest farmers) remain categorized as poor households.
- From the environmental perspective, this has been a growing concern, especially after a devastating flood in urban area of Garut year 2016.
 - Agricultural activities done on the CBFM plots that should be planted by coffee, lead to more expensive forest clearing which are assumed as the cause of erosion and landslides in the upstream area.
- Simpang Village is located at the upstream of Cimanuk Watershed, one of prioritized critical watershed in Indonesia, especially in West Java Province [6] has a significant role as catchment area. However, this village is also potential for its vegetable production.
- Based on a SWAT analysis in 2014, conducted by BRDAS Cimanuk, Simpang is part of the sub-basin areas identified delivers highest proportion of sediments to Cimanuk [2].

OBJECTIVES

- To evaluate implementation of CBFM Coffee in Simpang Village, with focus on:
 - rationales of the shift continue vegetable farming or protection from economic perspectives through analyzing the profit earned from either coffee or vegetable farming
 - contribution of income from coffee to the annual household expenditure of the forest farmer.
- To define problems have been encountered during CBFM Coffee implementation to then follow up with several policy recommendation.

RESEARCH QUESTIONS

- From the community perspective, what are the economic rationales on keep continuing vegetable farming activity on forest land after implementing CBFM Coffee?
 - How coming from coffee differs from that of vegetable farming?
 - How income from coffee covers farmer's household expenditure?
- How CBFM Coffee been carried out in Simpang Village? What has been the problems of CBFM Coffee's implementation?

HYPOTHESES

- Income from coffee is noticeably lower than from vegetable farming.
- Income generated from CBFM is not sufficient to sustain farmer's living because it could not cover the main household expenditures of farmers.
- There are some issues has been faced on the management of CBFM Coffee.

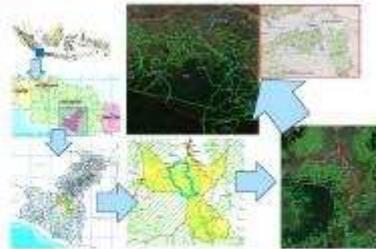

Figure 1. Area of CBFM Coffee in Simpang Village, Garut Regency, Indonesia

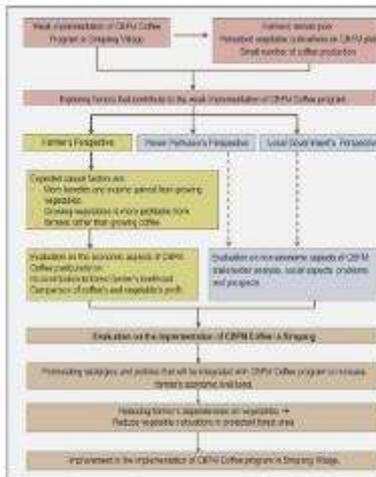

Figure 2. Conceptual Framework
Source: Author, 2014

METHODOLOGY

To present a comprehensive evaluation about the implementation of CBFM Coffee, both quantitative and qualitative approach are utilized in this study.

- **Quantitative analysis:** to analyze the economic rationales as farmer's income, expenditure and profit of both coffee and vegetable cultivation. (105 respondents from four forest farmer groups namely Ciba-Laksono, Giri Wana Lestari, Sumber Rezeki and Mulya Tani)
- **Qualitative approach:** to analyze the problems faced in the implementation of CBFM Coffee.

FINDINGS AND DISCUSSION

Source: Author, 2014

Table 2. Problems and Prospects of CBFM Coffee

Problems	Prospects
Limited skills and knowledge on coffee cultivation	Lack conflict between Perhutani as the forest manager with the forest adjacent community
Fluctuated price of coffee in local market	Increasing demand of coffee in local, national and global market
Problems with wild fires and crop collection (High dependency for farming inputs, high input/output)	Provisional government to support coffee farmers construction, coffee processing machinery support.
Vegetable farming as local culture. Use unconsolidated of related inputs/inputs	Successful stories of CBFM Coffee implementation at neighboring villages → motivate to improve coffee cultivation → better quality → higher price of coffee.
Low support and assistance from Perhutani to community	Weak coordination between Perhutani with other stakeholders, especially local (regency level) government.
Landlessness of adjacent community	

Source: Interview with Perhutani and Local Government of Garut Regency 2014

POLICY RECOMMENDATION

- Deliver more financial supports to improve coffee farming, so that farmers will confident enough to continue and increase their participation on CBFM Coffee
- Encourage more dialogue and communication between Perhutani and community as well as with other related stakeholders, especially local government [6].
- More economic attractive policies combined with CBFM Coffee, that will bring higher returns from coffee.
- Assigning certain parts of protection forest to fully utilize by the community for farming activity, that within this zone, community is allowed to conduct any farming activities even vegetable farming with as long as conservation principles are still be held.

1105 GRADUATE MIGRATION IN GERMANY - NEW EVIDENCE FROM AN EVENT HISTORY ANALYSIS

ABSTRACT

Human capital is a key determinant of regional development and universities are supposed to play a crucial role for human capital accumulation in regions (Gennaioli et al. 2013). However, graduates of local universities will only increase the human capital endowment if they stay in the university region and especially for smaller regions out- migration of graduates might be an issue. Therefore, understanding the migration decision of graduates is of particular importance for less developed regions with institutions of higher education (Haapanen

1131 WHY DO WOMEN EARN MORE THAN MEN IN SOME REGIONS?

ABSTRACT

It is a stylized fact that women earn less than men in Germany. Viewed from a regional perspective, however, large disparities in the gender pay gap (GPG) appear. Whereas women earn 60 percent less than men in some regions in Germany, their wages outweigh male wages by up to 16 percent in other regions. So far, the reasons for these regional differences and especially the question which role regional characteristics play in comparison to individual and job-related factors have not been fully resolved. Therefore, the aim of this paper is to shed light on the determinants that drive the regional differences in the GPG. Besides providing detailed descriptive evidence for the NUTS 3-regions, we quantify the impact of regional, individual and job-related factors. Our analysis rests on a comprehensive data set that encompasses all German employees liable to social security contributions in the year 2015. We combine the commonly used Blinder-Oaxaca decomposition with quantile regressions. This method allows us to decompose the GPG into an explained part related to differences in observed characteristics and another part related to differences in returns to these characteristics along the entire distribution of the GPG. First decomposition results hint towards a dominant role of individual and establishment factors. Their explanatory impact differs across quintiles, emphasizing personal endowments and the regional economic structure as important forces driving regional differences in the GPG. Results for the regions with a very large GPG highlight the prominent role of the local sectoral and plant size structure in providing well-paid jobs especially for men.

1191 EFFECTS OF RESIDENTIAL MOBILITY AND MIGRATION ON STANDARDS OF LIVING IN DAR ES SALAAM, TANZANIA: A SEQUENCE ANALYSIS OF RESIDENTIAL HISTORY DATA

ABSTRACT

Intra-urban residential mobility and rural-to-urban migration could play an important role in improving standards of living for urban poor. This paper investigates the effects of both intra-urban residential mobility and rural-to-urban migration on standards of living for poor households in Dar es Salaam, Tanzania. We particularly examine the complete residential history of households using a representative sample of 2397 households. We measure various levels of five housing conditions, namely, access to water, access to sanitation, access to permanent structure, security of tenure, and sufficient living space, and use sequence analysis to find similarities and dissimilarities in evolution of households’ living conditions. We then use cluster analysis to establish patterns of pathways to improved housing conditions for each of the five housing elements described above. We then study how these patterns relate to household’s migration to the city and residential mobility within the city. We analyze and identify positive impacts that residential mobility have on housing conditions. The main objective of this study is to demonstrate how migration and residential mobility could work for improving living conditions for urban poor.

ABSTRACT

We examine how changes in house prices affect when eligible individuals start receiving Social Security Retirement Income (SSRI). Since changes in house prices and receipt of SSRI are likely to be correlated with unobservables, we employ an instrumental variables strategy using the land supply elasticity of an MSA interacted with changes in the national house price index as an instrument. We find that the elderly delay SSRI claiming when house prices increase during a boom period, but not during a bust. Our findings highlight that the cashing-out of home equity can be used to finance expenditures to delay SSRI receipt.

Key words: Social Security Retirement Income (SSRI); housing wealth shock; land supply elasticity

1. INTRODUCTION

It is widely recognized that the United States, like many other countries, is moving into an aged society. The proportion of individuals over the age of 65 in the U.S. rose from 8 percent in 1950 to 13 percent in 2010 and is expected to rise to over 20 percent by 2030 as the Baby Boomer generation ages (Lee, 2014). The rapid increase in the share of the elderly population is something policy makers are cognizant of, as it raises concerns about the financial readiness of the retirement system at all levels of government. Therefore, it is important to understand how elderly households draw upon different assets to finance retirement. Among the various financial assets of the elderly, Social Security Retirement Income (SSRI) and home equity are typically the two largest components of their balance sheet, especially for low-income households (Poterba, 2014). While many researchers have examined the role of Social Security in financing retirement,¹ little research thus far has considered the role of home equity, and, in particular, the extent to which it may substitute for SSRI in financing retirement expenses. Given the importance of home equity for the elderly and the recent fluctuations in house prices, studying how the elderly utilize this asset has become increasingly important.²

This paper examines how changes in house prices affect when elderly individuals decide to start receiving SSRI. We focus on the timing of receiving SSRI because once the Average Indexed Monthly Earnings (AIME)³ has been determined based on previous earnings, the amount received depends on when an individual starts claiming the benefits. Specifically, an elderly individual who starts receiving SSRI as soon as he or she is eligible will face a reduced monthly benefit versus if receipt is delayed.⁴ The reduced benefit amount is usually substantial and permanent.⁵ We examine the trade-off between home equity and SSRI, as elderly individuals may choose to draw upon their home equity when the value of their house increases in order to delay receiving SSRI benefits and avoid the reduction in monthly benefits. Studying this issue will allow us to gain a better understanding of the substitutability of these two assets as a source of income for the aged population.

When considering the interactions between housing wealth and the decision to receive SSRI, there are likely to be endogeneity issues present. First, house prices may respond inversely to SSRI receipt as homeowners may engage in more home maintenance and renovation efforts with the additional income. Second, there may be unobserved local demand shocks that are correlated with both changes in house prices and when an elderly individual decides to receive SSRI. For example, unobserved positive local demand shocks may contribute to higher house prices and, at the same time, overall price inflation in the area, which would increase the likelihood of receiving SSRI benefits early. Alternatively, if house prices decline in an area, it is likely that the local economy is also experiencing a negative demand shock in the labor market, which may cause individuals to claim SSRI earlier. Therefore, the failure to directly control for unobserved

1 For example, see Hurd and Boskin (1984), Burtless (1986), Gruber and Wise (1998), Samwick (1998), Gustman and Steinmeier (2005), Van der Klaauw and Wolpin (2008), Liebman, Luttmer, and Seif (2009), Mastrobuoni (2009), Laitner, and Silverman (2012).

2 Based on the Survey of Income and Program Participation (SIPP), the average ratio of home equity to total household net worth was 36.07% in 2005 for individuals under the age of 35 and this ratio increased to more than 45% as individuals reach 65 years old, as seen in Figure 1. Due to the fact that the elderly had a larger amount of home equity prior to the Great Recession, they suffered a more substantial decrease in total assets after the decline in real estate prices in 2007, as shown in Figure 1.

3 The AIME takes the top 35 highest earning years up to age 60 and indexes it for wage growth, and then averages it to get a monthly amount. The AIME approximates earnings over the beneficiary's lifetime at today's wages.

4 Individuals are eligible to receive SSRI at age 62. Sixty-five is the full retirement age (FRA) for cohorts born before 1938. The FRA increases gradually for cohorts born after 1938. If an individual delays receiving SSRI from 62 to the FRA, the benefit level as a percentage of the primary insurance amount rises. For example, suppose that an individual turns 62 in 2017, his or her full retirement age is 66 and 2 months, and his or her monthly benefit at the FRA is \$1,300. If the same person starts receiving benefits at age 62, the monthly benefit will be reduced by 25.8 percent to \$964. Examples can be found at <https://www.ssa.gov/pubs/EN-05-10147.pdf>. We will describe the specifics of the program later in the paper.

5 Most people receive monthly benefit for the rest of their lives after deciding when to claim. However, there are some exceptions. For more details, see <https://www.ssa.gov/planners/retire/withdrawal.html>.

local demand shocks would lead to an omitted variables problem that could bias OLS estimates either positively or negatively.

To address these endogeneity concerns, we utilize two different instrumental variables. First, we use MSA house price changes as an instrument for the change in individual house prices to alleviate concerns regarding reverse causality.⁶ We argue that this approach addresses individual level endogeneity issues that are unlikely to drive changes in the MSA house price index. Our results suggest that MSA house price changes are strong predictors of changes in individual house prices. However, the Wald test fails to reject the null of exogeneity of the instrument. This is likely because of the broader endogeneity induced by unobserved local demand shocks that are not accounted for with this instrument. To address this second endogeneity concern, we draw upon geographic variation in the land supply elasticity of an MSA, developed by Saiz (2010), as the topological characteristics of an area are unlikely to be correlated with local demand shocks. We interact the supply elasticity measure with the change in the national house price index and use this interaction as an instrument for the change in local house prices. Our identifying assumption is that the cross-sectional variation in local house prices is driven by the underlying exogenous differences in local land supply elasticities, which is not correlated with time-varying local economic activity.⁷

After using the second instrument, we find that larger increases in house prices caused elderly individuals to delay SSRI claiming during the boom period from 2002-2006. Specifically, we find that if house prices increased by 10 percent in the previous two years, the probability of claiming SSRI within one year of becoming eligible is reduced by 4 percentage points, and the probability of claiming SSRI within two years of becoming eligible is reduced by 5 percentage points. During the bust period from 2007-2009, we do not find a statistically significant effect on SSRI claiming, which is consistent with the idea that cashing-out home equity is only viable when house prices appreciate.

To examine the possible mechanism driving our results, specifically to see if what we are observing is due to cashing-out home equity, we consider the effect of house price appreciation on the total home loan amount. Using the same identification strategy, we find that elderly individuals are more likely to increase the amount of their home loan (the first mortgage, any additional mortgages, and any home equity lines of credit) when house prices appreciate. This result is consistent with the cashing-out of home equity, suggesting this could be a viable channel to obtain additional funds to finance expenses that allows elderly individuals to delay receipt of SSRI.

Our research contributes to the literature in several ways. First, we fill a gap in the literature by highlighting the trade-off that elderly households make when deciding which assets to utilize to finance consumption. For a typical elderly individual with an average level of wealth, SSRI is the main source of income and housing is the largest asset in their portfolio. The latter lends itself to the opportunity for liquidation and generates another substantial income source. These two income sources may substitute and affect each other in financing the consumption of the elderly. In particular, the timing of claiming SSRI will affect the amount of SSRI which not only contributes to individual life-cycle financial planning decisions but also aggregates to a dramatic shift in timing and amount claimed at the national level. Understanding how this cycles along with housing market fluctuations is important for policy makers to make the necessary adjustments in managing Social Security funds. To our knowledge, our paper is the first to examine the direct causal link between a change in home equity and if an eligible individual chooses to start receiving SSRI immediately.⁸

Second, we contribute to the literature that attempts to explain Social Security early claiming decisions. There is a large literature documenting large gains in lifetime wealth from delaying SSRI receipt.⁹ Yet, despite the large gains from delay many people still choose to claim SSRI soon after becoming eligible (Shoven et al., 2017). There are many potential explanations for this behavior, such as leaving the labor force, liquidity, poor health, and concerns about future benefit cuts due to policy changes (Card, Maestas and Purcell, 2014; Munnell and Soto, 2005; Hurd, Smith, and Zissimopoulos, 2004). This paper contributes to the literature by highlighting how home equity may affect the early claiming decisions. We show that when home equity is more likely to be a viable source of income due to house price appreciation, individuals are less likely to claim SSRI early.

Finally, we add to the literature on how home equity affects the consumption and saving behavior of the elderly.¹⁰ In particular, Mian et al (2013) and Aladangady (2017) suggested that the home equity based borrowing channel is a viable means for individuals to finance consumption. Bostic, Gabriel, and Painter (2009) found that fluctuations in housing wealth have a larger effect on changes in consumption than changes in stock market assets. Furthermore, Engelhardt (1996) and Jiang, Sun, and Webb (2011) found asymmetric effects of changes in housing wealth on savings and consumption behavior, specifically with regards to whether it is a housing boom or bust period. However, this research has not considered the elderly specifically and how they may use their home equity to cover expenses versus receiving SSRI benefits. We therefore contribute to the literature by highlighting the decision elderly households make when

6 Several papers have used variation in the house price index at the MSA level to proxy for the change in individual housing wealth, although they approached this as a reduced form regression instead of using the MSA specific house price index as an instrument. See, for example, Lovenheim (2011), Lovenheim and Mumford (2013), Lovenheim and Reynolds (2013), and Zhao and Burge (2017a, 2017b).

7 This instrument has been used previously in the literature by Mian and Sufi (2011, 2014), Chaney, Sraer, and Thesmar (2012), Mian, Rao, and Sufi (2013), Cvijanović (2014), Dettling and Kearney (2014), Aladangady (2017), and Chetty, Sándor and Szeidl (2017).

8 Shoven, Slavov, and Wise (2017) used survey evidence to gain insights into the reasons individuals choose to claim Social Security.

9 See, for example, Coile et al. (2002), Munnell and Soto (2005), Sass et al (2013), Mahaney and Carlson (2007), Meyer and Reichenstein (2010), and Shoven and Slavov (2014 a, b).

10 See Engelhardt (1996), Gan (2010), Campbell and Cocco (2007), Bostic, Gabriel and Painter (2009), Browning, Gørtz and Leth-Petersen (2013), Cooper (2013), Ong, Parkinson, Searle, Smith and Wood (2013), Aladangady (2017), Cooper, (2013), Burger et al., (2015), Mian and Sufi, (2011, 2014), Jiang, Sun, and Webb (2011), Mian, Rao and Sufi, (2013), Aladangady, (2017), and Cloyne et al. (2017).

choosing how to use their housing wealth to finance consumption and possibly delay receipt of SSRI to receive the higher monthly benefits.

The rest of the paper will proceed as follows. Section 2 discusses the key institutional details of the Social Security Retirement Income program in the U.S. Section 3 discusses the conceptual framework of our research. We discuss our identification strategy in Section 4 and data and summary statistics are provided in Section 5. Results are presented in Section 6. Section 7 concludes and discusses the policy implications of this research.

2 SOCIAL SECURITY RETIREMENT INCOME IN THE UNITED STATES

The Social Security Retirement program, adopted in 1935, is a form of social insurance that provides benefits to elderly individuals.¹¹ The program is progressive in that the benefits replace a greater percentage of wealth for low earners than for high earners. Working individuals contribute to the program, which pays for currently retired individuals, with the idea that the young will receive the benefits back when they retire. Social Security has become essential in the U.S., with over 50 million people receiving retirement benefits.¹²

SSRI benefits are determined based on an individual's lifetime earnings. The Social Security Administration adjusts actual earnings to account for changes in average wages since the year the income was received. Then, the Average Indexed Monthly Earnings (AIME) during the 35 years in which the person earned the most are calculated and a formula is applied to these earnings to arrive at the basic benefit or primary insurance amount. This is the amount that each individual can receive at the Full Retirement Age (FRA).

There have been three notable changes to the retirement age since the program's inception. First, the age at which all individuals are eligible for SSRI was lowered to 62 in 1961. However, the benefits received are lower the earlier the beneficiary begins claiming. The argument is that individuals will get a larger reduction if they claim earlier because they will receive benefits for a longer period. The government intends for this reduction to be actuarially fair, though there are questions as to whether this is true in reality (Munnell and Sass, 2012; Heiland and Yin, 2014). Second, in 1972, the government provided Delayed Retirement Credits (DRC) to increase benefits for people who delayed claiming past age 65, but the benefit increase is capped at age 70. Finally, in 1983, the FRA was increased for people born in 1938 or later,¹³ making the reduction in benefits birth-year cohort specific. For example, the reduction in benefits for claiming SSRI at age 62 is 20 percent for people born in 1937 or earlier, but is 20.8 percent for people born in 1938. The maximum reduction at age 62 is 30% for the cohort whose FRA is 67.¹⁴ The credit to delay claiming past the FRA is also cohort specific, with a larger benefit for people born later.¹⁵

Despite the penalty for early claiming, there is still a large claiming spike at age 62. According to the Social Security's *Annual Statistical Supplement*, 56% of eligible individuals claimed SSRI at age 62 in 2002 and 8% of eligible individuals claim within a year after becoming eligible.

3. CONCEPTUAL FRAMEWORK

For a large portion of the elderly population, Social Security is the main source of income and housing is the largest asset in their portfolio. The ability and the extent to which individuals can tap into either of the two sources will have significant impact on a set of decisions, including decisions regarding the labor market.¹⁶ Meanwhile, because SSRI can be claimed anytime between ages 62 and 70 with increasing monthly benefits if claiming is delayed until a later age, the timing of when to start receiving Social Security will affect the amount of SSRI received each month. In fact, the potential benefits associated with delaying when an individual claims SSRI has been established by many researchers in a conceptual framework.¹⁷

11 There are other retirement plans in the U.S., such as a 401k plan which is a voluntary retirement savings plan sponsored by employers. For more details, please visit <https://www.irs.gov/retirement-plans/401k-plans>. We do not consider these other retirement programs, only the Social Security program run by the federal government.

12 The original program only provided retirement benefits to the worker. Social Security changed from a retirement program for workers into a family-based economic security program in 1939 by adding payments to the spouse and minor children of a retired worker and survivor's benefits paid to the family in the event of the premature death of a covered worker. More information is available at <https://www.ssa.gov/history/briefhistory3.html>.

13 The FRA is 65 and 2 months for the cohort born in 1938, 65 and 4 months for the 1939 birth cohort, 65 and 6 months for the 1940 cohort, 65 and 8 months for the 1941 cohort, 65 and 10 months for the 1942 cohort, 66 for individuals born between 1943 and 1954, 66 and 2 months for cohort born in 1955, 66 and 4 months the 1956 cohort, 66 and 6 months for the 1957 cohort, 66 and 8 months for the 1958 cohort, 66 and 10 months for the 1959 cohort, and 67 for individuals born in 1960 and later.

14 For example, if a beneficiary born in 1938 starts receiving retirement benefits at age 62/63/64, he/she will get 79.2%/85.65%/92.2% of the FRA monthly benefit. The corresponding amount will be 78.3%/84.4%/91.1% for the 1939 birth cohort, 77.5%/83.3%/90.0% for the 1940 cohort, 76.7%/82.2%/88.9% for the 1941 cohort, 75.8%/81.1%/87.8% for the 1941 cohort, and 75.0%/80.0%/86.7% for people born between 1943 and 1954. For more details, please visit <https://www.ssa.gov/planners/retire/ageincrease.html>.

15 For example, the yearly rate of increase for delayed claiming is 3.0% for 1917-1924 birth cohort, 3.5% for 1925- 1926 cohort, and 8.0% for people born in 1943 and later. The monthly rate of increase is one-twelfth of the yearly rate of increase. For more details, please visit <https://www.ssa.gov/planners/retire/delayret.html> and https://www.ssa.gov/oact/quickcalc/early_late.html.

16 Zhao and Burge (2017a,b) considered this specifically with regards to the labor supply decisions of the elderly. This includes looking at the decision to retire and leave the labor force entirely, moving from full-time to part-time work, or even un-retiring.

17 Clark and Gohmann (1983) take into consideration of the delayed claiming after retirement for the life-cycle budget constraint. Mirer (1998) indicates that it is optimal in many context to delay claiming SSRI after reaching eligibility based on a model of life cycle behaviour with no bequest motive. Coile et al. (2002), in particular, have shown significant gains associated with claiming delays in a wide variety of cases based on financial calculations and simulations of an expected utility maximization model. Hubener, Maurer, and Mitchell (2016) further emphasize the claiming timing decided based on Social Security rules has strong influence on life-cycle financial decisions

Despite the theoretically calculated benefits of claiming at a later age, in reality delaying the receipt of SSRI is not as prevalent as expected given the large gains associated with delay.¹⁸ There are several explanations for this behavior. Card, Maestas and Purcell (2014) found that labor market shocks lead to current and future increases in the fraction of workers who initiate SSRI at the earliest claiming age. In other words, if individuals who are age eligible suddenly lose their job, they decide to leave the labor market and start receiving benefits early versus trying to find another job. Other research has shown that individuals who have a higher subjective mortality tend to claim early (Munnell and Soto, 2005; Hurd, Smith, and Zissimopoulos, 2004).¹⁹ Recent studies have shown that behavioral factors also affect the timing of SSRI claiming. For example, Behaghel and Blau (2012) found that individuals have a frame regarding when they will retire and choose to start claiming at that age, regardless of what may be the optimal strategy to maximize lifetime utility. Brown, Kapteyn, and Mitchell (2011) found that when an individual reports he/she will start claiming SSRI depends on the way in which the decision is framed, suggesting that how the benefits are explained may affect when individuals start receiving SSRI.

Another important factor that may contribute to early claiming is that individuals may want to leave the labor force at age 62 but lack the wealth and liquidity to fund their consumption.²⁰ If individuals are constrained financially and claim early to fund current expenditures, then an unexpected increase in wealth may allow individuals to delay receiving SSRI benefits.²¹ This increase in wealth could be in the form of financial or housing wealth. Therefore, individuals who want to delay claiming SSRI to receive the larger monthly benefits can draw upon their home equity to finance expenses. A large segment of the population is income-poor but house-rich (Mayer and Simons, 1994; Merrill, Finkel, and Kutty, 1994), making home equity an important source of wealth for many households. Older households have a larger fraction of home equity that they can use to fund home equity loans and obtain reverse mortgages (Sinai, 2007). However, there has been limited research thus far examining how changes in housing wealth affect if an individual chooses to claim SSRI.

While the relationship between housing wealth and SSRI claiming has not been studied directly yet, there is an extensive literature examining the relationship between housing wealth and consumption and savings decisions.²² Engelhardt (1996) examined the relationship between house price appreciation and savings, finding an asymmetry in savings behavior. Specifically, households that experience capital losses change savings behavior, but those that experience gains do not adjust savings. Jiang, Sun, and Webb (2011) looked at the recent housing boom to see if it affected consumption of the elderly, finding that when house prices increased there was a modest increase in consumption, but did not find an effect of a house price decline on consumption.²³ Bostic, Gabriel, and Painter (2009) found that housing wealth had a larger effect on consumption than changes in financial wealth through stock market fluctuations.

We expand upon the literature by exploring the substitutability between cashing-out home equity and receiving SSRI benefits earlier for the elderly. By focusing on the elderly population, we can provide insights for policy makers as to how these individuals trade-off between the two assets. Also, consistent with the literature that has found an asymmetric response to positive and negative changes in home equity, we compare the housing boom and bust periods separately to examine if there are heterogeneous effects with regards to how the elderly respond to house price appreciation versus depreciation.

4. EMPIRICAL STRATEGY

To determine the effect of changes in the value of a home on the decision of an elderly individual to begin receiving SSRI, we exploit the recent housing market fluctuations and conduct our analysis separately for the housing boom (2002 to 2006) and bust (2008 to 2010) periods.²⁴ We separate our sample into these two time periods because households may respond differently to house price growth versus decline. Specifically, households have the ability to withdraw home equity when house prices appreciate, but not when house prices decline (Mian and Sufi, 2011). Therefore, during bust periods, the elderly may need to consider other options if they want to delay receiving SSRI.

We consider the impact of a percentage change in housing values on the probability of claiming SSRI once individuals become eligible. To do so, we estimate the following Probit regression:

$$claim_t^{i,m} = \Phi(\beta_1 \Delta \% H_t^{i,m} + \beta_2 X_t^{i,m} + \gamma_{1s} + \delta_{1t} + \varepsilon_t^{i,m}) \quad (1)$$

18 Coile et al. (2002), for example, show that delays are empirically important for early retirees but are fairly unimportant for late retirees.

19 An extensive literature has also considered how health insurance, specifically Medicare, affects the timing of retirement, as most workers lose employer-provided health insurance upon retirement. Therefore, workers may delay leaving the labor force until age 65 to ensure ongoing health insurance coverage (Madrian, Burtless, and Gruber, 1994; Rust and Phelan, 1997; Blau and Gilleskie, 2006 and 2008; French and Jones, 2011).

20 Crawford and Lilien (1981) argued that individuals start receiving SSRI due to liquidity constraint, where low-income workers do not save enough while working and thus claim earlier to finance consumption.

21 Benitez-Silva, Garcia-Perez, and Jimenez-Martin (2015) found that negative wealth shocks increase early claiming and time in the labor market.

22 For the effect of housing wealth on consumption, see Gan (2010), Campbell and Cocco (2007), Bostic, Gabriel, and Painter (2009), Browning, Gørtz, and Leth-Petersen (2013), Cooper (2013), Ong, Parkinson, Searle, Smith, and Wood (2013), and Aladangady (2017). Several recent papers have examined the effect of changes in housing wealth on the labor supply decisions of the elderly, finding mixed results (Disney, Ratcliffe, and Smith, 2015; Goda, Shoven and Slavov, 2011; Farnham and Sevak, 2007; Zhao and Burge, 2017a, 2017b; Ondrich and Falevich, 2016).

23 Researchers are considering these issues in other countries as well. Campbell and Cocco (2007) found that the largest effect of changes in house prices on consumption for UK residents was among older individuals. Gan (2010) found a similar relationship between housing wealth and consumption in Hong Kong

24 Although house prices started to decrease before 2008, we focus on 2008 to 2010 because we use the house price change in the previous two years.

where $claim_t^{i,m}$ is an indicator variable equal to one if individual i , living in MSA m , began receiving Social Security benefits after becoming eligible in year t . We allow t to be within one or two years of reaching age 62, depending on the specification. Φ is a standard normal cumulative distribution, $\Delta\%H_t^{i,m}$ is the percentage change in house value in the previous two years for individual i , living in MSA m in year t . We use the two-year change in house prices because our data, the Health and Retirement Survey, is a biannual survey and thus we only observe house prices every other year. We control for individual attributes, $X_t^{i,m}$, including gender, race, marital status, tenure at last job, education, total non-housing wealth, self-assessed health status, and retirement status. We include state fixed effects, γ_{1s} , to control for unobservable state specific attributes and year fixed effects, δ_{1t} , to capture unobservable shocks that are specific to a given year.

As discussed earlier, a simple Probit model likely suffers from two confounding issues that would bias our estimates. The first is reverse causality. Individual house values may inversely respond to when an individual starts receiving Social Security because the additional income from SSRI could be used for home maintenance and renovations that increase property values. To address this concern, we use an MSA specific house price index as an instrumental variable for changes in individual house prices. A similar approach was used previously by Lovenheim (2011), Lovenheim and Mumford (2013), Lovenheim and Reynolds (2013), and Zhao and Burge (2017a, 2017b).²⁵

This approach entails estimating the following first-stage regression:

$$\Delta\%H_t^{i,m} = \rho_1\Delta\%P_t^m + \rho_2X_t^{i,m} + \gamma_{2s} + \delta_{2t} + v_t^{i,m} \quad (2)$$

where $\Delta\%P_t^m$ is the two-year percentage change in the MSA housing price index. v_t is the error term.

Our initial findings using this instrument suggest that using the MSA house price index as an IV is unlikely to fully resolve the endogeneity concerns. Specifically, we believe it is likely that unobserved local demand shocks may be correlated with local house price appreciation which may simultaneously affect when individuals choose to start receiving SSRI.

To address the omitted variable bias, we utilize an alternative instrument. We use the MSA housing supply elasticity, proposed by Saiz (2010), interacted with the change in the national house price index as an instrument for a change in individual house values within the MSA. We argue that this is a valid instrument because in response to a nation-wide positive demand shock, MSAs with more inelastic housing supply (i.e. areas with more mountains or near water such as New York City, NY or San Francisco, CA) will experience larger house price changes than MSAs with a more elastic housing supply (i.e. flat areas such as Houston, TX or Kansas City, MO). The housing supply elasticity is likely to be exogenous to local demand shocks, as this is a supply-side measure driven by exogenous topological factors and policy regulations. This instrument has been extensively used in the literature, including by Mian and Sufi (2011, 2014), Chaney, Sraer, and Thesmar (2012), Mian, Rao and Sufi (2013), Cvijanović (2014), Dettling and Kearney (2014), Akadabgadt (2017) and Chetty, Sándor and Szeidl (2017).

Using this instrument, we estimate the following for our first stage regression:

$$\Delta\%H_t^{i,m} = \theta_1\Delta\%P_t^{US} \times Elasticity^m + \theta_2X_t^{i,m} + \gamma_{3s} + \delta_{3t} + \epsilon_t^{i,m} \quad (3)$$

where $\Delta\%P_t^{US}$ is the two year percentage change in the national house price index, $Elasticity^m$ is the Saiz (2010) estimate of the housing supply elasticity in MSA m . ϵ_t is the error term.

5 DATA AND SUMMARY STATISTICS

Our analysis relies on three data sources. The primary data source is the Health and Retirement Study (HRS) with restricted-access geographic data. The HRS is a longitudinal household survey of more than 26,000 Americans over the age of 50 and is collected every two years. The public version provides detailed information on demographics, financial and housing wealth, health, labor market status, etc. The restricted geographic version adds additional details on the county in which the respondent lives. Given that the instrumental variable we employ is at the MSA level, we use the restricted data to have the necessary geographic detail to conduct our analysis. After a preliminary screening, our sample includes 19,027 individuals.²⁶

The second dataset we utilize is the national house price index and MSA house price indexes constructed by the Federal Housing Finance Agency (FHFA).²⁷ The FHFA index has been widely used to capture national and local price trends of housing markets (i.e. Himmelberg, Mayer, and Sinai 2005).

The third data source is the housing supply elasticities for 269 MSAs provided by Saiz (2010). He estimates land supply elasticities by processing satellite-generated data on elevation, the presence of bodies of water, and the Wharton

²⁵ These papers explored the variation in MSA housing price in a reduced form setting. They utilized a difference-in-differences strategy, comparing renters to homeowners. We do not use a differencing strategy as it is likely that there are unobservable differences between elderly individuals who choose to own versus rent. Instead, we use MSA housing price variation as an instrument initially but rely more on the exogenous source of the variation driven by MSA land supply elasticity later as our main identification strategy.

²⁶ Initially, the sample had 37,319 elderly individuals. We exclude the 5,729 individuals who report receiving Social Security benefits before becoming age eligible to receive SSRI. We also exclude the 706 respondents who report ever receiving disability retirement benefits. Further, we include only individuals whom we observe before they turn 60 (two years before the eligibility age), which causes us to lose 11,857 more respondents.

²⁷ <http://www.fhfa.gov/DataTools/Downloads/Pages/House-Price-Index-Datasets.aspx#qat>.

Regulation Index (WRI), which is a measure of the stringency of land use regulation. Land use regulations play a role in differences in the availability of land (Glaser and Gyourko, 2003; Glaser, Gyourko and Sakes, 2005), together with physical constraints. This supply elasticity measure has been widely used as an instrumental variable for house prices or housing wealth, as mentioned earlier.

We match MSAs and counties using the Geographic Correspondence Engine.²⁸ Given that we use the MSA-level housing supply elasticity as our main instrumental variable, in our primary specification we limit our sample to the counties located within the MSAs covered by the Saiz (2010) topography-based elasticity measure. We also drop households that experienced a percent change in house prices above the 99th percentile or below the 1st percentile, as well as individuals who moved in the previous two years to ensure that the change in home equity is due to price appreciation/depreciation of the same housing unit. This reduces the sample to 8,959 individuals within 1,235 counties in 215 MSAs.²⁹

Table 1 presents summary statistics for all variables included in our analysis. We present the mean and standard deviation of each variable for three periods: the full sample (2002 to 2010), the boom period (2002 to 2006), and the bust period (2008 to 2010). In the full sample, around 52% of the elderly claim SSRI within one year of becoming eligible, which is consistent with the number reported by Munnell and Chen (2015) who use data from the U.S. Social Security Administration. This number is higher in our sample during the boom period but decreases during the housing bust. The lower probability of claiming early during the bust period is likely driven by the deteriorated macroeconomy. This also highlights the importance of controlling for macroeconomic shocks in our model estimation.

Note that, although the HRS is conducted every two years, the respondents report the actual year and month when they started receiving SSRI. This information allows us to expand the biannual panel to an annual panel and record precisely the SSRI withdrawal timing. However, because we only have reported house values during the survey years, we still need to use the two-year change in house prices. For survey years, we take the difference in reported house prices between the two surveys. In non-survey years, we use the reported house prices in the adjacent two years and the MSA house price index to extrapolate the house value in the non-survey year. For example, for 2005 we use the reported house values in 2004 and 2006, as well as the MSA house price index in 2004, 2005, and 2006, to estimate the reported house value in 2005.

With regards to the change in house prices, we see in Table 1 that the two-year average percentage change in house values for our sample is 12% from 2002 to 2010. The national and MSA house price appreciation rate, however, are both approximately 10%. From 2002-2006, this number increased to approximately 19% for our sample and about 17% at the national and MSA level. However, during the bust period from 2008-2010, house prices declined in our sample by about 4%, nationwide by approximately 8%, and by approximately 8.5% in MSAs.³⁰

The average housing supply elasticity is around 1.73%. Approximately 57% of respondents are female, 86% are white, and 82% are married. Older workers with more than ten years of service at in their last job are 35% of our sample. Approximately 56% of the sample has completed high school and 28% have a college degree. The average non-housing wealth is about \$428,063. The average self-assessed health status is 2.48, which suggests that elderly individuals assess their health as “good” on average.³¹ Given the important role of retirement decisions in assessing SSRI claiming, we also control for retirement status. Approximately 38% of respondents are retired and no longer working. These averages are similar for both the boom and bust periods.

6 RESULTS

Effect of Changes in Home Values on Claiming SSRI Early

We begin our analysis by estimating Equation (1) using a simple Probit regression. Results are presented in Table 2. Columns (1) and (2) examine whether an individual claims SSRI within one year of becoming eligible during the housing boom (2002 to 2006). We control for state fixed effects in both columns and add year fixed effects in Column (2) to capture any unobserved time-varying, nation-wide shocks. Columns (3) and (4) examine whether an individual claims SSRI within two years of becoming eligible, with Column (3) including only state fixed effects and Column (4) adding year fixed effects. Columns (5) to (8) follow the same structure as Columns (1) to (4) but cover the bust period (2008 to 2010). All specifications include controls for gender, race, marital status, tenure at last job, education, non-housing wealth, self-assessed health, and retirement status. We report the coefficients from the Probit model in the upper panel and the corresponding marginal effects in the lower panel. T-statistics are reported in parentheses and are calculated using standard errors clustered at the MSA level.

28 <http://mcdc2.missouri.edu/websas/geocorr2k.html>.

29 This sample size is before we restrict observations to the boom and bust periods and to those with valid entries for all included control variables.
30 One explanation for why our reported house values are above the national and MSA house price changes is that we are only considering a select sample of the elderly while these indices are based on the entire population. An alternative explanation is that individuals tend to overestimate the value of their home. The evidence on what determines the possible reporting errors is mixed. Haurin, Moulton, and Shi (2017), who examined just the elderly population, found that the size of the error changes with income, credit score, and ethnicity. Goodman and Ittner (1992), however, found that this reporting error is uncorrelated with characteristics of the home, the local economy, and the homeowner. We include a variety of controls to try to minimize any bias in the error term. Other research has used self-reported house values in their analysis, given data constraints such as ours, including Corradin and Popov (2015) and Harding and Rosenthal (2017).

31 The variable “self-reported general health status” includes five values, with 1 for “excellent,” 2 for “very good,” 3 for “good,” 4 for “fair,” and 5 for “poor.”

Looking at the results in Table 2, we do not find consistent evidence of an effect of changes in house value on Social Security benefit claiming during either the boom or bust period. The only statistically significant effect we find is a negative effect in Column (3), which, while this is the anticipated sign, is only marginally significant at the 10% level.

However, as discussed previously, a simple Probit estimation is likely to suffer from endogeneity issues due to reverse causality at the household level and omitted variable bias at the local level. We address these concerns by using two different instrumental variables. First, we use the MSA house price index as an instrument for the change in house value. The corresponding results are presented in Table 3, where the columns follow the same structure as in Table 2. Panel A presents the second stage results, both the estimated coefficients and the marginal effects, and Panel B shows the first stage coefficients.

Looking at the first stage results in Panel B, we see that the change in the MSA house price index is a statistically significant predictor of individual house price changes. However, the Wald test of exogeneity generally fails to reject the null hypothesis, except in the specifications without year fixed effects in the boom period. This may suggest that the MSA house price index is not a valid instrument, possibly because of the presence of omitted variable bias. In the second stage results presented in Panel A, we again do not find that changes in home value have a statistically significant effect on the probability of claiming SSRI at an earlier age.

To address the potential endogeneity arising from both unobserved local demand shocks and household level reverse causality, we use the interaction of the housing supply elasticity and the change in the national house price index to instrument for changes in home value. Table 4 reports IV Probit regression results using this instrument variable. The structure is the same as Table 3. The first stage results presented in Panel B suggest that this instrument is valid, as the Wald test of the exogeneity of the instrumented variables rejects the null hypothesis.

Panel A of Table 4 presents the second stage coefficients from the IV regression. We find a negative and statistically significant effect of a change in house prices on the likelihood of claiming SSRI benefits early during the boom period. This negative coefficient suggests that when house prices increase, elderly individuals delay receiving SSRI. Specifically, our results indicate that when housing values increase by 10%, the probability of claiming SSRI within one year of becoming eligible is reduced by 4 percentage points and the probability of claiming SSRI within two years of becoming eligible is reduced by 5 percentage points. This translates into an 8% decrease in the probability of claiming within one year of eligibility and an 8.3% decrease in the probability of claiming within two years of eligibility. The negative coefficient indicates that when house prices increase, elderly individuals may draw upon their home equity to finance expenditures and hence delay receipt of SSRI to receive higher monthly benefits. However, we do not find a statistically significant effect during the housing bust period. This is also consistent with our expectations, as when house prices depreciate the decline in home equity takes away this alternative source of finances.

Gender Heterogeneity and the Role of Life Expectancy

Next, we consider the possible gender heterogeneity of the effects of changes in house prices on the timing of claiming SSRI. We believe that the SSRI claiming response to a change in house value will be different for males versus females. Previous research has found that with regards to labor supply decisions, females are more sensitive to policy changes, possibly because men are more likely to be the primary earner (Zhao and Burge, 2017a, 2017b). It has also been well documented that females on average have a longer life expectancy than males. Given these differences, it is plausible that men and women respond differently with regards to claiming SSRI.

Table 5 reports the IV Probit results stratified by gender using the interaction of changes in the national house price index and the housing supply elasticity as the instrument variable as this is our preferred specification.³² We focus on the boom period given the results from Table 4 that the effect of house price changes on SSRI claiming appears to only be present when house prices appreciate.³³ We do not find a statistically significant effect for males but we do find a strong, statistically significant negative effect for females.³⁴

Even though the gender difference in SSRI claiming in response to changes in home values could be due to other factors, we highlight the possible role of life expectancy in determining claiming decisions. A key trade-off in deciding when to claim SSRI is that when an individual claims earlier, he/she gets benefits for a longer period of time but the monthly benefit is lower. Females, who have a longer life expectancy, may be more inclined to delay SSRI claiming since they will benefit for longer from the increased monthly benefits.

To quantify and compare the benefits/losses for females and males based on claiming time, we calculate how the net present value of SSRI benefits differs if an elderly individual chooses to claim at all months from 62 to 70. For simplicity, we assume that the monthly benefit is \$1,000 at the Full Retirement Age (FRA) for each birth cohort and gender. We then apply the reduction for claiming before the FRA and the credit for delayed claiming past the FRA from the Social Security

32 We estimated the standard Probit model and IV Probit using the MSA house price index as an instrument. For both models, like the pooled sample we do not find consistent, statistically significant effects. These results are available from the authors upon request.

33 Like the pooled model, when examining the bust period, we do not find any statistically significant effects, and in the interest of brevity do not show them. These results are available from the authors upon request.

34 Zhao and Burge (2017a, 2017b) also find that females are more responsive than males to changes in housing wealth, but they focus on labor force participation. They find that in response to a doubling of housing wealth, labor force participation rates for females are more than twice as responsive as those for males.

Administration.³⁵ We use the Life Tables by birth cohort and gender provided by Poterba (2014), which gives the mortality rate based on Bell and Miller (2005). We then impute the survival rate from age 62.³⁶ The final imputed net present value of retirement benefits, assuming an annual discount rate of 3%,³⁷ are shown in Figure 3 and Figure 4.

The figures suggest that females have a higher present value than males to delaying SSRI receipt given their longer life expectancy. The net present value tends to peak at a later age for females, versus for men who the peak appears to be around 62. This indicates that females should claim SSRI later than males, all else equal. At the same time, because females achieve the maximum present value beyond the first two years of eligibility, they have an incentive to delay receiving SSRI, especially if they are able to find alternative income sources. For men, the present value of retirement benefits actually decreases after the first two years of eligibility. These net present value predictions are consistent with our findings in Table 5 that women are more likely to delay receiving SSRI when house prices appreciate.

Borrowing against Home Equity

Our results thus far suggest that elderly individuals tend to delay SSRI claiming when house prices appreciate. Theoretically, an increase in housing wealth could provide additional income for a household through the collateral borrowing channel (see Cooper, 2013; Mian and Sufi, 2011; 2014; Mian, Rao and Sufi, 2013; Akadabgadt, 2017). To provide evidence of the cashing-out of home equity, we examine whether the total amount of home loans (primary mortgage, additional mortgages, and all home equity loans) increases when houses appreciate in value. We present these results in Table 6. The first stage results suggest that the change in the national house price index interacted with the land supply elasticity are strong predictors of changes in individual house values, although the Wald test of exogeneity of our instrumental variable does not reject the null hypothesis except in the specification without year fixed effects in the boom period. The second stage regression indicates that when house prices appreciate, the likelihood that the total home loan amount increased in the previous two years becomes higher. The magnitude of the change is much higher during the boom period than the bust period.³⁸

We then directly examine whether the additional income from borrowing against home equity will affect the probability of claiming SSRI within one or two years of becoming eligible. These results, presented in Table 7, show that when the total home loan amount increases, the probability of claiming SSRI within one or two years become significantly lower. The Wald test of exogeneity of our instrumental variable rejects the null hypothesis, but the instrument is not a strong predictor of the housing loan amount, possibly due to missing the individual house price change as the bridging predictor for the probability of increased total home loan amount. In addition, consistent with previous results, we find a significant effect during the boom period but we do not find a statistically significant effect during the housing bust period.

Our results indicate that home equity affects the timing of claiming SSRI through the borrowing collateral channel, which is consistent with previous studies. Even though the results might suffer from weak IVs, which cannot be fully resolved in our setting, we do find consistent evidence in the second stage regressions. Together with the previous results on claiming SSRI early, the evidence seems to suggest that house price appreciation increases the possibility for elderly households to borrow against their housing equity which may substitute for SSRI in financing retirement expenses.

7 CONCLUSIONS AND POLICY IMPLICATIONS

Social Security and the timing of when the elderly decide to claim these benefits has become increasingly important due to the rapid increase in the aging population in the U.S. Besides SSRI wealth, most elderly households carry a large fraction of their asset portfolios in their home equity. In this paper, we use restricted access HRS data to investigate the effects of changes in housing wealth on the probability of claiming SSRI when individuals become eligible during the recent housing boom and bust periods.

Simple Probit estimations are likely to suffer from endogeneity issues due to unobserved individual characteristics and unobserved local demand shocks. To address the endogeneity problems, we utilize two different instrumental variables for the changes in home equity: (1) changes in the MSA house price index and (2) the interaction between changes in the national house price index and a measure of the housing supply elasticity. The second instrument constitutes the central identification strategy of our paper, as we find that using the MSA house price index as an instrument likely does not address all endogeneity issues.

We find consistent evidence that when house prices increase, individuals delay receiving SSRI after immediately becoming eligible. This estimated effect is statistically significant during the boom period but not during the bust period. We also find that females are more likely to respond and delay receiving SSRI after an increase in house prices, consistent with a longer life expectancy encouraging the delay. We further find that people are more likely to increase the total amount of home loans (primary mortgages, any additional mortgages, and any home equity line of credit) when house

35 The reduction for early claiming and credit for delayed retirement were obtained from <https://www.ssa.gov/planners/retire/ageincrease.html>, and <https://www.ssa.gov/planners/retire/delayret.html>, respectively.

36 The mortality rate in Poterba (2014) is the probability of dying within one year at a certain age (conditional on living to a certain age). We calculate the monthly mortality rate to be $1 - (1 - \text{annual mortality})^{(1/12)}$, giving us the probability of dying within the next month at a certain age. We then calculate the survival rate at age 62 based on the conditional mortality rate.

37 This discount rate is the long term inflation rate in the U.S. and has been used in previous papers such as Munnell and Soto (2005) and Heiland and Yin (2014). Consequently, the monthly discount rate is 0.25%.

38 Note that the sample size increased significantly as we do not restrict the sample to within one or two years of an individual becoming eligible to receive SSRI and we do not restrict respondents to have a well-defined early claiming dummy as in previous regressions.

prices appreciate. This finding suggests that these individuals are borrowing against their home equity to obtain the necessary finances to cover their expenses instead of receiving SSRI earlier.

Overall, our findings suggest that the elderly treat increases in home equity and SSRI as substitutes to finance retirement expenses. A simple present value calculation suggests that the value of a female's retirement benefits could increase by about 17-19 percent if she claims later rather than when immediately eligible. Moreover, individuals may prefer to utilize home equity given the option of a reverse mortgage or the consideration that drawing upon home equity is contingent on current house price appreciation while SSRI is a permanent and safe asset. If home equity provides an alternative source of income that is more contingent on market conditions, elderly females will have the incentives to delay receiving their SSRI benefits and use housing equity to finance their expenditures when this option is available.

1402 STATUS DISCREPANCY AND THE STRUCTURE OF INDIVIDUAL AND COLLECTIVE PATHWAYS OF RESIDENTIAL MOBILITY FOR THE CHICAGO METROPOLITAN AREA (2006-2015)

ABSTRACT

Urban planners and housing policy analysts have long been concerned with neighborhood income mix. The theoretical rationale holds that mixed income neighborhoods will foster more robust social networks, social controls, behavior, and political economy for residents at all income levels within the neighborhood (Joseph, Chaskin, and Webber, 2007). Particular emphasis has been placed on the potential stabilizing effects of mixed-income neighborhoods for low-income households. U.S. low-income housing programs such as HOPE VI and the Moving to Opportunity for Fair Housing Demonstration Program have, as a matter of policy, relied upon developing mixed-income housing on former public housing sites to promote uplift for low-income residents. Outside of these special contexts, however, the process through which naturally occurring mixed-income neighborhoods evolve and are sustained remains elusive. In this paper, I build upon the work of Galster and Turner (2017) who examine the role of status discrepancies – the differences between household income and neighborhood income structure – on the likelihood of residential mobility. Status discrepancy theory suggests that when individual incomes become much higher or lower than neighborhood income that the likelihood of residential mobility will increase. In their analysis conducted in Oslo, Norway, Galster and Turner find that status discrepancy mattered both for the mobility behavior of low-income and high income households, suggesting a long-run tendency towards homophily in neighborhood income structure. Drawing upon a novel source of longitudinal household-level data, I examine the applicability of Galster and Turner’s findings to the Chicago, Illinois metropolitan area. Specifically, I use data from the InfoUSA Consumer Database (2006-2015) to construct longitudinal household-level residential mobility histories for over 8.1 million households in the Chicago MSA. Over this period, more than 1.2 million unique household moves were made. I model the likelihood of moving as a function of status discrepancy at origin and at destination. I then pool residential mobility data into an origin-destination matrix representing the shares of flows between different neighborhoods. I use this derived network to examine the contribution of status discrepancy to the shares of flows between neighborhoods and to broader processes of economic sorting of households within the metropolitan area. While this type of network-based analysis remains rare within housing policy analysis (Depwolf and Lyles, 2012), several researchers are using data with network structures to engage with housing policy issues (Greenlee and Wilson, 2016; Gaumer, Jacobowitz, and Brooks-Gunn, 2014; Sanchez, 2015). This approach has substantial implications for interpretation of regional demographic trends including population loss, the suburbanization of poverty, and continued patterns of racial and economic segregation within the metropolitan area. This work also underscores the previously identified challenges associated with policy-based approaches to sustaining mixed-income neighborhoods.

1527 WHERE WE CHOOSE TO LIVE AND WHY? A CASE STUDY OF ACCESSIBILITY FACTORS INFLUENCING RESIDENTIAL CHOICES

ABSTRACT

Buying a home is one of the biggest decisions an individual makes in their life. Renting a home is also a major decision. These decisions are motivated by major life events and the circumstances of job and/or requirement of companionship. Urban policies may not be able to influence when an individual buys/rents a home. However, where they will buy/rent a home is heavily influenced by the decisions made by the urban planners and development authorities of the city. The way infrastructure is developed makes certain neighbourhoods more likely to become the preferred choice for residential development. The primary indicator of suitability is the price/rent value since the demand drives these values up (or brings them down). The way these residential location choices are made varies across the nations, cities, genders, income groups and numerous other behavioural variables. This research tries to understand how these decisions are made and what variables affect it the most. To illustrate the phenomenon of housing choice dynamics, the case undertaken is the urban area in the vicinity of urban metro rail. Accessibility significantly influences the housing choice. A study of neighbourhoods near metro rail in comparison to the control group of areas with lower accessibility will highlight the decision making in residential choices.

1666 REVISITING THE FUNDAMENTAL LAW OF ROAD CONGESTION USING QUANTILE REGRESSION

ABSTRACT

We revisit Duranton and Turner's (2011) paper on the effect of lane kilometres of roads on vehicle-kilometres travelled (VKT) in US cities. The main conclusion of Duranton and Turner (2011) is that increasing road and highway availability would not reduce traffic congestion as VKT rises proportionately to the availability of roads. However, this result might seem counterintuitive even after accounting for the usual suspects. Common sense tells us that for all the over-worked road networks, increasing road availability should alleviate congestion at least by certain amount, however small that might be. In order to solve this apparent puzzle, we use quantile regression method on Duranton and Turner's data. Quantile regression can help us understand how elasticity of vehicle kilometres travelled with respect to lane kilometres of roads varies for the different percentiles of the vehicle kilometres travelled. In our quantile regression estimate, using a panel of metropolitan statistical areas (MSA) in the United States for the years 1983, 1993, and 2003, we find that there is a significant variation in terms of elasticity of vehicle kilometres travelled with respect to lane kilometres of roads for different quantiles of vehiclekilometres travelled. In the 10th percentile, the elasticity is 0.96 whereas in the 50th percentile it is 0.82, and in the 90th percentile it is 0.72. These results are obtained after controlling for geography (elevation within the MSA, ruggedness of terrain within MSA, heating degree days, cooling degree days, sprawl in 1992), demographics (share of college educated workers, average income, 1980 segregation index, share of poor, share of manufacturing employment), decennial population variables from 1920 to 1980, and census division dummies. As is evidenced by our elasticity estimate, the percentage change in vehicle-lane kilometers traveled is not uniform across different percentiles following a percentage change in available lane kilometers of roads. Hence, we may argue that for MSAs with an already lower rate of congestion, additional roads built might not bring congestion level any further down. However, for MSAs experiencing significant amount of congestion, additional roads being built might be successful in reducing the congestion level. As a result, it might be beneficial after all to build more roads and highways in regions experiencing higher level of congestion.

1090 PUBLIC INFRASTRUCTURE AND REGIONAL GROWTH RELATIONSHIP FROM A SPATIAL PERSPECTIVE WITH A TIME-VARYING SPATIAL WEIGHT MATRIX*Zeynep Elburz, K. Mert Çubukçu***ABSTRACT**

The aim of this study is to analyze the spatial effects of land transport infrastructure on regional economy in Turkish NUTS 2 regions between 2004 and 2014. We employ an augmented Cobb-Douglas production function model and use spatial Durbin model to estimate spatial effects. Apart from previous studies that employ spatial econometric models, we create eleven different spatial weight matrices based on inverse distance matrixes that change over time between 2004 and 2014. According to the results land infrastructure investment has significant and positive spatial spillover effect on regional growth.

Keywords: Transport infrastructure, spatial weight matrix, spatial Durbin model

1 INTRODUCTION

The economic effects of transport infrastructure on economics have been attracting a great deal of attention both from policy makers and researchers since the pioneering works of Aschauer in the late 1980s. Although there is a strong belief in a positive link between transport infrastructure and regional economic performance, the impacts of transportation infrastructure on regional economy are still uncertain regarding the sharp differences in the results of empirical studies. From the policy makers' point of view, the provision of infrastructure, which generates positive externalities and promotes the productivity of firms, is an important policy tool for promoting regional growth and reducing regional disparities. For this reason, like most of the developed and developing countries, Turkey has invested in transportation infrastructure in its less-developed regions to diminish the regional economic inequalities since the early 1960s. To accomplish economic development goals, 26.3% of the total public investment has been assigned to transportation and communication infrastructure between 2000 and 2011. In the beginning of the 2000's, the total length of the dual-carriageways in the country was 6,101 km. In less than ten years, this number has been raised to 23,522 km. However, this serious change in the transport infrastructure stock has captured little attention in the literature. To our knowledge, this study is the first attempt to measure the latest developments of transportation infrastructure in twenty-six NUTS 2 regions in Turkey with from a spatial perspective.

The aim of this study is to examine spatial effects of public land transportation infrastructure investments on regional economic growth. We employ a Cobb-Douglas production function model, and estimate the model with spatial panel regression taking into consideration the high and significant Moran's I statistics for the residuals of the non-spatial estimation. The novelty of the paper lies on selecting the most appropriate spatial weight matrix for detecting the spatial effects more accurate. Instead of employing conventional contiguity based spatial weight matrices, we create 11 different spatial weight matrices pertaining to each year for the period 2004-2014, which reflect the change over time, to capture the impacts of recently built-up dual-carriageways or extension the existing ones on regional economic growth. We use network analysis to calculate the distances in minutes between the regions based on 3 different road categories with different speed limits each. Eventually, we run 11 spatial panel regressions that includes 11 spatial weight matrices each. The results of the spatial Durbin model show that land infrastructure investment has significant and positive spatial spillover effect on regional growth and employing time-varying spatial weight matrices matters for obtaining the significant and accurate findings.

The remaining part of the paper is organized as follows. Section 2 reviews briefly the literature which uses a production function model to estimate the effects of different types of transportation infrastructures. Next Section 3 and Section 4 provide an overview of the methodology and data, while Section 5 presents the results of the econometric modeling analyses. Finally, Section 6 offers a conclusion from our research, suggesting also new pathways for the futures.

2 LITERATURE REVIEW

Aschauer (1989)'s study which suggested that the stock of public infrastructure may explain the economic output has triggered much attention from both academics and policy makers. In his study Aschauer (1989) entitled streets and highways, airports, electrical and gas facilities, mass transit, water systems, and sewers as core infrastructure and finds that the estimated elasticity for the core infrastructure is 0.24. This result has interpreted as there is a strong and significant relationship between economic output and infrastructure and subsequently Munnell (1990) found similar strong relationship with a lower elasticity (0.15) at the subnational level. A number of studies have analyzed the effects of transportation infrastructure investments especially highway investments in different countries and found similar significant results with Aschauer (1989) and Munnell (1990) (see Table 1).

On the other hand, many studies claim that the results from Aschauer (1989) and Munnell (1990) are problematic for not taking into account the causality between dependent and independent variables and the nonstationary of the data. Eisner (1991) underlined a serious question for state output and public capital by asking which one is cause and which one is effect. Evans and Karras (1994) used panel data between 1970-1986 from 48 US states to estimate the stock of highway capital on Gross State Product (GSP) and reached significant and negative results. Garcia-Milla et al. (1996) also employed panel data from 48 US states and examined highway investments with fixed effects and concluded insignificant effects on highway on GSP.

The 1990's was the golden years for the infrastructure investment studies following the seminal work of Aschauer (1989). More recently, studies mostly concentrated on the spatial effects of transport infrastructure by using spatial econometric models as well as causality and non-stationary issues which have been highly criticized in the literature since 1990's. Cohen (2010) used the USA states highway capital stock data for 1996 to investigate the broader effects - indirect effects- of transportation infrastructure. The results based on spatial lag model with contiguity weight matrix showed a positive effect of transport infrastructure on the output. Cohen (2010) concluded that ignoring spatial effects may cause omitted variable bias. Jiwattanakulpaisarn et al. (2009) also find positive spillovers of highway infrastructure to neighboring states with spatial panel model for the case the USA. On the contrary, Del Bo and Florio (2012) investigated the EU case for the effects of motorways with a spatial Durbin model and found that the spillover effect varies on the type of the transportation infrastructure. Motorways and roads have different spatial spillover effects on EU regions.

Transportation infrastructure investments have been used as an important policy tool for policy makers in Turkey since 1960's. However, the number of studies that focuses on the effects of transportation infrastructure on regional economic growth is limited. Kuştepelı and Akgüngör (2010) investigated this phenomenon by using cross section data from 2000 with 26 NUTS 2 regions in Turkey and concluded that transportation investments have positive effect on regional Gross Value Added (GVA). Recently, Elburz et al. (2017) studied the role of transport infrastructure stock in the Turkish regions with different estimation methods. They used OLS, fixed-effects, 2SLS and Hausman-Taylor IV estimations with region and time effects from 2004 to 2011. The results confirmed road and highway infrastructure have significant and positive effects on Turkish regional GVA.

3. DATA

One of the main reasons of the limited number of studies on the effects of transportation infrastructure on Turkish regions is the problematic process of finding the appropriate data at the subnational level in Turkey. Along with the EU accession process, TurkStat released regional data based on NUTS 2 level instead of provincial data starting from 2004 which diminish the number of observation. Another limitation on the data is about the time period. Gross Domestic Product (GDP) data is only available for the time period between 2004 and 2014 which is launched by TurkStat at the end of 2016. Therefore we use macroeconomic data from 26 NUTS 2 regions from 2004 to 2014 (see Table 2).

Table 2. Definitions of variables

Variables	Year Coverage	Description	Data Source
Y (GDP per capita)	2004-2014	Gross Domestic Product per capita	TurkStat
K (Private Capital)	2004-2014	Industrial electricity consumption per capita	TurkStat
L (Labor Force)	2004-2014	Labor force	TurkStat
H (Human Capital)	2004-2014	University graduates divided by total population	TurkStat
T (Transport Infrastructure)	2004-2014	Divided roads and motorway infrastructure (km) divided by total surface area	TurkStat

We use an augmented Cobb-Douglas production function to measure the role of transport infrastructure on regional economic performance with GDP per capita as regional output. Since private capital stock data is unavailable in Turkey, we use industrial electricity consumption per capita as a proxy for private capital stock as proposed in Moody (1974). We use employment data as an input variable and, following Barro (1990) we add human capital variable to the model which is the proportion of the university graduated to the total population. Finally, we augmented the production function by adding transportation infrastructure variable. We measure transport infrastructure stock by adopting physical measurement instead of monetary measures as indicated in Bröcker and Rietveld (2009) and Vickerman (2008) that monetary measure is less accurate than physical measurement of transport infrastructure stock. We employ length (km) of total highway and divided roads which are standardized with the total surface area of a region (see Table 2).

Table 3. Descriptive statistics of the variables

Variables	Observation	Std. Dev.	Min	Max
Y (GDP per capita)	286	0.52025	8.02715	10.59638
K (Private Capital)	286	1.07473	-3.50348	1.511887
L (Labor Force)	286	0.604826	12.11724	15.44397
H (Human Capital)	286	0.706927	-2.656185	1.781816
T (Transport Infrastructure)	286	0.1962483	-2.792852	-1.94226

4. METHODOLOGY

In the present study, we use an augmented Cobb-Douglas production function approach which is the most preferred function to investigate the link between transport infrastructure stock and regional economic growth, for 26 NUTS 2 regions in Turkey. We added transport infrastructure as an input variable to the function and take the log of both side of the equation. The augmented production function model can be expressed as:

$$\ln Y_{it} = \alpha \ln K_{it} + \beta \ln L_{it} + \gamma \ln H_{it} + \delta \ln T_{it} \tag{1}$$

where Y, K, L, H, T, i, and t denote, respectively, output, private capital, labor force, human capital, transport infrastructure stock, region, and time.

Taking into account the spatial spillover effects that highlighted in the literature review section, we test spatial autocorrelation in the model by using Moran's I statistics. Before applying spatial analysis, it is needed to determine the spatial weight matrix which is the simplest measure of spatial influence (Bavaud, 1998). Anselin (1988) states that a misspecified spatial weight matrix may cause inconsistent and misleading results however there is no true spatial weights that fits all cases (Bavaud, 1998). In the literature most of the studies prefer to rely on contiguity matrices which is simple and easy to interpret (see Table 1). In this study we follow a different path from the previous studies to generate

spatial weight matrix. We create 11 different spatial weight matrices pertaining to each year for the period 2004-2014, which reflect the change over time, to capture the impacts of recently built-up dual-carriageways or extension the existing ones on regional economic growth. Approximately 30% of the total public investment has been transferred to transportation investments since 2004 and it is clear that there is a change in the land infrastructure stock in terms of length of the state highways, provincial roads and motorways in Turkey between 2004 and 2014 (Figure 1 and Figure 2). As expected, building new road network and/or extension of the existing ones cause a reduction of the travel times between regions. Based on this fact we believe a simple contiguity weight matrix would not reflect the real changes in Turkish transportation infrastructure and thus would not measure the spatial influence properly. Therefore, we create 11 different spatial weight matrix for each year from 2004 to 2014. We use network analysis to calculate the distances in minutes between the regions based on 3 different road categories excluding village roads, with different speed limits each. After obtaining the annual changes in the distance between regions we generate 11 different inverse distance spatial weight matrices ($1/d^2$) for 26 NUTS 2 regions and transform them with row-standardization.

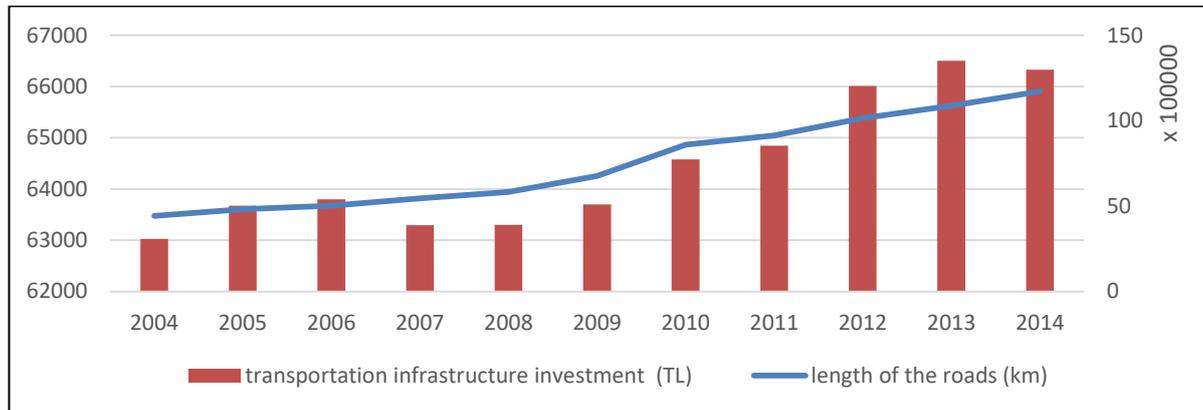

Figure 1. Transportation infrastructure investment and total road length changes

Figure 2. State highways, provincial roads and motorways in Turkey

First we apply Moran’s I statistic test to all variables -both dependent and independent variables- and reach highly significant results of an existing spatial autocorrelation. Then we repeat the Moran’s I test for the residuals of the OLS regression for the equation (1). The findings (Table 4 and Table 5) support the previous results so it is necessary to consider spatial models since simple OLS is not an appropriate estimation method (Anselin and Florax, 1995). Therefore, the next step is to analyze the relationship between transportation infrastructure and regional economic output by using spatial econometric models.

2011	7.639 (0.000)	21.782 (0.000)	27.069 (0.000)		0.191 (0.662)	5.478 (0.019)	
2012	7.733 (0.000)	21.707 (0.000)	26.963 (0.000)		0.188 (0.665)	5.444 (0.020)	
2013	7.733 (0.000)	21.707 (0.000)	26.963 (0.000)		0.188 (0.665)	5.444 (0.020)	
2014	7.764 (0.000)	21.707 (0.000)	26.989 (0.000)		0.194 (0.660)	5.476 (0.019)	

5. RESULTS

We run non-dynamic spatial Durbin model with region fixed-effects since all the data are stationary according to the Levin-Lin-Chu unit-root test results (Table 4). The results of the spatial Durbin models are shown at Table 6. According to the findings, the spatial autocorrelation coefficient rho is positive and significant across all years. Spatial lag of transport infrastructure and spatial lag of labor variables are significant and positive in all cases indicating the existing externalities.

Following LeSage and Pace (2009), summary measures of direct, indirect and total impacts were computed to assess the importance of spatial spillovers. Table 7 presents the estimates of the direct and spillover effects. The results of the direct effects reflect that human capital, private capital and labor variables in region i have significant and positive effects on regional output in the same region. On the other hand, transportation variable has positive and significant indirect (spillover) effect which shows that transportation infrastructure investment in region i has an effect on regional output in other regions. And lastly, total effect results indicate that all explanatory variables are significant and positive meaning that all four explanatory variables in region i affect dependent variable in all regions.

6. CONCLUSION

The effects of transportation infrastructure investment have captured a lot of attention from both researchers and policy makers since 1980's. After the global economic crisis in 2008, the governments started to re-consider the effect of transportation infrastructure as an important regional policy tool. As an emerging economy, the number of studies which investigates the relationship between transportation and regional economy is rather limited in Turkey. In this study we aim to examine the spatial effects of transportation with spatial panel econometric model. We create 11 different spatial weight matrices based on annual change in the distance between regions to underline the boost of land transport stock in Turkey since the beginning of the 21st century. According to the SDM results, it is clear that transportation infrastructure investments in Turkey has significant and positive effect on regional economy. But the most important conclusion is that transport investment in a region has much more effect on other regions indicating a strong spillover effects. Subsequent studies may analyze this relationship by taking into account the causality problem which we ignore in our study.

Table 6. Estimation results of SDM with region fixed effects

1147 THE MISSING MILLIONS: UNDERCOUNTING URBANIZATION IN INDIA

ABSTRACT

The measurement and characterization of urbanization crucially depends upon defining what counts as urban. According to The Indian Planning Commission, less than a third of the Indian population lives in urban areas, and while Indian cities are increasingly important to the economy, India is perceived fundamentally as a rural country. In this paper, we show that this received wisdom is an artefact of the definition of urbanity and the official statistics vastly undercount the level of urbanization and its importance for development policies in India. We begin by creating temporally-consistent, high-resolution population maps from sub district level population data available from the Indian Census for 2001 and 2011. The modeling framework is a two-step process that applies a Random Forest-based model to generate a prediction weighting layer subsequently used to inform a gridded dasymetric redistribution of original census counts at 100 m resolution (Stevens et al. 2015). We then apply density thresholds, contiguity conditions, distance based clustering and minimum population sizes to construct urban agglomerations for the entire country. Compared to the official estimates, we find that this approach counts 8%-30% (depending on thresholds) more urban population in 2011. We find large urban agglomerations that span large portions of Kerala and the Gangetic plain. Thus, while official estimates count more cities in the country, we delineate fewer cities but large urban regions that span jurisdictional boundaries. This has implication for urban policies. We also characterize the changes in the urbanization pattern between 2001 and 2011. Of all Indian states included in the Census, only three experienced rapid urbanization (>5%) over the last decade. Our results show that this level of urbanization is much more common and is consistent with notion of subaltern urbanization where growth in smaller cities is often overlooked (Denis and Zérah 2017; Pradhan 2013). We conclude with the discussion about the extensive and intensive growth patterns of these urban agglomerations.

1540 MAKING ROOM APPROACH: AN ALTERNATIVE TO CONVENTIONAL PLANNING APPROACH FOR MANAGING INDIA'S RAPID URBANIZATION?

Jaykrishnan A Pillai, Rutool Sharma

CRIUPA, Nagpur, India

Assistant Professor, CEPT University, Ahmedabad, India

ABSTRACT

Urban population in India is around 377.10 million, according to the Census of India 2011. As per the estimates in 'World Cities Report 2016 – Futures' by UN Habitat, India will add another 300 million people by 2050. To accommodate this fast paced urbanization, there is not only a need to rebuild and retrofit our existing cities, but also to build new cities. Else, this unprecedented urban growth will pose several challenges, which will have consequences on our living conditions, economic growth as well as environment. If not planned and properly managed, our cities will be congested, chaotic and haphazard, giving rise to several conflicts. Thus there is an urgent need to relook at the way in which we plan and manage our cities.

An important planning aspect that is generally neglected when we plan our urban areas is related to delineation of urban boundaries. An analysis by IIHS shows that top 100 largest cities inhabit 16% of the country's population, but occupy only 0.24 percent of India's geographical area, which is very less compared to the size of its urban population. Indian cities are planned by conventional approach of delineating an area as 'urban' area, and then preparing a Master Plan or a Development Plan. Generally, the delineation of urban boundary adopts a conservative approach, mainly with an intention to contain urban growth from sprawling in contiguous rural hinterlands. These boundaries become too stringent and restrict the supply of urban land, result of which is evident as development outside the earmarked developable zone. Thus, this approach is unable to match the pace of urban growth, and is not capable to meet development needs of the city. Because of this, the gap between actual plan, actual growth and development needs is ever widening.

The paper revisits compact city versus sprawling city debate and its significance for urbanizing countries like India. Research tries to understand the aspect of limiting growth boundaries, and whether it creates scarcity of overall availability of urban land. It tries to draw attention towards the direct effect of restricting overall supply of urban land, and its relation with proportion of available urban land per person. For this analysis, planning approaches adopted by three large cities in India, viz. Hyderabad, Nagpur and Bangalore have been reviewed in detail. These planning approaches have been reviewed in reference to Shlomo Angel's 'Making Room' paradigm, which consists of four components:

1. Realistic projection of urban land needs
2. Generous metropolitan limits
3. Selective protection of open spaces
4. Arterial road network integrated with land-use

Using these four components, the study compares previous master plans, statutory urban boundaries and urban growth envisaged in the master plan versus actual resulting urban sprawl. Aim of the research was to understand whether making room paradigm can be used as an alternative planning approach for Indian cities, and if so what needs to be done.

INDIA'S URBAN GROWTH REALITY

India is witnessing steady urban growth over the last few decades. Looking at the demographic trends (table 1), it is clearly evident that India's urban population is constantly rising. After independence, the share of urban population was only seventeen percent (Census 1951), which has increased to 31 percent (Census 2011). Corresponding with increase in urban population, the number of urban areas has also increased substantially within this duration. According to Census 1951, there were 2843 urban agglomerations in India, which were reported 7935 in Census 2011. Thus, the number of urban agglomerations increased by 2.8 times during the same period.

Table 1: Urbanization trend in India (1901-2011)

Year	No. Urban Agglomeration town	Total population (in crore)	Urban population (in crore)	Urban Population %	Decadal Growth rate in urban population
1901	1827	23.83	2.58	10.8	
1911	1825	25.20	2.59	10.3	0.34
1921	1949	25.13	2.80	11.2	8.24
1931	2072	27.89	3.34	12	19.12
1941	2250	31.86	4.41	13.9	31.98
1951	2843	36.10	6.24	17.3	41.42
1961	2363	43.92	7.89	17.97	26.40
1971	2590	59.81	10.91	19.91	38.23
1981	3378	68.33	15.94	23.34	46.14

2001	5161	102.70	28.53	27.86	31.39
2011	7935	121.05	37.71	31.16	32.15

Source: (Deshmukh, 2015)

As per Census 2011, India has more than 500 urban areas with more than 1 lakh population, which were just 69 in number as per Census 1951. A similar rise in class 2 urban areas is also visible during the Census period between 1951 to 2011. The number of class 2 towns increased by 498 between Census 1951 and Census 2011. However, substantial increase can be observed in class 3, 4 and 5 categories of towns. The table below shows that the number of urban areas across all five class of urban areas are constantly rising.

Table 2: Urbanization by Class of Towns over Census years

Census Year	Class I: 100,000 & above	Class II: 50,000 – 99,999	Class III: 20,000 – 49,999	Class IV: 10,000 – 19,999	Class V: 5,000 – 9,999
1951	69	107	363	571	737

According to Census 1951, only 5 cities in India had population more than 1 million, which increased to 35 and 53 in Census 2001 and 2011 respectively. These 53 cities are estimated to produce about 32% of the GDP with only 13.3% of the population and with only 0.2% of the land area. The 100 largest cities by population in India are estimated to produce about 43% of the GDP with 16% of the population and only 0.24% of the land area (Revi, et al., 2012).

Table 3: Number of UA/Towns and Outgrowths

Type of UA/Towns and Outgrowths	Number of towns	
	Census 2011	Census 2001
Statutory Towns	4041	3799
Census Towns	3894	1362
Urban Agglomerations	475	384
Out growths	981	962

Source: (Census of India 2011)

One of the highlights of Census 2011 is the rapid growth in number of census towns since 2001 (table 3). From 1362 census towns in 2001 to 3894 towns in 2011 has seen the fastest growth of census towns. There are noteworthy number of Outgrowth (OGs) as per Census 2001 and 2011. These settlements are contiguous to a statutory town, and generally possess all the urban characteristics. However, these settlements do not technically qualify to be an independent town, as they do not satisfy the definition of an urban area.

To accommodate the increasing urban population the largest cities in India have expanded, they have significant population and built-up areas outside the ULB boundaries. (Revi, et al., 2012) study shows that in most cases, the proportion of built-up area outside the urban local body boundary of the city is greater than the proportion of population outside the administrative boundaries, implying relatively low-density sprawl. Comparing the spatial expansion from 1990-2000 and 2000-2010 shows that the expansion has accelerated between 2000 and 2010. To accommodate this fast-paced urbanization, there is not only a need to rebuild and retrofit our existing cities but also to build new cities. Else, this unprecedented urban growth housing problems, energy, water and sanitation challenges which will have consequences on our living conditions, economic growth as well as environment. If not planned and properly our cities will be congested, chaotic and haphazard, giving rise to several conflicts.

URBAN PLANNING APPROACH IN INDIA

One of the key instruments used for planning Indian cities is Master Plan or Development Plan. The Third Five Year Plan defined the term 'Master Plan' as a statutory instrument for controlling, directing and promoting sound and rational development and redevelopment of an urban area with a view to achieving maximum economic, social and aesthetic benefits (Meshram, 2006). Master Plan is visualized as a long term perspective plan, which is drafted considering the future growth of the city, its economic development potential and infrastructure requirement. Delhi Development Authority defines Master Plan as, "A Master Plan is the long term perspective plan for guiding the sustainable planned development of the city. This document lays down the planning guidelines, policies, development code and space requirements for various socio-economic activities supporting the city population during the plan period. It is also the basis for all infrastructure requirements." These plans are prepared under the Town Planning Acts, thus have legal backing and are statutory in nature.

Evolution

The evolution of contemporary planning practice in India starts with the Bombay Improvement Act 1920. Afterwards, the town and country planning act were enacted in various states. Later on the lines of the Town and Country Planning Act, 1947 the statutory process of master planning was adopted in India, as the improvement act did not have the provision for preparing the master plan of the whole city. In 1962, The Model Town and Regional Planning and Development Act, 1962 was adopted which provided the framework of planning to various states for enacting town and

country planning acts. The master plans in India are statutory in nature, and are used to regulate use of land in the city, envision the future growth of the city and are the instrument of land supply.

Current Urban Planning Process and its challenges

In India, Town Planning is a State function and is not included in the concurrent list of the Central Government (Mahadevia, Joshi, & Sharma, 2009). State Town & Country Planning offices overlook the mandate of preparation of urban plans. The provisions related to urban planning are practised under the statutory provisions of State level urban planning legislations. The legislations also have provisions to establish a specific development authority or planning authority for towns and cities, more specifically in case of large metropolitan cities. Major function of the state level town planning agencies is the preparation of Development Plans, Master Plans, Regional Plans, Zonal Plans, Town Planning Schemes, Urban Estates' Plans, Sector Plans, etc. In general, state level agencies are responsible for setting up General Development and Control Regulations (GDCR), preparing landuse plans and providing basic infrastructure in an area notified as urban area in the Master Plan or Development Plan.

(Mahadevia, Joshi, & Sharma, 2009) City level plan (i.e. Master Plan or Development Plan) is a long-term plan and is generally prepared for a horizon year of 10 to 20 years. The process begins with projection of population of an urban area and an estimate of an average household size, which together with income levels of different household categories; determine the demand for residential space. The requirements of industry, office, and retail spaces are based on projections of the economic prospects for the cities; the transport patterns follow from the land use pattern and the space requirement for transportation is typically a residual. The space needs for conservation of natural resources and protection of built heritage are also determined residually, unmindful of considerations of sustainability or contextual nuances (Ahluwalia). For preparation of an urban plan (as per the process mentioned above), a statutory urban boundary is delineated by the planning authority and approved by the state government. This boundary is typically known as 'Urban Growth Boundary (UGB)', and formally termed as 'Planning area or Development area' as per the legislations. The intention behind delineating such a boundary is to mandate the area inside the boundary to be used for urban development, while are outside this boundary is generally conserved in its natural setting or rural use. Delineation of this boundary is either based on the principle of urban containment or urban expansion.

Urban containment and expansion debate

Containing urban growth within a growth boundary has its supporters as well as detractors. The advocates of containment approach claim that it is an antidote to sprawl and limiting the growth of cities increase urban population densities, reduce the excessive fragmentation of urban footprints, reduce dependency on automobile, revitalize public transport protect farmlands, biodiversity, decrease the cost of infrastructure and save energy. However, this also means that the supply of land is artificially restricted, causing increase in the price and hence making housing unaffordable making it out of range to people and firms and making it non-competitive. This also imposes cost of monitoring, enforcing the strict and rigid regulation a acting against the development trends. Taking the global example of green belt in Seoul, which used the green belt as a containment strategy, prohibited the conversion of land to urban use in an area of 1482 sq. km. This green belt initially enjoyed wide public support. But later its detractors pointed out that it restricts urban land supply thereby creating artificial scarcity of land thereby increasing the price and making it less affordable. Thus, at one end of the spectrum there are those who advocate limiting the boundaries of the cities by all means and at the other end there are those who welcome it. (Angel, L., Civco, & Blei, 2011) quotes (Nelson, Sanchez & Dawkins 2004, 342) defining containment as *"Broadly speaking, urban containment programs can be distinguished from traditional approaches to land use regulation by the presence of policies that are explicitly designed to limit the development of land outside a defined area, while encouraging infill development and redevelopment inside the urban areas"*.

Metropolitan strategy for many cities in India also are based on the concept of urban growth boundaries using them to contain the urban growth through green belts or no- development zones. (Venkataraman, 2013) has highlighted the effects of restricting the supply of urban land by analysing the effects of urban growth boundary in the city of Bangalore. The city is enclosed within a green belt with zoning restriction to limit urban sprawl.

In the study it is pointed out that the land inside the urban growth boundary is valued higher than the land outside the urban growth boundary, this is consistent with the internal evidence but shows only part of story. He further goes on to explain that the land which is outside the growth boundary is generally converted to illegal revenue layouts that are sold in piece meal to public, this land at a later point awaits to be regularised. These areas of the urban growth boundary which are later regularised develop haphazardly, with lack of basic infrastructure, open spaces, arterial street network and even encroach on the environmentally sensitive areas.

The Making Room Paradigm by Shlomo Angel

(Angel, et al., 2005) brings to fore the unanswered question underlying the debate, whether expansion should be resisted, accepted or welcomed. The paradigm is grounded in the belief that there is a need to make minimal preparation for the sustainable growth and expansion of cities in urbanizing countries rather than to restrict and contain urban growth. It promotes the accommodation and rejects the placement of limits on urban expansion in rapidly urbanising countries.

The paradigm consists of four components

1. Realistic projections of urban land needs:
2. Generous Metropolitan limits

3. Selective protection of open spaces
4. An arterial grid of roads

ABOUT THIS PAPER

The intention of this paper is to probe further on the debate of urban expansion and urban containment. It tries to examine and assess the applicability of these two basic principles, which form the basis to determine the urban growth boundary in context to Indian cities. For this, the paper reviews ‘The Making Room’ paradigm being promoted by Shlomo Angel and attempts to analyse Indian cities in reference to four-step action being discussed in this paradigm. The study further explores whether this paradigm can be used as alternate paradigm for planning Indian cities. City level plans of Nagpur, Bengaluru and Hyderabad were taken as case studies.

REVIEWING MASTER PLANS OF INDIAN CITIES W.R.T ‘MAKING ROOM APPROACH’

Realistic projections of urban land needs

The making room paradigm suggests that while making projection for urban land needs consideration should be given to the declining densities in high density areas of the city and avoiding assumptions of unnecessary densification in already dense areas of the urbanizing country cities. Misplaced hopes for infill development should be avoided. The land projections that incline on the higher sides shall be considered so as to open up more land area. Urban growth boundaries like green belt, no development zone that makes the planning process and the urban expansion rigid should be discouraged.

- **Nagpur:** Master Plan of Nagpur proposed the total developable area proposed for development till 2011 (figure 1). The zone outside this area comes under the no development zone. Any construction activity is strictly discouraged in this zone. The total land in proposed developable zone the DP was 150.33 sq.km, and the no development zone was demarcated in an area of 57.74 sq.km, which is almost one third of the total area of the development zone.

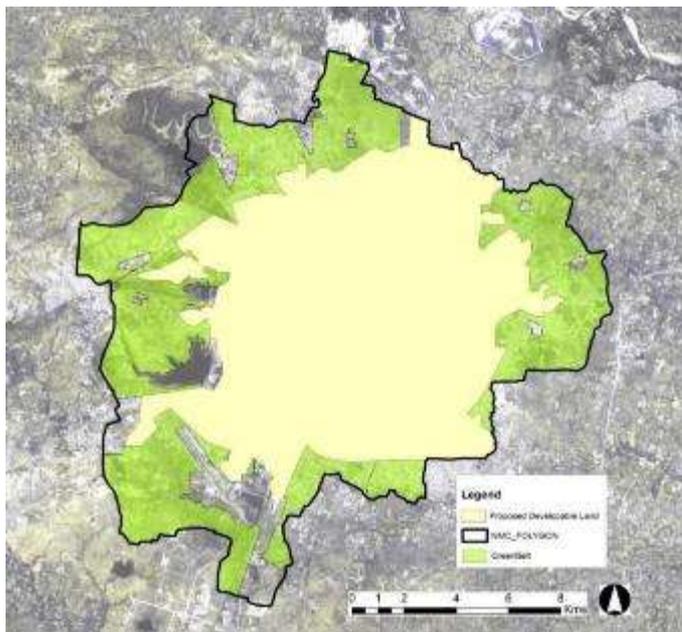

Figure 3 Map showing proposed developable area in Nagpur Master Plan 2011

In order to analyse the extent to which green belt was effective to contain the development, the urban land cover map was prepared through ArcGIS from Landsat imagery for the year 2011. Figure 2 shows that the urban growth has expanded beyond the developable land estimated in the Master Plan.

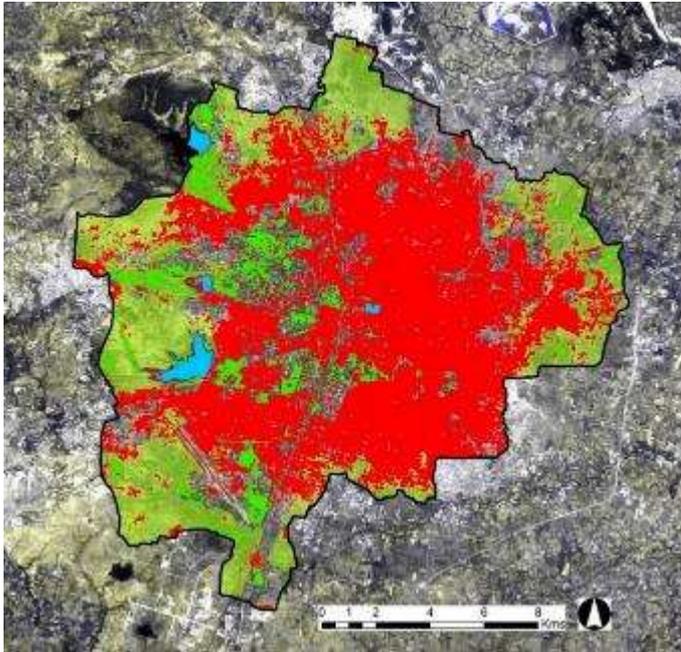

Figure 4 Map of Nagpur showing urban expansion in 2011

Area of the development outside the developable zone calculated based on the raster pixel comes to be 35 sq. km. This shows that around 60 percent of the area of the no development zone was urbanized as of 2011. Thus, the urban expansion went beyond the developable area, seems to be more towards south, east and north-west.

It has been observed that the land owners in the no development zone are subdividing the land and selling it as unauthorised revenue layout. These layouts are in a later stage regularised by the planning authority against a regularization charge. This is a clear breach of the core principles of 'green belt' based containment approach.

The actual area that was urbanised is the horizon year of the master plan was much more than the proposed land requirement estimated in the development plan. The growth that has taken place was not foreseen or facilitated by the development plan. Such development was regularised and thus had minimal physical and social infrastructure.

- Bengaluru:** In Master Plan 2015, Bengaluru's the developable zone was increased and adjoining growth centres were also added in the Bengaluru Metropolitan Area. Currently, the metropolitan planning area is 1300 sq.km, out of which 800 sq.km falls under the jurisdiction of Bengaluru Municipal Corporation. The city is also encircled by a green belt, with an objective to control urban sprawl beyond the organizable limit defined in the Master Plan. Area of the proposed green belt comes out to be 270 sq.km, which is approximately 20 percent of the total area of the metropolitan area. Additionally, the Master Plan also demarcated an area of around 174 sq.km (13.5 percent) as agriculture zone. The development restriction for both green belt and the agriculture zone are the same. So, the total developable area as per the master plan comes around 564.73 sq.km and the area of the green belt and the agriculture zone comes around 444 sq. Km (figure 3).

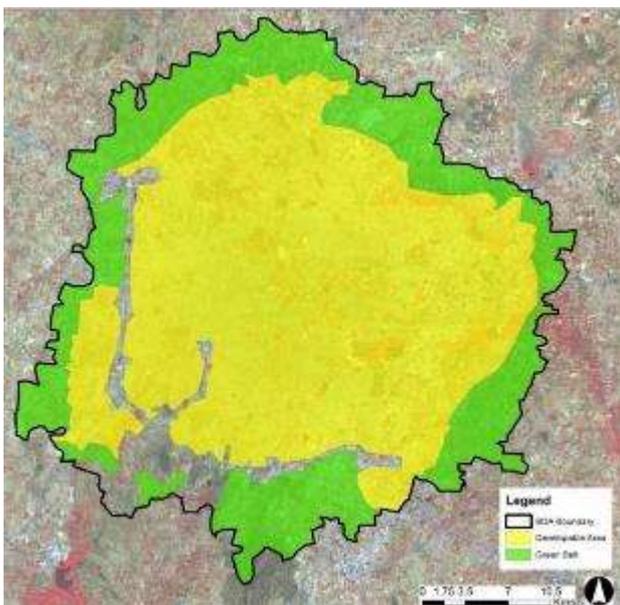

Figure 5 Map showing proposed developable area for Revised Bengaluru Master Plan of 2015

A study by (Venkataraman, 2013) quotes study by (Ravindra, et al., 2012) on land market assessment of Bengaluru that suggests around 11% of the green belt was converted into land used for non-agricultural purposes. Around 22.3 sq. km. of land had been developed without authorisations between 2003 and 2010. That is about 5.37 percent of the green belt area or 50 percent of the urbanised green belt land. Venkataraman has also observed in his study that there is extensive building on revenue layouts in the transition areas in the green zone. Revenue layouts are the private layouts that are made after converting land from agriculture use to non-agriculture use, often illegally and without necessary approval. The land cover analysis done on ArcGIS (figure 4) from the Landsat imagery of 2015, it is clearly seen that urban growth has expanded beyond the developable zone onto the green belt in certain areas.

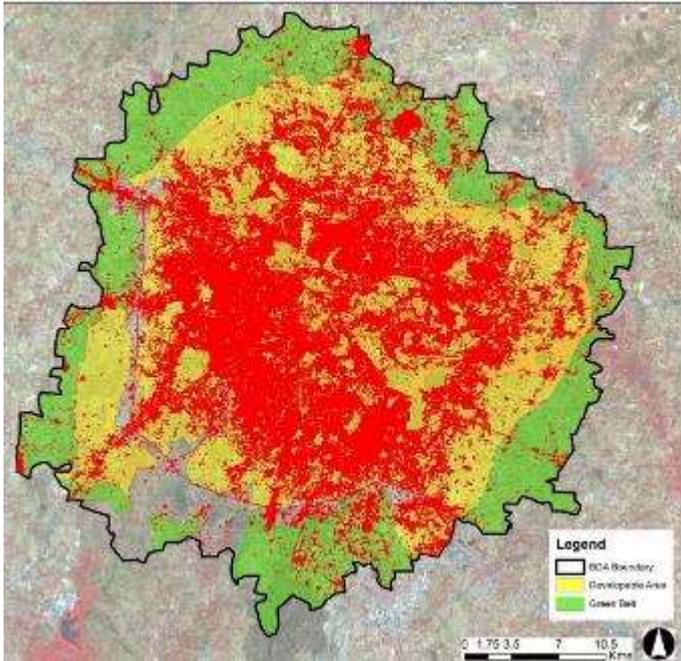

Figure 6 Map of Bengaluru showing urban expansion in 2015

- **Hyderabad:** Hyderabad Master Plan gave the areas to be developed by 2011. These areas are proposed as the extension of the developed areas in 1993. The developable areas in 1993 as well as the developable land area opened up for development till 2011 are shown in Figure 5.

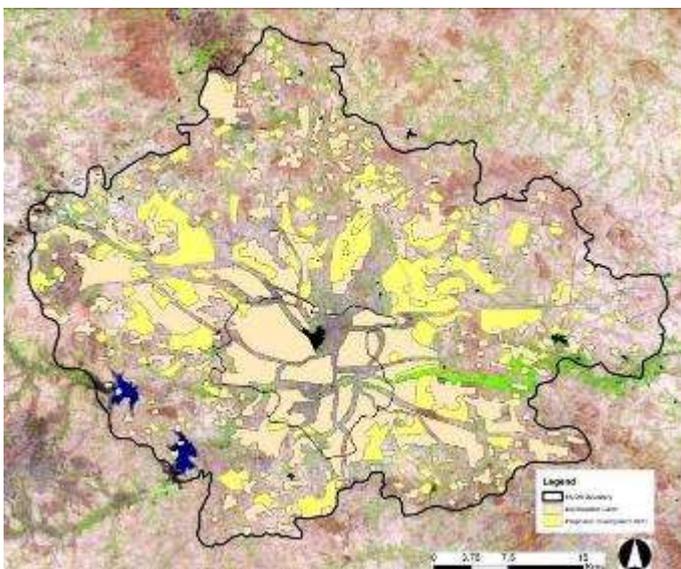

Figure 7 Map of Hyderabad showing proposed developable area

The extent of urban expansion in the city till 2011 shows that the areas opened up for development in the master plan was much more than the area that had actually urbanised till 2011.

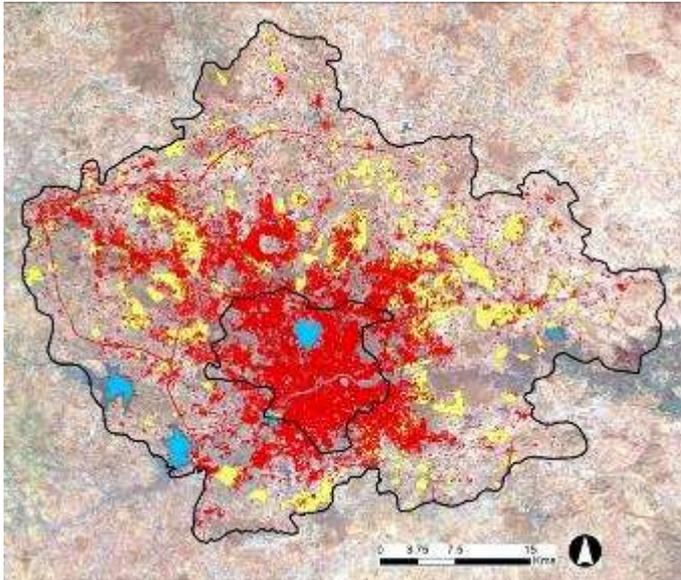

Figure 8 Map of Hyderabad showing urban expansion in the year 2011

This suggests that the land requirement may have been overestimated, which indicates that the development strategy was liberal in nature, which gives more room for the city to expand.

Generous Metropolitan limits

Making room paradigm suggests that the metropolitan limits have to be large enough to accommodate 20-30 years of urban expansion and should be periodically monitored if a revision in the boundary is required. In order to analyse growth of the city with respect to its planning boundary, a comparison of the metropolitan boundary against the physical growth of the agglomeration in two different time frames was done by analysing Landsat satellite images. Land cover for the base year and metropolitan boundary was compared with the land cover of urban expansion that took place in the horizon year.

- Nagpur:** Planning area in the Development Plan 1990-2011 for Nagpur city falls within the jurisdiction of Nagpur Municipal Corporation. The total area of NMC is 21,756 Ha. The city's planning boundary has not been revised since 1951. The population of the city was 4.5 lakhs in 1951, which has increased to 24 lakhs in 2011. Thus, even though the city's population has increased, as well as the city witnessed spatial growth through these years, the planning boundaries were not revised (figure 7). While, the development plan 2011 has reached its horizon year and the city has expanded much beyond the NMC boundary, there has been no effort to expand the boundary and comprehensively plan the outer expansion and the urban growth areas outside the city limits. Only until January 2018, when the Nagpur Metropolitan Region Development Authority's development plan was sanctioned, these areas outside the municipal limit were brought under the jurisdiction of metropolitan region development authority for planning these areas. Till early 2018, there was no planning metropolitan development plan to holistically plan the city and the surrounding growth centres. The areas just outside the periphery do not fall under the master plan, thus underwent unplanned growth.

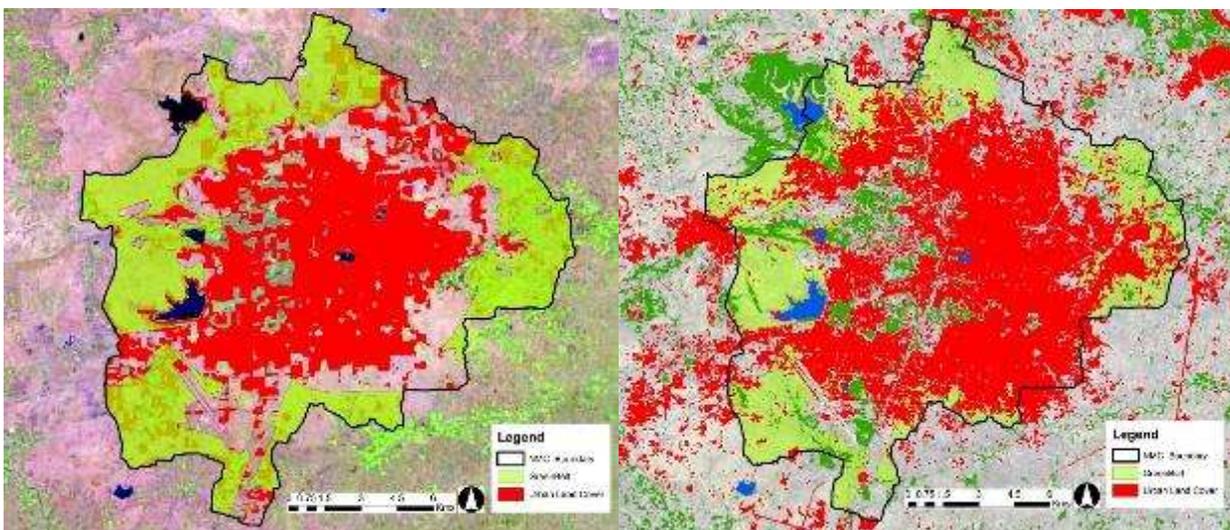

Figure 9 Map showing urban land cover of Nagpur in 1990 (L) and 2011 (R). The urban expanse of the city had gone beyond the planning boundary.

- Bengaluru:** Planning area in the Master Plan 2005-2015 for Bengaluru city falls under the jurisdiction of Bengaluru Development Authority (BDA). The total area of BDA is 1300 Sq.km. Even though the master plan's

horizon year was 2015, the agglomeration had already expanded much beyond the developable land and into the green belt to reach the periphery of the BDA Boundary. This area which is near the periphery does not fall under the Master Plan, thus causing uncoordinated growth. The map below shows the trend of urbanisation from 2005-2013. The master plan does not discuss about the future course of urbanisation in this regard, and the future boundary which could be taken up to accommodate planned urban expansion.

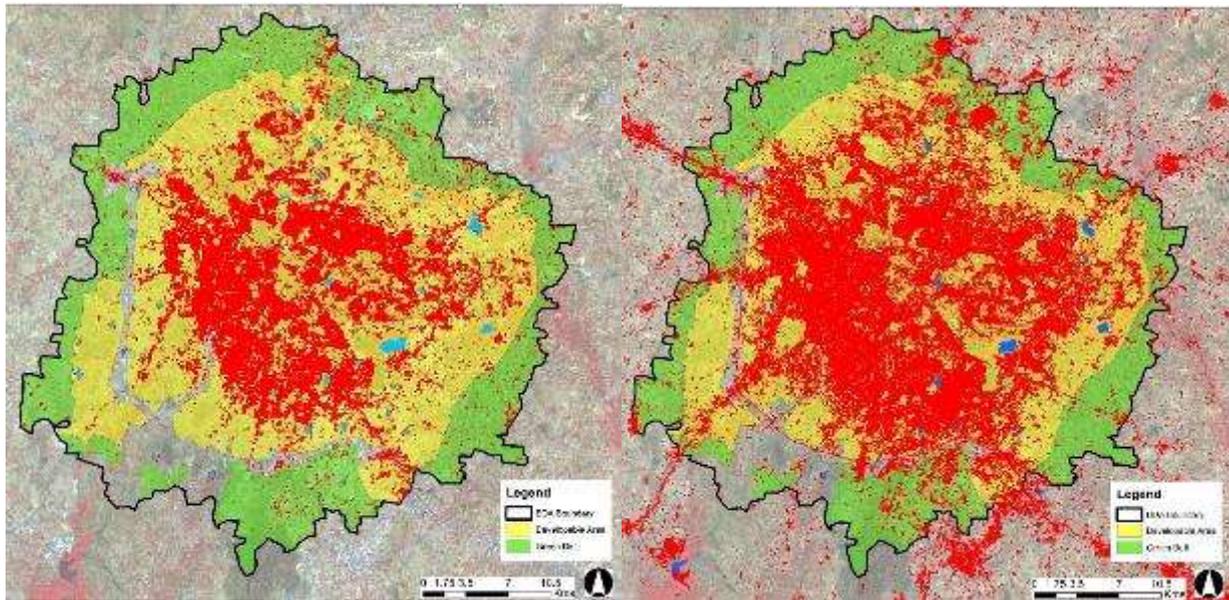

Figure 10 Map showing urban land cover of Bengaluru in 2005 (L) and 2015 (R) showing the growth of the town with respect to its planning boundary

- **Hyderabad:** The planning area in the master plan 1993-2011 for Hyderabad city was the area erstwhile Hyderabad Urban Development Authority (HUDA). The total area of HUDA was 1875 Sq.km. Only in the case of Hyderabad, the urban expansion of the city had not reached the periphery of the metropolitan boundary. Even though urban sprawl had taken place much before the master plan's horizon year- 2011, the agglomeration hadn't expanded till the periphery of the HUDA Boundary and large amount of land still had potential to urbanise.

Selective protection of open spaces

Making room paradigm describes this component for protecting environmentally sensitive areas and open spaces by making metropolitan open space plan. This plan should contain hierarchy of open spaces, ranging from playgrounds, parks, natural parks, fertile agriculture, etc. To enforce regulations that mandate the allocation of a certain share of private land for public use. Creation of institutional framework comprising public, private and civic organisation for aggressive protection of open spaces. This study does not cover the allocation of certain share of private land for public use and creation of institutional framework, since it limits the study to overall planning approach and does not venture into local level planning.

- **Nagpur:** Development Plan of Nagpur identifies open spaces of all hierarchy, ecologically sensitive areas, and proposes to protect these areas by developing these spaces by converting some of them into city level recreational spaces. Identification of parks garden at differential level, ranging from city level to neighbourhood level open space has been done in the plan. Identification of water bodies, urban forest, etc and proposal of lake front and international zoo were also included in the Revised Development Plan.

Thus, the Master Plan gives emphasis on the protection of open spaces, environmentally sensitive areas and reserving land for public use, identification of parks from city level open space to neighborhood level.

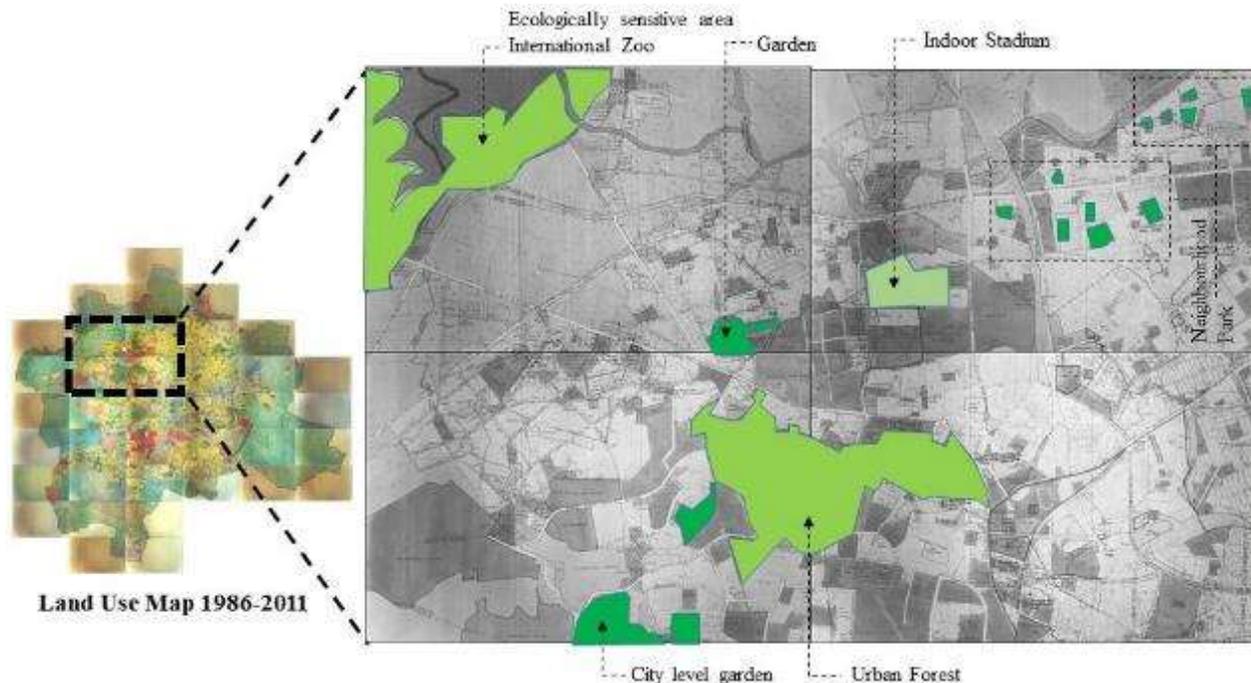

Figure 11 Hierarchy of open spaces in Nagpur master plan

- **Bengaluru:** Master Plan gives importance to the provision and protection of open spaces available in the city and the conservation of other open spaces in the city like lakes, natural drains, urban forests. However, (Thippaiah, 2009) in his study points out that Bengaluru witnessed the decline in the number of lakes, out of 262 lakes only 81 lakes survive now.

The plan does not give concrete strategy to protect of lakes, other than developing few selected ones. What happens to the other lakes and how they would be protected is not clear. This causes conflicts during implementation of master plan resulting in degradation of open spaces.

- **Hyderabad:** The master plan proposes to reserve land for new regional level parks. Smaller and local level parks created through the process of layouts development by reserving land for public purpose. In addition to these regional parks the proposed land use has reserved all hillocks, valleys, lakes and river banks as recreational areas and 'No development zones'.

An arterial grid of roads

Making room paradigm suggests that the planning for the arterial road network must be planned for next 20-30 years. The network should follow a hierarchy and should ensure that public transport is within ten-minute walk. The roads should also have wide right of way so that dedicated bus lanes and non-motorised transport can also be incorporated. Making room also suggest having an arterial grid of roads of one kilometre by one kilometre so as to encourage cycling, walkability and also to plan public transportation systems in these arterial grids.

- **Nagpur:** Master Plan covers transportation section in detail. It proposes ring roads and major arterial road in the city. It also proposes mass transportation solution for the city and promotion of NMT through improvement of footpath and introduction of cycle tracks. Proposals related to truck terminals on various location of the city to deal with goods traffic movement can also be found in the plan.
- **Bengaluru:** Bengaluru plan proposes road network, a ring road in the inner core and one at intermediate to decongest major arterial roads and also proposes outer peripheral ring road. Proposes separate bus rapid transport system with dedicated bus lanes. Proposes logistic facilities for goods transportation. Multi-modal transportation hub is proposed. The master plan also proposes mass rapid transport systems like metro rail.
- **Hyderabad:** Hyderabad Master Plan proposes outer ring road which has now been executed. Mass rapid transport system is proposed and the number of arterial road and flyovers proposed at different location in the city.

Key Findings

While reviewing the planning approaches of the city with respect to the four components of the making room paradigm it can be analysed that:

- With respect to the projection of urban land needs Hyderabad fared better. The city opened up more land area taking into account the population projection. In case of Nagpur and Bengaluru both cities had introduced urban growth boundary though no development zone or green belt. The urban growth did not stop with the green belts, the land cover map showed how the urban growth expanded into the green belt too. Both in case of Nagpur and Bengaluru it has observed that the land owners in the green belt and no development zone have subdivided

the plot and sold it to people as unauthorised layouts. These layouts are later regularised against conversion charges or betterment levy, leading to unplanned and peace meal development. The master plan does not address how the issue of creation of illegal layouts can be tackled. It was only Hyderabad which had opened up urban land for expansion generously allowing the urban expansion to take place.

- With respect to the second component i.e. Generous Metropolitan Limit, Nagpur had not revised its boundary since 1953. Even as the city's urban growth spread beyond the planning boundary yet the planning boundary was not revised until 2018, when the metropolitan region development plan was sanctioned. In case of Bengaluru the master plan document proposes the conurbation area for the future expansion of the city till 2031, but the land cover maps show that by 2015 itself the city had almost grown beyond the proposed developable areas in some parts and even outside the city metropolitan area in some areas. Only in case of Hyderabad the metropolitan limit was generously larger so as to make provision for the cities expansion for 20- 30 years.
- With respect to the selective protection of open spaces the Nagpur master plan does identify different hierarchy of open spaces, environmentally sensitive areas and reserving land for public use. Identification of parks from city level open space to neighbourhood level and it designates use of such parks for playground, garden, etc. It also does not allow any development in these open spaces thus protecting them. The Bengaluru master plan does focus on the preservation of ecologically sensitive areas but does not provide any concrete strategy on how the lake systems of the city would be protected and preserved. Hyderabad master plan proposes to reserve land for new regional level parks and creation of smaller level parks to be done through the process of layout development. Hence all the three cities give importance to protecting environmentally sensitive areas and open spaces in the city, fulfilling the making room paradigm
- With respect to the fourth component that is An Arterial Grid of Roads all the cities had prepared their road network plan proposing roads of different hierarchy with radial and ring roads. Also the master plans of the three cities went on to proposed mass transit systems and also laid out proposals for promotion of non-motorised transport. The suggestion from making room paradigm of having an arterial grid of one km by one km could not be assessed in the master plan.

CONCLUSION – CAN MAKING ROOM PARADIGM BE AN ALTERNATE PLANNING APPROACH FOR INDIAN CITIES?

The review of the planning approach of three cities with respect to the making room paradigm has brought to light the diverse approaches of planning between the cities. Also, on assessing these cities in reference to the four parameters of making room approach, it can be said that none of the cities completely corresponds to all these parameters. The planning approach adopted by the case cities against the making room paradigm is to understand that there were some approaches which were contradictory and some that were going hand in hand with making room paradigm. Nagpur and Bangalore had adopted a conservative approach by limiting the urban growth with introduction of urban growth boundaries resulting in the haphazard development in the green belt or no development zones. While Hyderabad opened up the much more area for urban development than required. The protection of open spaces and arterial road network were the strategies identified by the three cities.

The key point that could be understood by analysing these case study cities and their Master Plans, it is very clearly found out that the plan making process and the decision related to urban growth boundary did not seem to be based on strong analysis of the existing situation and growth patterns of the cities. Scientific basis and rationale behind fixation of urban growth boundary, using expansion approach or containment approach, was not found in either of these case studies.

It could be said that different cities may have to adopt dissimilar approach depending on their context. What we also need to consider is the economic growth of the cities and future population they would attract. This would alter the housing demand for the city and would change the land supply need for housing development. While projecting for the urban land needs and deciding the metropolitan boundary regional economics should also be considered, giving an insight to the city's and region's development in the future. This would enable the planners to foresee and integrate the said vision by adopting the suitable planning paradigm.

Whether making room paradigm can fully be adopted as a planning paradigm would need a much more in-depth study at the city level. But there could be some universal changes that can be brought about in the planning approach of rapidly urbanising Indian cities so that they can cope with the pressure of urbanisation. These are as follows:

1. The master planning process should be as dynamic as the city itself, it should be able to adapt the fast-changing scenarios in Indian cities. The city government should be able to revise the plans based on their study through continuous monitoring of the city's growth. Empowering the city governments to make planning decision involving making and revising master planning.
2. There is a need of getting rid of ideas of over densification of cities. Since Indian cities already have high densities; unnecessary densities create pressure on urban infrastructure. High densities, where required, should be supported by adequate infrastructure.
3. Letting go of growth boundaries like green belt, no development zone, etc. This could be replaced by more liberal planning approach where sectors for future development are earmarked for phase wise development.

4. While delineating metropolitan boundaries for the cities, the city and its surrounding growth centres shall be considered. A metropolitan plan or a city-region plan would have more holistic approach since it considers the economic vision for the whole metropolitan area.
5. Use of liberal zoning policies, mix land use zoning, varying FSI based on urban forms and density should be adopted.
6. Demarcating ecologically sensitive areas, open spaces, recreational spaces in the whole planning area and making strategies for its protection. Making a city level open space plan should also be considered.
7. Planning of the arterial grid road network that encourages walkability and public transport should be undertaken. Implementation of the road network could be in a phased manner so as to implement these roads as the city expands. The city should also start looking at preparing integrated mobility plans, that not only link public transport networks, but also include non-motorized means of transport.

The above recommendations which are inspired by the making room paradigm could be adopted for planning of Indian cities. The answer to whether making room paradigm could be an alternative planning approach for Indian cities, can only be answered though context and challenges faced by each city, its economic vision, geographical limitations and other challenges that are faced by each Indian city.

1000 DOES THE COHESION POLICY WORK IN CENTRAL AND EASTERN EUROPE? SPATIAL HETEROGENEITY MATTERS

ABSTRACT

Since the EU’s cohesion policy creation, this policy has aimed at reducing regional disparities, restructuring regional economies, creating jobs and stimulating private investment. In their article, BECKER ET AL. (2012) wondered whether this policy really helped to favour growth in the regions concerned. They concluded that reorienting the European aid that was more concentrated in targeted regions would improve the effectiveness of the spent funds. They were therefore able to demonstrate the spatial heterogeneity of the effectiveness of the cohesion policy in Europe. Despite the fact that the EU has been extended to eleven new Central and Eastern European countries, the question of the future of European policies, particularly the cohesion policy, remains problematic. As the aim of our article is more to identify the spatial nonstationarity of the effectiveness of the funds than to establish general rules and regularities about the studied phenomenon, we prefer using a local model rather than a global spatial model, like these scholars. Furthermore, this is what DALL’ERBA AND FANG (2015) recommend in order to reconsider the “one size fits all” theory, and therefore demonstrate that the European funds can have a significant positive impact in some regions and no or even opposite effects in others. We use the GWR - geographically weighted regression - to assume that there is a significant spatial variation in the influence of the factors instrumental in regional growth. One of our main objectives is to show the spatial heterogeneity of the effectiveness of European funds in the explanation of the growth of Central and Eastern European regions. Our article contributes to the understanding of the evaluation of the effectiveness of European structural funds over the last two programming periods. The analysis is based on a sample of 147 Central and Eastern European regions at NUTS 3 level over the period 2000-2014 using GWR. Although the favoured level of allocation of European funds is NUTS 2, we have made the decision to work on NUTS 3 regions in order to provide more detailed understanding of the effects generated by the EU Cohesion Policy transfer on growth (like BECKER ET AL., 2012 or GAGLIARDI AND PERCOCO, 2017). The choice of (i) focusing on Central and Eastern European regions, (ii) this level of analysis, NUTS 3 and (iii) this method is unprecedented in the literature.

1407 HAPPINESS INDEX: WHAT MAKES YOU HAPPY?

Prachi Jadhav¹, Nambram S Devi¹, Naveen Krishna Alla¹, Rathin Biswas¹

¹ Centre for Urban Science and Engineering, Indian Institute of Technology Bombay, Powai, Mumbai, 400076, India

ABSTRACT

There are many countries with having low Gross Domestic Product (GDP) and probably will not be able to come to the first quartile in the world. But that doesn't necessarily mean that citizens living out there, are not happy with their quality of life or service provisioning. So economic progress & provision of basic services does not guarantee certain happiness, it is necessary to measure citizen's aspirations & happiness-shortfall for policy amendment. Researchers tried to assess for various aspects, but overlooked composing as a whole, which was done here. Literature suggested that there are four major components - Health, Social Interaction, Governance & Services and Living Standards, which are the measures of Subjective Well Being (SWB), which contributed remarkably on happiness for Individual, Community, National, & Regional level. We have also identified the criteria of these major components. A web based app was developed to ideate citizen's happiness index by inclusive questionnaire incorporating those components and their criteria. We deployed our system to observe field-reaction and perceive disparities in SWB's domains in our result. Finally the Happiness Index was established as a representation of subjective wellbeing of citizen. Test-values from Cronbach's-alpha & Spearman-Brown-split-half, confirmed the reliable-results, which reveal predominant association of happiness with Education level, Health, Social tie (especially with family & friends), Living standard (Income, work-life balance & Educational facilities). The methodology and tools used in this study, creates a base or an example to evaluate citizens' happiness for all those backward countries, even they have low GDP. This study is very helpful for policy & decision makers in order to identify the focusing aspects of improvements. Researchers can conduct similar study in other contemporary societies. Further the larger dataset will provide better analytics and deeper insights.

Keywords: Well-being, Happiness, Index, Assessment, Indicators, Metric.

1 INTRODUCTION

Happiness - the ultimate human aspiration, and can also be a measure of social progress. America's founding fathers declared the inalienable right to pursue happiness. Pursuit of Happiness is a fundamental right mentioned in the America's declaration of Independence and is defined as: to freely pursue joy & live life in a way that makes a person happy, as long as the person do not do any illegal or violate the rights of others.

Happiness research was predominantly a domain for Psychology until it was linked to Economics. Since the late 1990s, economists from different part of world started to contribute to happiness research through large-scale empirical analyses of the indicators of happiness.

Many researcher have carried out research to find indicators of happiness, measure them, find the shortfalls and use them as a tool for making policy for enhanced wellbeing and quality of life. Happiness can be measured at Personal level, Community/ Organizational level, National level, and Regional level in at least two ways - the first as an emotion and the second as an evaluation.

Happiness is a fuzzy concept and can mean many different things to many people [1], for Psychologists it is individual perspective-personal flourishing. Sociologists and Economists focus primarily on society's perspective i.e. the Nation's or Community's flourishing.

So there is a need of generating a reliable dataset for analysis of policy, as objective dataset are not available. But the question is, can data on self-reported happiness collected through ICT provide critical insights into the prevalent policies and guide policy making? What are the relevant indicators of happiness in Indian cities? Are they different from earlier indicators of happiness found by researchers across the globe?

In this study, the major domains with their indicators, were identified through the exhaustive literature review over the globe. Then questionnaire formed with the expert help, and was embedded in an android app to take the survey. Then those collected data were analyzed to find out the most effective indicators, which are playing major roles behind happiness. The results further tested for reliability and sensitivity. And finally how this study can help the citizen, policy and decision makers, was discussed or concluded. Further spatial or area specific study can infer more stories.

2 PROBLEM STATEMENT

Happiness research has revealed that economic progress or other traditional prosperity measures like health, living standard individually do not necessarily translate into increase in people's quality of life. Provision of basic services and amenities to citizens do not necessarily guarantee happiness. For the average citizen, happiness is unlikely to be dependent on any single domain, but is rather the sum of the weighted indicators. There is need for bottom up approach to measure happiness of citizens to improve/ enhance quality of life. Governments are not aware of happiness status of the citizen and at the same time they are not aware of what is required to be done to make them happy. There is a need to develop a methodology to identify happiness indicators; to collect data; and to measure/ assess happiness, as a framework to identify the disparity; and to propose targeted policy interventions and amendments.

3 ASSESSMENT NEED & REQUIREMENTS

From the problem statement, it was apparent that the need of the study is to assess the happiness that is quantification of happiness, among individuals and to understand their life satisfaction in various domains of well-being.

The model is a system which collects responses from individuals, store the responses, calculate the aggregated score and display the result to user. The study team decided to collect self-reported happiness and life evaluation data from users through a mobile app and display to user their happiness measured in terms of an Index. It was contemplated that through this Happiness Index app:

- People will know their individual index in comparison to community or higher level.
- It will aid people in self-assessment of what makes them happy and what matters most to them.
- Government will come to know the inconsistency in various facilities which are directly associated with people's happiness/overall life satisfaction, needs of its residents which may help further to propose policy intervention or any amendment.

4 LITERATURE REVIEW

4.1 Prior Work

Prior attempts have been made to measure the overall average happiness of people located in cities using word frequency distributions collected from a large corpus of geo-located messages or ‘tweets’ posted on Twitter, with individual words scored for their happiness independently by users of Amazon’s Mechanical Turk service [2].

To explain the variation in happiness across different cities how individual word usage correlates with happiness and various social and economic factors is examined using the ‘word shift graph’ technique developed in [3], as well as correlate word usage frequencies with traditional city-level census survey data. The combination of these techniques produces significant insights into the character of different cities and places.

The Mappiness App is an iOS based mobile app created by Dr. George MacKerron and Dr. Susana Mourato of the Department of Geography & Environment and the Grantham Research Institute on Climate Change and the Environment at the London School of Economics and Political Science (LSE) for their academic research. The aim was to better understand how people's feelings are influenced by features of their current environment—things like air pollution, noise, and green spaces. Statistical methods were used to combine responses from everyone taking part. The location data were collected and used to estimate what the environment was like in the places where people responded give [4].

A City of Wellbeing [5] explained concisely about previous literature review on various Wellbeing Indices, targeted level, their descriptions, the "overall goal", that is, the problem the index was designed to resolve and Domains measured, adopted all over the world.

4.2 Literature Review on Indicators of Happiness

As mentioned in Problem statement, it is unfair to consider a domain to evaluate happiness Index. So, to identify the indicators and factors of Happiness, literature on happiness research was carried out, and indices of subjective wellbeing or happiness over the world were referred [5] and an exhaustive list (Table 5) of the indicators and factors were prepared.

Table 5. Different wellbeing indicators of various literature

	National Level			Local Level

5 SYSTEM DESIGN

The intent is to develop an app which will

- Calculate the Individual Happiness Index.
- Visualization dashboard which shows the Individual Happiness Index compared to the aggregated Community Level Happiness Index.

The need of the study was a system which collects responses through either a web interface or mobile app, store the responses, calculate the aggregated score and display the result to user.

System designed for the study works as described below, shown in Fig.13: The responses are collected either through an user interface web-page or through an android based mobile app. Once the user submit the filled-up the questionnaire form, then the responses are collected (with the predefined weights) and appended into a previously stored response file (.csv format) through form processing. After storing the data, score calculator read all the stored data and calculate the average score for the higher level. And then it reflects the scores or results to the user-interface.

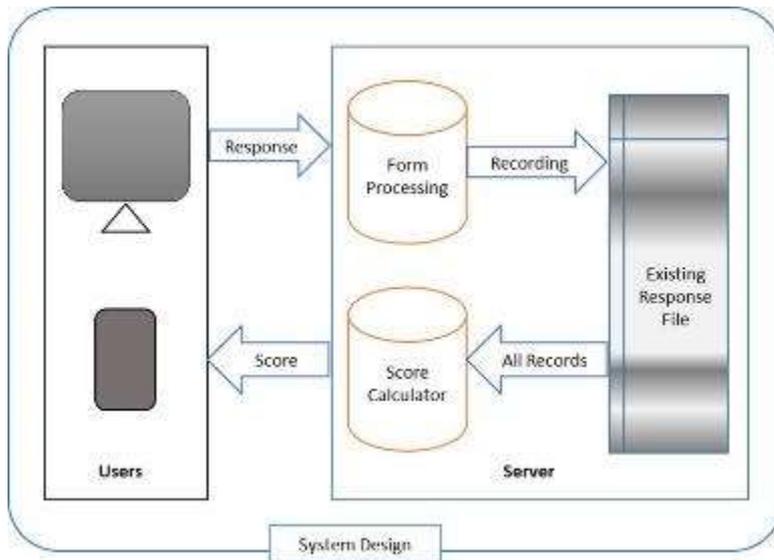

Fig.13. System Design

6 METRICS

6.1 List of Metrics

Scholarly research on measurement of Happiness revealed that it is measured in two ways. One as an emotional reporting and another as life evaluation. Emotional happiness is more correlated with variables such as social time [6] and life evaluation with variables such as income [7]. High income improves evaluation of life but not emotional well-being [8]. In our attempt to calculate Happiness Index, we have incorporated questions on both emotional reporting and life evaluation scores as measurement of Happiness.

6.1.1 Controlled experimental survey for questionnaire

The questionnaire is designed with reference to literatures on happiness research by notable scholars. While framing questions the points considered are: the reason why? For designing this particular app; and for whom? (Target audience); how will we quantify and aggregate the value and what will be our research output. The metric was tested within a controlled audience and their feedback was incorporated in the next levels of survey.

The questionnaire consist of six domains: Demographic, Social Interaction, Health, Governance and Services, Living Standards and Overall Perceived Happiness. The questions on demographic domain consist of user's nominal data on Age, Gender, Relationship status, Employment status, Education level, Number of family members, and PINCODE of current place of residence. Social interaction domain's questions consist of questions on level of socialization, number of close person (social contacts) and frequency of interaction with them. The questions on Health domain consist of questions on Psychological stress and Physical health. The question on Governance & Services domain consist of rating happiness of ten basic services provision of public open spaces and protection of environment, provision of good health facilities, provision of good educational facilities, Sanitation, Safety and security, Waste management, Transportation, Water supply and Electricity supply on five point ordinal scale and their predominant reason. The Living Standard domain consist of questions on income, current residential locality, housing and work life balance and individual's happiness rating on a five point scale.

6.2 Specific choices made

An attempt is being made to rationalize our questions and the weight given to our questions through literature reviews. Friends and family are a long-established support for subjective well-being [9]. Happiness depends not just on the

number of close friends, but also the frequency with which they are seen [10, 11]. The survey asks about the number of close friends and relatives, and the frequency with which they are seen.

6.3 Index Construction

As stated above in section 4, happiness is unlikely to be dependent on any single domain, but is rather the sum of the weighted indicators. The weighting scheme designed for the Happiness Index follows the Alkire and Foster method [12], developed by Sabina Alkire and James Foster of University of Oxford, who presented a weighting scheme for the multidimensional poverty index. Gross National Happiness Index of Bhutan also follows the same weighting method. The following weighting scheme is an adaptation of Alkire and Foster method:

- a) Domains have equal weight in the index
- b) Sub-domains have equal weight within Domains

Fig.14 shows major domains and it's sub-domains with respective weights, adapted from Alkire and Foster Method

Fig.14. Weighing Scheme

Responses to questions covering the sub-domains are in ordinal scale and variable scores are assigned to them based on their relative importance and contribution to the Happiness within the sub domains. That means responses who are correlated to Happiness are assigned scores based on the nature of correlation (positive or negative).

Happiness Index = Weighted aggregates of score of responses.

7 WORKING OF THE SYSTEM

7.1 Pilot Survey

A pilot survey was conducted on Survey Monkey which is a web based platform from 26th February 2016 to 4th March 2016 with survey questionnaire consisting of 10 questions on five domains, Demographics, Social interaction, Health, Governance & Services and Living standard. On an average it took 8 minutes 18 seconds to completely answer the questionnaire. Another survey of above survey questionnaire was conducted using Google forms to check the sensibility of construct of survey questionnaire. It consisted of only two questions, first question was "Are the questions are understandable to you?" and second one was "Do you think it is a lengthy questionnaire". The response options were 'Yes' or 'No' and the respondents were asked to select questions which are not understandable and which they find lengthy. Total 16 responses to the question "Are the question understandable to you?" were collected. Out of which only 18.8% i.e. 3 respondents responded that question number 9 on Governance & Services is ambiguous and need clarity. 81.3% i.e. 13 respondents can understand our questionnaire without difficulty. Total 15 responses to the question "Do you think it is a lengthy questionnaire?" were collected. Out of which only 26.7% i.e. 3 respondents responded that the questionnaire is lengthy and particularly one respondent responded that question number 9 on Governance & Services is lengthy. 73.3% i.e. 12 respondents did not consider the questionnaire lengthy.

Another pilot survey on Survey Monkey was carried out from 16th March 2016 to 20th March 2016 consisting of 19 questions on six domains: Demographics, Social interaction, Health, Governance & Services and Living standard and Overall Perceived Happiness. Responses collected till 20th March 2016 were selected for the analysis. On an average it took 9 minutes 40 seconds to completely answer the questionnaire.

7.2 Happiness Index

A Web Questionnaire Survey was designed to collect user-responses to calculate and display Individual Happiness as well as aggregated Community level Happiness Index. It also provide information on individual's performance on each domain. Once user submit the filled-up form, then the server stored the data as per the pre-defined weights and calculates the happiness scores both for the individual & higher level. After that, server reflects those score at the user interface as shown in Fig.15. It also shows that, in which domain(s), that particular user is happy enough and where he/ she is lacking, with the detailed score breakdown of each attribute (domain), in comparison between individual and community level.

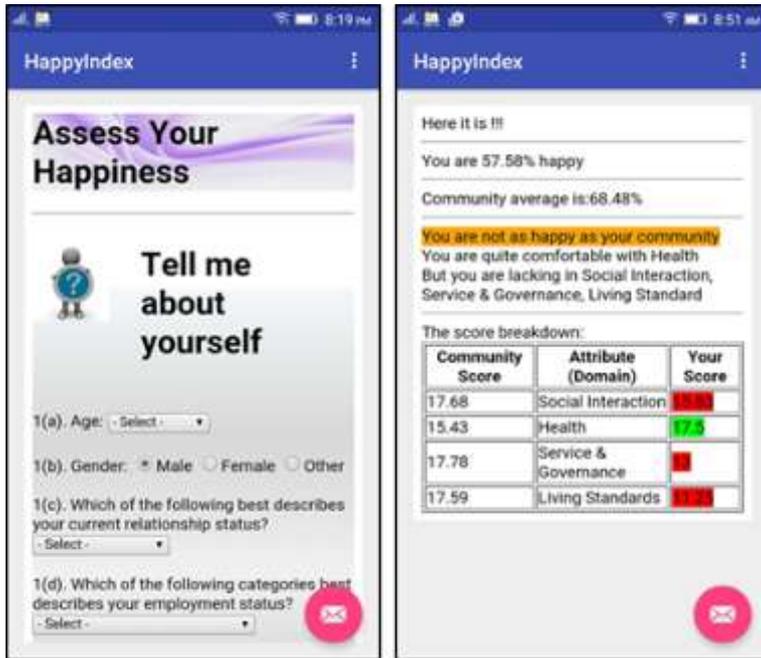

Fig.15. Screenshot of an HI App.

8. TEST RESULTS

8.1 Reliability & Sensibility

In this section, Reliability of the questionnaire using survey responses is carried out. Reliability used to test the random error in measurement. The type of reliability test depends on the type of questionnaire (ordinal, nominal, and interval) [13]. To test the Reliability of the survey responses, both Spearman-Brown split-half reliability and Cronbach's alpha test were performed. These two methods measure the internal consistency of the responses among all survey questions. The two tests were performed in SPSS (Statistical Package for Social Science) version 22. The SPSS guidelines for both the tests, are:

- > 0.9 Very Highly reliable
- 0.8 - 0.89 Highly reliable
- 0.7 - 0.79 Reliable
- 0.6 - 0.69 Marginally reliable
- <0.6 Unacceptable.

In our analysis, the Spearman Brown split-half reliability value was 0.934 and Cronbach's alpha value was 0.813 respectively. Thus the overall Reliability of our study was highly reliable.

8.2 Sample Profile

The objective here is to investigate the relationship between overall happiness and various independent variables as mentioned in Table 6. The Demographics variables with sample size shown in brackets is categorized as shown in Table 6. The style of the table has adapted from [14].

Table 6. General profile of 127 citizens.

Age	Marital Status	Employment Status	Family Size
18 to 30(68)	Single(65)	Employed, working full-time(60)	1 to 2(12)
30 to 45(50)	Married(56)	Employed, working part-time(6)	11 to 20(1)
45 to 60(7)	Divorced(3)	Full time homemaker(3)	3 to 5(97)
above 60(2)	Live in Relationship(3)	Not employed(2)	5 to 10(16)
		Retired(2)	above 20(1)
Sex	Education Level	Student(35)	
Male(78)	Post Graduate(85)	Student with or without scholarship(13)	
Female(49)	Graduate(37)	Unemployed looking for work(1)	
	Higher Sec.(5)	Unemployed not looking for work(1)	

8.3 Correlation Analysis

Due to the limited responses, only Pearson's chi square value and significance values has included as shown in Table 7. The correlations among all categories shows significant relation except basic services. The domains such as social score, living standard score and health has high significant correlation. The correlation analysis was performed at 99% and 95% confidence interval level.

Table 7. Correlation Score.

		Social Score	Health Score	Basic Service	Living Standard	Overall Happiness Score
Social Score	Pearson Correlation	1	.461**	0.181	.221*	.541**
	Sig.(2-tailed)		.000	0.05	0.016	.000
	N	127	127	127	127	127
Health Score	Pearson Correlation	.461**	1	0.099	.210*	.512**
	Sig.(2-tailed)	.000		0.288	0.023	.000
	N	127	127	127	127	127
Basic Service	Pearson Correlation	0.181	0.099	1	.744**	.821**
	Sig.(2-tailed)	0.05	0.288		.000	.000
	N	127	127	127	127	127
Living Standard	Pearson Correlation	.221*	.210*	.744**	1	.869**
	Sig.(2-tailed)	0.016	0.023	.000		.000
	N	127	127	127	127	127
Overall Happiness Score	Pearson Correlation	.541**	.512**	.821**	.869**	1
	Sig.(2-tailed)	.000	.000	.000	.000	
	N	127	127	127	127	127

**Correlation is significant at the 0.01 level (2-tailed).

*Correlation is significant at the 0.05 level (2-tailed).

8.4 Chi square Test Statistics

The chi square test for total 28 variables is carried in this study. The results of the chi square test are presented in Table 8.

Table 8. Chi square Test Results.

Sr. No.	Group	Variable name	Pearson chi square value	Significance value
1	Services & Governance	Public Open Spaces	21.64	0.360
2		Health facilities	19.32	0.501
3		Education facilities	35.64	0.017
4		Sanitation	19.23	0.507
5		Safety & Security	20.82	0.408
6		Waste Management	27.49	0.122
7		Transportation	18.9	0.528
8		Water supply	26.56	0.15
9		Electric supply	25.55	0.18
10		Reduction of corruption	18.85	0.531
11	Social Network	Family, friends & neighbors	42.09	0.013
12		With family	38.71	0.001
13		With friends	34.36	0.005
14		With neighbors	31.44	0.05
15		Social tie	18.48	0.296
16		Time spent	22.92	0.11
17	Health	Psychological stress level	54.73	0.001
18		Physical stress level	59.23	0.000
19	Personal Details	Age	20.67	0.192
20		Gender	9.66	0.067
21		Marital status	8.74	0.725
22		Education	26.007	0.001
23		Family size	37.37	0.04
24		Employment status	73.69	0.10
25	Living Standards	Income	56.45	0.000
26		Locality	29.79	0.073
27		Housing	25.81	0.172
28		Work life balance	53.55	0.00

The significant values are less than 0.05, which is the conventionally accepted minimum level of significance. Thus it indicates that there is a strong influence on citizen's overall happiness. From Demographics data, Education level & Family size are having significance values 0.001 and 0.04 respectively. The significance value for Education facilities under Governance & Services, is 0.017. Physical and Psychological health variables having 0.000 & 0.001 values. Whenever any person is in touch with Family, friends & neighbors, it shows significant values 0.001, 0.005 & 0.05 respectively indicates your happiness level is raising. Citizens in study area, becomes more disturbed due to Work Life imbalance, having significant values 0.00

8.5 Limitation

The methodology is able to reveal successfully the association between overall happiness and components of SWB and able to find relevant components of happiness, but in our case the limitation is, sample size considered for the study. Hence it is not scalable for a particular region.

Because of the varying sample size for demographics variables, we are not able to emphasize which variable say Gender, Cohort, Marital status are dominant components which influence citizen's happiness.

9 CONCLUSION

The Model is developed to assess happiness, both for Individual & aggregate level along with informing user about those factors which are affecting their happiness strongly by highlighting in an App as shown in Figure 4. According to the survey, the significant indicators which influence the happiness strongly are from Health, Social Network & Living Standards domains as mentioned in section 8.4

The foremost indicators are lack of Education and its facilities, increasing stress, health issues, and inconsistencies in social ties, Income and Work life balance. So, the implication for Governments and policy makers is that to focus on these basic needs, to improve citizen's happiness and alternatively zonal development.

There is still scope to enhance this study in terms of geo tagging the responses and analyzing the data spatially. This kind of study will be very effective in making specific area based policy. The mobile app can be made more user friendly and additional features like auto pop up, auto reminder and visualization dashboards for users' location can be added. This was a cross sectional research and the indicators used in the study are highly significant in measurement of happiness, but there is still possibility to add/subtract indicators based on their significance over a period of time through longitudinal research.

ACKNOWLEDGEMENTS

We take this opportunity to express our heartfelt gratitude to Prof. Krithi Ramamritham & Prof. Arnab Jana for their valuable input to this research. We are grateful to Mr. Karan Punamiya for his guidance. We are thankful to all the respondents. And lastly, we are thankful to all our colleagues and friends for their valuable comments and support.

1626 THE BREW PATH: ANALYZING THE ECONOMIC EFFECTIVENESS OF CRAFT BEER TOURISM PROGRAMS

ABSTRACT

The size and influence of the U.S. craft brewing industry has increased significantly in recent years which has many communities building upon a tradition of food and beer tourism by initiating policies and programs to use the industry’s success in efforts to stimulate local tourism and economic development. Similar to the renowned Kentucky Bourbon Trail and Napa Valley wine trails, craft brewery trails are being introduced around the country wherein individuals obtain stamps in a “brew passport” from each participating brewery, ultimately to be exchanged for pride and prizes upon completion. This paper employs a difference-in-difference methodology using proprietary sales data from participant and non-participant breweries in northeast Ohio’s Summit Brew Path to analyze the effectiveness of a brewery passport program managed by the local visitor’s bureau. Additionally, we test the reliability of social media locational check-in data as a proxy for brewery sales to further analyze similar programs from around the country. This paper builds upon a growing literature on craft beer research, utilizes novel data and data collection methods, and presents causal results that inform policies and practices of local breweries and tourism agencies.

1227 CLIMATE VARIABILITY AND FERTILITY: EVIDENCE FROM BRAZILIAN REGIONS

ABSTRACT

According to the literature, temperature directly impact fertility in at least two ways: i) climate can affect sexual behavior; ii) temperature could influence factors related to reproductive health, such as sperm mobility and menstruation. There is evidence that both an extremely cold winter and a very hot summer have an impact on births. However, the effects of climate variability on fertility in developing regions are not well known, since most of the existing studies focus mainly on families from rich countries. To isolate the effects of temperature, we consider the following natural experiment: year-to-year climatic fluctuations in each region are effectively random and therefore a possible test is to verify whether births in a region have changed after an exceptionally hot or cold year. In this sense, our objective is to verify whether climatic variations had any effect on fertility in Brazilian regions. For this, we estimate a panel model. As a dependent variable, we use the number of children by women aged 15 to 49 years living in region i in a given year t . We use as independent variables: the difference between the mean temperature of year $t-1$ and the temperature of the mean of year $t-2$ of region i ; a set of controls that vary in time and at the level of the region; region specific fixed effects; year fixed effects. Adding the fixed effects of the region, we will control for unobserved characteristics invariant in time, while time dummies will capture the trend of fertility that is common in all areas. Regarding the data, we constructed a panel with information obtained from the Demographic Census conducted by the Geography and Statistics Brazilian Institute (IBGE) for the years 1980, 1991, 2000 and 2010. The survey covers the entire national territory and has all the variables necessary to estimate the panel model. The second source of data comes from the Climatic Research Unit at University of East Anglia. The results suggest that climatic variations have a significant effect on fertility. This result is relatively important in a climate change scenario. This is because current research has pointed out that climatic variations occurred in greater intensities in poor and developing regions. In addition, the Brazilian fertility rate is below the replacement level. Thus, results showing evidence of the relationship between climatic variability and fertility is important for planning public policies.

1349 AN EFFICIENT AND EFFECTIVE DISASTER RISK REDUCTION PLANNING THROUGH SMART LOCATION INTELLIGENCE AND ACTIVE COMMUNITY PARTICIPATION

ABSTRACT

Natural hazards are natural phenomena that potentially cause loss to human lives and properties. When natural hazard is turned into a disaster, it unsettles the normal livelihood and often causes incomparable losses to the society. It disrupts economic activities, environmental set up and usually takes a considerably longer time to recover. According to National Disaster Management Authority, GoI, "India is vulnerable, in varying degrees, to a large number of disasters. More than 58.6% of the landmass is prone to earthquakes of moderate to very high intensity; about 12% of its land is prone to floods and river erosion; close to 76% of the coastline is prone to cyclones and tsunamis; 68% of its cultivable area is vulnerable to droughts." Disaster preparedness is the key measure to disaster prevention or at least to reduce its effects. It involves activities like disaster risk zone identification, mitigation measures for vulnerable population and efficient execution to deal with the consequences. Sendai Framework for Disaster Risk Reduction 2015–2030 has been accepted worldwide. Government of India has also taken several initiatives for strengthening disaster reduction strategies and formulated India's first National Disaster Management Plan based on Sendai Framework having four priority themes - understanding disaster risk, strengthening disaster risk governance, investing in disaster risk reduction (through structural and non-structural measures) and enhancing disaster preparedness, early warning and building back better in the aftermath of a disaster. Structural measures include physical construction to reduce or avoid possible impacts of hazards, or the application of engineering techniques or technology to achieve hazard resistance and resilience in structures or systems. Whereas, non-structural measures use knowledge, practice or agreement to reduce disaster risks and impacts, in particular through policies and laws, public awareness raising, training and education. The efficacy of any disaster preparedness largely depends on community involvement in both planning and execution phases as part of non-structural measures. Coupled with information technology and location intelligence, local crowd sourcing enables effective, realistic and coordinated disaster preparedness planning, reduces ambiguities of efforts and key personnel and increase the overall response efforts. Community participation, in particular, plays significant role in hazard mapping, identification of facility requirements, evacuation route planning and etc. Based on the experience of community participation and interaction for formulating disaster prevention plan in Sapporo, Japan, a similar measure is proposed for India in this study. A web based public information system is suggested to be prepared which would create a bridge between the administrators or decision makers and the citizens ensuring information dissemination in both vertical and horizontal direction. A possibility of real-time data sharing with locational information from local citizens will play a vital role in developing the core competencies of the disaster preparedness and survival planning. Disaster preparedness is a continuous and integrated process resulting from a wide range of activities and people participation. A proper locational and strategic data dissemination tool for disaster preparedness integrating both decision makers and citizens would minimize the disaster risk and loss.

1408 CLIMATE CHANGES IN BRAZIL: REGIONAL VULNERABILITY AND ECONOMIC IMPACTS ON AGRICULTURAL PRODUCTIVITY³⁹

Bruno S. de Souza, Eduardo A. Haddad

NEREUS – The University of São Paulo Regional and Urban Economics Lab.

ABSTRACT

Climate variation are one of the main causes of productivity losses for the agricultural sector around the world. However, most of the theoretical framework applied to estimate this effect across regions focuses only on the estimation of the direct economic impact that such changes will have on the agricultural activity of a given locality. In addition, little is discussed about the vulnerability that different regions of a given country may face. According to the definition of the Intergovernmental Panel on Climate Change (IPCC), the most vulnerable regions in terms of climate changes will be those that – beyond of facing harsher process of climate change - have little adaptive capacity to deal with such changes and depends more heavily on the agricultural sector in its productive structure.

This paper measures the economic impact that the projected climate changes for Brazilian regions may have during this century. In particular, estimates the direct impact that such shift on climate pattern will have on the productivity of the country's main agricultural crops, and the indirect impact of this changes on the Brazilian economy as a whole. In addition, builds an index of vulnerability that allows to detect which are the Brazilian regions more vulnerable in terms of climate changes in this century.

To do so, it uses a physical model - that takes into account the most recent projections of climate changes from IPCC - to predict the effect of such changes on the productivity of Brazilian agriculture. This physical model is integrated with the computable general equilibrium model (CGE) B-MARIA27 - which has the most recent available data on its calibration - in order to assess the systemic impact that changes in agricultural productivity may cause in the level of activity, well-being and production of the Brazilian states.

The analysis is conducted using data on soybean, sugarcane, maize, beans, coffee and orange between 1994 and 2015. These crops account for about 82% of the country's agricultural production. In addition, the CGE interregional model uses the 2011 data in its calibration and captures the regional interdependence of the 27 Brazilian states. Finally, the work uses the projections for the regional climate changes pattern provided by the IPCC's Fifth Assessment Report (AR5).

The preliminary results points to a very heterogeneous economic impact among the Brazilian regions. Estimates indicate that the southern region of Brazil, while experiencing an intense increase in temperature until the end of the century, will face deep costs from changes in climate. The northeastern region of Brazil, which is notoriously the least developed in the country, will be the most affected since the projections indicate that will suffer a slow process of desertification until 2100. The northern region, which houses the Amazon Forest, is the one that will face the most extreme events of intense rainfalls and prolonged droughts being the region that will have the biggest change in its agricultural pattern during the century.

Key words: Climate Changes, Regional Economics, Brazil.

1 INTRODUCTION

"I've wasted time enough," said Lestrade rising. "I believe in hard work and not in sitting by the fire spinning fine theories."

The Adventure of the Noble Bachelor

The United Nations Framework Convention on Climate Change is the largest international cooperation treaty aimed at mitigating the harmful effect that human activity can have on the environment. This treaty defines climate change as changes in climate that are attributed directly or indirectly to human activity by changing the composition of the global atmosphere beyond natural climate change (in comparable periods). Its aim is to stabilize the emission of greenhouse gases (GHGs) in the atmosphere at levels that prevent their interference in the global climate system.

Brazil, the host country of the conference, was the first country to sign the treaty, ratifying it at the beginning of 1994. In this sense, the country recognized its influence on the phenomenon of climate change by voluntarily undertaking to comply with and respect the terms arranged in the agreement. Some 140 countries are signatories to this conference, signaling to the world that efforts to mitigate the human impact on climate are a topic of great attention on most of the planet. Although the treaty did not initially set clear and specific targets of the signatory countries on the amount of greenhouse gas emissions over time, it set a precedent for the elaboration of protocols (the most famous of which is the Kyoto Protocol) which would create binding emission limits for signatory countries.

In 2008, Brazil presented the National Plan on Climate Change, whose main objective is to encourage the development and improvement of emission mitigation actions in the national territory. One of the pillars of this plan is to generate research and development aimed at the measurement and studies of impact, vulnerability and adaptation on climate change in Brazil and worldwide.

³⁹ We would like to thank Instituto Escolhas, Rede Clima and the INCT for Climate Changes for the financial support.

The recent water crisis observed in Brazilian Southeast in 2014 was an alert for how the country's economy may be vulnerable to climate change. The impact of these on the productivity of Brazilian agriculture is a subject extensively explored in recent literature. However, there are few studies that explore the second and third order effects of climate change on the country's economy.

Certain productivity shocks on agricultural goods in the Brazilian regions can affect - in a differentiated way - the local demands of the most diverse economic agents. Spatial and sectoral relations may also play a key role in the process of economic adjustment: the food sector of a given region, when facing a relative shortage of agricultural genres for its production, will have to pass on part of its cost increase to consumers. These, in turn, will become poorer in that they will have lower real income to acquire such products. As a result, they will have to reduce their demand for goods from other sectors, while these sectors will tend to decrease their production and prices, and potentially have to dismiss part of their workforce in response to a possible drop in demand. The net effect on economic variables can be quite complex to predict in the various sectors and regions of the country in both the short and long term.

In this context, the objective of this work is to analyze the economic vulnerability of the regions in relation to potential climatic variations in the country, besides the consequent effect that such changes in the climate can cause on the Brazilian economy in its several sectors. To do so, the framework provided by the computable general equilibrium models is used to integrate physical and economic models with the purpose of evaluating the impacts of the most diverse orders on the Brazilian economic system.

On the one hand, physical models on agricultural production provide estimates of the direct effect that climate change can have on the productivity of a given crop. On the other hand, interregional general equilibrium models account for such estimates in order to capture the effect that changes in agricultural productivity can generate for the economic system by considering the links that the agriculture sector has with other sectors of the country, in addition to the effects different regions of Brazil.

The work is divided into 5 other sections besides this introduction. The next section deals with the literature that uses economic methods applied to measure the impacts of climate change, highlighting the numerous dilemmas that may arise in this process. Section 3 discusses the methodology used, emphasizing the integration of the physical model - which relates the impact of climate changes to agricultural productivity - with the general computable equilibrium model used in the work. The fourth section provides a detailed analysis of the agricultural, economic and climatic data constructed, as well as justifying the choice and construction of the scenarios used for the analysis of the work. Section 5 shows the results, presenting the direct and indirect impacts of climate change on the Brazilian economy, and proposing a methodology to deal with the uncertainty of the results in an explicit way. The sixth and final section concludes the text, summarizing the main results of the work.

2 ECONOMICS AND CLIMATE CHANGE: A GENERATIONAL CONFLICT

"You know my methods. Apply them."

Sherlock Holmes

The Sign of the Four

Economic science has much to say about the impact of climate change on the world's economy and well-being. Measuring and assessing the risks associated with such climate change is now - and increasingly - key to design impact mitigation policies and mechanisms for the various nations of the planet.

The impact of changes in global climate has the potential to affect the most diverse dimensions of human life over time: food production, health, access to water, natural resources, among others. In this sense, the impact of such changes on the world economy is not easy to measure. Stern (2006) collects a series of results from economic models and argues that if no change in the direction of reducing human emissions is made by the middle of this century, the cost of the impacts and risks that climate change will cause on the economy of the globe can be equivalent to losing between 5% and 20% of world GDP annually forever. It also argues that, contrary to what is expected, the cost of moving towards greenhouse gas emission reductions is around 1% of world GDP per year.

In the economic sense, climate change can be considered one of the largest and most comprehensive market failures in history. More specifically, the planet atmosphere can be considered a public good, whereas the emission of GHG an externality: the well-being of a given individual is a function of its consumption and the quality of the atmosphere. Therefore, those who produce GHG are generating a cost of well-being for the entire population today and at all times in the future (even though they do not directly and immediately face the impacts of their actions).

Thus, a change in the quality of the atmosphere changes the well-being of all the people of the globe, but not in a homogeneous way: certain sectors, populations and regions can benefit from climate change, while others can suffer severe losses. The emission pattern itself is not homogeneously distributed around the globe (TOTH et al., 2001). Countries with high emission rates have - so far - few incentives to reduce them since, ironically, they are the least vulnerable to the effects of climate change. Moreover, nations that avoid mitigation policies have the classic incentive of free-riding, that is, to benefit from the potential positive impacts of the actions of other countries (HALSNAES et al., 2007). All this inequality in the distribution of the costs and benefits of mitigation actions makes an international emissions reduction agreement very difficult.

Another aspect well discussed in the literature concerns intergenerational welfare transfers. In other words, anthropogenic impact mitigation actions in the global climate can be considered as a transfer of well-being from current generations to future generations (TOTH et al., 2001). The magnitude of mitigation today has the potential to determine the amount of natural resources (water, arable land, etc.) that future generations receive to consume. However, across generations the costs and benefits of mitigation actions are not equally distributed: future generations benefit without incurring costs while current generations incur cost without seeing benefits.

Yet, another factor of relevance for assessing the economic impacts of climate change involves comparing its consequences at different points of time. To do so, economists generally use discount rates to be able to compare the economic effects over the years. This makes it possible to equate impact trajectories over time by calculating the present value. Therefore, the magnitude of this discount rate is critical to determining the relevance of the economic effects of future climate change. The choice of the discount rate has considerable effects for assessing the economic costs of climate change (HALSNAES et al., 2007): since the magnitude of climate change tends to increase over time (IPCC, 2013), how bigger (lower) are the discount rates considered, the smaller (larger) will be the economic impacts of climate changes in present value.

If we consider that mitigation actions can be seen as an investment, then the (probably positive) return on that investment will require positive discount rates over time. In addition, the return on such investment can be used to decide how much can be spent for mitigation. These rates may be described as prescriptive or descriptive. The descriptive view is based on the discount rates observed in the behavior of individuals when making their daily decisions (IPCC, 2007). Its main advocate, William Nordhaus, argues that the descriptive approach "assumes that investment to slow climate change competes with investment in other sectors."

The prescriptive view chooses the discount rate if it is based on what is considered the most compatible for the interests of future generations. This view is defended by Nicholas Stern, who considers that any positive discount rate is unethical for future generations (WEYANT, 2017). Ackerman (2007) argues that his approach defines the intertemporal discount rate as one that leads to a scenario in which the present generation and future generations have equitable resources and opportunities. A rate equal to zero would indicate that all generations are treated equally. According to Stern, the present generation, which has the decision-making power to design policies to mitigate climate change, has a moral obligation to treat future generations with equality. He advocates a lower discount rate that forces the present generation to invest for future generations to reduce the risks of climate change.

One of the main effects of climate change is the influence, especially in the Brazilian case, on agricultural productivity. Agriculture is one of the economic sectors most vulnerable to changes in the climate as it may be significantly affected by fluctuations in temperature and rainfall. Although Brazil is a country of relative abundance of arable land and water, the limited supply of these concomitant to the growing urbanization of the country enters in this context as potential risks to the development of the sector over time. Nevertheless, the direct effects of climate on Brazilian agriculture are essentially related to frost, severe rain and floods, droughts, and other losses due to extreme short-term climatic events.

Concern about the relationship between climate and agricultural productivity goes back to the earliest times in the history of mankind. The place and period of origin of agriculture is, like almost everything in prehistory, a subject of much controversy among historians. However, it is assumed that its emergence occurred concomitantly in various parts of the globe at some point in the Neolithic period, between 12,000 and 10,000 years BC (DIAMOND, 1997).

In a given climatic region, the conditions of temperature, rainfall, solar energy and soil are practically constant. In essence, such conditions condition fertility and, therefore, the productive capacity of a particular crop in a particular region. Thus, it is to be expected that certain current crops are more or less adapted to particular regions, while consistent climate changes may not only alter the productivity of these crops but also their geographical distribution across the globe.

This is considered one of the main factors for the emergence of the first cities of human history on the famous banks of the Nile River, Mesopotamia, North Sea, Baltic, Siberia and Ganges River valley around 5000 years ago. The literature also considers as a necessary condition for the development of societies that there is a wide and consistent process of food production in an autonomous way in order to guarantee their subsistence. In this sense, the climatic or geographical variations that the people of different parts of the globe have encountered explain, to a large extent, the different destinies that such peoples have faced throughout history (DIAMOND, 1997). The most basic channel to understand this problem comes from the idea that the availability of more calories for consumption - from a possible agricultural surplus - implies a greater surplus of food to be stored, thus guaranteeing the basic conditions for the formation of great densely populated societies of history. Botanic studies estimate that, at the beginning of the process of domestication of wild plants for agricultural cultivation, the productive surplus guarantee that each calorie spends on cereal cultivation was compensated with 50 calories of food production (ZOHARY and HOPF, 1993).

Throughout this process, there is also concern about the determination of seasonal climatic patterns of nature aiming at ensuring a minimum level of agricultural productivity in order to ensure the subsistence of the growing human population. It is assumed that the agricultural revolution during the Middle Ages generated productivity gains of around 100% for cereals (DUBY, 1977).

All this allowed the advancement of human society to the current economic and demographic level. In this process, the increase in economic activity and consequent increase in the magnitude of human impacts caused in nature culminated in the huge debate about human activity exerting influence on the phenomenon of climate change. Here is a distinction: climate change can be seen as a "systematic change in the long-term state of the atmosphere over multiple decades or

more" (IPCC). Such a term is distinct from climatic variation, which is a term that refers to the natural variation of the climate that occurs over the months and years. El Niño, for example, which changes temperature, rainfall and wind patterns in many parts of the globe over 2 to 7 years, is a good example of natural climatic variation.

Yet, it is important to note that while long-term climate change has the potential to change patterns of land use and agricultural irrigation, short-term changes directly affect farmers agricultural productivity and well-being. The growing concern about the phenomenon of climate change in recent years has led to a significant increase in the number of studies attempting to quantify the impact they may have on the world economy.

Since the 1960s, studies aimed at estimating the effect of rainfall and temperature on agricultural productivity have been developed. Oury (1965) suggests a positive relation between agricultural productivity and precipitation and negative relation between productivity and temperature. In addition, it is one of the first to propose an index of aridity and its potential effect on maize productivity in the United States.

In a famous paper, Deschênes and Greenstone (2007) find that the effect of temperature on soybean growth and development is consistently negative and non-linear in the USA. Nonetheless, they estimate that climate change projected for the US will have the potential to increase annual profits from agricultural activity by about 4%. Kucharik and Serbin (2008) indicate that the increase of 1°C in temperature during the summer months has the potential to decrease soybean and maize yields by 16% and 13%, respectively.

However, while much of the empirical studies on the subject agree that climate change will have malefic effects on world agriculture, some point the other way. McCarl (2008) finds that higher temperatures have a positive and statistically significant effect on soybean yield, and no significant effect on other crops. Lobbel et. al. (2008) using aggregated data for various regions of the world between 1961 and 2002 find that the change in agricultural productivity can range from -21% to +8.7% depending on the crop and region studied.

Concerning the effect of rainfall on agricultural productivity, studies are also controversial. McCarl (2008) estimates that increased rainfall projected for the US may have a negative effect on wheat yield, while it may be beneficial to cotton production and insignificant on maize, sorghum and soybeans productivity. Deschênes and Greenstone (2007) and Kucharik and Serbin (2008) suggest that the same increase projected for the North American regions will tend to have a positive impact on corn and soybean production.

Schlenker and Roberts (2009) estimate that global warming can reduce agricultural productivity by around 30% to 82%, depending on how fast the global warming will last by the end of the century. In this sense, the climatic projections for the speed of this phenomenon are also diverse. Such projections are based on a series of biophysical models that attempt to represent the Earth's atmosphere through a vast system of equations. A more detailed description of such projections is made in section 4.3.

In the Brazilian context, Haddad, Porse and Pereda (2013) also estimate the indirect effects of climate variations on the Brazilian economy. By integrating a physical model with an interregional computable general equilibrium model, they evaluate the economic impact of climate Anomalies observed in 2005 in Brazil. Their results indicate that the loss of R \$ 1.00 in agricultural production caused by climate change in 2004 has an impact of causing losses of R \$ 3.25 in the whole Brazilian economy. The authors argue that the links between sectors and regions, besides the effect of prices, are the main channels for the propagation of the evil effects of the loss of Brazilian agricultural productivity. Asuncion and Chein (2016), using data from the Municipal Agricultural Production (PAM) survey and the 2000 demographic census, estimate that global warming under current technology and land use patterns has the potential to decrease Brazilian agricultural productivity in about 18% on average. When they analyze these variations in the municipalities, they find values ranging from -40% to +15%.

This paper aims to contribute to this debate by integrating an econometric model - which relates climatic anomalies with the agricultural productivity of the most relevant agricultural crops for the national production - with an interregional computable general equilibrium model calibrated for the year 2011. For this purpose, aims to quantify what are the direct and indirect impacts of the effect that the projected climatic changes will have on the Brazilian economy by the end of the century.

Yet, the work differs in using the latest climate projections, agricultural data, and climatological data to generate its estimates. Nevertheless, it seeks to innovate in the temporal granularity of climate projections using the monthly projections for climate changes provided by the IPCC's 5th Assessment Report.

3 METHODOLOGY

"I'm afraid that I rather give myself way when I explain", said he. "Results without causes are much more impressive".

Sherlock Holmes.

The Stock-Broker's Clerk

The methodology that will be used in this work has as its basis the computable general equilibrium (CGE) models, a class of economic models that seek to represent a given economy in its most diverse sectors and regions. With a calibrated model for Brazil in 2011, the objective is to map the direct and indirect effects that climate change may have on Brazilian regions.

For this, it will be necessary to generate a productivity shock in the theoretical structure of this model. The magnitude of this shock will be calculated from a set of econometric estimates that relate climate to agricultural productivity. With such estimates in hand, it will be possible to use the climate projections provided by IPCC until the end of century to estimate the future agricultural productivity shocks in the Brazilian economy.

In essence, what we intend to do is to estimate the impacts that temperature and precipitation have on agricultural productivity and to multiply them by projections of climate change with the intention of projecting agricultural productivity in the different regions of Brazil. With such a change in computed productivity, it will be possible to use the Computable General Equilibrium model calibrated for Brazil in 2011 and, thus, to compute the effects of first and second order from such changes in Brazilian agricultural productivity.

3.1 Econometric Model

One of the main channels of influence that determined climate change may have on the agricultural sector is its productivity. In this way, understanding the relationship that it has with potential variations in rainfall and temperature is the first methodological step necessary for the elaboration of the work. For that, the idea is to examine how projected changes in these climatic variables can affect the average productivity of the most diverse agricultural crops in Brazil. The empirical strategy used for such estimation initially needs to define a theoretical specification that relates the productivity y_{it}^h of a given crop h in the municipality i of the State s at some period t with the weather, prices and technology available in that period:

$$y_{it}^h = f(\text{climate}_{\{it\}}, \text{prices}_{\{st-1\}}, \text{technology}_{\{st\}}) \quad (1)$$

Thus, the econometric methodology used is initiated through the construction of a city-level panel elaborated through data provided by the Brazilian Institute of Geography and Statistics (IBGE) Municipal Agricultural Production survey to estimate the effect of climate on conditional agricultural productivity to fixed effects of municipality and state. Thus, the parameters of interest will be identified through specific climatic variations in a given period in relation to the historical average in the municipalities after controlling for common shocks to all cities within a state. In short what will be estimated is the following equation:

$$y_{it}^h = \alpha_i + \gamma_{st} + \sum_c \theta_c f_c(W_{cit}) + X'_{it}\beta + \epsilon_{it} \quad (2)$$

Where i represents a certain municipality, s determined state, t determined year and c determined climatic variable. Such specification allows controlling for a fixed effect of municipality α_i , a state-year fixed effect γ_{st} , a vector of control variables specific to municipalities X'_{it} and a vector of climatic variables W_{cit} , which is constructed from the percentage deviations of average temperature and accumulated rainfall in the municipalities in relation to their respective historical averages. Nevertheless, quadratic terms are included in order to capture the non-linearity of these effects. In this way, the parameter of interest will be θ_c , which will measure the impact that a given climate variable has on the productivity of some crop h .

The agricultural data used come from the Municipal Agricultural Research survey, an annual survey that covers all municipalities in the country and provides information on production, planted and cropped area, average yield and value produced from the main Brazilian agricultural crops. The climate data, in turn, come from the National Institute of Meteorology (INMET) which provides on its website historical climate data from its 265 stations throughout Brazil. For the study in question, monthly observations collected from January 1994 to December 2015 will be used. Such data are spatially interpolated in order to create municipal measures of accumulated rainfall during all months between 1994 and 2016.

With these estimates obtained, we intend to multiply each coefficient of the above equation by its respective projection of climatic Anomaly provided by the IPCC climatic models until the end of the century (better described in the next section). Such a calculation will generate a forecast of the commodity's productivity change h for each year from 2020 to 2100. Such prediction will be fundamental to the construction of the agricultural productivity shocks used in the computable general equilibrium model (described below).

3.2 Projections of Rainfall and Temperature for Brazil

A number of entities develop and estimate their different climate models to reliably reproduce and design the global climate system. Each model uses different scenarios to make its projections and each scenario, in turn, is based on different assumptions about the trajectories of emissions of carbon, aerosols, deforestation, sea currents and mitigation actions of the human society, leading to different results and forecasts.

What should be emphasized about these models is that they are based on physical principles, and they are now able to reproduce many important aspects of the observed climate (IPCC, 2013). With this, the scientific community argues that there is great confidence about their ability to quantify future climate projections.

Each set of estimates of an individual model is called an ensemble member, and in general, the scientific community uses the average estimates of a series of ensemble members to make their projections. When comparing the variations of results among ensemble members it is possible to generate an estimate of the degree of uncertainty associated with climatic variation. Using the average of all these members gives a measure of the scientific community's expectation of such projections (IPCC 2007, Annex to Working Group I, p.945).

The IPCC's 5th Assessment Report emphasizes that the future climate will depend on the warming caused by both past emissions and the anthropogenic emissions and natural climatic variation that will occur in the future. These emissions, in turn, are largely dependent on population and economic growth, world consumption patterns, land use and energy, technology and climate policies.

In this way, the entity generates so-called Representative Concentration Pathways (RCPs), which are used to create future emission projections. These are used as inputs to carry out the simulations of the climate models that create the climate projections for the future. These RCPs are divided into 4 scenarios: a rigorous mitigation scenario (RCP 2.6), two intermediate scenarios (RCP 4.5 and RCP 6.0) and a scenario with very high greenhouse gas emissions (RCP 8.5).

The scenarios are named from the level projected for the difference between the solar radiation absorbed by the planet and the radiation that is reflected back into the space relative to the pre-industrial level of the same measure. This difference is known as radiative force and is defined as an index of the magnitude that solar radiation has as a potential mechanism of climate change. Thus, scenario RCP 4.5 considers that the radiative force by the end of the century will be 4.5 times higher than it was in the pre-industrial level.

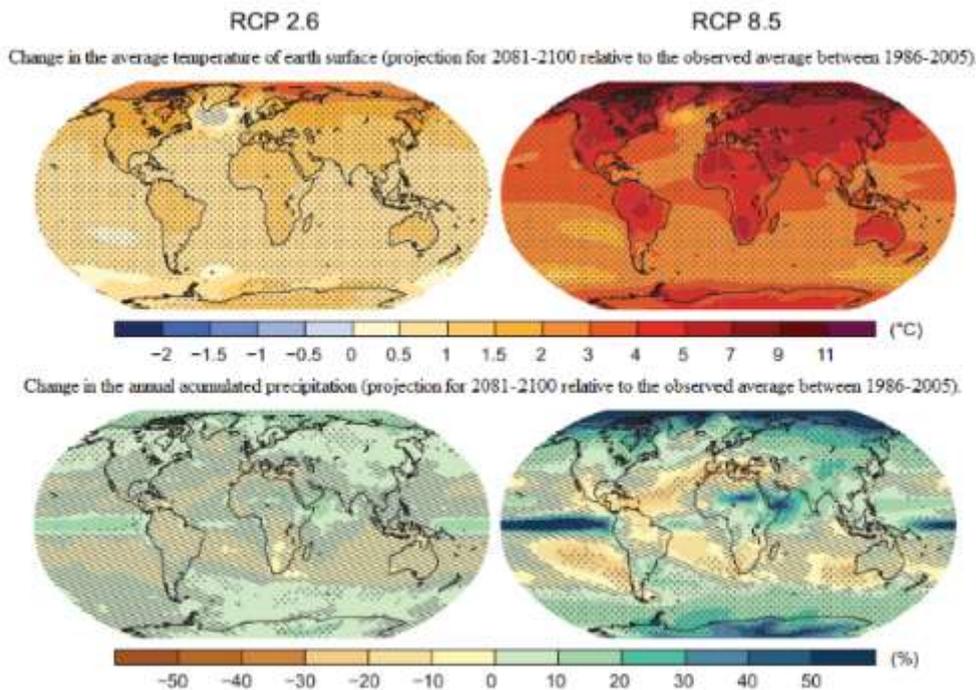

Figure 16 - IPCC Projections (2013).

The figure above shows the global representation of rainfall and average temperature projections performed by the IPCC under the scenarios RCP 2.6 and RCP 8.5. The results indicate that, at least in Brazil, the average temperature will increase between 1°C and 1.5°C in the most optimistic scenario and in more than 4°C in the pessimistic scenario. In terms of rainfall, the estimates project a fall of at least 10% in the annual rain accumulated in the optimistic scenario, and a marked regional difference in the pessimistic scenario: in the Amazon region a fall of 10 to 20% and in the south region an increase of the same magnitude. In addition, the literature on the subject has some consensus about some stylized facts about the projected climatic changes until the end of the century:

- The planet's average temperature is increasing. Since 1900, the average temperature of the globe has been estimated to have increased by 0.8 ° C, with much of this increase occurring in the mid-1970s. In addition, climate projections indicate that the average temperature of virtually all regions of the planet will increase by 2100.
- The low earth atmosphere is becoming hotter and wetter as a consequence of the higher concentration of greenhouse gases. This creates greater potential to accumulate atmospheric energy for storms and extreme weather events (hurricanes, tornados, torrential rains, prolonged droughts). The occurrence of such events will be increasingly frequent and volatile.
- Even if the emission of greenhouse gases were stopped immediately, the average temperature of the planet would not return to the pre-industrial level.

3.3 CGE Model

With the given projections it is possible to use the framework provided by the computable general equilibrium models in order to capture their effect on the economic system as a whole.

This class of models has attracted considerable attention in recent years not only in academic circles but also in policy-making debates. By "general equilibrium" one must understand the analytical framework that sees the economy as a complete and interdependent system whose components (sectors, families, government, investors, importers and

exporters) interact with each other. Such models consider that the economic shocks in a particular sector do not only affect this one but end up generating a chain effect that creates repercussions through the system as a whole.

By "applied", it should be understood that the main focus of these models is to provide results that allow quantitative analysis of policy and economic problems across countries, sectors or regions. To that end, this framework needs data that are obtained, in essence, in the input-output matrices of the Brazilian economy over the years. These matrices are constructed based on the data disclosed through the IBGE national accounts.

Considering that one of the main contributions of this methodology is to consider the parts of an economic system (sectors, regions, families, governments, etc.) as components of an interdependent system that allows analyzing the policy effects and shocks of sector / region for the other sectors / regions of the country.

The regional cut that is intended to be used in the study divides the Brazilian economy into 27 regions (the 26 states of the federation, besides the Federal District) that produce, consume and commercialize goods produced by 68 sectors. Among these goods, we intend to analyze the effect of climate change on the productivity of six of the country's main agricultural crops: sugarcane, soybean, maize, beans, coffee and orange. This effect can be analyzed in an isolated way, that is, considering only one agricultural commodity, or in a global way, when considering the effect of climate changes on the productivity of all agricultural goods at the same time.

Thus, each region has a representative consumer and investor, as well as state and federal government structures. All regions can trade among themselves, in addition to being able to import and export their production to an external sector (under a certain exchange rate). The scope of this class of models allows us to capture the effect of the change in agricultural productivity on a series of economic variables. Of particular note are: production, prices, welfare, employment, wages, household and government consumption, import and export volume, among others. It is worth mentioning that the effect on these variables can be analyzed both from a national and a regional point of view. It is possible to observe, for example, the effect of a change in the productivity of sugarcane cultivation in a given state on the level of wages in another.

From the point of view of production, each industry is able to produce a particular good using a composite good specification that considers each good to be manufactured by using a fixed combination of primary factors and intermediate goods. The factors used are, in general, capital, labor and land which, in turn, combine by means of a function of elasticity constant substitution to form the compound of primary goods. The intermediate inputs, which may have domestic and foreign origin, also combine with a constant substitution elasticity function to form the compound of intermediate inputs. Finally, intermediate inputs and primary factors combine through a Leontief function to generate firm output.

The model uses the structure proposed by Haddad (1999). The construction of the database required for its calibration is done through the top-down approach, which uses national results to create an interregional input-output system capable of generating a snapshot of the Brazilian economy at a given point in time⁴⁰. The model in question was calibrated for the year 2011 and assumes that the tax structure and national tariffs can be replicated for all regions of Brazil in the same year.

The data used for the calibration of this model are essentially derived from the IBGE national accounts system and are constructed from a system of interregional input-output matrices. As is usual in this class of models, the number of unknown parameters exceeds the number of equations required to identify them. In this way, the short-term and long-term closure approach is used, which allows the variation of some model variables to be locked in order to allow it to become exactly identified.

From the regional point of view, the reduction of agricultural productivity in a region ends, *ceteris paribus*, increasing the relative productivity of agriculture in other regions. This tends to cause the agricultural production of the affected state to migrate to other parts of the country, generating an increase in the level of activity of the other states and increasing the availability of factors of production within the affected locality. The excess supply of factors in this region will tend to cause a decrease in the remuneration of these factors and consequent decrease in the price level of the region. The net effect on the price level is unknown and can be measured after the necessary simulations have been carried out on short and long-term horizons. The aim of this study is to estimate the effect that the projected climatic changes in the coming years can have on agricultural productivity and, from such changes in productivity, to analyze the potential effect on the economy of the different sectors and states of Brazil.

4 DATA

"It is a capital mistake to theorize before one has data. Insensibly one begins to twist facts to suit theories, instead of theories to suit facts."

Sherlock Holmes

A Scandal in Bohemia

In order to implement the strategy described in section 3, the most recent data available on agricultural production, temperature, precipitation, and the most recent climate projections available in the IPCC's 5th Assessment Report were

⁴⁰ For more details, see Haddad, Gonçalves Júnior and Nascimento (2017).

collected. In addition, a portrayal of the regional input-output system used for the general computable equilibrium model used will be performed. The description of this data will be detailed in this chapter.

4.1 Agricultural Data

The data on production, value produced, average yield, planted area, proportion of total production and proportion of the total agricultural area are provided through the Municipal Agricultural Production (PAM) survey, made available by IBGE. Data were collected between 1994 and 2015 for all Brazilian municipalities. Six of the main agricultural crops of Brazil were chosen: soybean, sugarcane, maize, coffee, beans and orange.

Table 1 - Representativeness of Cultures Selected in Terms of Produced Value.

Year	2010	2011	2012	2013	2014	2015	Average
Soybean	24.21%	25.77%	24.74%	29.65%	33.58%	34.15%	28.68%
Sugarcane	18.36%	20.06%	19.83%	18.47%	16.76%	16.49%	18.33%
Maize	9.85%	11.37%	13.15%	11.50%	10.35%	11.25%	11.24%
Bean	3.21%	2.63%	3.05%	2.99%	2.06%	2.28%	2.70%
Coffee	7.51%	8.30%	8.19%	5.51%	6.24%	6.00%	6.96%
Orange	3.99%	3.35%	2.25%	2.05%	2.20%	2.15%	2.67%
TOTAL	67.13%	71.49%	71.22%	70.18%	71.19%	72.32%	70.59%

The criterion used to choose these crops sought to cover several dimensions of national agricultural production: crops most representative in terms of value produced (soybean and sugarcane); most representative crops in the agricultural GDP of the municipalities of most regions (maize and beans), crops in which Brazil has a dominant position in world production (coffee and orange). In addition, we tried to merge the analysis of temporary crops (soybean, sugarcane, corn and beans) and permanent cultivation (coffee and orange). Table 1 shows the representativeness of these crops in the value produced by Brazilian agriculture between 2010 and 2015.

Among these, soybean stands out both in terms of value produced (almost 30% of the total produced by Brazilian agriculture between 2010 and 2015) and planted area (38% of the total arable land of Brazil in the Period). Next came sugarcane (18.3% of the value produced and 13.8% of the total area), corn (11.2% of the total of agriculture and 20.8% of the plant area). Coffee, Beans and Orange, together represented 12.3% of the Brazilian agricultural GDP and 8.8% of the total planted area in the country. Together, these crops accounted for 70.6% of the total value produced and 81.36% of the area planted by the agricultural sector of Brazil between 2010 and 2015.

Table 2 - Representativeness of Cultures Selected in Terms of Planted Area.

Year	2010	2011	2012	2013	2014	2015	Average
Soybean	35.70%	35.26%	36.26%	38.58%	39.76%	41.93%	37.92%
Sugarcane	14.02%	14.11%	14.09%	14.11%	13.71%	13.25%	13.88%
Maize	19.83%	19.96%	21.77%	21.69%	20.78%	20.63%	20.78%
Bean	5.59%	5.73%	4.60%	4.20%	4.46%	4.07%	4.78%
Coffee	3.31%	3.15%	3.07%	2.89%	2.63%	2.59%	2.94%
Orange	1.30%	1.20%	1.10%	0.99%	0.90%	0.89%	1.07%
TOTAL	79.75%	79.42%	80.90%	82.47%	82.25%	83.36%	81.36%

To avoid possible distortions, all data described below will be presented as municipal averages between the years 2010 and 2015. Table 16 in the appendix also shows the representativeness of each crop added by state⁴¹

4.1.1 - Soybean

Soybean is the main agricultural commodity in Brazil reaching, in 2015, almost R\$ 105 billion of production value at market prices in the country. Brazil is the world's second largest producer of grain, responsible for about one-third of all Soybean produced on the planet. The production of the crop - in terms of value - is concentrated mainly in the Midwest, responsible for almost 45% of the total produced in the country. Soon after, comes the South region, responsible for about 37%.

Table 3 - Soybean Importance (in terms of produced value) in Brazilian Regions.

Region/Year	2010	2011	2012	2013	2014	2015	Average
North	2.68%	2.73%	3.82%	3.27%	3.92%	4.02%	3.41%
Northeast	8.10%	8.38%	9.59%	6.38%	7.42%	8.89%	8.13%
Southeast	7.03%	6.05%	7.80%	6.70%	6.12%	6.53%	6.70%
South	39.38%	39.60%	29.89%	40.06%	37.10%	37.67%	37.28%
Midwest	42.80%	43.25%	48.90%	43.58%	45.44%	42.89%	44.48%

The maximum yield of the crop occurs when the accumulated precipitation throughout its productive cycle is between 450mm to 800mm and average temperature during the day around 30°C (EMBRAPA). The vegetative growth of the crop is almost null when the average temperature during the day is less than 10°C and the growth rate is highly impaired under temperatures above 40°C. Such conditions are aggravated under the occurrence of water deficits.

⁴¹ This will be important, since the computable general equilibrium model that will be used will be on the state level, so that aggregating the municipal data for the states will become necessary later.

With this, the culture has different periods of planting and harvesting throughout the Brazilian regions. In the Midwest and Northeast, the planting period runs from October to January and in the South and Southeast regions this period runs from September to January. The harvest season goes from January to May in the South, Southeast and Midwest and from February to May in the Northeast.

4.1.2 – Sugarcane

Sugarcane is considered a semi-temporary planting crop, since after planting it is cut several times before being replanted. Its productive cycle is, on average, six years (or five cuts). Brazil is currently the world’s largest producer of sugarcane, accounting for about 30% of the total area devoted to the cultivation of the product around the world (FAO, 2008).

Table 4 – Sugarcane Importance (in terms of produced value) in Brazilian Regions.

Region/Year	2010	2011	2012	2013	2014	2015	Average
North	0.66%	0.90%	0.87%	1.20%	1.10%	0.81%	0.92%
Northeast	14.27%	12.54%	10.64%	10.30%	12.90%	10.20%	11.81%
Southeast	65.26%	66.12%	66.37%	63.86%	61.17%	61.99%	64.13%
South	6.88%	5.97%	6.45%	6.32%	6.35%	6.31%	6.38%
Midwest	12.92%	14.48%	15.67%	18.32%	18.48%	20.70%	16.76%

Most of Brazil’s sugarcane production is concentrated in the southeastern region, responsible for about 64% of the national production. Next comes the Midwest and the Northeast, responsible for 16.76% and 11.8%, respectively.

The crop lacks specific climatic conditions for its development. The ideal temperature for budding of the canes varies from 32°C to 38°C. Ideal temperature conditions during the day should range from 22°C to 30°C during the plant growth period. Temperatures below 20°C tend to hinder their development.

Thus, the crop presents two distinct planting and harvesting regimes in the Brazilian regions: planting from October to March (December) in the Southeast (Center-West) and from November to January in the Northeast. Harvest from April to September (December) in the Southeast (Midwest) and September to April in the Northeast.

4.1.3 – Maize

The United States Department of Agriculture estimates that in 2017, Brazil was the 3rd largest producer of corn in the world (behind the US and China) producing about 95 thousand tons of grain in the same year.

Maize is one of the crops studied that shows the greatest regional spread in productive terms. The South and Center-West regions are each responsible for about one-third of the total produced in Brazil between 2010 and 2015. The Southeast has about 19% of this total. The plant, native to Central America and cultivated since pre-Columbian civilizations, is usually planted during the rainy season. Like sugarcane, it is considered a rainfed crop since it only requires water from the rain, while the precise determination of the dry season is fundamental for its good cultivation over time.

The maximum productivity of the crop occurs with average water consumption of about 500mm and 800mm during the growing season and lacks a minimum consumption of 350mm to develop without the need for irrigation.

In terms of temperature, the ideal is that the average during the day varies between 25°C and 30°C and average temperatures below 10°C and above 40°C cause considerable delay in germination (making the beans unusable).

Due to the great diversity of the climatic system of the Brazilian regions, the plant is cultivated in different periods in the country: it is usually planted between August and December in the South and North regions of the country and between October and December in the Southeast, Northeast and Central West regions. The harvest period also varies, going from December to June in the South, January to June in the North and from February to June in the Southeast, Northeast and Midwest.

Table 5 – Maize Importance (in terms of produced value) in Brazilian Regions.

Region/Year	2010	2011	2012	2013	2014	2015	Average
North	3.49%	2.96%	2.86%	2.72%	3.10%	3.62%	3.13%
Northeast	10.01%	10.61%	6.99%	8.23%	10.94%	8.73%	9.25%
Southeast	23.44%	19.56%	18.32%	18.10%	17.69%	16.52%	18.94%
South	40.32%	38.09%	34.50%	35.87%	34.06%	30.04%	35.48%
Midwest	22.73%	28.78%	37.33%	35.08%	34.20%	41.08%	33.20%

4.1.4 – Coffee

The coffee culture, although quite representative in Brazilian history for its commercial importance until the 1930s, currently accounts for only about 4.7% of the value produced by national agriculture. Still, according to the International Coffee Organization (ICO), the country accounted for just under a third of world production in 2017.

The production is mainly in the southeastern region of Brazil, responsible for about 88% of all national production. Because it is a permanent crop, its planting time is quite variant, but it is estimated that after planting it takes between two and three years for the plant to begin to generate grains. The coffee plant has a bi-annual production cycle: in one year it produces enough and the following year it generates a smaller quantity of grains.

In Brazil two species are cultivated: *100rabica* and *robusta*. The first one lacks the average ideal temperature between 19°C and 22°C during the germination period. This species is, however, quite sensitive to frost having growth inhibition at temperatures below 10 ° C. Arabica coffee is also a plant more susceptible to pest proliferation and risk of infection with average temperatures above 22°C. The robust coffee, in turn, is more resistant to high temperatures and diseases. It is well adapted in regions with average temperatures between 22°C and 26°C.

Table 6 – Coffee Importance (in terms of produced value) in Brazilian Regions.

Region/Year	2010	2011	2012	2013	2014	2015	Average
North	3.16%	1.91%	1.99%	2.11%	1.94%	1.91%	2.17%
Northeast	5.00%	5.30%	4.23%	5.48%	5.94%	6.93%	5.48%
Southeast	85.95%	87.35%	89.34%	88.19%	90.06%	87.24%	88.02%
South	4.94%	4.76%	3.63%	3.32%	1.36%	3.14%	3.53%
Midwest	0.95%	0.68%	0.81%	0.90%	0.70%	0.77%	0.80%

Both species react well to periods of drought not exceeding 3 months and the plant is better adapted to regions that have a uniform annual rainfall regime that accumulate between 1500mm and 1900mm of precipitation per year. Irregular rains can deform the flowering of the coffee tree, causing uneven maturity in its fruits. Its harvest period goes from May to August in the Southeast, and from May to November in the South.

4.1.5 – Bean

Beans are considered the main subsistence culture of Brazil. For this reason, it is the crop with the most homogeneous production along the Brazilian regions: the South region leads with 29.6% of the total national production, followed by the Southeast (28.2%), Central West (19.7%), Northeast (19%) and North (3.4%).

Table 7 - Bean Importance (in terms of produced value) in Brazilian Regions.

Region/Year	2010	2011	2012	2013	2014	2015	Average
North	3.86%	4.02%	3.97%	3.03%	3.26%	2.19%	3.39%
Northeast	23.10%	27.28%	10.91%	14.46%	19.89%	18.59%	19.04%
Southeast	28.22%	26.30%	34.70%	30.27%	22.56%	27.49%	28.26%
South	25.97%	25.00%	28.01%	32.27%	35.54%	30.91%	29.62%
Midwest	18.85%	17.39%	22.40%	19.97%	18.75%	20.81%	19.70%

The main species cultivated in Brazil is *Phaseolus*, which has numerous varieties of colors and flavors. The plant lacks average temperature during the day ranging from 18°C to 24°C and during the night from 15°C to 21°C. Under temperatures above 35 ° C, there is practically no growth of their pods.

During its productive cycle, the crop needs about 300mm to 400mm of well-distributed rainfall throughout its germination period. In the South region the planting period goes from August to December and the harvest period from October to March. In the Southeast, Midwest and Northeast, its planting period varies from October to December and the harvest is from January to April.

4.1.6 – Orange

Orange is the permanent culture in which Brazil is most representative on the world stage. The US Department of Agriculture estimates that in 2016 the country produced about 19.2 thousand tons of the fruit, more than 3 times that China (second place, with 6.2 thousand tons) produced in the same period.

Because it is a kind of permanent crop, its production tends to be more concentrated regionally. The Southeast was responsible for more than 3/4 of all national production between 2010 and 2015. Its production is concentrated mainly in the State of São Paulo and West of Minas Gerais.

Orange is a fruit of the genus *citrus*, which lacks annual rainfall average between 1800mm and 2400mm, with a minimum of 1200mm per year. Any deficits in these values can be remedied by means of irrigation water.

Table 8 – Orange Importance (in terms of produced value) in Brazilian Regions.

Region/Year	2010	2011	2012	2013	2014	2015	Average
North	1.73%	2.24%	4.12%	4.65%	4.18%	5.46%	3.73%
Northeast	8.89%	7.80%	10.88%	11.46%	9.81%	9.77%	9.77%
Southeast	81.68%	81.71%	72.97%	71.15%	74.89%	73.33%	75.95%
South	6.65%	7.27%	10.69%	11.37%	9.76%	10.06%	9.30%
Midwest	1.05%	0.97%	1.35%	1.38%	1.36%	1.39%	1.25%

4.2 Climate Data

The climate data, in turn, come from the National Institute of Meteorology (INMET) which provides on its website historical climate data from its 265 stations throughout Brazil. For the study in question, monthly observations of cumulative precipitation and average compensated temperature⁴² were collected between January 1994 and December 2015. Such data are spatially interpolated in order to create municipal average precipitation and temperature

⁴² According to INMET, the mean compensated temperature of a meteorological station is one that, within a one-day period, calculates a weighted average of the maximum (weight 1), minimum (weight 1), noon (weight 1) and of midnight (weight 2) within the 24-hour period.

measurements throughout all months between 1994 and 2016. This interpolation aims to create an annual panel with climatic information of each of the 5563 Brazilian municipalities between 1994 and 2015. Thus, each of the analyzed years will have information of average temperature compensated and cumulative precipitation in all its months.

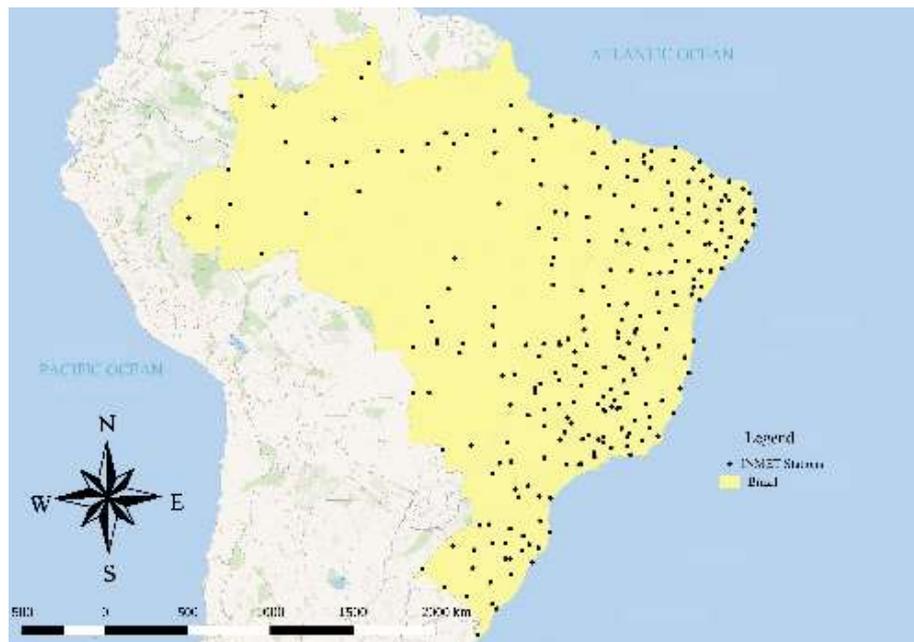

Figure 17 - INMET Meteorological Stations.

Figure 2 shows the spatial distribution of all meteorological stations that had data available in the analyzed period⁴³.

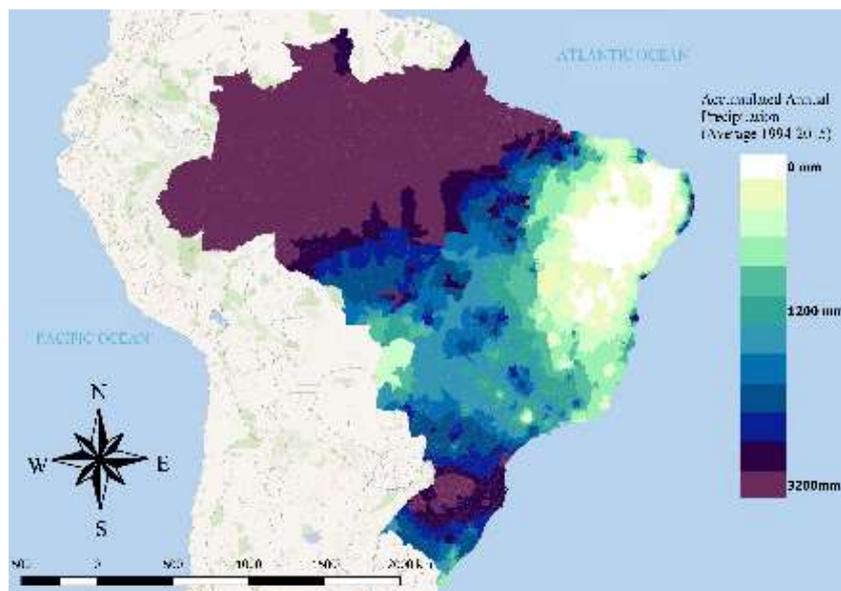

Figure 18 - Cumulative Precipitation - Annual Average (1994 - 2015).

Figure 3 shows the average annual precipitation pattern of Brazil between 1994 and 2015. Its analysis shows the different microclimatic patterns in Brazil: quite humid in the South and North of the country, quite dry in the northeastern semi-arid region and intermediate in the rest of the central- southern Brazil.

Figure 4 shows the average compensated temperature differentials across Brazil. Their analysis is straightforward: the north-central part of Brazil with higher average temperatures (over 26°C averaged over the year), the South with subtropical temperatures (below 19 °C on average over the year), and the Southeast with median temperatures (between 20°C and 23°C throughout the year).

4.3 Climate Projections

As described in section 3.2, the climate models used to generate the impacts of climate change on agricultural productivity in Brazilian municipalities are based on the IPCC's 5th Assessment Report. More specifically, the data provided by the National Center for Atmospheric Research (NCAR) climate model, which provides monthly projections for numerous

⁴³ With the exception of the state of Rondônia - the only state that does not have any meteorological station - all the units of the federation are covered by at least 3 meteorological stations well scattered throughout their territories. For this reason, the state of Rondônia was removed from all econometric analyzes. This decision is based on the absence of historical climatic information for the state, and considering that Rondônia was responsible for only 0.78% of all national agricultural production between 2010 and 2015.

atmospheric and climatic parameters for the various regions of the globe, were used. The data collected relate to the most recent outputs of the latest model developed by NCAR (CCSM-4) and are on a global scale⁴⁴.

In the field of climate change, emission scenarios are used to explore the extent to which humans can contribute to climate change given a series of uncertainties in factors such as growth and economic development, population, and the creation of new technologies. Scenarios have been used for a long time by planners and decision makers to analyze situations that have uncertain outcomes.

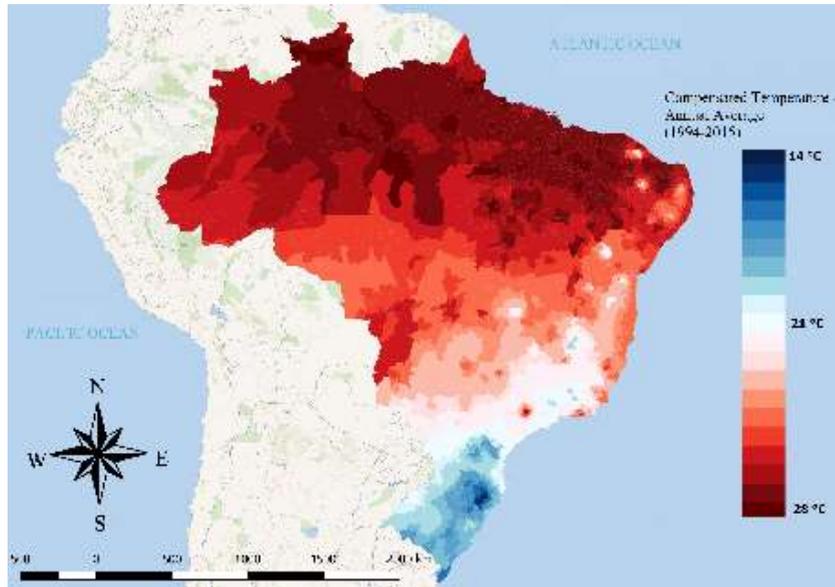

Figure 19 – Compensated Temperature – Annual Average (1994 – 2015).

Projections and scenarios of future social and environmental conditions may take into account different states of nature on the planet: for example, states in which the world is poorer and scenarios in which it is richer. The purpose of using scenarios is not to predict the future but to explore the scientific and socioeconomic implications under different plausible future situations. In developing the AR5, scientists have developed a new framework for creating and using scenarios in the context of climate change.

For the study in question, monthly temperature and precipitation projections were collected from January 2020 to December 2100. In addition, the scenarios RCP 2.6 and RCP 8.5 are considered to perform the work analyzes. It is worth remembering that the first is a scenario built on the premise that the concentration of greenhouse gases in the Earth's atmosphere will reach its peak in the middle of the century and, from there, begin to decline. It is called the low-emission scenario and was developed by the PBL Environmental Assessment Agency of the Netherlands and considers that ambitious targets for greenhouse gas emissions will be put into practice over time. Its main premises are:

- Decrease in oil use.
- Population of 9 billion people around 2100.
- Considerable growth in the use of energy generated from biomass.
- Emission reduction around 40%.
- Current CO₂ emissions remain constant at the current level by 2020 and begin to decline thereafter, becoming negative as of 2100.
- The CO₂ concentration in the atmosphere peaked in 2050, showing a slight decline by 2100.

RCP 8.5, on the other hand, assumes that the concentration of these gases increases continuously throughout the century. It is called a high-emission scenario and is consistent with a future in which no emissions reduction policy is in vogue in the world. It was developed by the Insitute of Applied Analysis of Austria and has as premises:

- CO₂ emissions three times higher than current levels by 2100.
- Rapid growth of methane emissions.
- An increasing increase in land use for agriculture that is driven by strong population growth.
- World population of 12 billion people by 2100.
- A low rate of technology growth.
- High resilience of the use of fossil fuels.

⁴⁴ Data provided by NCAR on the global scale use Gaussian quadrature to generate its estimates and provide data for equally spaced points by 1.25° longitude and 0.94° latitude. On average this corresponds to a resolution of 105km. To transform such projections on a global scale to the municipal scale, we used the same spatial interpolation method described in the previous section.

- No implementation of mitigation policies.

For this reason, each scenario leads to distinct temperature and precipitation trajectories throughout the century (including between Brazilian regions). The data used relate to the average of the 9 ensemble members of the model in question.

Figure 5 shows the average projections of annual precipitation anomalies⁴⁵ in Brazilian regions under RCP 2.6. Because it is a more conservative scenario, its results are more discrete and homogeneous over time. In essence, the tendency to decrease precipitation in the Brazilian mid-north (in the order of 10%) and a discrete increase in the southern end of the country (about 5%) stands out.

RCP 8.5, on the other hand, is much more dramatic. Figure 6 shows such projections until the end of the century. Their analysis allows to infer that, in addition to being more intense, the predicted precipitation anomaly is much more volatile in time. In the decades of 2020-2040, the average precipitation fall in Brazil is of the order of 5%, whereas at the end of the century this fall is 3 times greater. Nevertheless, the scenario predicts a worsening of the drought in the northeastern semi-arid region (a stylized fact widely accepted in the scientific community about the desertification of the Brazilian semi-arid), with a mean rainfall of up to 35%. The South of the country, in turn, will face more intense rainfall regimes, reaching an average rainfall increase of 15% at the end of the century.

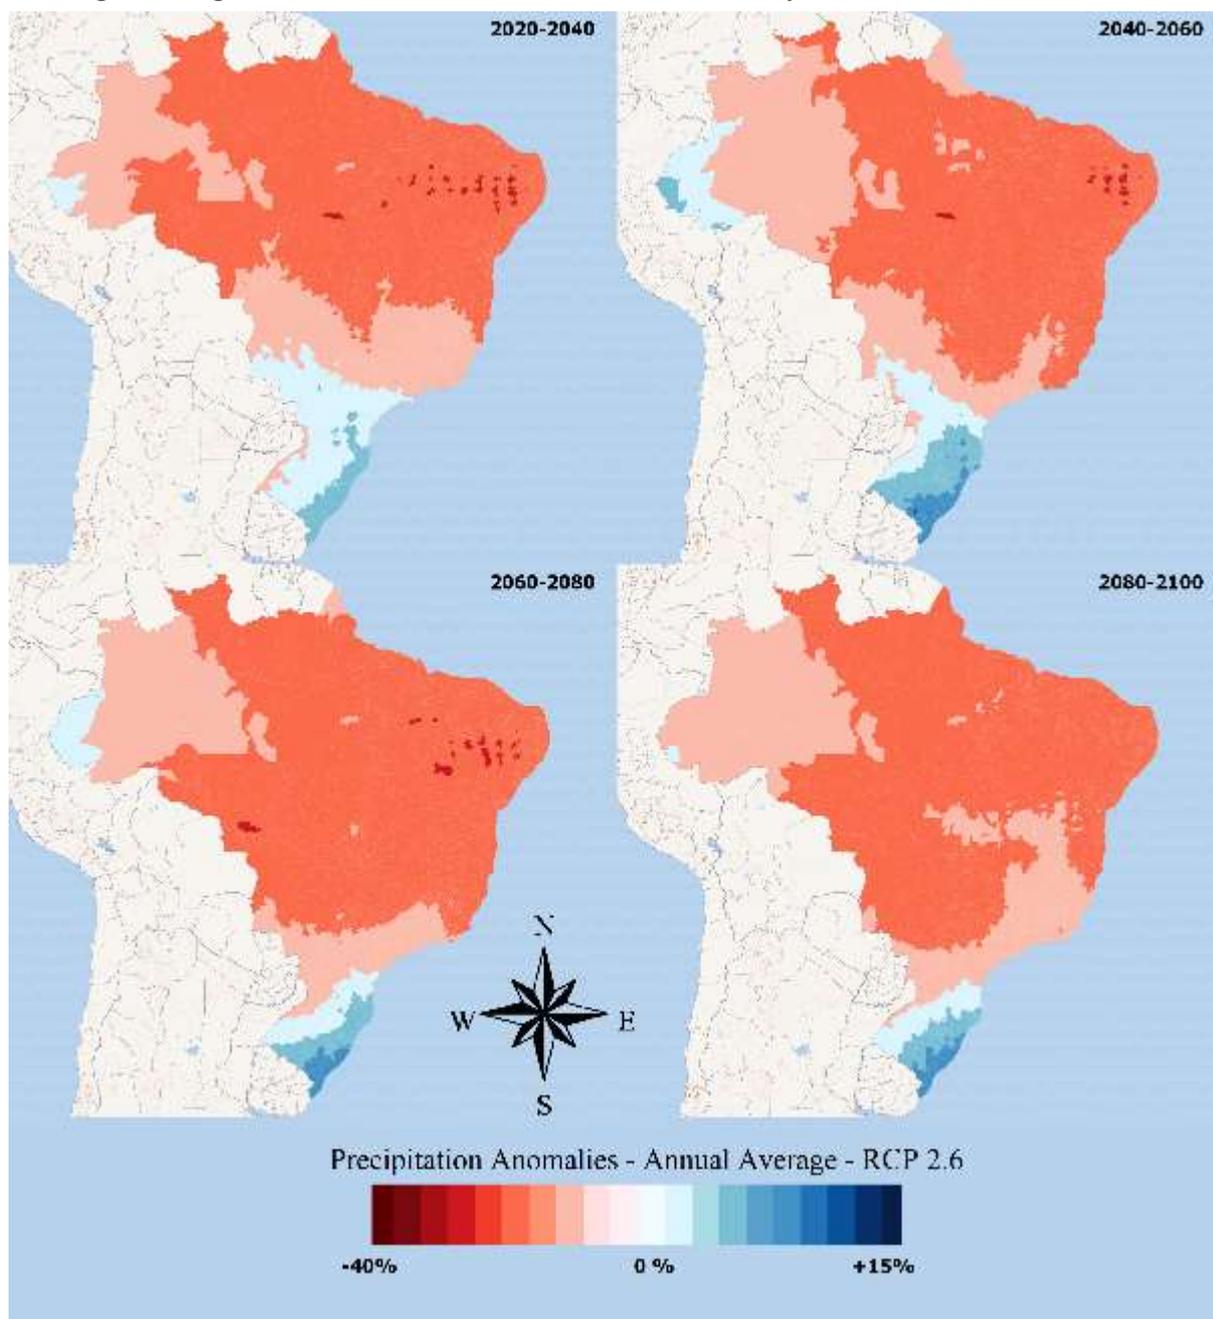

Figure 20 – Annual Precipitation Anomaly – RCP 2.6.

⁴⁵ Climatic anomaly is described in the literature as the percentage difference between the value that a given climatic variable assumes under a given scenario and a historical average of that same variable. For this study, all temperature and precipitation anomalies are calculated on the basis of the averages of the period 1960-2000.

In terms of temperature, the predicted by all scenarios is that of its increase during the century, but with different magnitudes and speeds depending on the scenario analyzed. Figure 6 denotes the mean annual temperature anomaly projections over the century under RCP 2.6. This scenario predicts a median increase of 4% (around 0.9 ° C) by the end of the century, with the South of the country being the most affected region. The figure also denotes a curious fact of this scenario: the reversal of the warming process in the states of Mato Grosso and Mato Grosso do Sul between the decades of 2040 and 2100.

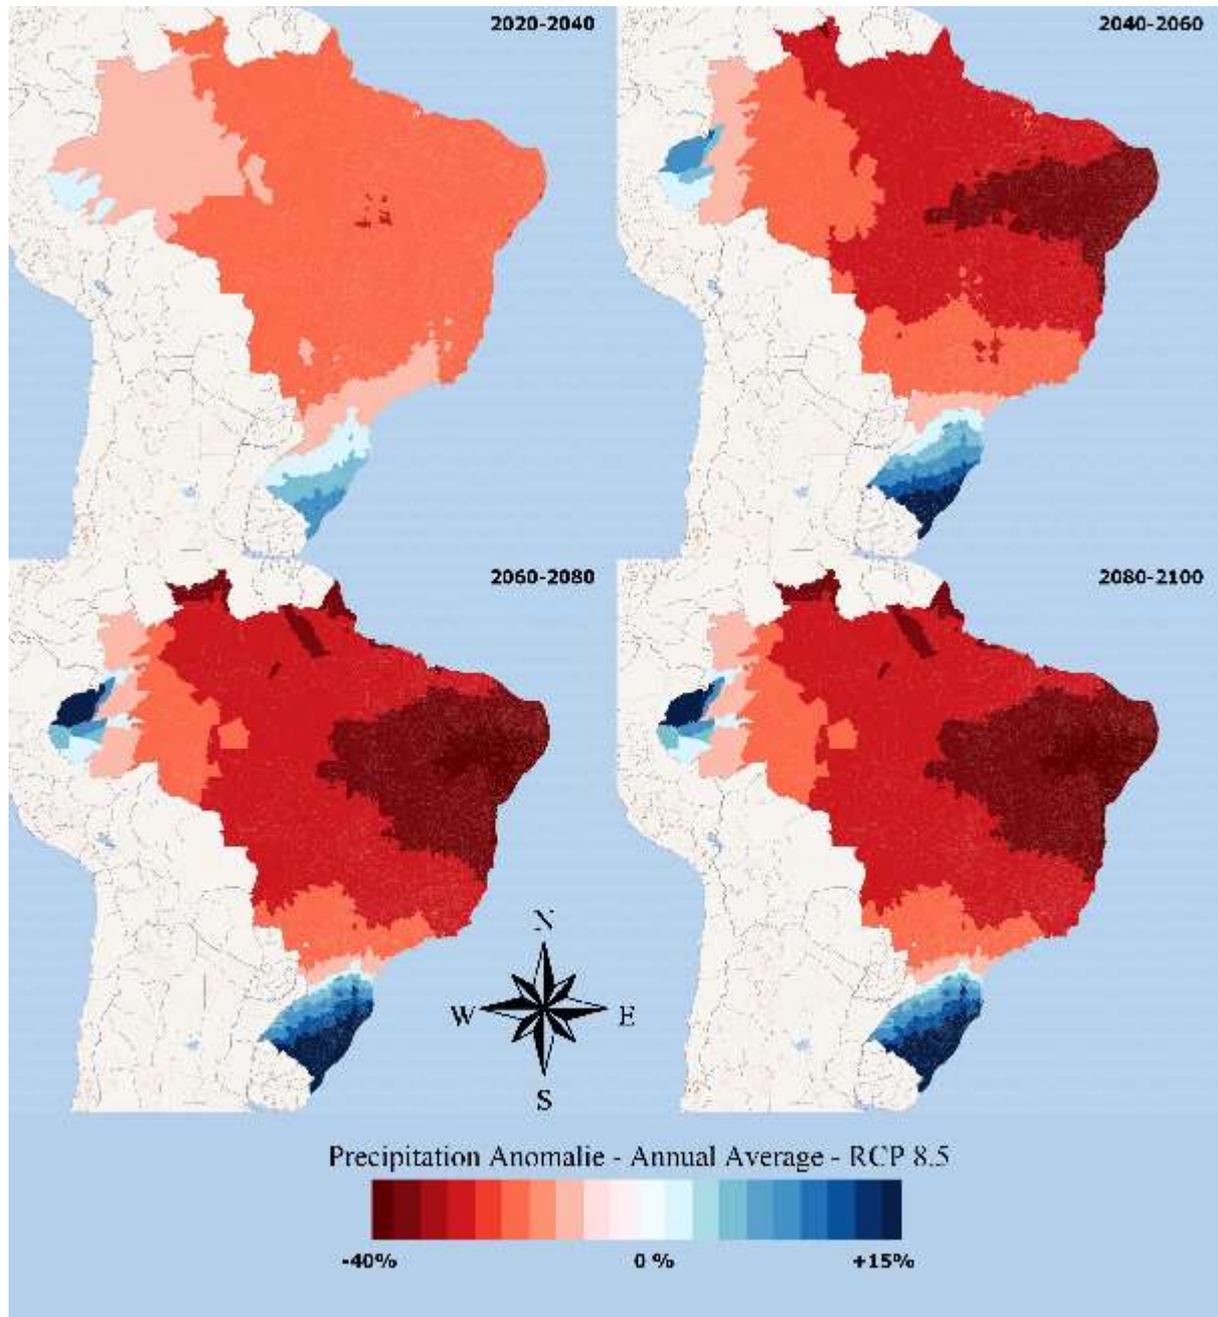

Figure 21 – Annual Precipitation Anomaly – RCP 8.5.

Under RCP 8.5, however, the changes are more intense (Figure 8). While at the beginning of the century the projected average warming is around 5% (1 ° C), by the end of the century this increase is about 17% (or 3.8 ° C), reaching 25% in the municipalities of the South.

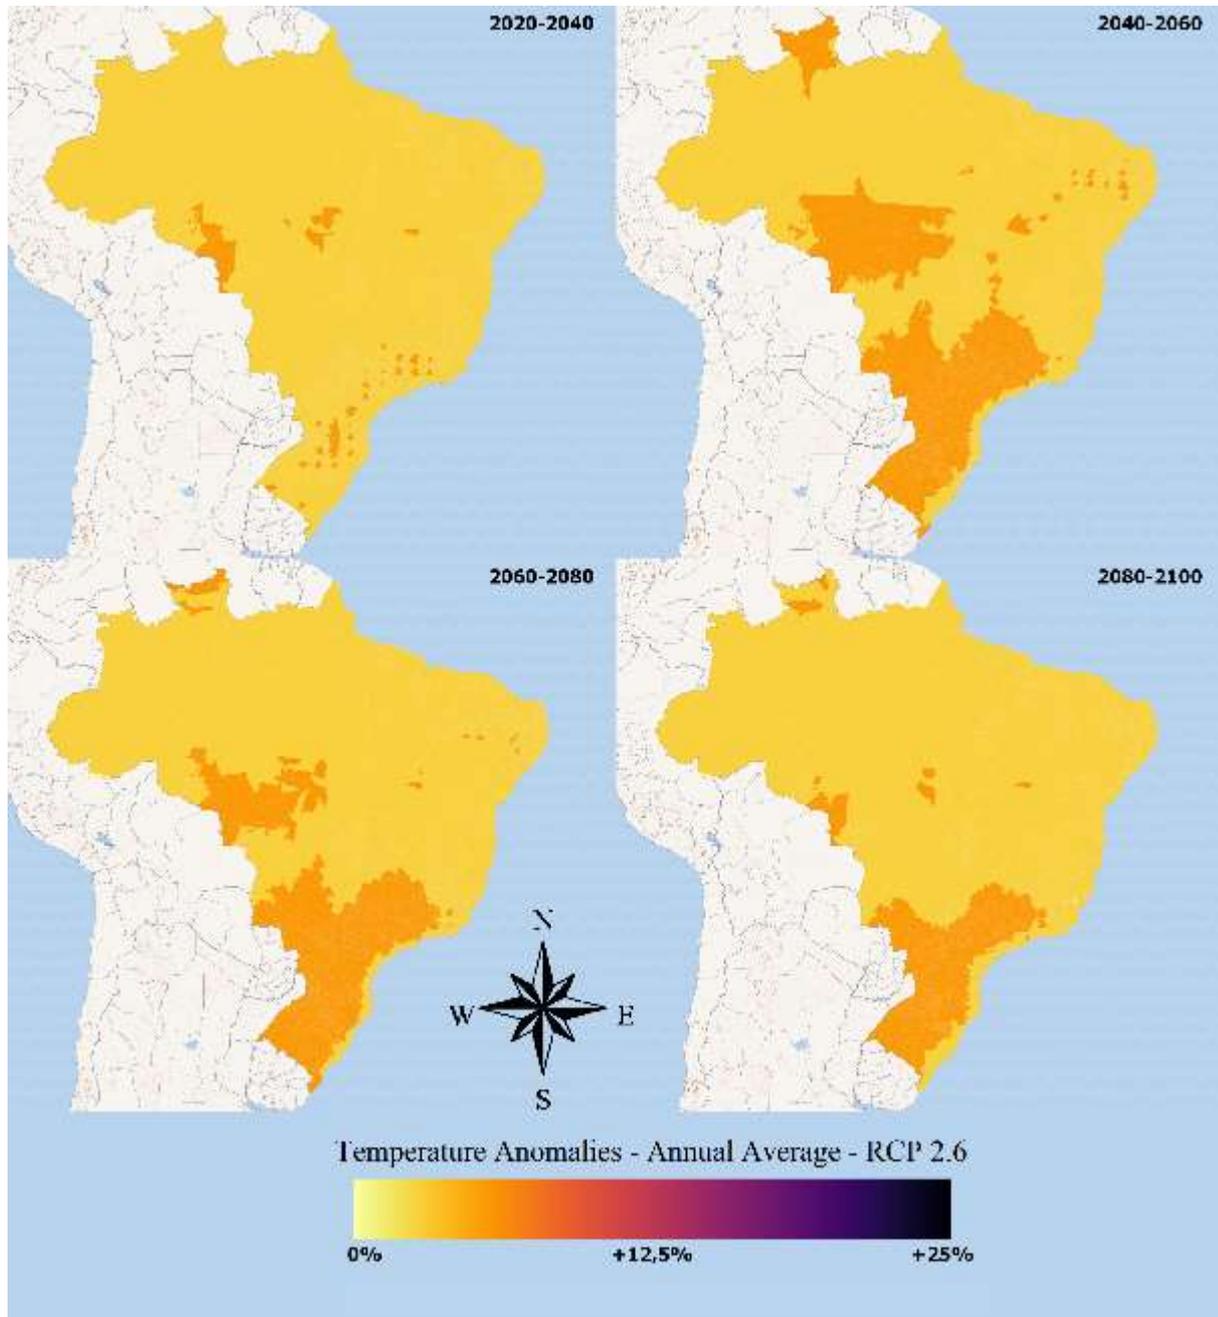

Figure 22 – Annual Temperature Anomaly – RCP 2.6.

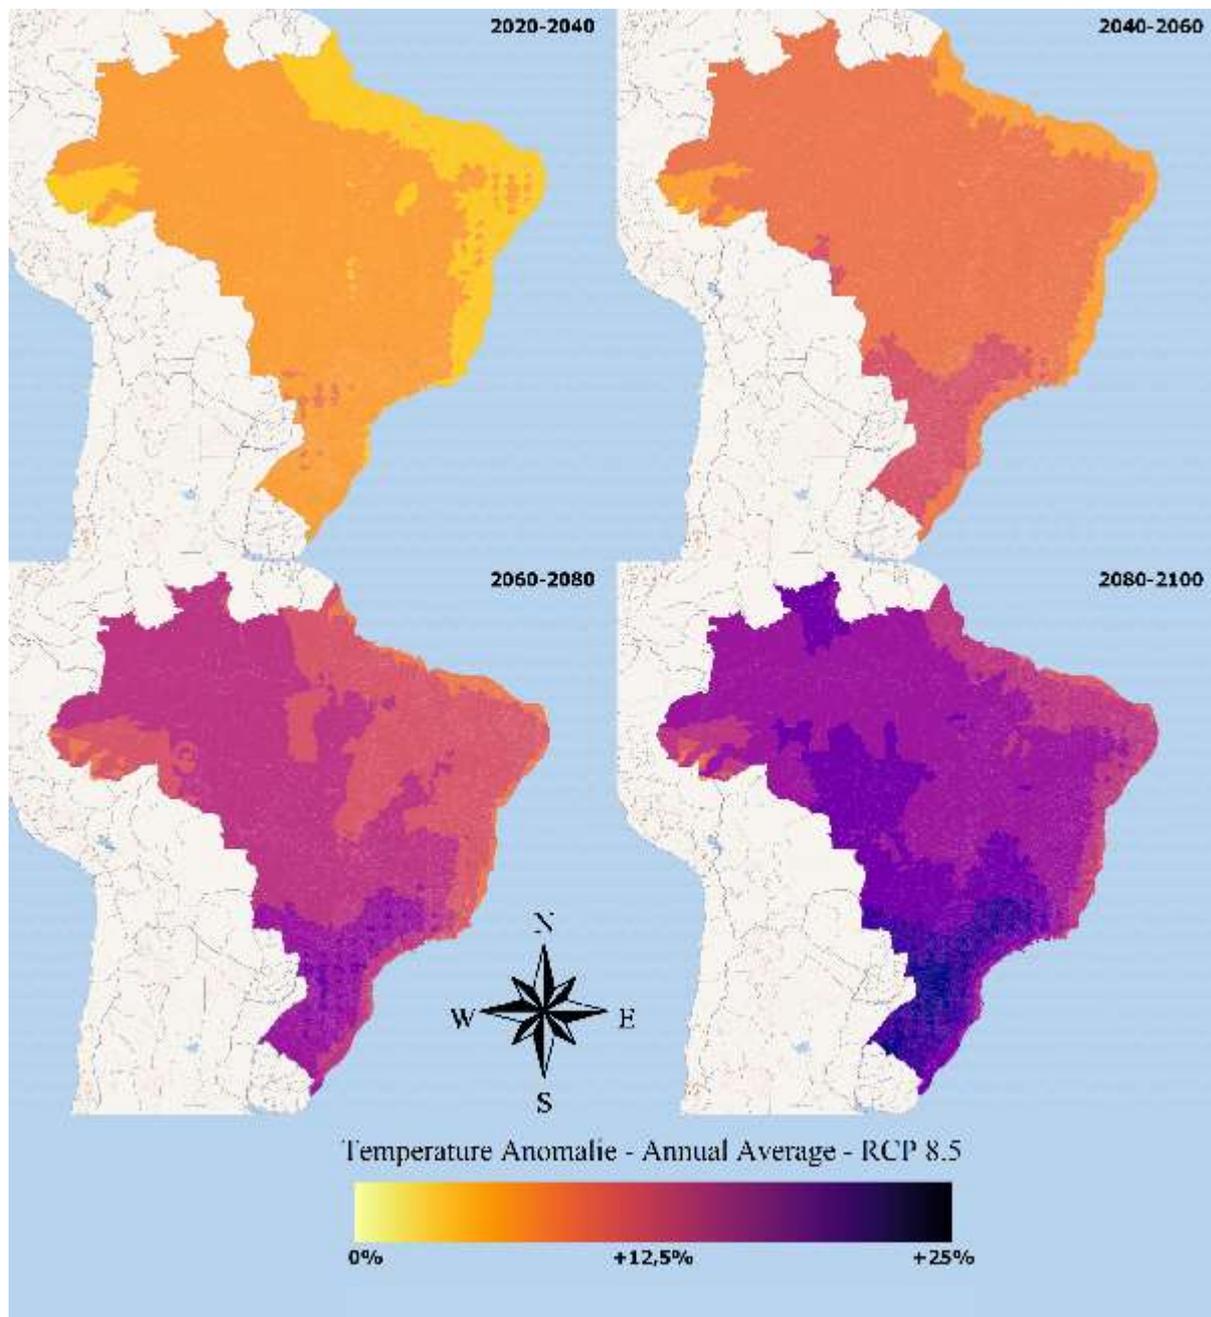

Figure 23 – Annual Temperature Anomaly – RCP 8.5.

4.4 Computable General Equilibrium

The B-MARIA 27 is a computable general equilibrium model calibrated for the Brazilian economy in the year 2011. Its functional structure tries to capture the interdependence relations of the sectors and regions of Brazil and can be understood as a photograph of the Brazilian economy that year. The model is structurally divided into 27 regions (the states of the federation plus the federal district) and is composed of 68 sectors. The construction of its database makes use of the top-down approach, which uses national aggregated results to disaggregate information in the regional dimension.

In essence, the model has a representative consumer and investor by region, regional and federal government structure, and a single external sector that can be marketed to any domestic region. The model is calibrated for 2011 and assumes that the tax structure and national tariffs can be replicated for all regions of Brazil that same year.

From the point of view of production, each sector is able to produce a particular product using the composite good specification that considers that each good is manufactured using fixed combination of primary factors and intermediate goods. The factors used in B-MARIA are Capital, Land and Labor which, in turn, combine by means of a function of elasticity constant substitution to form the compound of primary goods. The intermediate inputs, which may have domestic and foreign origin, also combine with a constant substitution elasticity function to form the compound of intermediate inputs. Finally, intermediate inputs and primary factors combine through a Leontief function to generate firm output.

As is usual in this class of models, the unknown number of parameters exceeds the number of equations to identify them. Thus, it is necessary to use the short and long-term closure approaches that allow the variation of some variables of the

model to be locked in order to allow it to become exactly identified. The short and long-term closure structure of the model is analogous to that used in the usual computable general equilibrium models: real wages and capital stock are considered exogenous in the short term and endogenous in the long run. Employment and return on capital are endogenous in the short run and exogenous in the long run. In addition, the model has a migration module, which allows capturing the effect of different exogenous shocks in the economy for the migration of people between the regions of the model. However, such migration is only possible in the long term.

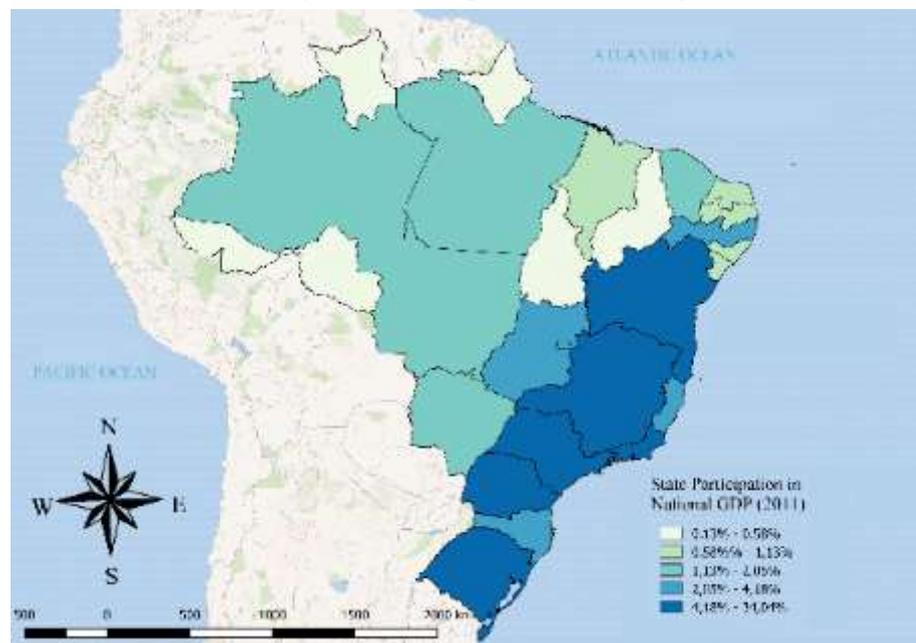

Figure 24 – State Participation in the Brazilian GDP – 2011.

Figure 9 shows part of this relation, indicating the proportion of the Gross Regional Product (PRB) of the Brazilian states in relation to the GDP of the country in 2011. The image shows the vast regional heterogeneity in the productive structure of Brazil, besides the preponderance of the axis South-Southeast in the Brazilian economy. In this sense, São Paulo accounted for about 35% of national production in 2011, while Acre accounted for only 0.16% of all that was produced in Brazil in the same year.

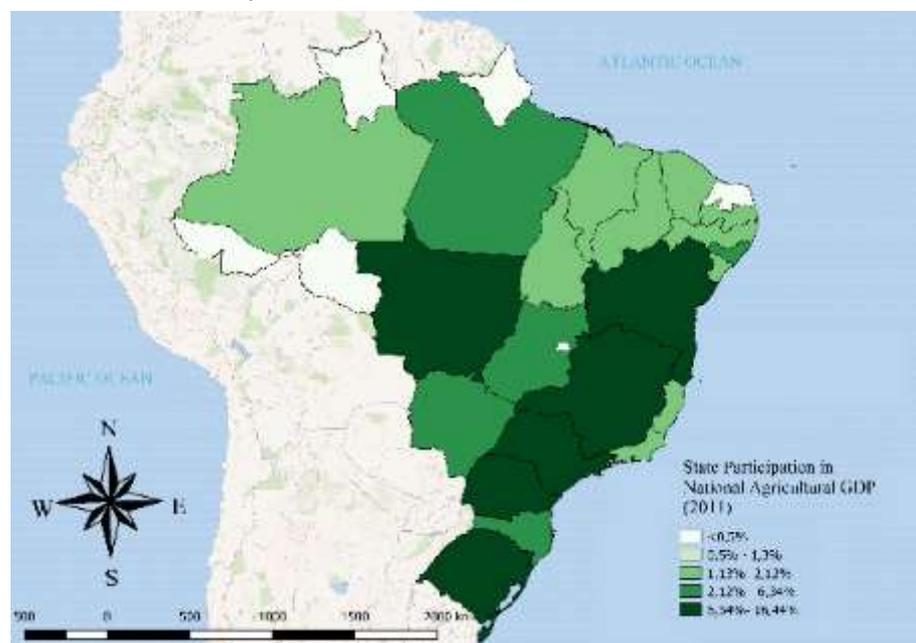

Figure 25 – State Participation in Brazilian Agricultural GDP – 2011.

Figure 10, in turn, shows the relative importance of each Brazilian state in the formation of the GDP of the country's agricultural sector. Here again, there is a regional heterogeneity in the productive structure of the country, but with a similar pattern in the concentration between the Brazilian regions, with an increase in the importance of the Central-West region. Again, São Paulo stands out, being responsible for about 16% of national agricultural production in 2011, followed by Minas Gerais, Paraná and Mato Grosso, responsible for 12.5%, 11.6% and 11.1%, respectively. At the other end, the states with the lowest relative importance in the national agricultural production are Rondônia, Acre, Roraima and Amapá, responsible for 0.35%, 0.24%, 0.05% and 0.04% respectively.

Finally, figure 11 shows the relative importance of the agricultural sector in the GDP of the states. Here again, the regional heterogeneity of such a measure is shown throughout the Brazilian regions. In this sense, the state of Mato Grosso is the one that depends most on agriculture in its productive structure (almost 18% of Mato Grosso's production in 2011 came from agriculture), followed by Alagoas (9.44%), Mato Grosso do Sul (8.95%) and Tocantins (6.5%). In the other direction, Rio de Janeiro, Federal District, Amapá and Roraima are the least dependent less on agriculture for the composition of their GDP in 2011 (with 0.18%, 0.36%, 0.63% and 1, 14%, respectively).

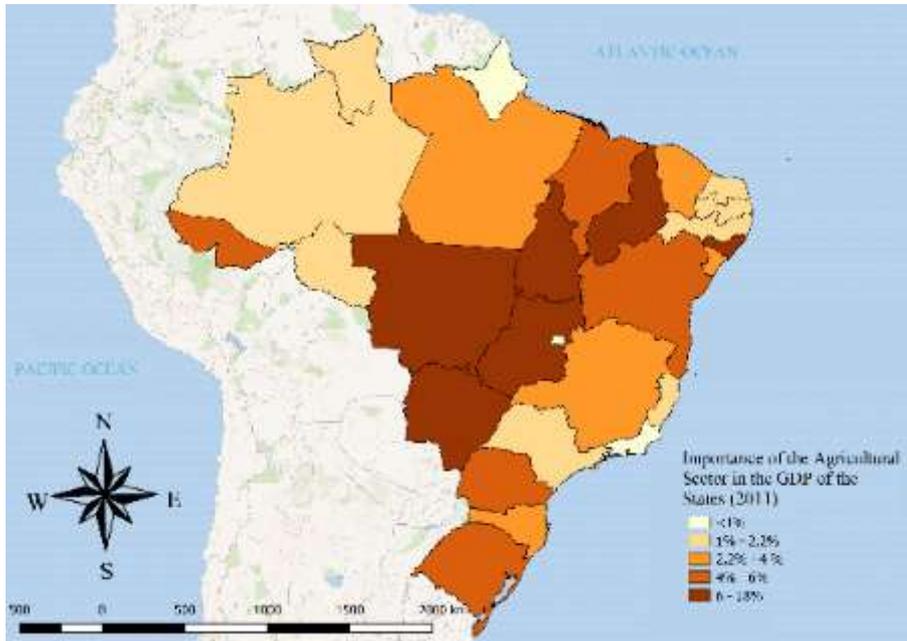

Figure 26 – Agricultural Sector Participation in the GDP of the States – 2011.

5. RESULTS

“Their cumulative effect is certainly considerable, and yet each one of them is quite possible in itself.”

Sherlock Holmes and Dr. Watson.

The Adventure of Abbey Grange

This chapter is divided into 5 subsections. The first presents the estimates of the econometric model described in section 2.1. The second uses such results to – with the help of the climatic projections described in section 3.3 – generate the projections of impact on the productivity of the crops studied. The third subsection presents the projections of direct impact that climate change will cause in the agricultural sector of the Brazilian states. The fourth subsection describes indirect impacts from the CGE model and the last subsection proposes a methodology to address the uncertainty problem explicitly.

5.1 Econometric Model

We now estimate equation (2) using the variation of climatic Anomalies for the Brazilian municipalities as an explanatory variable to the productivity differentials of the studied crops. The vector W_{cit} contains the available variables related to the municipal climatic conditions: compensated average temperature anomaly and cumulative precipitation anomaly in the month. For each year considered (1994 to 2015), monthly anomalies (January to December) were used as control variables. Following Mendelsohn et. Al. (1994), the quadratic specification for such anomaly variables was used in order to capture any non-linearities in the relationship between climate and productivity.

Thus, a municipal panel of 21 years was constructed for each of the six cultures studied. Equation 2 was thus estimated six times considering a series of specifications. For the purposes of this study, the final specification used follows Deschênes and Greenstone (2007), who use a panel of municipal fixed effects for their estimates. Thus, fixed effects of municipality were used in order to capture all the unobservable factors specific to each municipality that do not vary over time. Another possibility would be to include a fixed temporal effect that controls all the annual productivity differentials that are common to all municipalities. However, in the final specification, fixed state-year effects were used instead of fixed year effects to control for annual productivity differentials that are common to all municipalities within the same state. This, besides controlling for an important unobservable factor in determining municipal agricultural productivity (prices), the model identifies the parameter of interest θ by means of climatic anomalies observed in municipalities over time after controlling for shocks common to all municipalities within of a state⁴⁶. Control variables

46 Deschênes and Greenstone (2007) argue that such variation tends to be orthogonal to the unobservable determinants of agricultural production, providing a potential solution to alleviate the problem of bias of variable omitted.

(described in appendix 8.2) were also used, and all estimates used clusters at the state level and were weighted by the square root of the area planted in each crop⁴⁷. The results for each culture studied are presented in the appendix.

5.2 Impact Projection

With the estimates in hand, it is possible to combine them with the projections described in section 3.3 to generate predictions of impact on the productivity of the analyzed crops. The analysis of such impacts on crops reflects, to a large extent, the behavior of the climate scenarios considered and described in section 3.3: they present similar trajectories until the middle of the century but depart from 2050 with a deep aggravation under the scenario RCP 8.5 and a nearly constant path in RCP 2.6. In this way, all cultures will have different trajectories depending on the scenario considered.

Under RCP 2.6 the projected rates of change in productivity are nearly constant around zero in all crops. However, under RCP 8.5, the worsening of productive losses is evident in all crops studied. Beans, corn and soybeans show less significant annual losses, culminating in an annual production loss of approximately 16%, 22% and 30% at the end of the century, respectively. Sugarcane, Orange and Coffee, on the other hand, presented more severe loss trajectories in the house of 33%, 34% and 50%, respectively, until the end of the century.

Figures 12 to 17 show the predicted variations for the productivity of each of the crops studied between 2020 and 2100 for the two scenarios analyzed⁴⁸. In addition, consider the possibility of increasing their productivity through some kind of technical progress. To this end, each culture has an annual rate of specific technical progress accumulated over time. To estimate this rate, the average growth of the average yield of each crop in Brazil was used. Table 9 computes these averages for a series of periods from the data provided by PAM.

Table 9- Average Growth of the Productivity of the Cultures Analyzed.

Culture/Period	1974-2016	1990-2016	2000 - 2016	2011-2016
Sugarcane	1.20%	0.75%	0.62%	0.41%
Soybean	2.37%	1.94%	1.67%	0.15%
Maize	3.21%	3.46%	3.43%	0.54%
Bean	2.11%	3.27%	2.52%	1.69%
Coffee	3.94%	2.98%	1.55%	2.29%
Orange	-0.20%	-1.09%	1.71%	1.95%

For the figures below, it was considered that between 2020 and 2100 each of the crops studied will have annual technical progress rate referring to the values of the period 2011-2016.

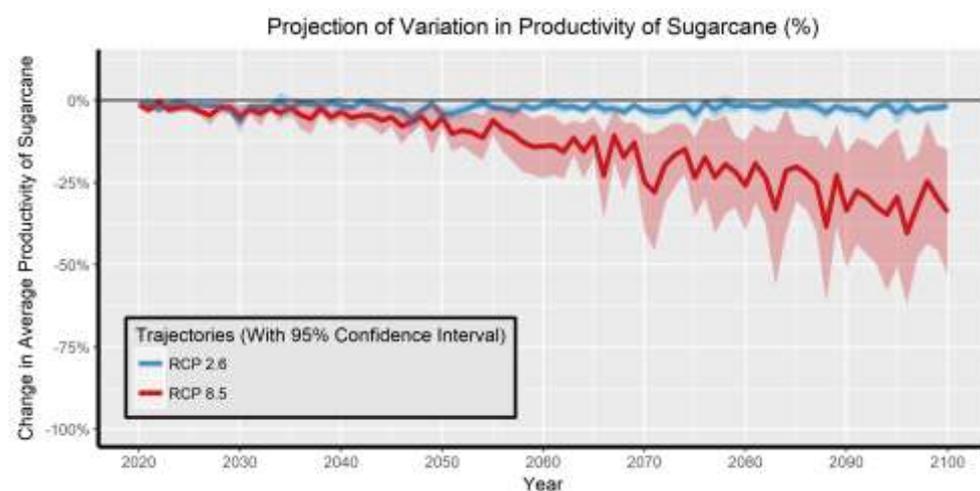

Figure 27 – Projection of Sugarcane Productivity Trajectory.

Sugarcane has a predicted productivity decrease in both scenarios. As is to be expected, however, RCP 8.5 leads to more drastic drops in average productivity, and from the 2070s onwards, sugarcane productivity would have more dramatically, even with the annual productivity growth rate of 0.41%.

47 Again, Deschênes and Greenstone (2007) argue that there are two main reasons for using weights in this context: the first is that the estimates of production and value produced tend to be more accurate in relation to cities that have a small operation of the crop in question. In addition, such weights correct for heteroskedasticity associated with differences in accuracy in such measures. Second, the weighted average of the dependent variable is equal to the mean value of this variable at the national level.

48 It is worth remembering that such trajectories are constructed from the weighted average of the trajectories of each of the Brazilian municipalities. The weight of each municipality for the calculation of this average is calculated considering the weight of the municipality in the total of the value produced by it within the country in the respective crop (again, considering the average value produced between 2010 and 2015).

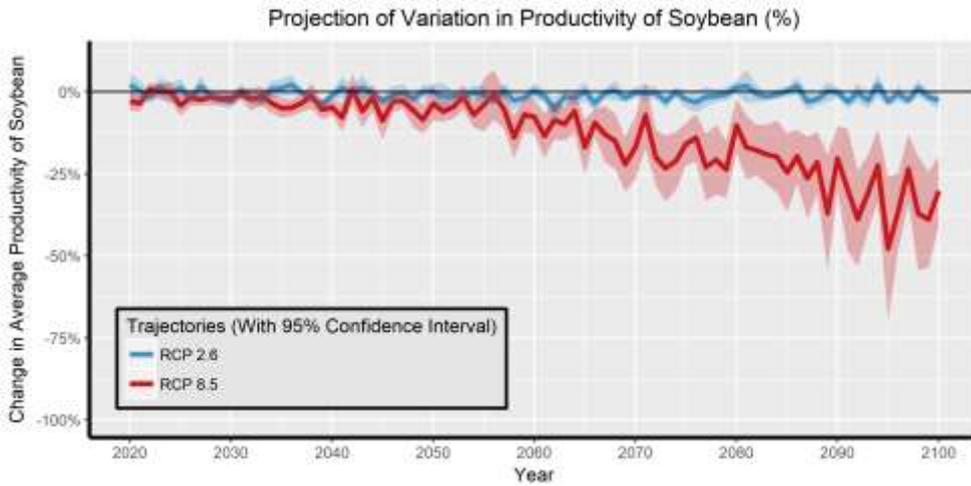

Figure 28 - Projection of Soybean Productivity Trajectory.

Soybeans, on the other hand, have constant trajectory under RCP 2.6 with annual technical progress of 0.15% per year. Under RCP 8.5, however, it is estimated that by the 1970s the average yield of soybeans in Brazil will start to fall more intensely, with almost 50% of productivity loss by the last decade of the century.

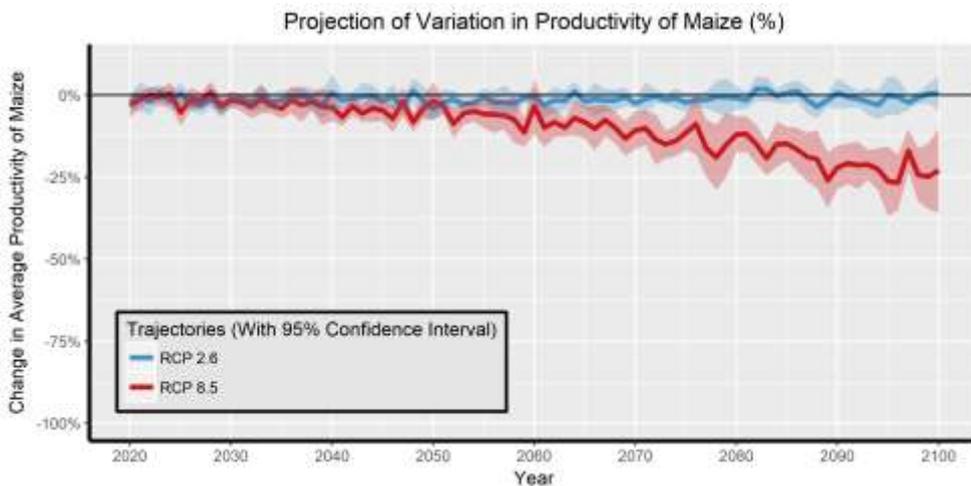

Figure 29 – Projection of Maize Productivity Trajectory.

Figure 12 shows the maize productivity variation trajectory. Again, under RCP 2.6 is expected an average variation around zero, but in the RCP 8.5 scenario the loss in productivity might reach 25%.

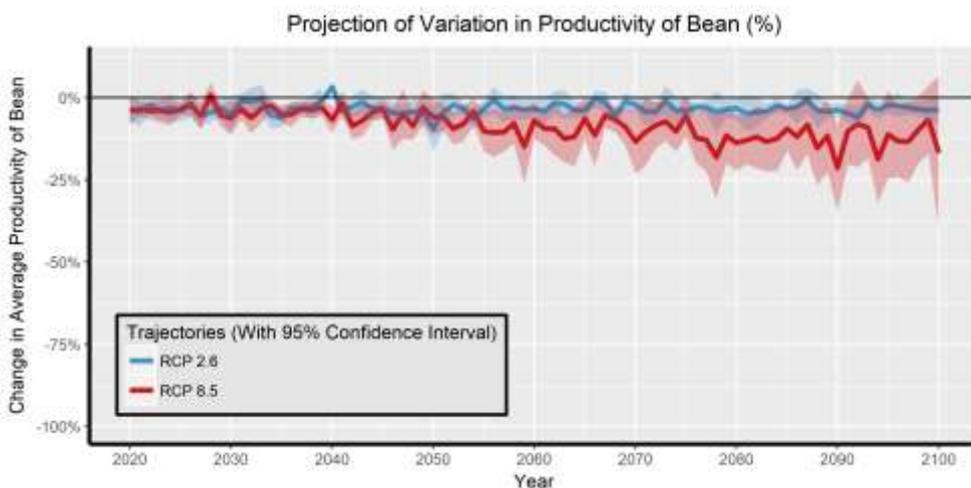

Figure 30 – Projection of Bean Productivity Trajectory.

Figures 13, 14 and 15 show a pretty similar pattern described above: not significant variation rates at RCP 2.6, and huge losses under RCP 8.5. The difference about coffee, bean and orange is that, under the more pessimistic scenario, the uncertainties are higher, leading to rates of productivity loss statistically non-different of zero.

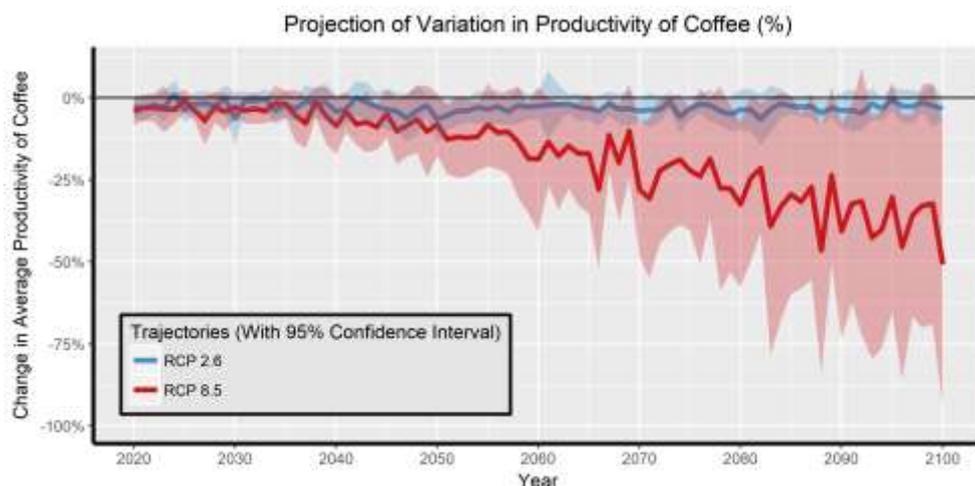

Figure 31 – Projection of the Productivity Trajectory of Coffee.

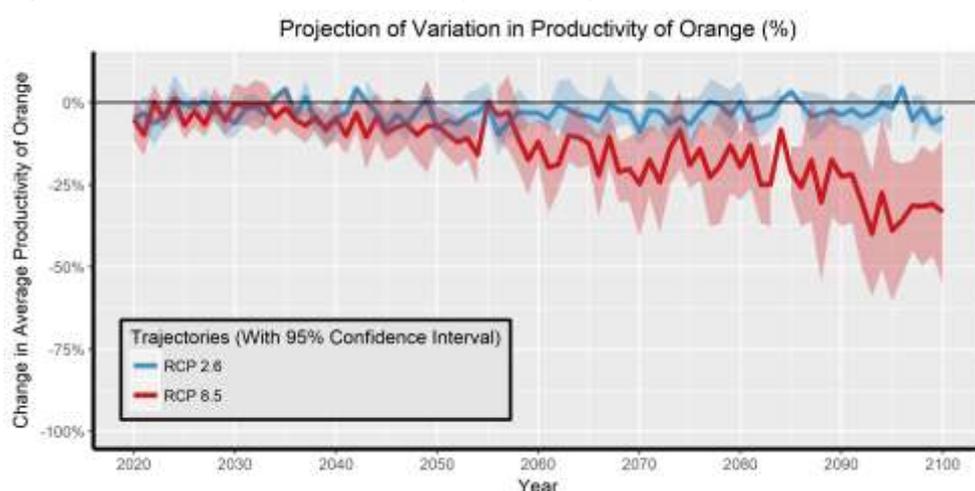

Figure 32 – Projection of the Productivity Trajectory of Orange.

5.3 Direct Impacts of Climate Changes on Present Value

This section presents estimates of the direct economic impacts of projected climate change by the end of the century. Table 30⁴⁹ in the appendix show the impacts of climate change described in section 5.2. Its total average impacts correspond to losses of R\$ 646.9 billion in current values (around 9.7% of Brazilian GDP 2017) under RCP 2.6 and R\$ 3.7 trillion (around 55.6% of the Brazilian GDP 2017) under RCP 8.5.

The most significant losses are concentrated on domestic production of sugarcane (R\$ 163.46 billion), beans (R\$ 154.2 billion) and corn (R \$ 148.8 billion) under RCP 2.6. Under RCP 8.5, the losses of maize (R\$ 1.01 trillion), sugarcane (R \$ 975.6 billion) and soybean (840.8 billion) stand out. As a basis for comparison, the value of total agricultural production in Brazil was R\$ 317.5 billion in that year. Considering only the crops studied, this value was R\$ 233.65 billion.

This implies that the direct losses due to the climatic changes in the six crops studied in this study are equivalent, in present value, to accumulated losses of about 277% of the national agricultural production under RCP 2.6. Under RCP 8.5, such losses are equivalent to stopping the country's agriculture for more than 11 years.

Under the regional aspect, the states facing the most significant losses are São Paulo, Minas Gerais and Paraná, responsible for 20.8%, 16.4% and 13.7% of losses under RCP 2.6, respectively. Under RCP 8.5, São Paulo's share of total losses jumps to 27.8%, while Paraná and Minas Gerais account for 14.1% and 13.4% of losses, respectively.

However, in order to assess the vulnerability of each state to these impacts, a vulnerability index was used that considers the direct impact of climate change on the state s (DI_s) by the weight of the total agricultural GDP of that state

Thus, the greater the importance of agriculture within a given state, the greater its vulnerability to the direct effects of climate change on its agriculture. Table 10 presents the state results under the two scenarios studied and indicates that, under both scenarios studied, the state of Mato Grosso is the most vulnerable, followed by Mato Grosso do Sul, Minas Gerais, Paraná and Goiás.

49 For calculations, discount rates of 0.1%, 1% and 3% were considered under the RCP 2.6 and 8.5 scenarios with specific technical progress. Table 30 shows only the estimates using the average discount rate (1,36% per year). All figures are in R\$ 2018.

$$VI_s^{direct} = \frac{\frac{DI_s}{\sum_{s=1}^{27} DI_s}}{\frac{GDP_s^{agriculture}}{\sum_{s=1}^{27} GDP_s^{agriculture}}}$$

In an economy without regional differentials of any order, one would expect such an index around one, so that the direct impact of the state would be proportional to its importance within the national economy. However, Table 10 shows that, at least in terms of vulnerability, the Brazilian economy is quite heterogeneous. The importance of the direct impact of the importance of the national GDP is more than 5 times higher in the states of Mato Grosso and Mato Grosso do Sul in both scenarios. On the other hand, such importance is more than 95% lower in states whose importance in the agricultural sector is low (Amazonas, Amapá and Rio de Janeiro, for example).

However, to assess the indirect impact that such direct losses will generate on the Brazilian economy, the next section draws on the framework provided by the computable general equilibrium models.

Table 10 - - Vulnerability Index

State	Importance of Agriculture in State Production	GDP	RCP 2.6		RCP 8.5	
			Direct Impact	VI_s^{direct}	Direct Impact	VI_s^{direct}

5.4 Indirect Impacts of Climate Changes

This section presents the results concerning the indirect economic impacts of the effect of climate change on the productivity of the crops studied. For this, as described in section 4.4, it uses a computable general equilibrium model applied to Brazil. Here again, we used a simulation strategy that considers the two climatic scenarios studied to build the necessary productivity shocks in the B-MARIA functional structure.

Thus, in order to construct the necessary productivity shocks for the model, we considered the impact trajectories described in section 5.2 (considering the rate of specific technical progress per crop). For this, the difference between the current level of productivity⁵⁰ of each crop and its projected productivity level in 2100 for each scenario. Thus, the percentage difference in crop productivity h, in city i, between the present and the end of the century will be given by:

$$\Delta prod_i^h = \frac{prod_{i,actual}^h - \widehat{prod}_{i,2100}^h}{prod_{i,actual}^h}$$

Where $prod_{i,actual}^h$ represents the current level of productivity of culture h, in city i today and $\widehat{prod}_{i,2100}^h$ the projected productivity level at the end of the century. However, since the B-MARIA model is built at the state level of disaggregation, it is necessary to aggregate the municipal data appropriately. Thus, for each municipality i within a given state S, we have:

⁵⁰ All estimates consider the current productivity level to be the average productivity of each Brazilian municipality between 2011 and 2015. Once the projected climatic projections begin in 2020, the 2011-2015 average is considered as the initial productivity level in 2020.

$$\Delta prod_S^h = \sum_{i \in S} w_i^h * \Delta prod_i^h$$

Where w_i^h represents the weight of municipality i in the total that the state S produces from culture h . Finally, given that the sectoral breakdown of the model considers only one large sector of agriculture (without product breakdown), the weight of each crop h must be considered within the total produced by the agriculture of each state S :

$$shock_S^h = p_S^h * \Delta prod_S^h$$

Where $shock_S^h$ is the productivity shock with respect to culture h in the state S and p_S^h is the importance of crop h within state S agriculture (described in table 16). Finally, consider $H = \{Cana, Soja, Milho, Feijão, Café, Laranja\}$. The state productivity shock that will be introduced in the B-MARIA structure will be given by:

$$final_shock_S = \sum_{h \in H} shock_S^h$$

Its analysis allows us to understand three different dimensions: first, the impact of the relationship between the projected change in the climate and the productivity of each crop studied. Second, how important is this impact to the agricultural sector of each state. Finally, to what extent do the scenarios differ in the two previous dimensions.

The sugarcane under RCP 2.6 presents vast heterogeneity in their shocks. Alagoas and São Paulo are the main affected states, with losses of 54.9% and 43.3%, respectively. Such magnitude is, to a large extent, influenced by the importance of culture within the agricultural sector of each state (90% in Alagoas and 60.8% in São Paulo). Under RCP 8.5 the regional pattern is the same, with only one change in magnitude of shocks.

Soybean, in turn, is the culture that presents the biggest difference between the scenarios. The culture presents a productivity gain situation under RCP 2.6 and loss under RCP 8.5. In the first case, such gain is driven by the high rate of technical progress used for the crop at the confluence with a low impact of projected climate changes under this scenario. In the second case, however, the more pronounced climate changes lead to more expressive productivity losses.

The corn, beans and coffee grains, because they are less representative crops within the states, have a less expressive magnitude of shocks in both states. The major coffee losses in Minas Gerais (shock of 29.9% in RCP 2.6 and 28.6% in RCP 8.5) are noteworthy. Orange is the crop with the least impact in both scenarios largely because of its little importance within the agricultural sector of all states.

In order to these shocks be introduced into the B-MARIA simulation structure, it was necessary to distribute them in a homogeneous way over time. Such a transformation is necessary so that these can be simulated under the long-term closure of the model, described below. In other words, it is assumed that such shocks are evenly distributed throughout the century in periods of 5 in 5 years. Thus, table 11 presents the final shocks on each state that will be introduced in the structure of the B-MARIA model in order to evaluate the indirect impacts of climate change on the Brazilian economy. Their analysis is quite clear: on average, the impacts under RCP 8.5 are much more intense than in RCP 2.6.

To conduct simulations in the B-MARIA model, long-term closure will be used, which assumes that the level of real wages, regional GDP and capital investment are endogenous while the level of employment and technology are exogenous. The productivity shocks described in table 11 will be implemented in the model structure through the parameter $a1prim$, which refers to the factor of technological increase of the primary factors (capital, labor and land). In other words, the introduction of productivity shocks into the functional structure of the model assumes that the primary factors of the agricultural sector in each of the Brazilian regions will lose efficiency following the same magnitude described in the table above.

Simulations will be conducted using the long-term closure. The choice of a particular closure reflects two different dimensions: the first is associated with the idea of the time scale of the simulation, which is the period of time that is necessary for the economic variables to adjust to a new equilibrium. The time scale hypothesis affects the way market factors are modeled. For example, in a long run simulation the possibility of variation in the stock of fixed capital of the economy is generally considered. The idea is that the capital stock takes some time⁵¹ to settle in the economy after some exogenous shock.

The second dimension for choosing a particular closure concerns the needs of a particular simulation and the researcher's view of the variables that the model does not explain. For example, B-MARIA says little or nothing about the effect of climate change on agricultural productivity. Thus, by considering the productivity of the agricultural sector as something exogenous to the model (and therefore not explained by it), it becomes possible to establish such a relation in a module outside the model (section 5.2) and to use the framework provided by it measure the indirect effect that such a change may have on the economic system.

In essence, the main differences between a short and long-term closure in the B-MARIA functional:

- Capital inventories can adjust freely to ensure fixed rates of return across sectors.
- The aggregate level of employment remains constant and what is adjusted are real wages. This is consistent with the idea that, in the long term, both the labor force and the natural rate of unemployment are determined by mechanisms exogenous to the model.

⁵¹ Horridge (2006) argues that to be considered short-term, a given simulation should generally consider the time horizon of 1 to 3 years.

- Government and consumer spending move together to accommodate the constraint that the balance of payments importance relative to GDP is constant. This idea is guided by the hypothesis that, in the long term, the rest of the world may be reluctant to finance a growing deficit.

Moreover, the model also does not provide any mechanism to explain the absolute price level, which determines, in a discretionary manner, what changes in the real exchange rate manifests or how changes in the domestic price level or change in the nominal exchange rate. Labor supply is also determined exogenously in the model so that the average (real or nominal) wage or the level of employment is exogenous depending on the closure (in the case of the long term, the level of jobs considered exogenous). Finally, changes in the size and composition of the absorption level are also not explained by the model. This implies that either one of the components of the absorption or the level of the trade balance is considered to be considered exogenous in order to arrive at a balance in the model.

Table 11 – Final Shocks Among States.

State	Total RCP 2.6	Total RCP 8.5	Difference
AC	-0,006%	-0,103%	-0,098%

RN	-1,096%	-1,149%	-0,052%
RO	-2,020%	-4,797%	-2,777%
RR	-0,427%	-0,687%	-0,260%
RS	0,409%	-4,283%	-4,691%
SC	0,003%	-3,533%	-3,536%
SE	-3,649%	-4,847%	-1,198%
SP	-4,530%	-6,546%	-2,017%
TO	-0,859%	-7,023%	-6,164%

Finally, Table 12 presents the indirect economic impacts from the agricultural productivity shocks mentioned above for each of the scenarios. As expected, the most dramatic impacts are under RCP 8.5. For the selected aggregate variables, it is estimated that the impact under the worst case scenario is, on average, 7.4 times larger than the RCP 2.6 scenario.

Table 12 - Indirect Impacts on some Economic Aggregates (in percentage points).

Aggregate	RCP 2.6	RCP 8.5	Difference
National Consumption	-0.22403	-1.03464	-0.81062
National Investment	-0.16377	-0.76967	-0.60589
Nominal Wage paid to Workers	-0.21991	-0.99615	-0.77625
National Employment Level	-0.00057	-0.01146	-0.01088
Equivalent Relative Variation	-0.43459	-1.82902	-1.39443
Nominal GDP	-0.18396	-0.85914	-0.67519
Real GDP	-0.05499	-0.26783	-0.21284
Exports	-0.02486	-0.27009	-0.24523
Imports	-0.16738	-0.79966	-0.63228
Terms of Trade	0.01243	0.13528	0.12285

In terms of aggregate consumption and investment, the cumulative five-year variation is -0.22% and -0.16% under RCP 2.6 and -1.03% and -0.77% under RCP 8.5. In both aggregates, the impact under the second scenario is 4.6 times greater than under the former. The nominal wage level of workers accumulates fall of -0,22% and -0,99% under RCP 2.6 and 8.5, respectively.

Well-being, measured by the equivalent variation of income, fell by 0.43% and 1.82%, respectively. Among all the analyzed aggregates, this is the one that presents the greatest divergence among the scenarios: the welfare loss under RCP 8.5 becomes 20 times greater compared to RCP 2.6.

In terms of production, the results point to real losses of 0.055% every five years (0.87% of GDP by the end of the century) under RCP 2.6 and 0.26% (4.11% of GDP to the end century) under RCP 8.5. Finally, the drop in imports is about 6.7 times larger than the drop in exports under RCP 2.6 and 3 times higher under RCP 8.5.

Table 13 shows the corresponding indirect impacts by state for consumption, number of people employed and regional GDP. In terms of household consumption. Under RCP 2.6, Alagoas reigns with the highest losses, accumulating five-year losses of 0.3%, 0.18% and 0.5% for consumption, employment and GDP, respectively. In terms of the number of people employed, there is a relative balance in the sign of the effect between the regions.

Under RCP 8.5, finally, losses are more geographically dispersed in terms of GDP, especially the average five-year loss rates of 1.29% in Mato Grosso and 1.21% in Alagoas.

Table 13 – Indirect Impacts Among Brazilian States (in percentage points).

State	Family Consumption		Employment		State GDP

Table 14 presents the second indirect vulnerability index (analogous to that described in the previous section) for the Brazilian states. This index, which measures the relation between the weight of the indirect impact of the states in relation to the weight of the state in terms of the agricultural GDP of the country, denotes the extreme vulnerability of Alagoas under RCP 2.6 and the relative homogeneity of the states under RCP 8.5.

Finally, Table 30 in the appendix presents the direct, indirect and total impacts of climate change on Brazilian states translated into 2018 values. Under RCP 2.6, the indirect negative impacts under the Brazilian economy from climate change amount to R\$ 95,4 billion while under RCP 8.5 such impacts add up to losses of R \$ 1.78 trillion. In the most optimistic scenario, Mato Grosso, Rio Grande do Sul, Goiás and Pará add indirect gains of R \$ 24.1 billion, while São Paulo, Minas Gerais, Rio de Janeiro, Pernambuco and Alagoas accumulate losses of R \$ 112.7 billion. Under RCP 8.5, indirect losses are more extensive, with São Paulo (R \$ 624.5 billion), Rio de Janeiro (R \$ 179.5 billion) and Minas Gerais (R \$ 155.5 billion) being the states that accumulate the greater losses.

Thus, it can be concluded that the indirect effects of climate change on the Brazilian economy represent 12.9% of the total effect under RCP 2.6 and 32.5% under RCP 8.5. Finally, it is estimated that the total impacts on the Brazilian economy from projected climate changes by the end of the century amount to R \$ 742.3 billion (under RCP 2.6 and 5.48 trillion (81.8% of GDP in 2017) under RCP 8.5.

However, all of the aforementioned impacts (direct and indirect) carry a series of uncertainties inherent in the methodology used. Thus, the next section proposes methodology to deal with the degree of uncertainty about state productivity shocks explicitly.

5.5 Dealing with Uncertainties

Stern (2006) argues that the science of climate changes, while reliable, deals with a number of uncertainties. One cannot say with certainty when and where particular impact will occur. There are uncertainties that hamper the accurate quantification of the economic impacts of climate change.

The econometric model used integrates two sources of uncertainty in the construction of its database. The first one concerns the reliability of the agricultural database described in section 4.1. The second is related to the uncertainty regarding information provided by INMET stations (section 4.2) and to possible friction and measurement errors in their construction. The confluence of these two factors is still added to the uncertainty regarding the econometric model itself, which produces not necessarily accurate estimates (Table 18 to Table 29).

In addition, the climate projections generated by the IPCC models themselves have their degree of uncertainty, as described in section 4.3. Stern (2006) illustrate that such models reflect a cascade of uncertainties inherent in the scenarios considered: political uncertainties, emission levels, global mitigation actions, population growth, technological progress, among others. Although we have attempted to deal with some of these uncertainties in previous sections, a broad set of climate model parameters make climate projections have a high level of intrinsic uncertainty.

Then comes the uncertainties related to the direct impact projections described in section 5.4. These involve, initially, uncertainties regarding the intertemporal discount used to evaluate them, not to mention the hypotheses of constant prices and maintenance of the pattern of the productive structure of the agricultural sector throughout the century, implicit in the methodology used.

Concerning the construction of the productivity shocks of the CGE model, described in section 5.5, the uncertainties takes into account both the projected productivity trajectories in both scenarios (Figure 12 to Figure 17) and the specific technical progress rates of each culture.

Finally, the analysis of the indirect economic impacts of climate change, besides of accumulating all the uncertainties mentioned above, involves a series of hypotheses about the regional and sectoral productive structure of the Brazilian economy, represented by the interregional input-output system used to calibrate the B-MARIA⁵².

The confluence of all these uncertainties generates a well-documented "snowball" effect in the science of the economic impacts of climate change (STERN, 2006). To try to deal with this effect, this section proposes and formalizes methodology that treats this process explicitly. To implement such method, the potential connections of a physical model with the functional structure of the CGE model are explored.

For the case in question, the idea is to conduct simulations that mimic the behavior of a given set of endogenous B-MARIA variables. Thus, it is enough to replicate the desired information within the set of exogenous variables of the model and simulate their shocks in order to achieve the best combination of effects for their endogenous variables.

In other words, we will consider the long-term closure described in the previous section, use the results described above⁵³ and put them as target for the replicate CGE model. In order to do that, the idea is to calibrate the exogenous productivity shocks in the B-MARIA structure that will endogenously generate the aforementioned target results.

⁵² For more details, see Haddad, Gonçalves Júnior and Nascimento (2017).

⁵³ In our case, the endogenous variable that will be used as target will be the GDP of the states.

The CGE model in question is included in the class of models known as Johansen models, which obtains its solutions by solving a system of linearized equations⁵⁴. Thus, consider a certain set of B-MARIA equations:

$$F(V) = 0 \quad (3)$$

Where V represents an equilibrium vector of dimension n (number of variables) and F is a function vector of order m (number of equations), which is assumed to be differentiable. For the purpose of solution, it is assumed that $n > m$, while $n - m$ variables should be considered exogenous. In addition, it is assumed that the model has a solution, that is, $\exists V = V^*$ such that $F(V^*) = 0$ and that such solution is known (the CGE model is calibrated).

Thus, Johansen's approach is to use a linearized version of (5), which can be represented as:

$$A(V)v = 0 \quad (4)$$

Where $A(V)$ is an array of order $m \times n$ that contains the partial derivatives of $F(V)$ and v represents the percentage changes in the V vector. v represents the percentage changes in the V vector consists in evaluating $A(.)$ at an initial equilibrium vector V^I and solve (6). For this, it is necessary to partition $A(.)$ and v in two parts, separating the endogenous and exogenous variables from the closure of the model. Call α the index for the endogenous variables and β the index for the exogenous. It has been that:

$$A(V^I)v = A_\alpha(V^I)v_\alpha + A_\beta(V^I)v_\beta = 0$$

Rearranging:

$$v_\alpha = -A(V^I)^{-1}A_\beta(V^I)v_\beta$$

Take $-A(V^I)^{-1}A_\beta(V^I) = B(V^I)$ such that:

$$v_\alpha = B(V^I)v_\beta \quad (5)$$

Where v_α is a $m \times 1$ vector that contains the expected percentage changes in the endogenous variables resulting from the exogenous shocks contained in the vector v_β . Now consider (7) represented as follows:

$$\begin{bmatrix} v_{\alpha 1} \\ \dots \\ v_{\alpha m} \end{bmatrix} = \begin{bmatrix} B_{11} & \dots & B_{1(n-m)} \\ \dots & \dots & \dots \\ B_{m1} & \dots & B_{m(n-m)} \end{bmatrix} \begin{bmatrix} v_{\beta 1} \\ \dots \\ v_{\beta m} \end{bmatrix}$$

It can be rearranged such that:

$$\begin{bmatrix} v_{\alpha 1} \\ \dots \\ v_{\alpha m} \end{bmatrix} = \begin{bmatrix} B_{11} \\ \dots \\ B_{m1} \end{bmatrix} v_{\beta 1} + \begin{bmatrix} B_{12} \\ \dots \\ B_{m2} \end{bmatrix} v_{\beta 2} + \dots + \begin{bmatrix} B_{1(n-m)} \\ \dots \\ B_{m(n-m)} \end{bmatrix} v_{\beta(m-n)} \quad (7')$$

Equation (7') allows one to directly see two properties that will be employed. The first is that when considering a shock in a certain exogenous variable q ($v_{\beta q}$), the effect on the vector of endogenous variables v_α will be proportional to the vector that multiplies this variable in (7'). In addition, when assessing the effect of a multidimensional shock (as in the case in question, where we will assess shocks on the 27 states of the federation), the total impact on v_α can be computed as the sum of the effects of the shocks on the separate endogenous variables.

Then suppose that a subset of K -dimension of elements of v_α is selected as target. So, you build the vector $t_{(k \times 1)}$ that contains all of these targets. Also assume that a subset of order J of the vector is identified v_β which contains exogenous variables considered relevant to influence the variables in $t_{(k \times 1)}$. Now, just rewrite (7') by zeroing all the elements of v_α That are not contained in $t_{(k \times 1)}$ and all the elements of v_β that are not in the sub-set of order j above. Call it a \widehat{v}_α the vector of endogenous variables considered for analysis and \widehat{v}_β the exogenous vector is considered important to determine them.

Using the same notation as (7):

$$\widehat{v}_\alpha = \widehat{B}\widehat{v}_\beta \quad (6)$$

Or, even:

$$\begin{bmatrix} \widehat{v}_{\alpha 1} \\ \dots \\ \widehat{v}_{\alpha k} \end{bmatrix} = \begin{bmatrix} \widehat{B}_{11} \\ \dots \\ \widehat{B}_{k1} \end{bmatrix} \widehat{v}_{\beta 1} + \begin{bmatrix} \widehat{B}_{12} \\ \dots \\ \widehat{B}_{k2} \end{bmatrix} \widehat{v}_{\beta 2} + \dots + \begin{bmatrix} \widehat{B}_{1j} \\ \dots \\ \widehat{B}_{kj} \end{bmatrix} \widehat{v}_{\beta j}$$

In essence, it is noted that \widehat{v}_α It will depend on the choice of values for the exogenous variables contained in \widehat{v}_β . So, given the values of a target t The best choice for \widehat{v}_β will be the one who solves:

$$\min_{\widehat{v}_\beta} \frac{(\widehat{v}_\alpha - t)^2}{t^2} \quad (7)$$

Translating, the best choice for exogenous shocks \widehat{v}_β will be the one that minimizes the quadratic percentage distance of the values of the selected endogenous variables with the target Selected. Finally, the solution of the equation above, \widehat{v}_β^* , will generate a corresponding endogenous variable vector, \widehat{v}_α^* .

54 For more details, see Dixon and Parmenter (1996).

In order to apply such a methodology in the context of this work, one or more channels of transmission in the functional structure of the model CGE in order to capture the impact of interest from agricultural productivity shocks. Figure 18 schematics such channels and their respective effects that will be used as *targets* in the structure of model B-MARIA.

We will use as *target* the results on regional GDP from the simulations described in the previous section. In other words, the vector of *target* it will contain the GDP variations of the States constructed from the estimates obtained from the shocks described in the table 11 for each of the scenarios studied.

The shocks contained in \widehat{v}_β will relate to the 27 productivity shocks in the agricultural sector of Brazilian states, as described in the previous section. Thus, the equation (8) will represent a vector of 27 lines (one for each state) as the multiplication of an array of order 27 (the cross-effects of the variation of the productivity of each state on the GDP of these) and a vector of 27 lines (the shocks of agricultural productivity).

To implement the method, however, an estimate is required for matrix B. To obtain it, just perform a simulation of the impact of a unit shock of agricultural productivity set in the 27 states and capture the corresponding cross-elasticities of these on the regional GDP of the Brazilian federation units.

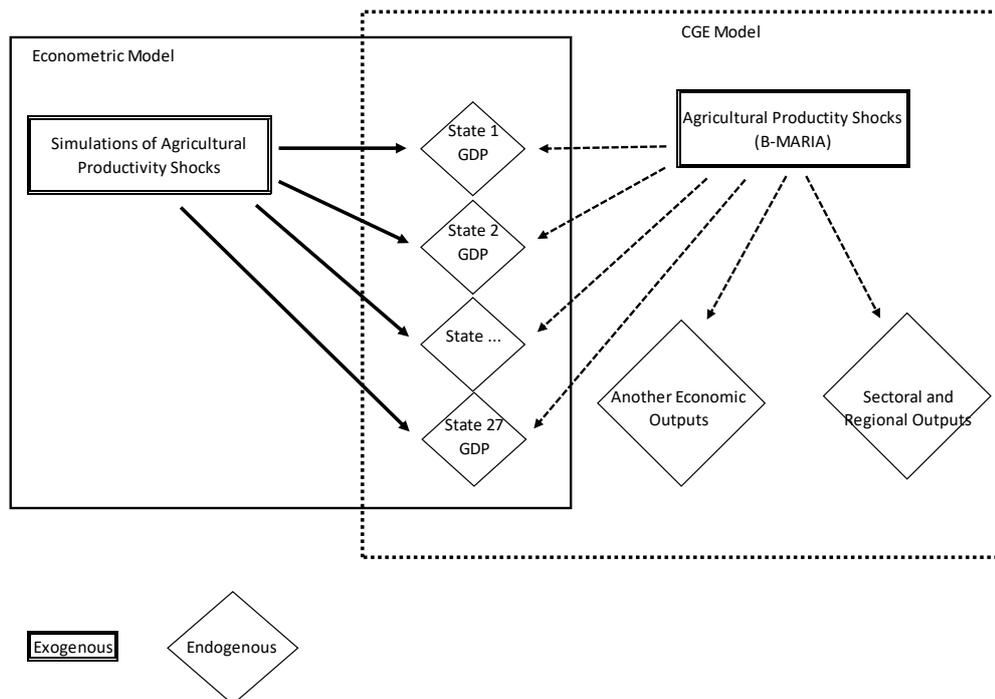

Figure 33 - Transmission Channels and the CGE Model.

Thus, given the intrinsic uncertainty in the magnitude of the agricultural productivity shocks of the states, such a method can be applied in order to integrate the results described between the sections 5.1 and 5.4 with the structure of the model B-MARIA and thus to treat the uncertainty in an explicit manner in the construction of the shocks of the agricultural productivity.

That way, we use it as *target* the impacts on the states GDP derived from the results of the simulations described in the previous section. The estimates built from the econometric model described in the section 3.1 are used as a starting point for simulations of exogenous shocks (\widehat{v}_β). For this work, we run 10000 simulations of productivity shock (\widehat{v}_β) in order to assess the one that minimizes (9).

Each simulation was built from a random draw to the state productivity shock from a Gaussian distribution with average equal to the shock described in the

Table 11 and variance calculated from the econometric estimates combined with the climatic projections described earlier.

Figure 19 shows the distribution of these simulations for each Brazilian state. Their analysis allows comparing both the magnitude and the difference of the agricultural productivity shocks between the scenarios. The comparison of the averages of the distributions of shocks of agricultural productivity allows to verify that these have smaller averages under RCP 8.5, according to what is expected in this scenario. When comparing the dispersion of these distributions, however, we can note a greater heterogeneity among the states. Roughly, Northeastern states have less variability of shocks under RCP 8.5 while states of other regions have greater dispersion under the most pessimistic scenario.

Figure 20, on the other hand, shows the effects on the state GDP \widehat{v}_α corresponding to each simulation of state agricultural productivity shock. Here, the analysis becomes more complex, with cases in which the distribution of impacts on the GDP of the states has average less worse under RCP 8.5 than RCP 2.6. However, the behavior on the dispersion of these shocks has the same pattern as those described in the previous image.

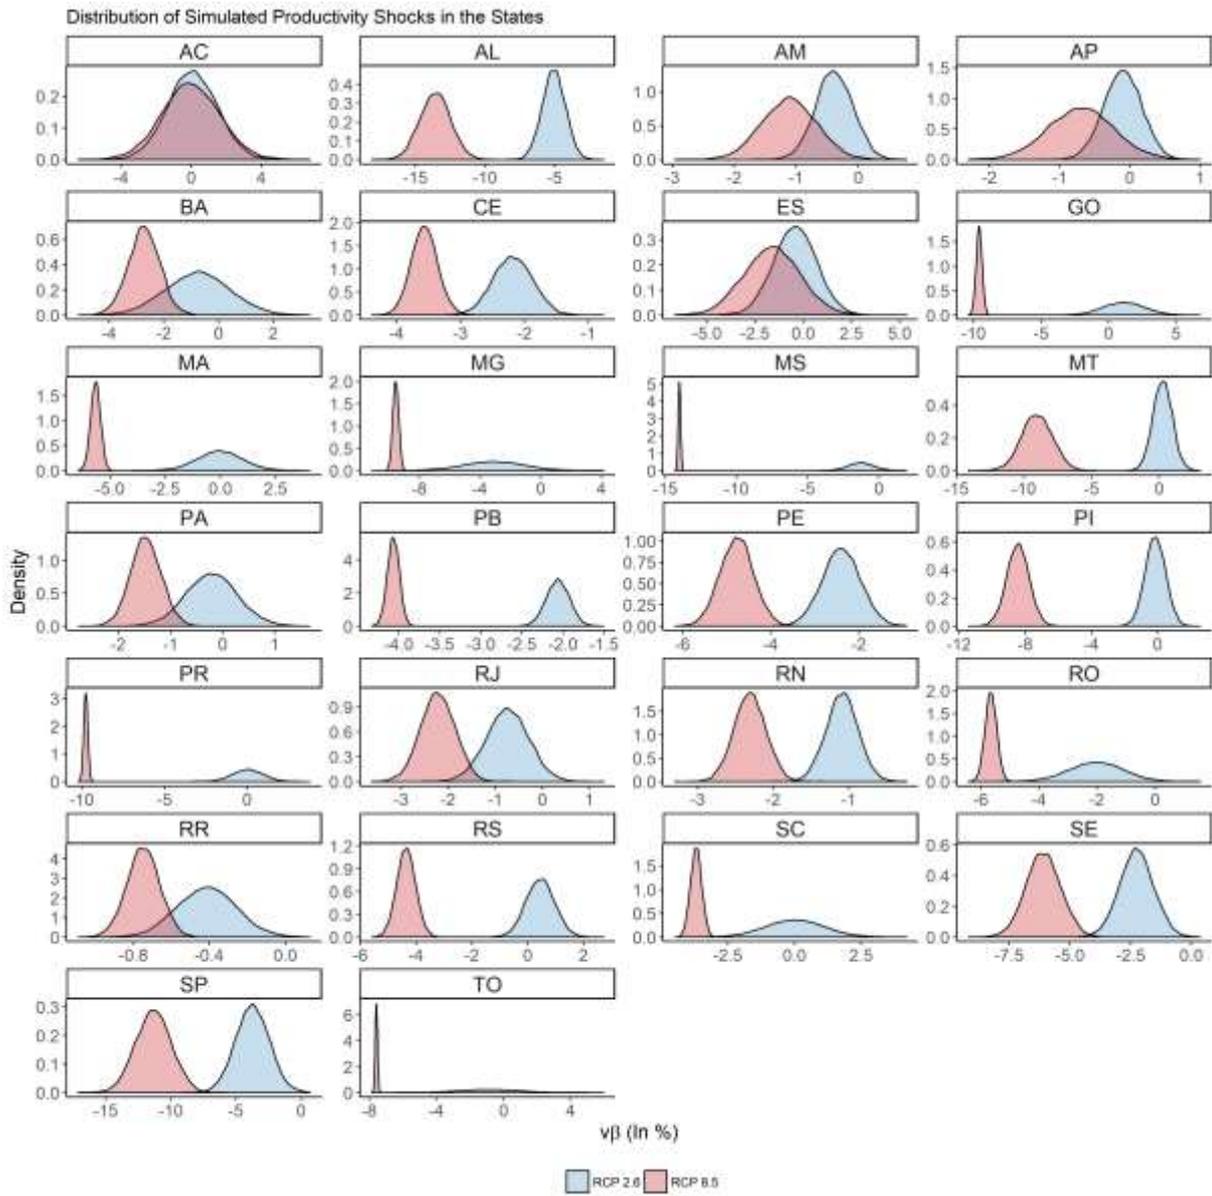

Figure 34 - Simulated Shocks Distributions.

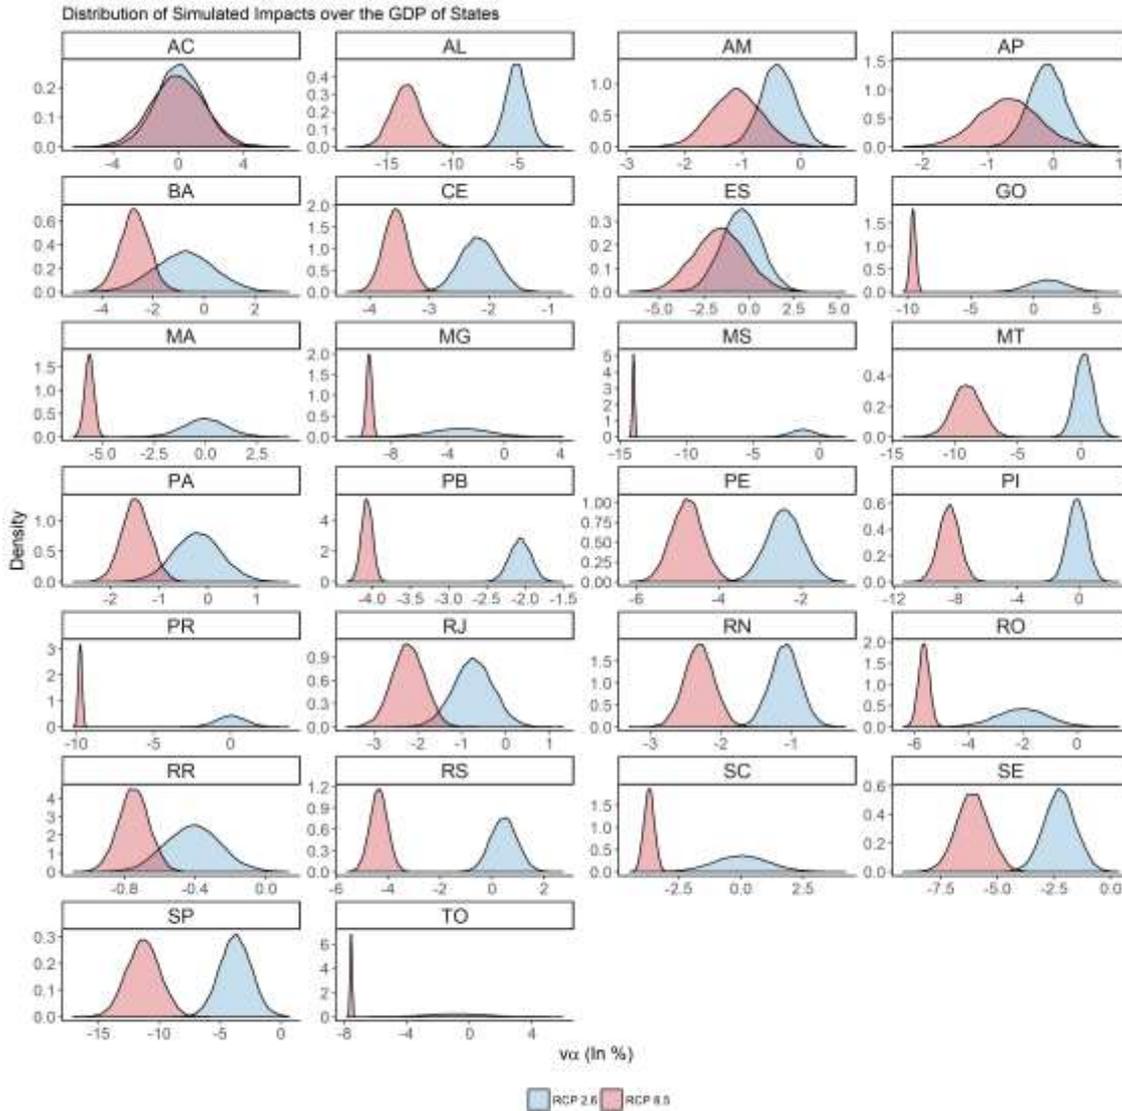

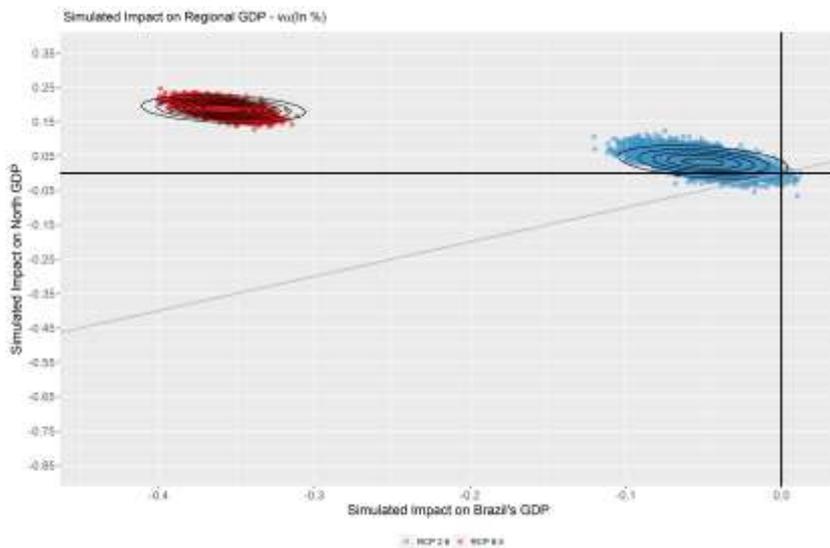

Figure 35 - Simulated Impacts over Regional GDP.

Figures 21 to 25 show the relation of the simulated impacts on the regional GDP of the five large Brazilian regions ($v\alpha$) in relation to the simulated impacts for the national GDP. The gray line represents the set of points in which such simulated variation is the same in regions and in the country.

The analysis of these images allows to infer that the effect of climate change on the GDP of the regions, besides being quite heterogeneous regionally, varies substantially depending on the scenario analyzed⁵⁵.

⁵⁵ Here again, the caveat: these impacts should be considered as the variation of average five-year production from the projected climatic changes until the end of the century.

Figure 36 - Simulated Impact on National GDP and PRB of Region North.

There are three possible dimensions to be analyzed through the images: the relationship between regional and national GDP in an isolated way, the same relation between the climatic scenarios studied, and the dispersion of these summarized impacts.

Under RCP 2.6, the relationship between regional impacts and national impacts shows a more homogeneous relation between the regions: Northeast and Southeast have modest losses (but higher than the national average) of the order of 0.15%, while North, South and Midwest show average production gains of 0.025%, 0.03% and 0.10%, respectively (better than the national average).

Under RCP 8.5, however, the effect is more complex: the North region has production gains, but little expressive in view of its small importance in the formation of national GDP (figure 21).

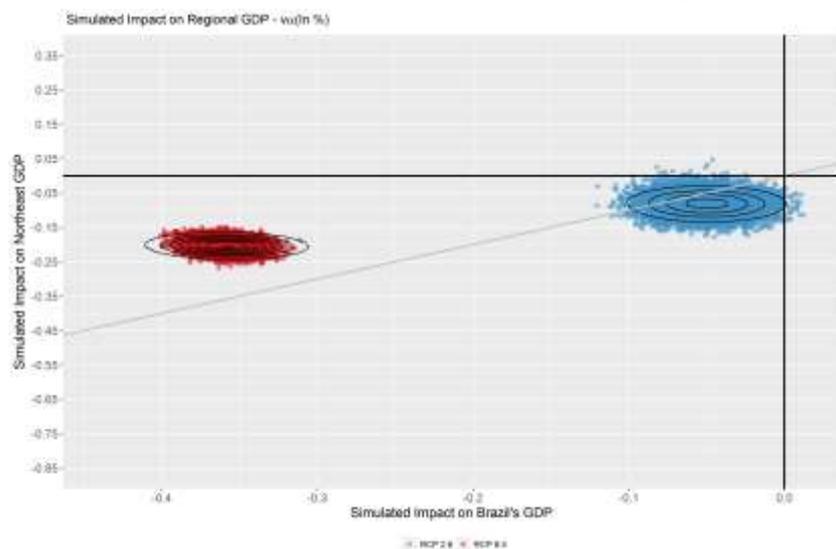

Figure 37 - Simulated Impact on National GDP and PRB of Region Northeast.

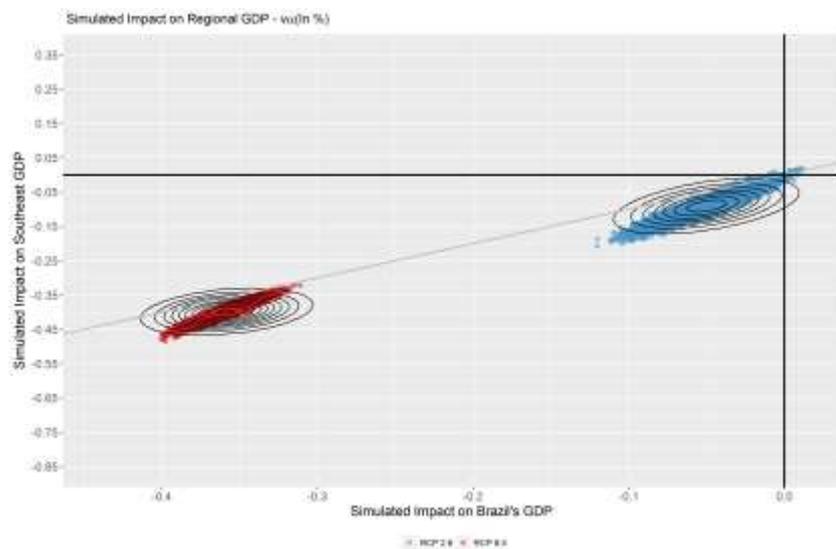

Figure 38 - Simulated Impact on National GDP and PRB of Region Southeast.

The Northeast region (figure 22), in turn, although presenting better performance than the national average (it is above the 45° gray line), presents average losses in the order of 0.2%. figure 23 shows this relationship for the Southeast region and shows that the region's impact relation to Brazil is inverted depending on the scenarios: although under RCP 2.6 the region is better than the national average, under RCP 8.5 Southeast is worse off, with simulated average impacts of around 0.45%. The southern region also presents a similar pattern to the one of the Southeast in what concerns the relation between scenarios with simulated dispersion slightly bigger.

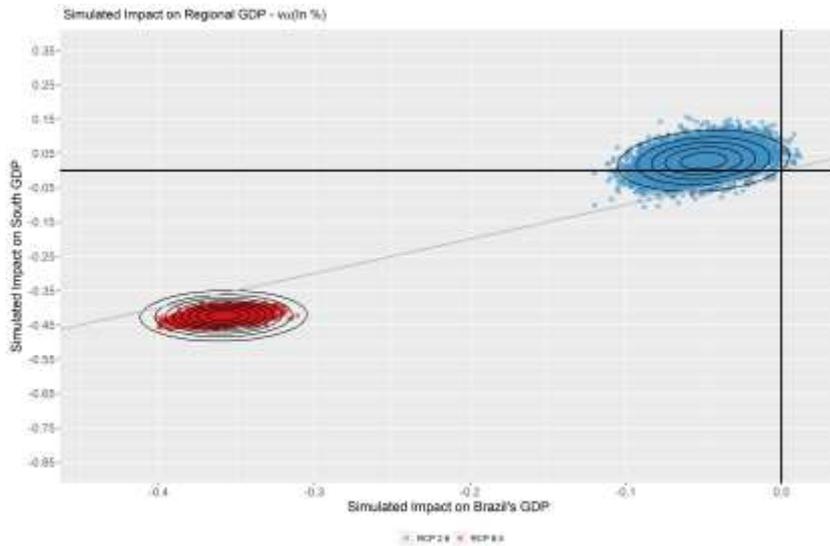

Figure 39 - Simulated Impact on National GDP and PRB of Region South.

Finally, the Center-West region is the one with the greatest dispersion of results in both scenarios. In addition, it is the one that shows more expressive losses in terms of PRB under RCP 8.5 (around 0.6%, on average), much due to its high dependence on the agricultural sector in its production.

In summary, the analysis of the above images sends a very clear message: the relative loss of the Northeast and Southeast regions compared to the rest of the country under RCP 2.6 and the relative gain of the North and Northeast regions under RCP 8.5. Two possible conjectures to explain this behavior are related to the intensity of climate change in the different scenarios and the structure of economic integration between regions: the indirect climate impacts under RCP 8.5 (much more intense than the optimistic scenario) are amplified due to the economic integration of the center-south of Brazil, making the losing regions precisely the most economically integrated.

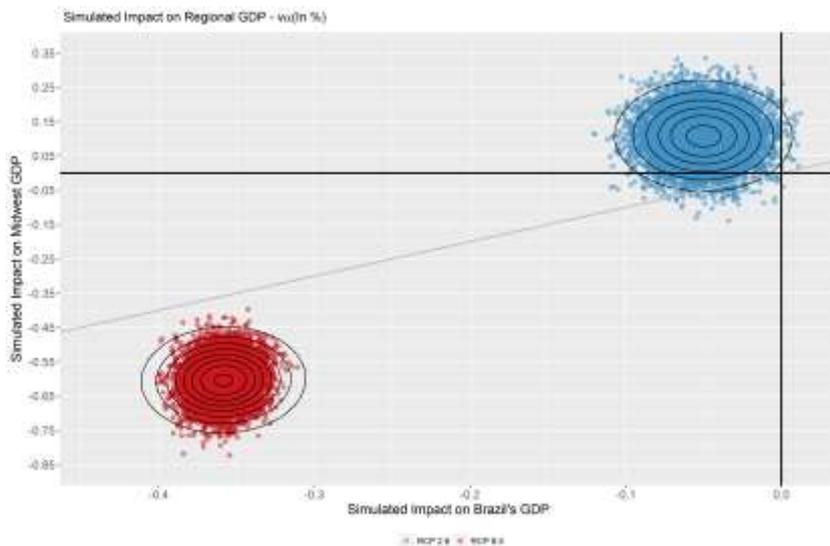

Figure 40 - Simulated Impact on National GDP and PRB of Region Midwest.

Finally, Figures 26 and 27 show the optimal simulated shocks (\widehat{v}_β^*) - calculated from the criterion described in equation (9) - and the impacts on the GDP of the corresponding states (\widehat{v}_α^*), respectively.

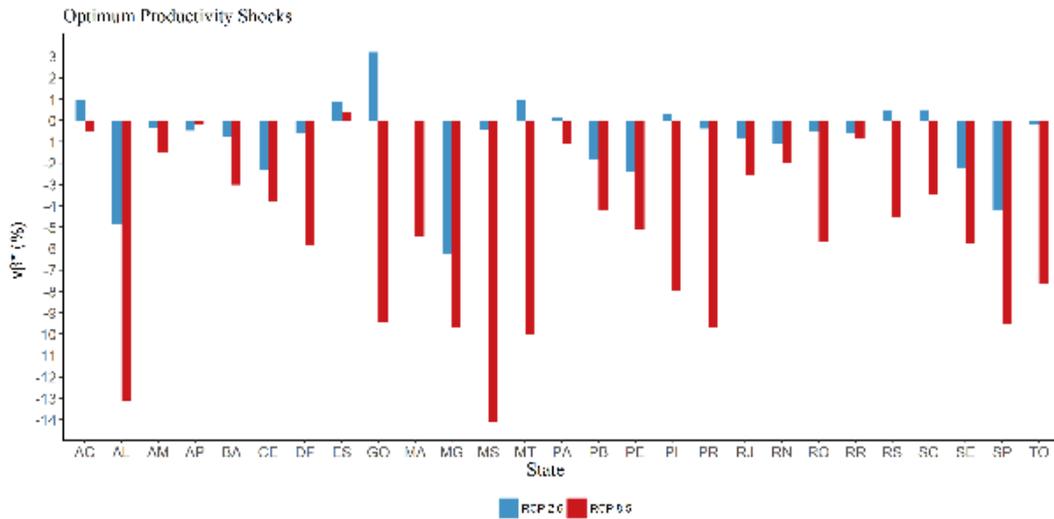

Figure 1 - Optimum Value of Simulated Productivity Shocks.

Here again, one has what is expected under each scenario: both agricultural productivity shocks and their respective effects on state GDP change tend to have more negative outcomes under RCP 8.5 in relation to RCP 2.6.

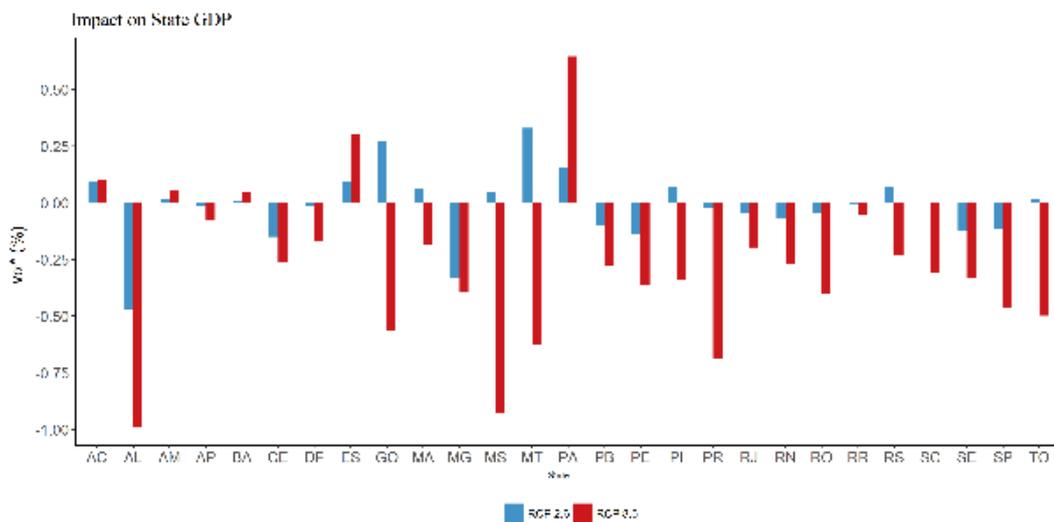

Figure 41 - Impact on State GDP.

If, instead of using equation (8) to generate the estimates for \hat{v}_α^* , we use \hat{v}_β^* as productivity shocks to run a simulation of B-MARIA, we obtain the following results for the variation of the state GDP ($\hat{v}_\alpha^{B-MARIA}$):

Table 15 - Comparison of the Simulated Impacts through Model B-MARIA with the Impacts Reconstructed from Equation (8).

State	RCP 2.6		RCP 8.5	
	$\hat{v}_\alpha^{B-MARIA}$	\hat{v}_α^*	$\hat{v}_\alpha^{B-MARIA}$	\hat{v}_α^*

DF	-0.0132	-0.0143	-0.1699	-0.1699

The analysis of table 15 shows the maintenance in the order of the impacts under the state GDP in each of the scenarios (denoted by the ordering of the colors - cold for increase in GDP, hot for decrease), besides the good aptitude of the aforementioned methodology to replicate the simulated results using the B-MARIA model.

6. FINAL REMARKS

“Education never ends Watson. It is a series of lessons with the greatest for the last.”

Sherlock Holmes

The Red Circle

Projected climate change presents a serious challenge for humanity until the end of the century. Its most intense impacts will be felt in the more distant future, although the actions necessary to mitigate them in a significant way should be done today. There is a growing consensus on the idea that increasing human emissions into the atmosphere will have the potential to generate distortions in the global precipitation and temperature pattern, generating a high risk of losses to the agricultural sector of the regions. Literature on the subject, while finding ambiguous evidence about the impact that climate change may have on global agricultural productivity, agrees that its risks must be taken into account in order to better formulate adaptation and mitigation policies around the world.

In this work, we propose to estimate the impacts that the projected climatic changes up to the end of the century can have on the Brazilian economy. In addition, the objective was to analyze vulnerability and regional differentials in the face of such changes in the climate, and to address the uncertainties of the results in an explicit way.

Estimates point to a broad regional heterogeneity of direct and indirect impacts to the Brazilian economy through changes in the productivity of the country's main agricultural crops, using the more and less optimistic scenarios created by the IPCC (RCP 2.6 and 8.5, respectively). The five-year variation in agricultural productivity projected averages up to the end of the century can range from + 1.16% under the scenario of low emissions up to -11.6% under the most pessimistic scenario.

These productivity variations have the potential to generate total productive losses equivalent to 11.1% of Brazilian GDP under RCP 2.6 and up to 81.6% of GDP in the country under RCP 8.5. In addition, when analyzing the vulnerability of the Brazilian regions to such impacts, it is observed that the states of the Central-West region of Brazil are those with the highest average economic vulnerability, due to the great importance of the agricultural sector in their economy.

Finally, in dealing with the uncertainties inherent in the methodology used explicitly, it was possible to conclude that the Northeast and Southeast regions will be consistently more negatively affected under RCP 2.6, while under RCP 8.5, due to their greater regional integration, the South, Southeast and Central West regions are the most affected.

Still, there is plenty of room for refinement of the methodology and data used. The impossibility of the methodology to deal with the adaptability of the Brazilian productive structure in response to the climatic changes observed concomitant with the low availability of climatic and agricultural data are the main point of future improvement of the work. However, it is believed that the results described above can contribute to a broader and more detailed discussion of the strategies for mitigation and adaptation of the Brazilian regions for the future and, consequently, to transmit to some creature the legacy of climate change research in Brazil.

Control Variables

Table 17 – Variables used in the Econometric Model.

Variable	Source
Precipitation Anomalie	INMET
Precipitation Anomalie ²	INMET
Temperature Anomalie	INMET
Temperature Anomalie ²	INMET
Production (in tons) of culture X	PAM (IBGE)
Production (in 2000's R\$) of culture X	PAM (IBGE)
Proportion of culture X in the total produced (in R \$) by the municipality	PAM (IBGE)
Area for the cultivation of culture X	PAM (IBGE)
Proportion of the area destined to the planting of culture X in relation to the whole planted area of the municipality	PAM (IBGE)
Area for crop harvest X	PAM (IBGE)
Proportion of the area destined to the crop of the culture X in relation to all harvested area of the municipality	PAM (IBGE)

Note: "X" representa cada uma das 6 culturas analisadas, ao passo que cada um dos 6 modelos estimados utilizou as informações de produção, área plantada, área colhida e valor produzido de todas as culturas como variáveis de controle.

1063 THE IMPACTS OF BLACKOUTS ON MICRO, SMALL MANUFACTURING ENTERPRISES PERFORMANCE: EVIDENCE FROM INDONESIA

ABSTRACT

Indonesia, home to more than 3.5 million micro-, small-sized enterprises (MSEs) in the manufacturing industry, is struggling to provide reliable electricity supply in some regions. While some people may be pessimistic on the role of MSEs in the economy, in Indonesia MSEs are essential mainly because they create large employment and are among priorities of the Indonesian government. Nevertheless, little is known about how blackouts affect MSE's performance. This paper estimates the impact of power blackouts on the productivity of Indonesia's manufacturing MSEs. We employ a pseudo-panel dataset covering six cohorts and 21 PLN-electricity company working areas for the period 2010–2015. The pseudo-panel data are constructed from repeated cross-sectional surveys on MSEs by grouping enterprises into cohorts based on factor intensity (labour, capital and resource) and size (micro, small), then tracking them over time. Our identification strategies involve examining blackouts determinants and controlling for factors that potentially affect productivity and are potentially correlated with blackouts. We find that under-investment in the power sector and PLN poor governance are among reasons why Indonesia has blackouts. We then use these factors as instruments for blackouts and conduct IV dynamic-panel fixed effects estimations while controlling for cohort characteristics, infrastructure, and weather factors. The IV estimates suggest that blackouts reduce the average labour productivity by 5.5 percent. This result robust to a set of robustness check.

Comparing the IV results with those of dynamic-panel FE estimates, we find that instrumenting blackouts helps to address endogeneity problems. Moreover, this study shows that adopting a captive generator, as one way to cope with unreliable power supply, is positively associated with productivity. MSEs that have a captive generator are benefited more when the power supply is poor. With this in mind, it is crucial to improving PLN electricity supply reliability. This paper also provides a discussion on the role of the government in addressing blackouts problem, such as by the introduction of a regulatory initiative. Our findings will be able to assist policy makers to prioritize relative to other economic disadvantages that MSEs face. To our knowledge, ours is among a few paper that uses extensive data on MSEs and provides the first known estimates of the impact of blackouts on MSEs in Indonesia. The estimates add to findings from other countries, which mostly focused on larger firms.

1277 SOCIAL INTEGRATION: INDIVIDUAL SOCIAL CAPITAL FORMATION AND THE STATE IDEOLOGY INDOCTRINATION COURSES IN INDONESIA

Rus'an Nasrudin, Budy P. Resosudarmo

Arndt-Corden Department of Economics, Crawford School of Public Policy, Australian National University

ABSTRACT

Indonesia is the largest archipelagic and multi-ethnic country in the world that has been facing a challenge to glue the nation together across various ethnic groups and well spatially distributed. The Soeharto regime had implemented a state ideology courses that taught norms and values of the social capital element which considered by scholars as the most pervasive effort in Indonesian history. This paper investigates the potential role of the Indonesian state ideology indoctrination courses during the period 1978–1998 on the long-run development social integration by mean of individuals' social capital formation. The reform in 1998 offers a setting to exploit a fuzzy regression discontinuity design focused on the effect of the termination of the courses on social capital. The results suggest that the course had limited impact on the individual social capital of. While it is shown that the expected adolescence period's participation is statistically significant between control and treatment cohort, the course the course did not alter changes in the individual social skills and social capital measures. Citizens aged 13 or older in 1998 who were exposed to the courses do not have statistically different social capital measures compared to citizens aged 12 or younger in 1998. The results are robust to the use of various bandwidth, the inclusion of predetermined socio-economic outcomes, and subsampling the observation by gender and location. The results suggest that the role of state ideology indoctrination courses of the type seen in Suharto's Indonesia might on social integration be limited. The implication for a policy context is that a further refinement is needed for any similar proposed program in the future both in Indonesia and elsewhere in the world with a similar background.

Keywords: state ideology courses, social capital, Indonesia

JEL Classification: D71, I25

1 INTRODUCTION

Is it possible to build the element social capital at the individual level? A large body of literature empirically tests the importance of *community development program* to build social capital acknowledging the notion of social capital as a measure at the community level (Dale and Newman 2010; Olken 2010; Torres-Vitolas 2017; Woodhouse 2001; Woolcock and Narayan 2000). More rarely it investigated how social capital formation is formed at the individual level (Glaeser 2001). Our investigation is about the potential role of education on individual social capital. Our focus is an individual educational experience that promotes collective action and so creates social capital at the individual level during their adolescence. Specifically, we test the impact of students' exposure to state ideology courses in Indonesia within the period of New Order Era on their social skills or personality traits related to social capital such as openness, extraversion and trust. The investigation will complement the mainstream analysis of return to education which often focuses on labour market outcome. Also, it will serve as cost-effectiveness analysis of the type of program for social capital formation against the standard social capital formation at the community level.

Social capital influences the key economic outcomes, such as poverty (Cleaver 2005; Narayan and Pritchett 1999), income (Zhang and Anderson 2011) and food security (Levien 2015; Martin et al. 2004). Beyond what is known as standard physical capital, the notion of social capital has demanded attention in the development analysis due to its nature of participatory, sustainability and the contextualization of the social dimension of development (Bebbington et al. 2004). Despite the important role of social capital for economic development, the definition and concept of social capital itself, however, have been evolved and covered a wide range of views and interpretations.

One of the definition, among others, is by Pierre Bourdieu: "the aggregate of the actual or potential resources which are linked to possession of a durable network of more or less institutionalised relationships of mutual acquaintance or recognition" (Bourdieu 1986). Other scholars emphasise the element of possession of social ties and collective action as the definition of social capital (Bloch, Genicot, and Ray 2007; Fukuyama 2001). Or, social capital simply can be defined as community resources that increase the welfare of that community (Glaeser 2001). The bottom line of the role of social capital is thus can be inferred coming from collective action's function in improving efficiency (Ostrom 1994).

Indeed, some empirical tests, have shown that collective actions improve social outcomes by correcting market failures such as correcting information asymmetry for local decision making (Olken 2010) and monitoring local governance for public goods provision (Olken 2007) and improve social targeting precision (Alatas et al. 2012). The role of social capital is also found in securing income fluctuation by informal insurance from friends, neighbour and the community to maintain welfare (Munshi and Rosenzweig 2016).

Specifically, empirical studies also show that individual social capital plays a significant role to improve food security. These include improving food availability (Matuschke and Qaim 2009) and improving income-the economic access to food (Narayan and Pritchett 1999; Simmons, Winters, and Patrick 2005) or establishment of food banks for the nutritional need of hungry people (Riches 2002). The author shows that the size of the individual social network increases their likelihood to adopt a more productive seed after isolating the peer effects among wheat farmers in India. Matuschke and Qaim (2009) demonstrates the evidence of the causal impact of village social capital on agricultural income and largely through the adoption of improved agricultural practices and better access to insurance in Rural

Tanzania. Still in the context of agricultural income improvement; Narayan and Pritchett (1999) show that participation in contracts farming induced by association with the farmer's social group yields better income than not participating.

There has been abundance literature examines the role of social capital on social outcomes. However, the opposite, the analysis that puts social capital on the left-hand side, i.e. a question about social capital formation is relatively thin. One among few is the framework introduced by Glaeser (2001) who postulated the investment toward individual social capital as an analogue to investment in individual human capital. He suggests two possible intervention to promote social capital formation at the individual level: (i) education and (ii) environment, i.e. ethnicity heterogeneity. The conventional view of community-level social capital formation, on the other hand, is in favour of the community development-type intervention. This approach argues that social capital is an aggregate outcome at the community level which can be enhanced by stimulating the community to perform a collective action. Conventional community development programs take a form such as *Kecamatan Development Program* (KDP) in Indonesia (Prasta et al. 2004) and *Prodepine* in Ecuador (Bebbington et al. 2004). These programs, however, is not free from criticism and caveats resulted from some project implementation. The program has the mixed result whether it promotes community social capital (Labonne and Chase 2011), has limited ability to maintain local social structure, and results in other problems such as corruption such as elite capture (Woodhouse 2001) or unfavourable to the vulnerable group (Torres-Vitolas 2017).

This article emphasises the role of the specific type of education to build individual social capital. The argumentation is coming from the fact that the size of resource dedicated to the program was not trivial and account for opportunity cost of time for students for other beneficial activities. Moreover, the unintended positive effect of education on social capital is thinly examined. If investing the public fund through education also could create improvement in other social outcomes by social capital; we need to take it as another form of the return on this specific education. In contrary, if the program is not effective, a refinement of the design and lesson learned from the program itself is the worthwhile investigation.

Education in general or in a specific form such as citizenship education or moral education is one of the non-targeted programs that could play a role in enhancing, for example, food security through a social capital variable. The programs have a clear consequence on individual views on society, civic engagement and their political view (Heggart 2015; Print and Coleman 2003). These individual attributes are the elements of the social capital about the possibility of conducting a collection action, at the individual level.

The main question addressed in this article is whether the state ideology indoctrination courses seen in Indonesia's Soeharto era had an impact on individual social capital. Indonesia is among countries in the world which experienced a natural experiment. It is exposing adolescence period with the strong social environment that differ with the rest of time of their life. Other countries are China with its national movement to send urban junior and senior high school graduates to rural areas (Gong, Lu, and Xie 2015; Meng and Gregory 2002) or some post-Soviet countries with the communist environment (Alesina and Fuchs-Schündeln 2007; Nejad and Kochanova 2017). Indonesia introduced a pervasive and intensive effort in promoting citizenship education in the 1980s followed by an implementation of state ideology (indoctrination) courses known as P4. The P4 program in Indonesia, with the translation of "The Guidelines for Understanding and Practices of Pancasila (the state ideology)" is a program aimed at standardising citizen's understanding of the state's ideology during the New Order Era (Nishimura 1995). Among citizenship education appears in many developing or developed countries, P4 is notably as one of the programs with massive support devoted to it. The amount of budget dedicated is as comparable to Soviet's Communist Agency.

The unexpected discontinuation of P4 training in 1998 due to the political reform (*reformasi*) provides a natural experiment that allows us to test the effect of the program on individual social capital. The birth cohort exposed and non-exposed at around the cut-off year of a birth cohort of the discontinuation is valid treatment and counterfactual group to test the long-run impact of the courses taught in the P4 program on elements of individual social capital.

The result suggests that the program effect does not last in the long-run to affect individual social capital. While the course increases inter-faith and inter-ethnic trust, the course did not alter changes in the level of trust for practical matters and civic participation. The channel analysis supports the main outcome analysis. Indeed, the program did not change any latent personal skills related to social capital. The measures of extraversion, openness and trust are not different between the treatment and the control group. Also, the heterogeneous impact estimates show that it is a bit clearer for a subpopulation living in urban with idea level outcomes but not practical-related outcomes. It suggests that a combination of the course itself and the real-life facilitating environment could make the program is more effective. We conclude that the role of state ideology indoctrination courses of the type seen in Suharto's Indonesia on the individual social capital formation is limited. It will be limited to general social capital formation but relatively effective for promoting bridging social capital at the cognitive level. We infer that the non-targeted program's (within the area of education) role to build individual social capital, in the long run, is limited. This finding contributes to the literature into a debate whether the government can affect the formation of social capital through education.

This study is different to the previous literature in the sense that we focus on the large scale and education-embedded intervention to build individual social capital. Education is merely not intended as the substitute for a community development project-type approach to building social capital, but rather as an alternative perspective to compare 'a cost-effective' sense between the two approaches. The rest of the paper is organized as follow. Section 2 explains the framework and background of the (P4) program, Section 3 formulates empirical strategy, Section 4 describes the data, Section 5 presents the results and Section 6 concludes.

2 FRAMEWORK AND BACKGROUND

2.1 Social Skill Formation at Adolescence Time

We outline the stock of individual elements of social skills (X_t) formation in the spirit of (Cunha and Heckman 2007) as the following. X_t comprises both cognitive (such as a knowledge that one should trust others) and non-cognitive skills (such as extroversion and agreeableness). Let assume that X_t is formed in a multistage technology during individuals' period in the life cycle for example early childhood, adolescence, adulthood, etc. and each stage can have different technologies. The input in every stage are a parental investment, schooling, social environment, individual investment (such as participating in the social club) or policy intervention to produce outputs i.e. social skills at the next stage. The production function of such skill at time t is

$$X_{t+1} = f_t(X_t, I_t) \quad (1)$$

For all past inputs, the current stock of social skills for individual born with the initial condition of X_1 is

$$X_{t+1} = f_t(X_1, I_1, I_2, I_t) \quad (2)$$

We further assume a positive and diminishing return on investment in every stage, i.e. the production function f_t is increasing and concave with respect to I_t . However, every stage may have different productivity, such as the same non-cognitive skills investment made at adolescence yields higher return than at adulthood. If period t^* is a 'golden period' for producing non-cognitive skill X_{t+1} , then holding other constant, intervention that affect this outcome are more profound than in other stages ($s \neq t$).

$$\frac{\partial X_{t+1}}{\partial I_s} < \frac{\partial X_{t+1}}{\partial I_t}, \text{ for all } s \neq t \quad (3)$$

In an empirical application, we test the assumption that there a possibility of interaction between inputs over time. For example, the education intervention could yield higher X_{t+1} = *inter-ethnic trust* for individuals with better past inputs such as living in more heterogeneous ethnic than individual with the homogeneous environment. There would be also other input that matters such as gender dimension and parental investment for the interaction assumption. In this study, we test the gender interaction dimension as well. The opposite effect could also arise such as social tension arises from ethnic diversity. In Indonesia, ethnic tension is not surprising events such as in Maluku Province, hence, we test the possibility of such ethnic heterogeneity effect toward to the extent the lasting of the program effect.

2.2 Background

In 1978, the Indonesian government governed by late President Soeharto introduced a state ideology indoctrination course in Indonesian education system. Preceded by the compulsory education program in 1974, the government emphasise the program's importance by the massive school construction (Duflo 2001). The New Order government at the time, took the opportunity of a period of change of social-political from Soekarno regime. The government attempt to include the new 'interpretation' of the state ideology as teaching materials in schools, not only public but also a private school. They tried to ensure the state ideology became citizen's social norm and values inherently (Nishimura 1995).

The practical guidance of the state ideology which consists of 36 items derived from the five pillars of the state ideology, Pancasila, was used as the material of education (indoctrination). Some of the items in P4 emphasise the norm to enhance social engagement, trust, and collective actions which are the elements of social capital. The program was abandoned in 1998 at the same time of the fall of Soeharto regime along with the demand for national reform, the *reformasi*. Therefore, from 1978 to 1998, any Indonesian citizen entered formal education at junior, senior high school and university, i.e. *adolescence* period, was likely participating in a week, intensive workshop, known as *penataran P4*. Some scholars acknowledge that the training was also expanded in the non-education sector on an ad-hoc basis for civil servant recruit orientation days, farmers' association events and so on (Nishimura 1995), however, this paper does not focus on this type of program due to its difficulty to identify the participants.

We argue that this workshop can form long-term individual's social skills not only because it contains norms and values encouraging collective actions but also it happens at the 'golden time' period, i.e. adolescence time and in a 'well-supported environment'. The program was so intense in the sense that it supported by a strong environment of the dictatorship government which was fully backed up by the military. The social environment situation, for example, is illustrated by most of the media campaign were engineered by the regime to support the regime's development program effectiveness (G. J. Aditjondro 1994; G. Aditjondro and Kowalewski 1994). For these reasons, one would expect a quite effective effect to cast individual's non-cognitive skills. It was politically incorrect for Indonesian in the New Order period to criticise the norms and values during the course, otherwise social sanction will apply. The program, thus, is considered as a massive and intensive effort seen in the history of Indonesia. Our word frequency analysis on the P4 text shows that words such as attitude, cooperation, respect, mutual and unity are among words that appear in the most twenty percent word repeated in the text (Table 1). In addition to this, the jargon (*gotong-royong*) which means collective action and (*Bhinneka tunggal ika*) which means unity in diversity is also considered as a phrase that frequently used during the courses.

Despite this strong circumstance to support the existence of the long-term effect, the euphoria arises aftermath the program termination to disregard and abandon all life aspects associated with the New Order since the *reformasi* can against the direction of the long-term effect. This euphoria could undermine the impact as the euphoria effect offsets the build-up effect. We take into account this consideration and interpret the estimate as the lower bound of the treatment effect.

3 EMPIRICAL STRATEGY

3.1 General Framework

P4 introduction in 1978 and its unexpected discontinuation in 1998 both were a natural experiment which provides an opportunity to implement a regression discontinuity design. In 1978, the regime pervasively introduced the program for the whole citizen started with the civil servants and government official. In 1998, the program was forcedly stopped due to the political reform, the *reformasi*. The discontinuation, especially, provides an exogenous shock as none of Indonesian anticipated this termination event. Thus, the birth cohorts belong to the implementation period are the treatment, and the cohorts belong to pre and post-program are the counterfactual group of the program.

Therefore, there are two options of cut-off for an RD design, the year of 1978 and 1998. The year of 1998 setting is less problematic for RD setting than the year of 1978. The introduction of P4 in 1978 was confounded by other major policies such as massive school construction (SD INPRES started in 1973) and compulsory education program (*WAJAR*) announced in 1984). These policies' effect, was deemed to be asymmetrically applied only to the treatment cohorts and not the control cohort. The cut-off will represent multi-treatment than the only P4 program. As for the case of the year 1998 cut- off, it seems less confounding appeared. As mentioned above, there had been euphoria to disregards norms and values associated with the New Order era. The euphoria seems to be uniformly experienced by most adult Indonesian who witnessed the reform, but not for young Indonesian. Its relevance to our analysis is that the euphoria will not invalidate our comparative analysis of the

program effect as long as we do not mix the control group with young Indonesian who did not acquire the euphoria. In another word, the correct use of bandwidth will be crucial for comparability purpose. Also, other event accompanied the political turmoil was the 1998 economic crisis that might also confound the estimate. We argue that the bias due to this case is less pronounced as the economic crises' effects are at national level and it should be symmetrically distributed across all cohorts.

To our best knowledge, there is no survey data that asked individual participation in the P4 program. Fortunately, the age and education specific component of the natural experiment provides us with the opportunity to extract available information in the survey data to reveal the expected, not the actual, treatment status of an individual. If an individual happens to be in the first year of junior, senior high school or university level during the period 1978-1998, put aside absenteeism at the time of the workshop, he/she should have participated in the program, i.e. treated. Under this approach, therefore, what we measure is the intention to treat-effect (ITT) and not the actual treatment on the treated-effect (ATE).

Accordingly, the set-up of a fuzzy-regression discontinuity is the following. In the first stage, we estimate the probability of individual being in either treatment or control group D_i on a dummy equals one if the normalised birth cohort is above the cut-off and 0 otherwise T_i . In the second stage, we estimate the outcome variable (i.e. social capital measure S_i) on \bar{D}_i . The estimating equations is defined as:

$$\text{First stage: } D_i = \alpha + \beta T_i + f(yob_i) + \varepsilon_{1i} \quad (4)$$

$$\text{Second stage: } S_i = \gamma_1 + \delta \bar{D}_i + f(yob_i) + \varepsilon_{2i} \quad (5),$$

and $f(yobi)$ is the polynomial function of the birth cohort (the running variable).

An indicator of whether an individual belongs to above or below the birth cohort cut-off serves as an excluded instrument in the two-stage least square (2SLS) regression of expected participation in the program on the outcomes (Aguero and Bharadwaj 2014; Klaauw 2002; Parinduri 2016). In our dataset context, the birth cohort before and after the program implementation exclusively affects the formation of individual social capital through their expected participation in P4 training. Given the fact that we produce a very high F-test when we implement this setup, we also run a sharp RD design of the following which does not alter significant changes in the estimated coefficient. The large F-test is as a result of perfect prediction for the treatment coefficient (β) for T=0 but not for T=1 or because perfect compliance was detected on at least one side of the threshold. This case is applied when we use the national representative survey data (SUSENAS), but not when we use IFLS 5 data .

$$S_i = \gamma_2 + \delta T_i + f(yob_i) + \varepsilon_{3i} \quad (6)$$

3.2 Estimate Particulars

Running variable and cut-off definition. Indonesian government changed the start of academic calendar from January to July in mid-1978 (Parinduri 2016), just at the same year when the P4 program was started. Accordingly, the academic calendar during the period of P4 implementation, i.e. the period of 1978-1998 follows July to August of the consecutive year-scheme. Furthermore, Indonesia's education system requires child aged minimum seven years old in July for elementary school admission. Thus, to approximate a time when an individual's spent for their first year in either the junior high school, senior high school or university, we employ information of the date of birth, what age did they enter each school level, and their education profile, i.e. school level completed. From this information, we can extract whether the time spent was within 1978-1998 in which P4 was implemented.

We define the running variable as the quarter birth cohort with the normalised value (equals to 0) at 1985-Q3 (third quarter). We also reverse the values for ease of graphical representation. The P4- program was discontinued in 1998 and the standard starting year for junior high school is 13 years old. Consequently, if individuals entered school with no early admission and younger than 13 years old in 1998 (born in 1985 or later) should not experience P4-program and in contrary, those who born before 1985 with no delay in school admission, should participate the P4 program. Their expected exposure to the program is conditionals to the education level experienced.

Optimal bandwidth. As it is general in RD design, greater bandwidth leads to greater efficiency but at the risk of including the observations that are not comparable. We calculate the optimal bandwidth using data-driven bandwidth selectors based on the recent work of Imbens and Kalyanaraman (2012) and (Calonico, Cattaneo, and Titiunik 2014). Then we interpret the optimal bandwidth by the circumstance of treatment intensity and cohort effect. The data-driven selectors provide justifiable optimal bandwidth on this ground. We separate the calculation of optimal bandwidth for each group of treatment category accommodating the possibility of differences in characteristics due to age. Then we take the minimum as suggested by Imbens and Lemieux (2008). To check the sensitivity of the result to the choice of bandwidth, we conduct the estimates with bandwidth from $h^* - 5$ to $h^* + 5$.

Standard error. The standard errors in the estimates are clustered at the birth cohort level to rule out the sampling error and obtain a conservative statistical inference.

Falsification tests. We do some falsification tests including the density-manipulation test (Cattaneo, Jansson, and Ma 2016) and using different cut-off, i.e. by omitting the observation with a year of birth 1985 and 1984. We follow the approach of Aguero and Bharadwaj (2014) for this falsification test.

Selection to education. The participation of the P4 program is a selective mechanism through education. In this context, there is a potential unobserved confounder of ability if we use the OLS approach for equation 6. Ability and individual social capital are likely to be correlated. Thus a selection to education might create bias due to the presence of ability bias as a standard problem in estimates dealing with education (Willis and Rosen 1979). However, the fuzzy RD setting ensures that ability in ε , is not correlated with ε . Therefore, the selection to education is solved using birth cohort as the instrumental variable as in the fuzzy RD setting.

Varying Treatment Intensity. The combination of education specific component of the program and age makes a heterogeneous treatment intensity. Individual P4-training dummy of D_i masks three cases of treatment intensities: an individual with one, two and three occasions of experiencing P4 training.

These three cases correspond to the group of individuals aged 13 to 15; aged 16 to 18; and aged 19-22 respectively due to their education level in 1998. Individual aged 13 to 15 were only able to get once P4 training even though they can pursue to higher education as the program terminated in 1998. It is not the case for two other groups of older individuals. The use of P4-training dummy has not incorporated these varying intensities. Hence, to incorporate the heterogeneous treatment intensity effect we use a standard fuzzy estimate with an interaction term (Stancanelli and Soest 2012).

4 DATA AND VARIABLE

We use both Indonesia Family Life Survey (IFLS) 5 of Rand Corporation, the latest wave of the longitudinal survey and SUSENAS Social and Culture Module data (2012) of National Bureau of Statistics (BPS) nationally representative sample of the Indonesian population. The datasets contain information on social capital and cohort of birth which allows us to perform the analysis. The IFLS data, especially, has the advantage to construct a finest running variable at the date of birth whereas SUSENAS at the year of birth only. On the other hand, SUSENAS is rich in the size of observation as it covers all of the Indonesian provinces than IFLS which only covers thirteen provinces. Both datasets are used for robustness purpose.

The treatment status and running variable. The treatment status (intention to treat) is equal to 1 if an individual experience first year of junior high school, senior high school or university level during the period of 1978-1998 and 0 otherwise. We impute this value from education-section of the survey combined with the information on year of birth, specifically from the question 'what age did you enter [junior high school/senior high school/University]' combined with the information of the birth of date in IFLS. In SUSENAS, however, we can impute the expected treatment status only from age and education profile, i.e. at year level. Hence, we have two different sets of running variable: birth quarter in IFLS and birth year in SUSENAS.

Outcome variable. We utilise three sections of IFLS 5 data: section personality (PSN), section trust (TR) and section community participation (PM) to generate the outcome variables. We divide the program effect into two parts. The first order-effect which covers effect on personality trait (section PSN) or we call it social skills (X'') in our theoretical framework; and the second order-effect which

includes individual trust (section TR) and individual social participation in club or group at the community level (section PM). All of these outcomes for second order-effect are considered as part of bridging social capital. Again, we relate the personality trait variable with the P4 program by the fact that P4 program in the context of our study happened in the adolescence period. Personality trait are formed throughout multiple stages over the life cycle and there are noticeable changes at different points of life such as early childhood, early adolescence and early adulthood (Roberts, Wood, and Smith 2005; Skirbekk, Blekesaune, and Staudinger 2015; Soto and Tackett 2015). Our main interest is to look at the program effect on personality trait which unravel the main program effect. Thus, we follow the analysis to look at whether at the more downstream outcome such as trust and community level it matters or not.

Section personality (PSN) of IFLS 5 becomes available in the latest wave of IFLS but not the previous waves. It covers fifteen questions related to the five-factor model. The five-factor model is a well- accepted taxonomy of non-cognitive skills that has been widely used in the recent psychology and economics literature. Elements in the five-factor model are considered as the individual trait that strongly determines social outcomes jointly with social capital. In the case of job market finding, for example, Baay et al. (2014) argue that the big five personality factors cause some individuals to use their network more intensively or effectively than others. For each factor, IFLS-5 asks three questions on a five-point Likert-type scale, with one indicates being strongly disagreed and five indicates strongly agree. We rescale some question to make it parallel with others and compute an averaged z- score for each of the five factors. We use the factor of extroversion, openness to experience and agreeableness are social skill at individual personality trait that we argue as the element of individual social capital. The summary statistics of key variables and pre-determined variables are presented in Table 2.

Table 2a. Questions to assess social capital measure in IFLS 5 data

Measures	IFLS 5 Survey Questions
Personal Skill Factor	how much you agree or disagree with each statement using the following scale (1. Disagree strongly 2. Disagree a little 3. Neither agree nor disagree 4. Agree a little 5. Agree Strongly)
Conscientiousness	Does a thorough job. Tends to be lazy (reversed). Does things efficiently.
Openness to experience	Is original, comes with new ideas. Has an active imagination. Values artistic, aesthetic, experiences.
Extraversion	Is talkative. Is reserved (reversed) Outgoing, sociable.
Agreeableness	Has a forgiving nature. Is considerate and kind to almost everyone. Is sometime rude to others (reversed).
Emotion Stability	Worries a lot. Get nervous easily. Is relaxed, handles stress well.
Trust dimension	We want to ask you about trust in this village TR01-I am willing to help people in this village if they need it. TR02-In this village I have to be alert or someone is likely to take advantage of me. TR03-Taking into account the diversity of ethnicities in the village, I trust people with same ethnicity as mine more. TR04-I would be willing to leave my children with my neighbours for a few hours if I cannot bring my children with along. TR05-I would be willing to ask my neighbours to look after their house if I leave for a few days?
Community participation	We would like to ask you about some community or government activities and programs that may have taken place in this village during the past 12 months (1. Yes 0. No) Community Meeting Cooperatives Voluntary Labour Improve the Village/Neighbourhood Youth Groups Activity Religious Activities Village Library Village Saving and Loans Health Fund PNPM Political Party Neighbourhood Security Organization (Siskamling) Water for Drinking System/Supply System for garbage disposal Women's Association Activities (PKK) Community Weighing Post (Posyandu) Community Weighing Post Lansia (Posyandu Lansia)

Source: IFLS 5 Section PSN, Section PM and Section TR.

Table 2b. Questions to assess social capital measure in SUSENAS data

Variable	Question	Category
Social participation	Do you participate in any of the following social activity in the last three months?	Bridging capital
	1. religious	
	2. skill	
	3. sport	
	4. art	
	5. saving (<i>arisan</i>)	
	6. funeral	
	7. art	
	8. other	
Trust [4=strongly trust; =no trust]	1. In general, do you trust that the head of village do his/her job properly?	Bridging capital
	2. In general, do you trust that the village leaders can do something to solve community member?	
	3. In general, do you trust that the religious leader acts as a moral role model in the village?	
	4. Do you trust your neighbour in entrusting your house when you are away?	
	5. Do you trust your neighbour in entrusting your children when you are away?	

Source: SUSENAS of Social and Culture Module 2012

Section trust (TR) was introduced in IFLS 4 and is continued in IFLS 5. It covers questions on about trust of neighbours and people in the village, and questions on tolerance of people of different faiths that we consider as the outcomes variable for our interest. We infer that the trust questions in this section are oriented toward a heterogeneous people as it put a context for example trust to other people by various dimensions such as ethnicity and religion. By this, the trust questions represent bonding social capital. Similar to questions in the section PSN, trust questions are a Likert-type scale that we convert into z-score to allow for comparison between questions.

Social or community participation can be seen both as an investment of social capital at the individual level because an individual can develop social skill in a group or club, and as a manifestation of social capital at the community level because an individual might participate in collective action in it.

Section social participation (PM) allows us to measure bridging social capital by counting the number of type of community activity that an individual engages with them. The participation represents bonding social capital as it deals with heterogeneous people both at the village and beyond village level. Activities such as community meeting, cooperatives, voluntary labour are such examples of the types to measure the network size.

From SUSENAS data, we use two measures of social capital to represent bridging capital, number of type of social activities (religious, skill, sport, art, saving, funeral, art and other) that an individual participates; and trust to various external parties (village head, village leader, local religious leader and 148neighbor). The first measure is extracted from individual and household head level and the second measure is from household head only. We use the sum of the Z-score of the Likert scale to obtain the trust score and the help assertiveness score. At the raw value, the trust score ranges from 1 to 20, in which 1 represent the lowest trust level and 20 is the highest. Table 2b lists the detail of questions to measure the social capital from SUSENAS data.

5 EMPIRICAL RESULTS

5.1 Graphical Evidence

To motivate our estimation strategy, we first describe the relationship between the running variable (birth cohort), treatment variable (participation of the P4 training) and the outcome variables (social skills, trust and community participation) using graphical representation. Figure 1a and 1b show the correlation between expected participation of the P4 training and the two cohort groups (treatment and control) using IFLS data and SUSENAS data respectively. Indeed, both figures show a large number of individuals exposed to the program than those who were not in the treatment cohort. Both show that on average the expected participation is about eighty percent (IFLS) and about seventy percent (SUSENAS) higher for treatment than the control group. Despite this high jump in the expected participation in the program, however, Figure 2 shows a non-discontinuity in social skill as the main channel of the program effect. Hence, we would expect that there will be no effect on outcome variables of social capital measures (trust and social participation). Figure 3a and Figure 3b show a non-discontinuity in a variable of trust. Figure 4a and Figure 4b show a non-discontinuity in community participation variable.

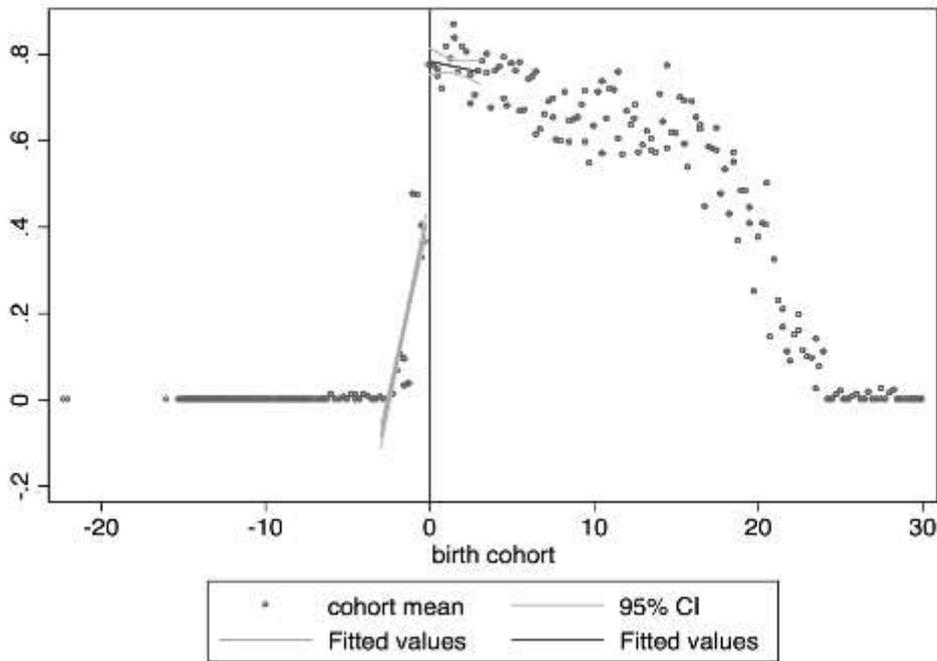

Figure 1a. Cohort Means of the P4 Training Participation: IFLS 5

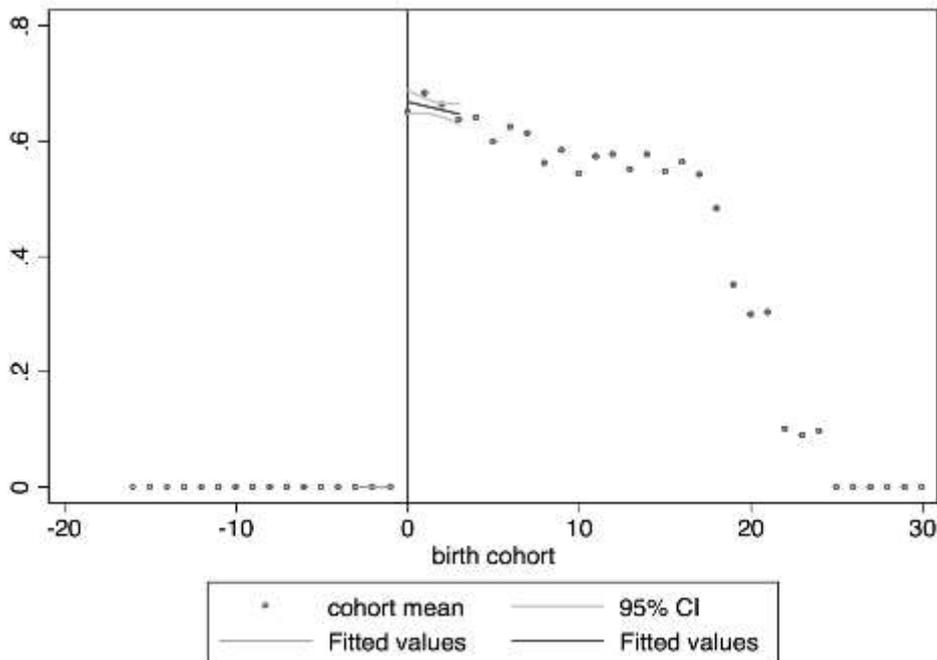

Figure 1b. Cohort Means of the P4 Training Participation: SUSENAS Social and Culture Module 2012

Note: Figure 1a and 1b plot the relation between the expected P4 training participation and birth cohort. Circles represent the average participation rate by bin (birth quarter). The solid lines indicate the fitted values from linear local regression and the dashed lines are the 95 percent confidence interval for observation within the optimum bandwidth (minimum value of 3 obtained from *rdwselect* command). The vertical line indicates the cut-off point (normalized to 0).

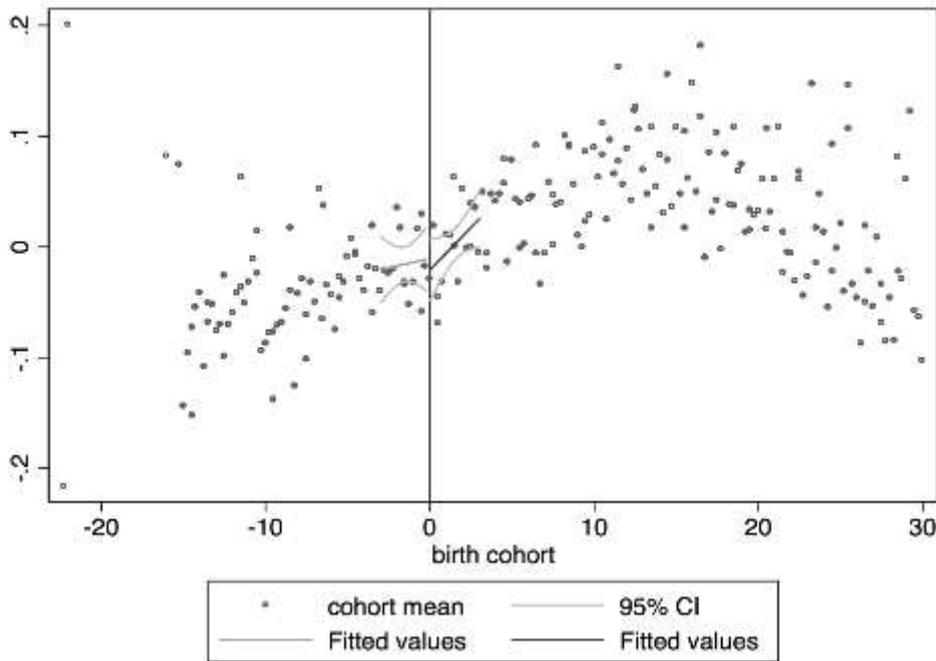

Figure 2. Effect of the P4 training on social skills index: IFLS 5

Note: Figure 2 describes the non-discontinuity in social skills index (consciousness, agreeableness, extraversion, emotion stability and openness). Circles represent the average value of the index by bin (birth quarter). The solid lines indicate the fitted values from linear local regression and the dashed lines are the 95 percent confidence interval for observation within the optimum bandwidth (minimum value of 3 obtained from *rdwselect* command). The vertical line indicates the cut-off point (normalized to 0).

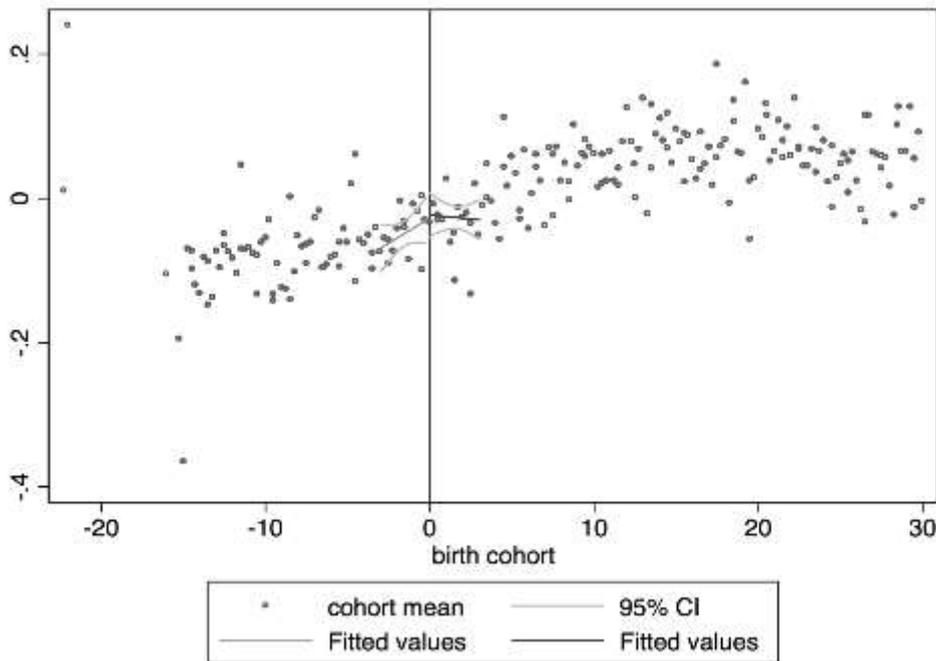

Figure 3a. Effect of the P4 training on trust: IFLS 5

Note: Figure 3a describes the non-discontinuity in trust index (trust to neighbourhood and village environment) using IFLS data. Circles represent the average value of the index by bin (birth quarter). The solid lines indicate the fitted values from linear local regression and the dashed lines are the 95 percent confidence interval for observation within the optimum bandwidth (minimum value of 3 obtained from *rdwselect* command). The vertical line indicates the cut-off point (normalized to 0).

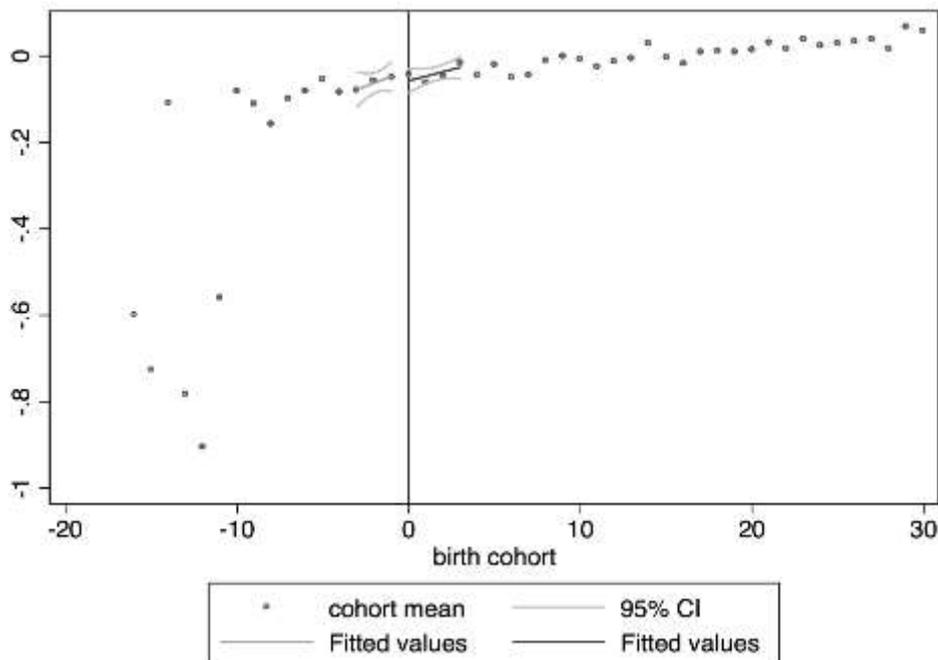

Figure 3b. Effect of the P4 training on trust: SUSENAS

Note: Figure 3b describes the non-discontinuity in trust index (trust to neighbourhood and village environment) using SUSENAS data. Circles represent the average value of the index by bin (birth quarter). The solid lines indicate the fitted values from linear local regression and the dashed lines are the 95 percent confidence interval for observation within the optimum bandwidth (minimum value of 3 obtained from *rdbwselect* command). The vertical line indicates the cut-off point (normalized to 0).

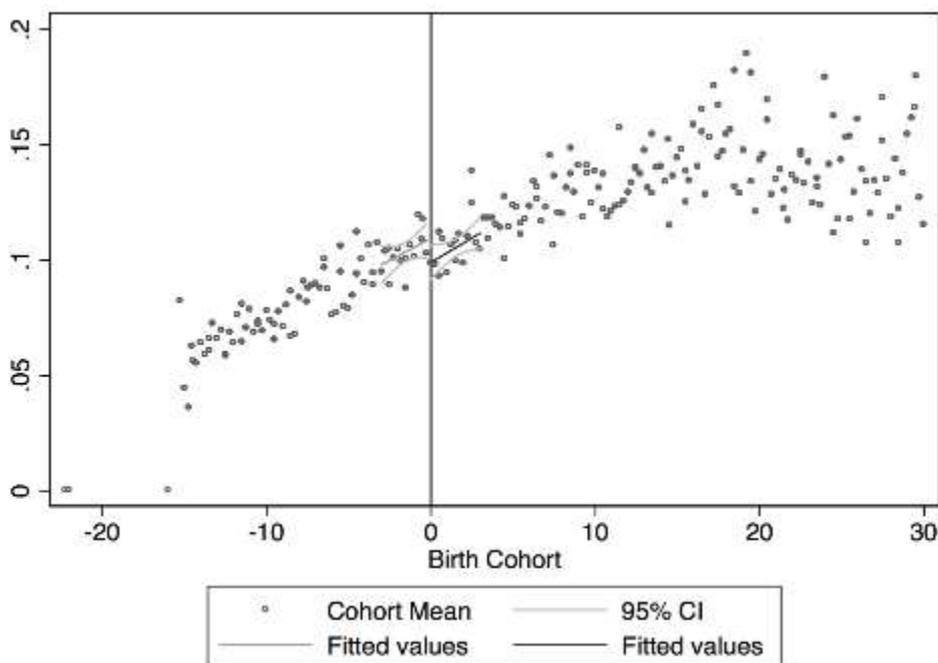

Figure 4a. Effect of the P4 training on social participation: IFLS 5

Note: Figure 4 describes the non-discontinuity in social participation (number of types of community, minimum 0 and maximum 17). Circles represent the average value of the index by bin (birth quarter). The solid lines indicate the fitted values from linear local regression and the dashed lines are the 95 percent confidence interval for observation within the optimum bandwidth (minimum value of 3 obtained from *rdbwselect* command). The vertical line indicates the cut-off point (normalized to 0).

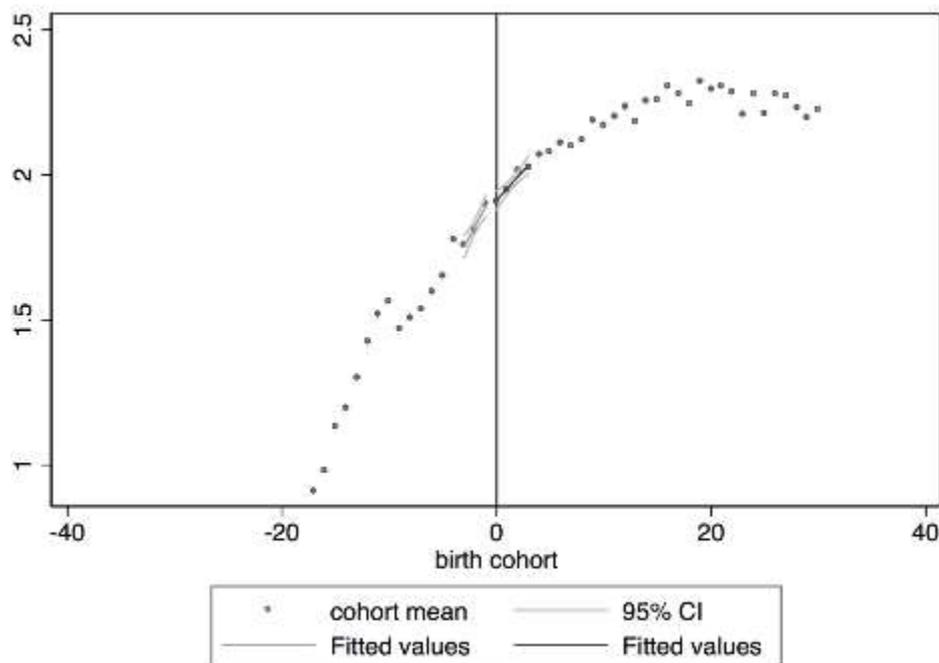

Figure 4b. Effect of the P4 training on social participation: SUSENAS Data

Note: Figure 4 describes the non-discontinuity in social participation (number of types of community, minimum 0 and maximum 7). Circles represent the average value of the index by bin (birth quarter). The solid lines indicate the fitted values from linear local regression and the dashed lines are the 95 percent confidence interval for observation within the optimum bandwidth (minimum value of 3 obtained from *rdwselect* command). The vertical line indicates the cut-off point (normalized to 0).

5.2 The First-Stage Estimates

Table 3a and Table 3b present the first stage estimate of the fuzzy RD design of equation 4 using IFLS and SUSENAS data respectively. It confirms the graphical representation of Figure 1a and Figure 1b. The first stage exists, and it shows that the participation rate of individual aged 13 or older in 1998 to the P4 training is about 30 to 45 percent when we use a more precise identification of treatment status using IFLS data. The SUSENAS data, on the other hand, suggest a larger point estimates of the participation rate by about twice, i.e. 70 percent. This is because the assignment of participation status uses a crude identification of combination birth cohort at year level and education profile. Consequently, the excluded F in SUSENAS data estimates produce a very high number which suggest a perfect compliance from the control group. This is not surprising since we assign a value of zero for all individual in the control group for the participation status which does not happen in the IFLS dataset.

Table 3a. First-stage Estimates: IFLS

	(1) Polynomial of degree one	(2) Polynomial of degree two	(3) Polynomial of degree two with covariates
Treatment Cohort=1	0.445*** (0.095)	0.314** (0.143)	0.294** (0.138)
Birth Cohort	0.046*** (0.017)	0.143** (0.065)	0.154** (0.063)
Birth Cohort ²		-0.024* (0.014)	-0.025* (0.014)
Observations	6664	6664	6443
Excluded F	21.86	4.85	4.52

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. The observations are within the optimum bandwidth of 4 (the minimum value obtained from the *rdwselect* command for all of the outcomes estimates). Covariates used are gender, location dummy, religion and all predetermined outcomes at the age of 12 listed in Table 2.

Table 3b. First-stage Estimates SUSENAS

Dependent variable: P4 Participation

	(1) Polynomial of degree one	(2) Polynomial of degree two	(3) Polynomial of degree two with covariates
Treatment Cohort=1	0.699*** (0.012)	0.708*** (0.015)	0.712*** (0.016)
Birth Cohort	-0.008*** (0.002)	-0.014* (0.008)	-0.016* (0.008)
Birth of Cohort^2		0.001 (0.002)	0.002 (0.002)
Constant	-0.021*** (0.008)	-0.025** (0.010)	0.219*** (0.070)
Observations	36008	36008	36008
Excluded F	3361.98	2293.93	1939.09

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. The observations are within the optimum bandwidth of 4 (the minimum value obtained from the *rdwselect* command for all of the outcomes estimates). A large value of F-statistics suggest perfect compliance was detected on the control group as we do not have information on exact time when individuals enter school. Covariates used are gender and locational dummy (urban/rural).

5.3 The Effect of the P4 training on Social Skills

The framework set by equation 1-3 guides us that the elements of social capital casted by the program at the adolescence period which have a long-term dimension is the social skill variable. Therefore, the main interest of this paper is to firstly check whether there is statistical difference in this variable. We do not such long-term effect of the P4 training on individual social skill variable *e*. The estimates in Table 4a and Table 4b confirm the above graphical representations. The estimates of the effect of the P4 training on either aggregate index of social skills or individual measures such as consciousness, extraversion, agreeableness, openness and emotion stability using IFLS data yield no statistical difference between individual participates in the P4 training and those who do not participate. These results set a foundation so that we expect for no higher order effect of the program on the social capital measure such as trust to neighbourhood or community participation.

Table 4a. Effect of the P4 training on social skills: IFLS 5

Dependent variable: social skills

	(1) Aggregate Index	(2) Consciousness	(3) Openness	(4) Extraversion	(5) Agreeableness	(6) Emotion Stability
P4_dummy	-0.030 (0.040)	-0.068 (0.086)	-0.001 (0.084)	-0.077 (0.062)	-0.012 (0.057)	0.006 (0.048)
Birth Cohort	0.011** (0.005)	0.028** (0.011)	0.002 (0.011)	0.007 (0.008)	0.010 (0.008)	0.010 (0.006)
Observations	6664	6664	6664	6664	6664	6664

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. We use 2SLS of a fuzzy setting and a local linear regression with optimal bandwidth calculated by the *rdwselect* command of Imbens and Kalyanaraman (2012). The first-stage estimates for all columns use polynomial degree of one which has the largest excluded F-statistics relative to other polynomial or the use of covariates.

Table 4b. Effect of the P4 training on social skills: IFLS 5 with covariates

Dependent variable: social skills

	(1) Aggregate Index	(2) Consciousness	(3) Openness	(4) Extraversion	(5) Agreeableness	(6) Emotion Stability
P4_dummy	-0.037 (0.042)	-0.070 (0.092)	-0.001 (0.087)	-0.108 (0.070)	0.002 (0.067)	-0.008 (0.055)
Birth Cohort	0.013** (0.005)	0.028** (0.012)	0.004 (0.011)	0.013 (0.009)	0.007 (0.010)	0.012 (0.008)
Observations	6443	6443	6443	6443	6443	6443

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. We use 2SLS of a fuzzy setting and a local linear regression with optimal bandwidth calculated by the *rdwselect* command of Imbens and Kalyanaraman (2012). The first-stage estimates for all columns use polynomial degree of one which has the largest excluded F-statistics relative to other polynomial or the use of covariates.

Covariates used are gender, location dummy, religion and all predetermined outcomes at the age of 12 listed in Table 2.

These results are robust for different set of specification of the birth cohort polynomial, inclusiveness of covariates, the falsification test and the use of different bandwidth. The results however are not replicable in SUSENAS data as there are no such questions in the survey.

5.4 The Effect of the P4 training on Social Capital

The effect of the program on social capital is tested both using both IFLS and SUSENAS data. The Estimates are presented in Table 5a and Table 5b. Both Table's estimates confirm the graphical representation in Figure 3a, Figure 3b, Figure 4a and Figure 4b. There difference of trust to neighbourhood and community participation between treatment and control group are not statistically significant. Hence there is no effect of the P4 training participation on social capital.

Table 5a. Effect of the P4 training on social capital: IFLS 5 Dependent variable: social capital

	(1) Trust neighbourhood	(2) onTrust neighbourhood	(3) onTrust neighbourhood -with covariates	(4) onCommunity Participation	(5) Community Participation	(6) Community Participation -with covariates
P4_dummy	0.012 (0.040)	0.037 (0.066)	0.054 (0.067)	-0.024** (0.009)	-0.037* (0.021)	-0.038 (0.023)
Birth Cohort	0.005 (0.005)	-0.004 (0.020)	-0.007 (0.021)	0.005*** (0.001)	0.010* (0.006)	0.011 (0.007)
Birth Cohort^2		0.002 (0.004)	0.002 (0.004)		-0.001 (0.001)	-0.001 (0.001)
Observations	6664	6664	6443	6664	6664	6443

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. We use 2SLS of a fuzzy setting and a local linear regression with optimal bandwidth calculated by the *rdwselect* command of Imbens and Kalyanaraman (2012). The covariates used for estimates in column 3 and column 6 are gender, location dummy, religion and all predetermined outcomes at the age of 12 listed in Table 2.

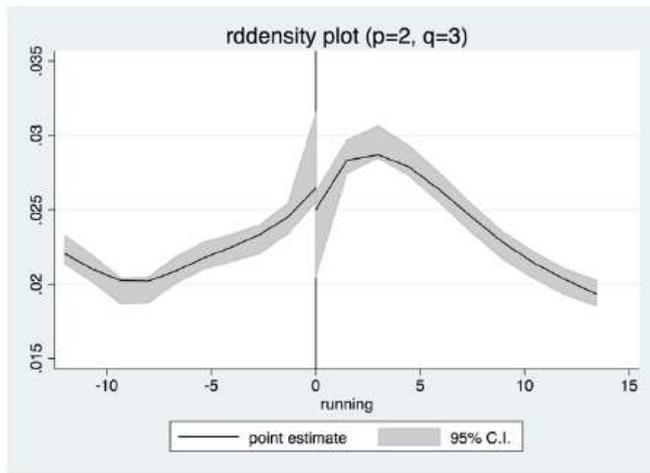

Table 5b. Effect of the P4 training on social capital: SUSENAS Dependent variable: P4 Participation

	(1) Community Participation	(2) Community Participation	(3) Community Participation with Covariates	(4) Trust Index	(5) Trust Index	(6) Trust Index with Covariates
Treatment Cohort=1	-0.002 (0.023)	-0.039 (0.031)	-0.045 (0.029)	-0.004 (0.017)	-0.002 (0.025)	-0.008 (0.023)
Birth Cohort	0.041*** (0.004)	0.068*** (0.014)	0.070*** (0.014)	0.006 (0.004)	0.005 (0.013)	0.008 (0.013)
Birth of Cohort^2		-0.006* (0.003)	-0.007** (0.003)		0.000 (0.003)	-0.000 (0.003)
Constant	1.913*** (0.017)	1.934*** (0.020)	1.611*** (0.042)	-0.051*** (0.010)	-0.052*** (0.014)	-0.323*** (0.015)
Observations	36008	36008	36008	12470	12470	12470

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. We use sharp RD design and a local linear regression with optimal bandwidth calculated by the *rdwselect* command of Imbens and Kalyanaraman (2012). The covariates used for estimates in column 3 and column 6 are gender and location dummy (urban/rural). The observations for community participation are all household member whereas for trust index are only representative individual (one for each household).

Even though in general there has been no effect of participation in the P4 training on social capital, there could be some dynamic complementarity of the program that offset the program impact as hypothesized in Section 2. To test such possible cases, we rerun the estimate into subpopulation by demographic factor. We use gender and location (urban/rural) as possible dynamic complementarity of the program effect. We argue that living in a more heterogenous environment such as higher ethnic diversity of ethnic like urban area could reinforce the program effect than the rural area. The gender effect also could be different between male and female, especially in the case that the way the program cast the personal social skill was through indoctrination. It could be the case that gender factor significantly differs in these respects.

5.5 Heterogenous Effect

The estimates for each subpopulation shows consistent profiles so that there is no impact of the program on both the channel and the outcome variables. Indeed, the significant different in the community participation estimates indeed driven by the tendency of urban population to be having more social activities than in rural area. The gender dimension also revealing the robustness of the impact estimates as well as proving that there are no dynamic complementary factors for the program. Table A6, A7, A8 and A9 in the Appendix present the heterogenous impact estimates by gender and location dimension respectively.

5.6 Robustness Check

To defend the robustness of our results, we employ several strategies. First is to use different set of datasets. The use of either IFLS or SUSENAS data barely change the results. Both estimates produced by these datasets show a consistent sign and statistical significance both in the first-stage and in the main equation. Second is the inclusion of the predetermined socio-economic characteristics of the subject. Our identification strategy relies on the assumption that, other than the P4 program, there has been no other thing happened in relation to social capital formation. To test this assumption, if the inclusion of pre-determined socio-economic characteristics should have a little effect to our estimate without these variables. All of the robustness checks of either use or not using covariates (Table 3a- Table 5b) suggest minor change in the coefficients magnitude.

Third is the falsification test. Aguero and Bharadwaj (2014) suggest of using different cut-off, that is by omitting the observation around the cut-off. This approach is to ensure that the effect is not due to coincidence gap at the cut-off. We implement this test by two techniques. First is to omitting observations of the year of birth 1985 and 1984 which are one year below and above the normalized running variable. The replication of estimates correspond to this test is presented in Table A3a-Table A5b). All of the replications show that the estimates results are barely change, except for the estimate in column 5 and 6 of Table 4a. These estimates suggest statistically significant different of the two cohort regarding the social participation in IFLS data. Interpreting this result, we argue that the statistical significance is not the program's effect as both the estimates using polynomial of degree one and using SUSENAS do not suggest the same result. relationship between average number of social group participation and age. In addition, Figure 4b shows a well-known inverted U-shape of average social group participation as in Glaeser, Laibson, & Sacerdote (2002) and Putnam (2000). Hence the statistical significance could also coincide with the quadratic functional form of the estimating equation. Second is to testing the density manipulation test at around the cut-off (Cattaneo, Jansson, and Ma 2016). Figure 5a and Figure 5b present the whether there is a jump of the distribution near the cut-off. The report shows that the statistical

test failed to reject the null of there is no jump in the distribution for SUSNEAS data (T statistics of 2.0153 and p-value of 0.0439) but not for IFLS data (T-statistics of -1.4839 and p-value of 0.1378). Interpreting this result, as for SUSENAS we argue that the jump is not the case of individual manipulating to be in the treatment group, but rather it is just due to the profile of distribution of SUSENAS block sample of the cohort. As for the case of IFLS the test rejects the null of there is no systematic manipulation of the running variable/the density of the units is continuous near the cut-off.

The last robustness check is the use of different bandwidth. We extend the bandwidth into plus five of the optimum bandwidth for each side below and above the cut-off. The robustness check of extending the bandwidth (Figure A4b, Figure A5a1 and Figure A5b1) also show stable result in term of statistical significance of the estimates.

6 INTERPRETATION

Up to this point, we have documented an empirical assessment to show that individuals' exposure to state ideology indoctrination courses in Indonesia does not have a long-lasting effect on individual social capital formation. There are two argumentations for this result. First is due to the reverse effect of the reform. For anti-New Order group, the reform in 1998 is a momentum to disregard all of norms and value dictated by the regime. Since it is not possible to identify whether individual are belongs to this group or the opposing group, New Order loyalist, we infer that the large portion of individual in our sample is coming from the former group.

The second argument is about the program design. The P4 program is lacking real life practice for the value and norms taught in the class to be effective. Moreover, the workshop is dominated by discussion and cognitive-building like activities. The effectiveness to cast a strong effect, despite the believe of indoctrination with a strong environment, seems to be weak as our results show. To see whether this claim is valid, we rerun the estimates and decompose them by types of trust level to show that the impact is only profound for outcome at the idea level (cognitive) but not at practical level.

Moreover, the impact is larger in a more facilitating and environmentally supporting area i.e., urban rather than rural area. Urban area for example, have more ethnicity heterogeneity that help participant to better form their understanding about inter-ethnic trust (Table 6).

Table 6. Interpreting the impact: type of trust by location
Dependent variable: Trust item Idea (TR03) and Practical(TR04)

	(1) Idea-Urban	(2) Practical-Urban	(3) Idea-Rural	(4) Practical-Rural
P4_dummy	0.315* (0.186)	0.039 (0.126)	0.025 (0.166)	0.050 (0.258)
Birth Cohort	-0.043 (0.028)	0.010 (0.019)	0.004 (0.019)	0.014 (0.028)
Observations	3895	3188	2769	2380
F	1.402	1.637	0.480	2.354

Note: Robust standard errors clustered at cohort level are in parentheses with * $p < .1$, ** $p < .05$, *** $p < .01$. We use 2SLS of a fuzzy setting and a local linear regression with optimal bandwidth calculated by the *rdwselect* command of Imbens and Kalyanaraman (2012) at bandwidth of 4. The estimates does not include covariates.

7 CONCLUSION

This study aims to test whether individual exposure to P4-program influences individual social capital formation in the long-run. The estimate results using both the fuzzy regression discontinuity design with IFLS data and a sharp RD design using the SUSENAS data exploiting the event of the termination of Pancasila Moral Education in Indonesia in 1998 suggest that the program effect do not last in the long-run to affect individual social capital. We argue that, despite it cost-effectiveness in the sense of an embedded program to build social capital in education, learning from such non-targeted program's in Indonesia Soeharto's era give us an impression that such program's role to build individual social capital in the long run is limited. A combination of an intense cognitive leaning and an environmentally supportive location might improve the program effectiveness. Such an indoctrination solely approach was not an effective way, despite the large amount of resource dedicated to preparing and train the instructor for the program. This result is can be generalized into a context of policy debate, whether government can promote social capital through education.

1244 WILLINGNESS TO PAY ESTIMATES: EVIDENCES FROM AN URBAN WETLAND HAVING RECREATION-CUM-FISHERY BENEFITS

ABSTRACT

The rationale behind the conservation and restoration of wetlands emerges from a set of ecological and economic values attributed for the welfare of the community. Water bodies have been supporting biodiversity, sustaining livelihood, providing goods, services and other amenities, controlling flood, generating employment and yielding recreation benefits. However, the dichotomy that urban development projects posit upon society - prosperity on the one hand and degradation on the other, is the basis of this study. The question that arises therefore is whether the costs incurred in the project are likely to exceed the benefits provided by water bodies while considering the overall impact upon the environment. Kolkata, the leading metropolitan city of Eastern India, being located on deltaic plain, is endowed with vast water resources in the form of rivers, drainage channels, wetlands, lakes, canals and ponds. However, the problem of restoring and preserving these water bodies emerges due to their consideration as “free” public goods which have no direct monetary value since they are not traded in markets, in spite of offering a wide range of benefits. Economic valuation of the services and benefits accrued from the water bodies can be instrumental in protection of these water bodies. Urban wetlands often play multiple roles in recreation-resource generation-livelihood protection. Selecting one such wetland which is a Nature Park and a long-established Cooperative Fishery, this study seeks to assess the major ecosystem services, the multifarious roles and the economic value generated by the system. Mudialy Fishermen Cooperative Society (MFCS) named as Nature Park, an important ecological entity in the south western fringe of Kolkata, is selected for the study. This paper attempts to find out how people perceive the wetland as an ecological entity and their preferences by assessing their willingness to pay. It also seeks to determine the drivers controlling their preferences. Non market valuation techniques are used to draw conclusions. Focus group discussions with members of the Cooperative and other direct stakeholders further substantiate the analysis of preferences. The study shows that determination of a substitute cost can be used as a proxy for the overall services that these water bodies provide for free. It has revealed the strong preference of the people who are directly dependent on it for their livelihood. The study finally concludes an economic rationale for the further development and preservation of the water body so as to avoid the further consequences of negligence of water bodies.

Keywords: welfare, economic value, public goods, economic valuation, substitute cost

1558 HUMAN VULNERABILITY ASSESSMENT FROM DEMOGRAPHIC, SOCIAL AND CLIMATIC DIMENSIONS

ABSTRACT

Human being are adversely affected by the changing nature of climate. The trend of the climate and associated occurrence of various hazardous phenomena are manifold higher than it was before. Population are more and more vulnerable towards different kind of climatic exposures, as manifest in various dimensions like demographic vulnerability, agricultural vulnerability, biophysical vulnerability etc. as a cumulative effect. Assessment of human vulnerability is a challenge in view of lack of systematic, quantitative data with respect to the climate change impacts. Also, there is an uncertainty on the methods of quantification of human vulnerability. This study is an endeavor to quantify human and climatic vulnerability, based on the analysis of the demographic, social variables along with meteorological data. Methods – The demographic and social dimensions of selected Indian states (from northern, eastern, southern and western regions of India) were gathered along with the IMD meteorological information with reference to time zones and season. Details statistical methodology was adopted to obtain apportionment of relative contributions of different variables, derived as coefficient matrices using Principal Component Analysis. The coefficient matrices were associated to selected climatic indices to demonstrate the climatic vulnerability. Results – Vulnerability is defined as the summated impacts of human exposure, sensitivity and their adaptive ability to a climatic condition. Analysis provided quantification of these components based on sample data drawn from selected states spatially shown through GIS mapping. This approach has a high promise to predict and project population vulnerability associated to its confounders in relation to climatic extremes.

1581 WETLAND CONSERVATION AND KOLKATA'S ECOLOGICAL RESILIENCE

ABSTRACT

Ecological resilience develops over time and space as result of the dynamic interaction of social-economic and ecological processes in multiple scales and magnitudes. The ecological resilience of urban ecosystem refers to the state in which the system able to tolerate the alteration without changing into a new structure and processes. Decline in the ecological niches of regions result in challenges to resilience. Wet lands remain acutely threatened as an ecosystem, even more so in urban regions simply due to anthropogenic pressures. Several reasons such as unplanned growth of the urban area at the cost of nature, lack of proper environmental strategy, lack of adequate implementation of management plans, failure of past management actions due to lack of environmental justice, and finally a general attitude of negligence of nature in urban localities as they lose their previous importance in serving the area reduce the cross- scale resilience, leaving the system vulnerable to change. At present, decisions are implemented based on the present needs of the human society and that shapes the ecological system. In these circumstances, assessment of the ecological services provided by the wetlands ecosystem is an important issue to understand the present situation. The present study is aimed at providing a background to the understanding of ecological resilience in terms of the East Kolkata Wetlands, an expansive tract of water bodies, streams, canals and channels – an intricate deltaic ecosystem that nurtures the megacity of Kolkata. Ecological service assessment methodology has been applied that can be used to assess multiple ecological services of the wetlands in urban areas and integrate them with socio-ecological conditions in urban neighborhoods. This study tries to point out the reasons which lead to arrive current situation through historical context analysis in order to conserve them in contemporary time. It is also important to analyze the past and present policies related with wetland conservation and management to identify the reasons behind its present condition. Result of the analysis will help to identify the gap between theoretical and practical implementation of the present planning policies related with the wetland conservation and management. In this context, mapping is an important tool towards spatial representation of the present vulnerable conditions of the wetlands using the resilience context of wet lands in urban areas. The study seeks to provide a set of technical and strategic alternatives towards modification of the policy framework that can significantly improve its effectiveness in establishing of wetland resilience.

1707 CHARACTERISTICS AND THE NATURE OF THE TREND OF CLIMATE IN THE CITY KOLKATA

Pradip Patra

Senior Research Scholar (CSIR-SRF), Department of Geography, University of Calcutta. Email: patrapradip1990@gmail.com

ABSTRACT

The changing nature of the climate of the city is experienced throughout all over the world, but its magnitude of change may differ from city to city. Complexity of the city structure influenced the rate of natural change of the climatic elements from its counter suburban or rural areas and the effect known Urban Heat Island (UHI) effect. So to measure the extreme climatic elements is the major task, by which special policy may formulate to overcome the situation. Here an attempt has been made to measure the nature of extremes climatic elements, which are recommended by Expert Team on Climate Change Detection and Indices (ETCCDI) as well as other relevant indices of the climate of Kolkata. For this purpose, daily climatic elements (Maximum Temperature, Mean Temperature, Minimum Temperature, Precipitation and Relative Humidity) has been used for the period of 1969-2012. Both parametric (linear regression test) and non-parametric (Mann Kendall test) has been used to detect the change and Sen's slope estimator used to degree of change. To detect homogeneity of the dataset four homogeneous test has been applied. Long term (1969-2012) trend of extreme temperature indices like TXa, TXn, TMa, TNx, TNa and TNn of monthly, seasonal and annual time step have follow positive increasing trends, while noticeable decadal positive change of 0.19°C-0.45 °C has noticed in mean Temperature. The intensity of the Precipitation of different scale also changed, but not significant ones. Other elements like relative humidity also changed over time and trend of average RH during 8.30 am and 5.30 pm shows alarming rate of change during monsoon, pre-monsoon and post monsoon seasons, high humidity in monsoon season increases higher heat index value.

Key Notes: ETCCDI, Mean Temperature, Precipitation Trends, Relative Humidity, Heat Index.

1. INTRODUCTION

Characteristics and trends of Extreme Climatic Indices (ECIs) like maximum temperature (TX) and minimum temperature (TN) and precipitation indices in the world have been analyses by different researchers and most of the findings reveal the fact that ECIs has increased in recent times (Easterling et al., 1997; Plummer, et al., 1999; Zhang, Hogg, & Mekis, 2001; Frich, et al., 2002; Vose et al., 2004;; Moberg & Jones, 2005; Rahmstorf & Coumou, 2011; Lee, Kwon, Modarres, Kim, & Chebana, 2016; Scherrer, et al., 2016; Lin , et al., 2017; Abbas, Sarwar , Ibrahim, Adrees, & Ali, 2018; Mukherjee, Aadhar, Stone, & Mishra, 2018; Tirkey, Ghosh, Pandey, & Shekhar, 2018). Not only indices of TX, TN, mean temperature (TM) increase more significantly while significant decreasing trend of Diurnal Temperature Range-DTR (Brázdil, 1996; Moberg, & Jones 2005; Dashkhuu et al., 2014; Ghasemi, 2015) has been noticed. After reviewing existing trends of ECIs and its future projection of 3rd, 4th and 5th Assessment Reports (AR) of the IPCC, Alexander (2016) finally concluded that the warm temperature would increase and cold temperature extremes would continue to decrease. Karl et al. (1993) quantify the trend and found that the rise of the TN was three times more than the rise of the TX, and the decrease of the DTR was equal to the increase of the TM in the land dominated northern hemisphere. The urban areas trap the heat and increase firstly the Land Surface Temperature (LST), and thereafter the local air temperature, by which it can be differentiated from its rural or suburban counterpart, the process is commonly known as the Urban Heat Island (UHI) effect. And due to this mechanism, trend of ECIs in urban areas becomes more observable compare to its counter rural areas. The study by different researchers has found the alarming rate of the change of ECIs (Alghamdi & Moore, 2014; Keggenhoff, Elizbarashvili, Amiri-Farahani, & King, 2014; Mishra, Ganguly, Nijssen, & Lettenmaier, 2015). Not only increasing trend, asymmetry has also been found in the temporal distribution of temperature where Long-term change (1901- 2003) shows a slight increase of the TX (0.07 °C/decade), while in recent time (1971-2003) both TX and TN have increased (>0.2 °C/decade) substantially (Kothawale, & Rupa Kumar, 2005). In India, studies conducted by different researchers at the national level like Rao et al., (2004), Oza and Kishtawal (2015), basin level (Shrestha, 2016; Hamid, 2014) and city (Dhorde, Dhorde, & Gadgil, 2009; Mohan et al. 2011a, 2011b, and 2012; Desai, Patel, Rathi, Wagle, & Desai, 2015; Korade, & Dhorde, 2016) have found that the extreme temperature events as well as relative events like warm nights, warm days, and cold nights are increasing with different magnitudes.

Increase of temperature of the city under warming phases, precipitation, extreme likely to be increased as a result of The Clausius-Clapeyron (C-C) relationship, as water holding capacity of the atmosphere increase approximately 6-7%/K increase of temperature (Trenberth, Dai, Rasmussen, & Parsons, 2003; Kharin & Zwiers, 2007). So, along with extreme temperature indices, precipitation indices needs to incorporate, as the later one has also socio-economic impacts, like-urban flooding. Studies by researchers also confirm that, intensity of precipitation has increased in recent times and will be in the upcoming future (Siswanto, van Oldenborgh, van der Schrier, Jilderda, & van den Hurk, 2016; Mukherjee, Aadhar, Stone, & Mishra, 2018) while different precipitation(ndices respond differently (Rahimzadeh, Asgari, & Fattahi, 2009)

Table 9. Extreme Temperature and Precipitation Indices

ID	Index name	Description	Unit
Temperature Extremes			
TXx	Maximum Tmax	Monthly maximum value of daily Tmax	°C
TNx	Max Tmin	Monthly maximum value of daily Tmin	°C

TXn	Min Tmax	Monthly minimum value of daily Tmax	°C
TNn	Min Tmin	Monthly minimum value of daily Tmin	°C
TXa	Average Tmax	Monthly average value of Daily Tmax	°C
TNa	Average Tmin	Monthly average value of Daily Tmin	°C
TM	Average Tmean	Monthly average value of Daily Tmean	°C
TN10p	Cool nights	Total no. days when daily TN less than 10th Percentile	Days
TX10p	Cool days	Total no. days when daily TX less than 10th Percentile	Days
Tn90p	Warm Nights	Total no. days when daily TN less than 90th Percentile	Days
TX90p	Warm days	Total no. days when daily TX less than 90th Percentile	Days
DTR	Diurnal Temperature Range	Annual mean value of difference between TX and TN	°C
Precipitation Extremes			
PRCPTOT	Annual Total Wet Day PR	Annual Total Number of Wet Day rainfall ≥ 0.001	Days
R10mm	Number of heavy rain Days	annual number of days when PR>10mm	Days
R20mm	Number of very heavy rain Days	Annual Number of days when PR>20mm	Days
R95p	Total annual PR from heavy rain days	Annual sum of daily PR>95 percentile	mm
R95pTOT	Contribution from very Wet days	$100 \times r95p / PRCPTOT$	%
R99p	Total annual PR from very heavy rain days	Annual sum of daily PR>99 percentile	mm
R99pTOT	Contribution from extremely Wet days	$100 \times r99p / PRCPTOT$	%
R*1Day	Maximum 1 day PR	Maximum 1 day PR total	mm/day
R*5Day	Max 5 day PR	Maximum 5 day PR total	mm/day
SDII	Simple Daily Intensity Index	Annual total PR divided by the number of wet days(when PR ≥ 0.01 mm)	

2. STUDY AREA, DATA AND METHODOLOGY

The Kolkata Metropolitan Area (KMA) is the 3rd largest Urban Agglomeration (UA) and oldest metropolis (more than 300 years old) of India, consists of three Municipal Corporation (MC-Kolkata, Howrah and Chandannagar), 38 Municipalities and 24 Panchayat Samitis. Kolkata Municipal Corporation (KMC) is the most populated MC of KMA. The Kolkata city has only one meteorological station, Alipore which is also the oldest meteorological station of the country. As the city has a long history of growth, the impact of growth on micro climate is not sudden, hence, the prime objective of the paper to find out the climatic trend of the city at present and also upcoming future. Spatio-temporal distribution of surface temperature- Land Surface Temperature (LST) using multi temporal Landsat Thematic Mapper (TM) imagery has been used. To fulfil the main objective of the paper, 44 years (1969-2012) of daily temperature (maximum and minimum), precipitation and relative humidity data, have been used, which has been collected from the office of India Meteorological Department (IMD), Alipore and Pune. The dataset having almost complete with less than 2% of missing data. The missing data are excluded as the distance is more in-between Alipore and other observatories. Quality control of the data have also been conducted according to the standard process described by Alexander et al. (2006). After analyzing extreme temperatures of a long-period (1850 to 2012), as per the IPCC fifth Assessment Report (AR5) it has been identified that 1983 to 2012 period was the warmest period of the earth; and current climate period also fall under this warming phase, hence it is expected that this study will enable to figure out the micro-climatic condition and its trend of Kolkata. The IPCC in its Special Reports managing the risks of Extreme Events and Disaster to Advance Climate Change Adaptation (SREX) in 2012 and AR5 in 2013 has given special emphasis to temperature and precipitation extremes in the context of climate change. Expert Team on Climate Change Detection and Indices (ETCCDI) recommended 27 core temperature and precipitation indices, out of which, most of the temperature indices (both absolute and relative) and precipitation indices which are suitable to analyses the climate of city have been analyzed here (table 1). Both parametric test (linear regression test) and non-parametric test (Mann-Kendall Tau test, MK) have been computed to know the nature of change either positive or negative in the areas, Theil Sen's Slope (SS) has also been computed to know the degree of change.

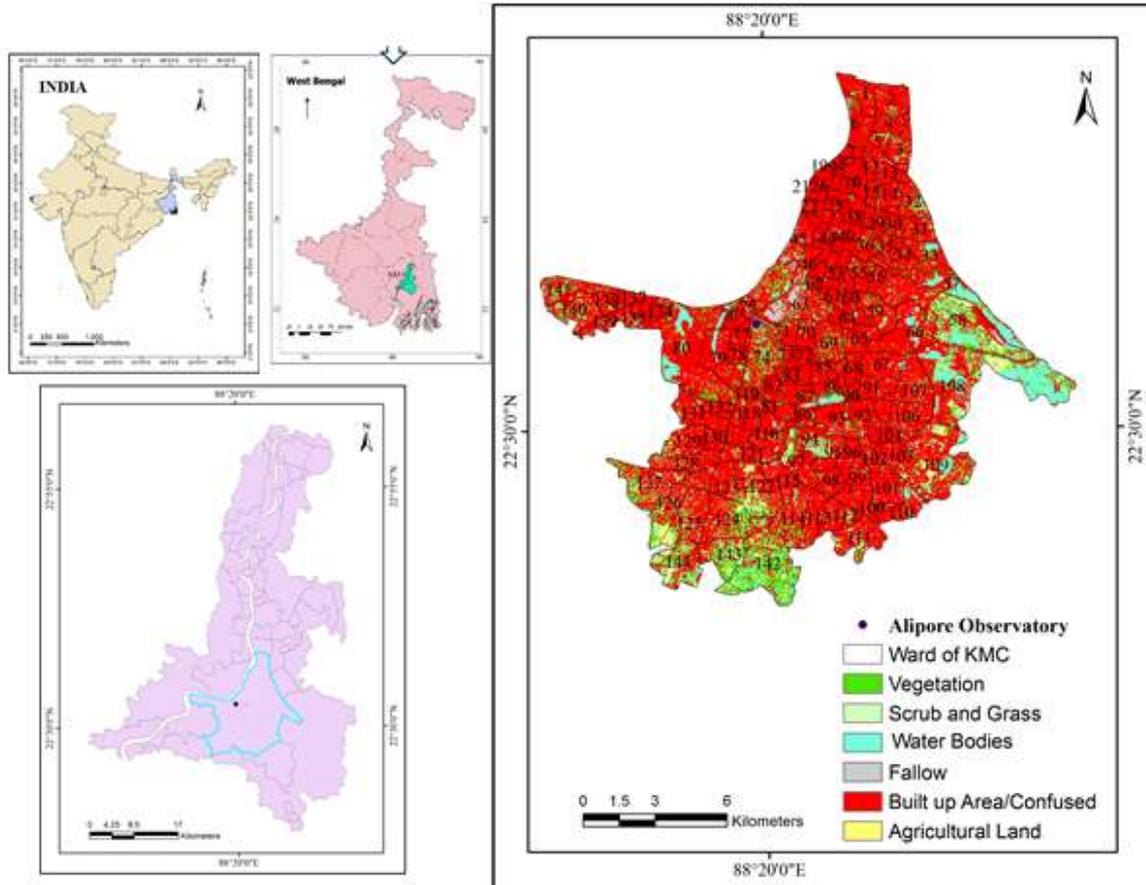

Figure 42 Location Map of the Study Area

Land Surface Temperature (LST)

In order to convert the DN value of Landsat Thematic Mapper 5, band 6 the following equation has been used-

$$L_i = L_{max} + (L_{max} - L_{min}) / Q_{dn} / Q_{max}$$

Where, L_i is the at-sensor spectral radiance ($MW \cdot cm^{-2} \cdot sr^{-1} \cdot \mu m^{-1}$); L_{max} is the maximum at-sensor spectral radiance; L_{min} is the minimum at-sensor spectral radiance; Q_{max} represents the maximum DN value of pixels and Q_{dn} represents the DN value of pixel. For Landsat TM 6 data, Equation can be expressed as Equation:

$$L_6 = 0.005632156 Q_{dn} + 1.238$$

Where, L_6 is the at-sensor spectral radiance of Landsat TM 6, and Q_{dn} is the DN value of pixel.

In order to convert the spectral radiance into at-sensor brightness temperature, the Planck's function can be used as:

$$T_6 = K_2 \ln (1 + K_1 / L_6)$$

$$K_1 = 60.776 MW \cdot cm^{-2} \cdot sr^{-1} \mu m^{-1}$$

$$K_2 = 1260.56 K$$

Where, T_6 is the at-sensor brightness temperature of Landsat TM 6; K_1, K_2 are calibration constants of Landsat TM and L_6 represents the at-sensor spectral radiance of Landsat TM 6. Further brightness temperature of Landsat TM6 is converted from Kelvin to Celsius.

Mann Kendall Test

Mann Kendall test is one of the effective non-parametric test which can significantly detect the trend of meteorological data series.

$$s = \sum_{i=1}^{n-1} \sum_{j=i+1}^n sgn(x_j - x_i)$$

Where, n is the periods or length of the data set and x_i and x_j represent data point in the time series of i and j , respectively ($i > j$),

$$sgn(x_j - x_i) = \begin{cases} -1, & \text{if } x_j - x_i < 0 \\ 0, & \text{if } x_j - x_i = 0 \\ +1, & \text{if } x_j - x_i > 0 \end{cases}$$

It has been documented that when $n \geq 10$ Then the distribution of S is normally follow

$$E(S) = 0$$

$$V(S) = \frac{n(n-1)(2n+5) - \sum_{i=1}^m t_i(t_i-1)(2t_i+5)}{18}$$

Where $E(S)$ is the mean and $V(S)$ is the variance, m is the number of the groups and t_i is the size of the i th tied group. The standard normal test statistics Z is given by

$$Z = \begin{cases} \frac{S+1}{\sqrt{V(S)}}, & \text{if } S < 0 \\ 0, & \text{if } S = 0 \\ \frac{S-1}{\sqrt{V(S)}}, & \text{if } S > 0 \end{cases}$$

Positive Z score indicates an increasing trend and negative shows negative trend or decreasing trend of the precipitation. If $|Z| > Z_{1-\alpha/2}$, null hypothesis H_0 for “no trend” in the time series is rejected and a significant trend exist. In the present study, significance level is fixed at 0.05. No Pre-Whitening is done as the data length is enough (Bayazit and Önöz, 2008).

Theil-Sen’s approach (TSA) (Theil 1950: Sen 1968) is used to determine the degree or magnitude if change. TSA slope i.e. β is defined as-

$$\beta = \text{median}\left(\frac{X_j - X_i}{j - i}\right)$$

Where X_i and X_j represent data points in time series i and j , respectively ($i < j$). A positive value of the slope, β indicates and increasing trend and vice versa.

Decadal change

Here, magnitude of the change computed in time step of decade. Yue and Hashino (2003) used percentage change of sen’s slope on their articles, here decadal change of temperature have been computed using the formula

$$\text{Decadal change (\%)} = \frac{\beta * N}{\bar{X}} * 10$$

Where, β is the slope value calculated by Theil-Sen’s formula and N is the data length and \bar{X} is the mean of the data.

3. RESULT AND DISCUSSION

3.1 Land Surface Temperature

Analyzing the spatio-temporal distribution and the characteristics of Land Surface Temperature (LST) is one of the important factors to study the micro-climatic condition of an area and due to changing Land Use and Land Cover (LULC) and conversion of any kind of land to impervious material, LST has significantly increased (Hu & Jia, 2009; Wang, Zhan, & Ouyang, 2017; Xiao, et al., 2018). Here two seasons i.e. summer and winter has been chosen to examine the behavior of LST during the seasons in different decades. To measures winter and summer season LST multiple year Landsat Thematic Mapper (TM) 5 (band 6) satellite images has been used. Details of the algorithm and band information has been given in the table 2. Here only one sensor data have been used to monitor the LST as the different sensor has a different reflectance and may give different results.

Table 10 Basic Information about the used Satellite Images

Imagery	Landsat Thermal Mapper (TM) 5 Winter Seasons (Jan-1990, 2001, 2010); Summer Seasons (April 1990, 1999, 2009)
Band Used	Thermal (Band no. 6)
Wave length	10.40 - 12.50 (µm)
Resolution	120 meter

LST has been measured across 144 wards of the KMC in two seasons; winter (1990, 2001 and 2010) and summer (1990, 1999 and 2009). From the Fig. 2(a-c) and 3 (a-c), it can be said that, LST has increased significantly during the time period in both of the seasons, while the rate of change is maximum in summer seasons with more than 2^o C. Both of the seasons shows a significant increase of LST in northern, eastern (ward no. of 75-80) and southern (ward no. 70-76, 80-84, 116-118) part of the study area.

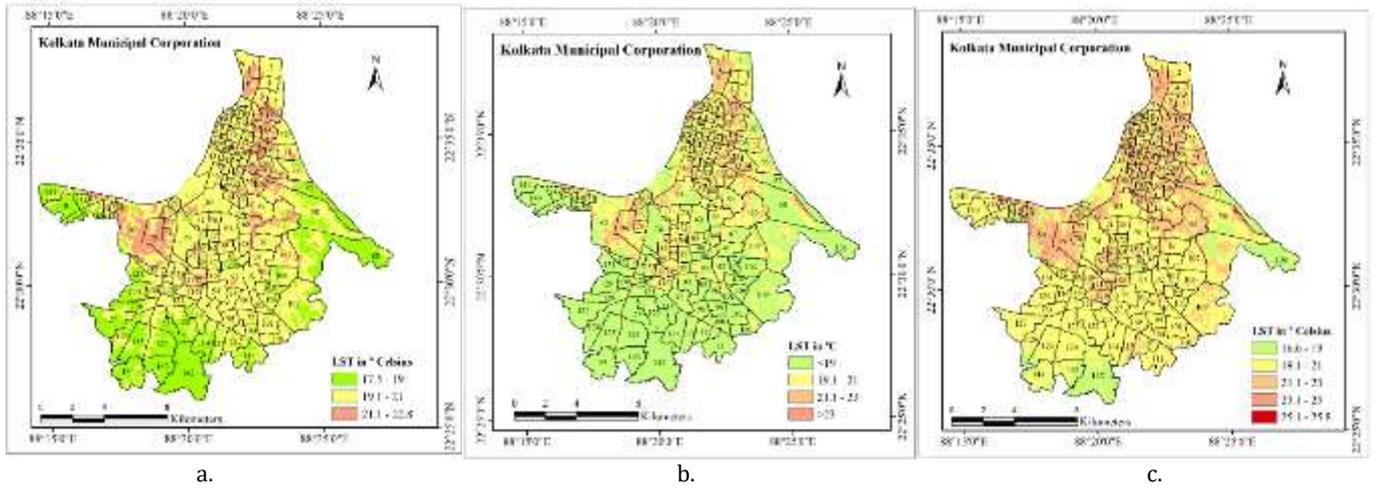

Figure 2 LST during Winter Season: January 1990 (a), January 2000 (b), and January 2010 (c)

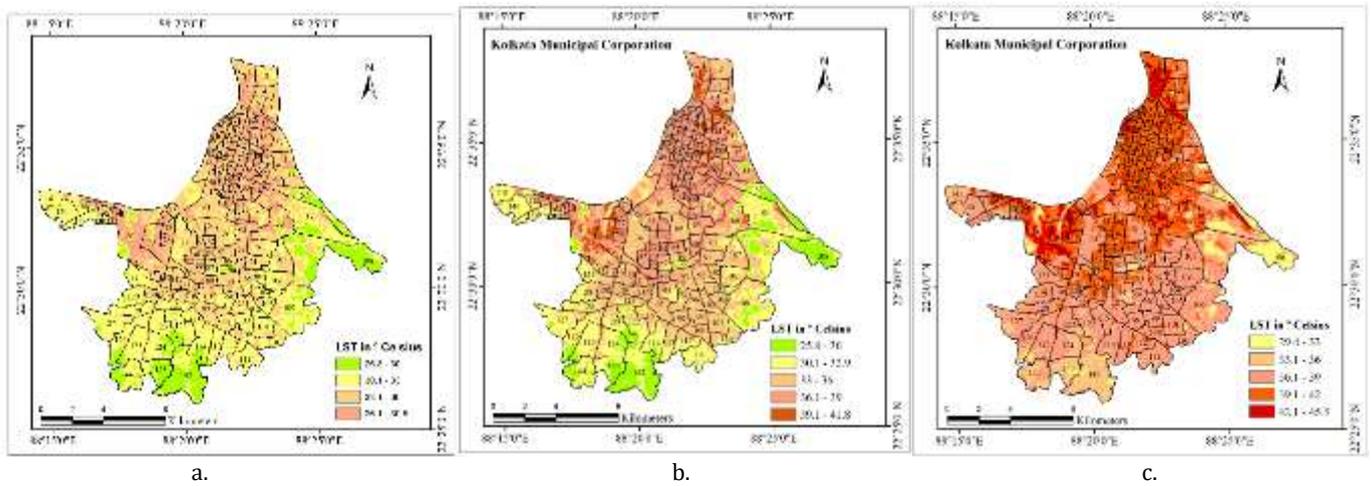

Figure 3. LST during Summer Season: 1990 (a), 1999 (b), and 2009 (c)

3.2 Temperature Extremes

3.2.1 Monthly Characteristics of T_I's and trends

3.2.1.1 T_X, T_{Xn}, T_{Xa}

Monthly T_X of Alipore has increased with insignificantly trend (table 1). Out of 12 months, nine months shows a slight increasing trend of T_X while March, April and May shows a slight decreasing trend. While significant increasing trend has been noticed in the August month and October month with positive trend of 0.16 °C/decade and 0.18 °C/decade respectively. Like T_X, T_{Xn} have also found similar trend with most of the month remains non statistical significant trend. Although, significant decreasing trend (1.80 °C/decade) of T_{Xn} in January month has been recorded. T_{Xa} as a whole is a good indicator to have an idea about whether monthly average T_X has increased or not. No Significant increasing trend of T_{Xa} has been found in most of the months, while statistically decreasing trend (0.50 °C/decade) of T_{Xa} has been observed in January month.

3.2.1.2 T_N, T_{Nn} and T_{Na}

Daily T_N is one of the most important parameters to define change of temperatures in the urban areas. An increase of T_N in all of the months has been found, where most of the months have indicated a significant increasing trend, with decadal change, of February (0.98 °C), March (0.60 °C), April (0.53 °C) and June (0.41 °C) at Dum Dum, and February (0.71°C), March (0.62 °C) April (0.59 °C) and December (1.13 °C).

It is very interesting to note that, T_{Nn} shows an increasing trend in all of the months while significant increasing trend has been also noticed in the months of January, February, March, June and August with decadal increasing trend of 1.41°C, 1.37°C, 1.28°C, 0.6°C and 0.40°C respectively.

T_{Na} also shows a significantly (both 5% and 1% significant level) increasing trend. Out of the twelve months of a year, around ten months significantly figure out the fact. Although the rate of the change of the temperatures differ from month to month; and noticeable decadal increasing trends have been noticed in the months of December (1.5°C) February (0.87°C) and March (0.89°C).

3.2.1.3 T_M

Monthly Tmean (TM) of the city have shown different kind of results. Although in all of the months of the Alipore Observatory indicate an increasing trend, the significantly increasing trend has been noticed in the months, with decadal change, of March (0.45 °C), July (0.19 °C), August (0.22°C), September (0.20°C) and December (0.53°C), and the remaining months represent non-significant trend.

3.2.2 Seasonal Characteristics of TI's and trends

Seasonal TXx, TXn, TXa of Kolkata also indicate varying results, where statistically significant increasing trend of TXx has been found in post-monsoon season (0.17°C/decade). Statistically significant decreasing trend of TXn of -1.66°C/decade have been found in the winter season. Whereas, no significant seasonal increasing trend of TXa has been found in Kolkata.

*Bold mark are statistically significant, while * and ** denotes 5% significance level and 1% significance level.*

TNx follows significant increasing trend in all of the seasons having alarming trend found in winter season with the decadal increasing trend of more than 0.96°C. An interesting finding is that, TNn has increasing trend at Alipore with statistically significant trend in the pre-monsoon (1.28°C /decade) and monsoon (0.46°C/decade) seasons. But TNa has got significant increasing trend in all of the seasons at both of the stations with noticeable increasing trend found in winter (0.83°C/decade), pre-monsoon (0.57°C/decade), monsoon (0.33°C/decade) and post-monsoon (0.72°C/decade) seasons at Alipore.

Seasonal TMa of both the stations shows an alarmingly increase trend throughout the year, and the maximum positive trend has been noticed in pre-monsoon, monsoon and post-monsoon seasons with decadal change of TMa varying from 0.21°C/decade to 0.48°C/decade, decadal change of TMa is the maximum in post-monsoon season with decadal change of 0.30°C/decade.

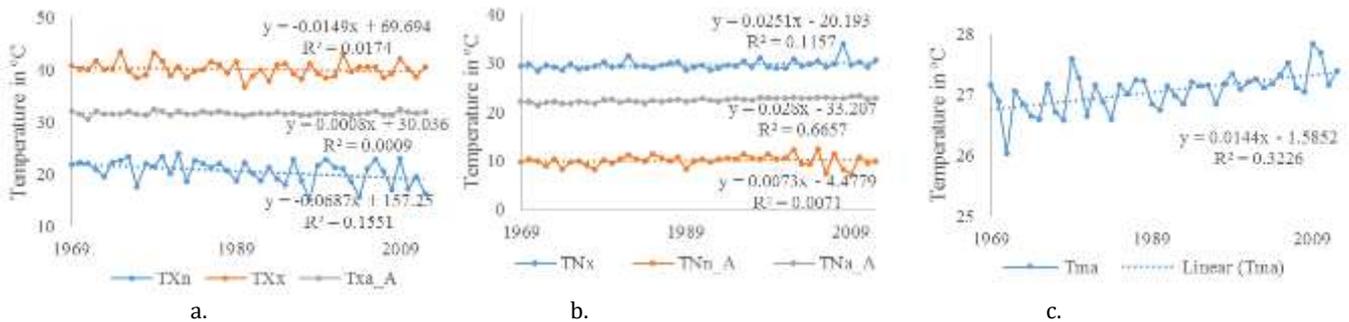

Figure 4. Annual Trend of TXx, TXn and TXa (a), Annual Trend of TNx, TNn and TNa (b) and Annual Trend of TMa (c) at Alipore meteorological station

3.2.3. Trend of annual extreme temperatures over Kolkata

Temperature extremes like TXx, TNn, TM, TXn, TNx, TXa and TNa in annual time step have been computed to know the trend of such elements (Fig 4). Both parametric and non-parametric tests have been computed to know the actual change of the temperature (table 3). No statistical change of TXx has been observed at any of the stations selected here. TXn of Alipore has decreased (-1.34 °C/decade) significantly with p value 0.013. Higher rate of increasing trend of annual TNx has been noticed in Alipore (0.25 °C/decade); while significant annual TNa has been recorded at Alipore with decadal change of temperature of 0.53 °C with p < 0.0001 and R² value of 0.41. Annual TNn have been recorded with increasing trends, but the results have no statistical significance at 5% or 1% significance level. TMa shows an increasing trend with

95% confidence level, with both parametric (R^2 values 0.1) and non-parametric test (0.21 °C/decade with $p = 0.0003$) result signifies the result.

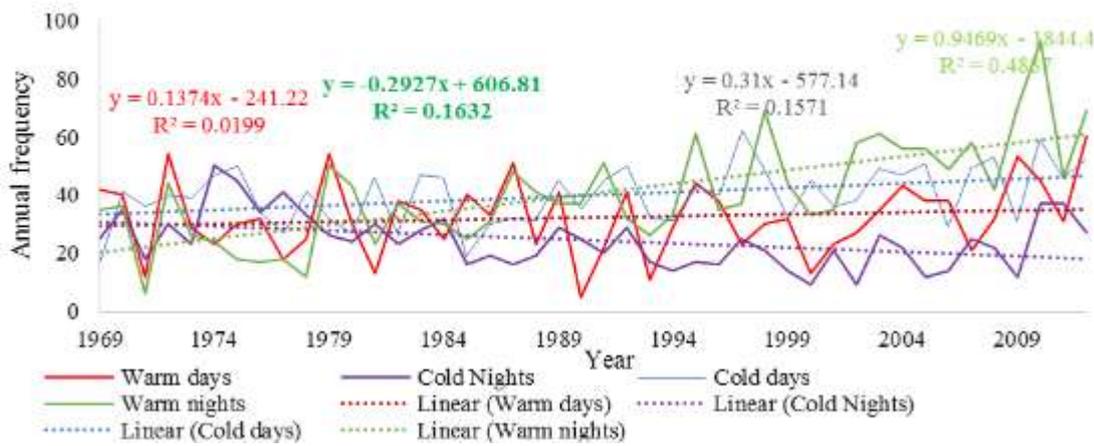

Figure 5. Frequency and Trend of Relative Temperature Extreme

Alipore

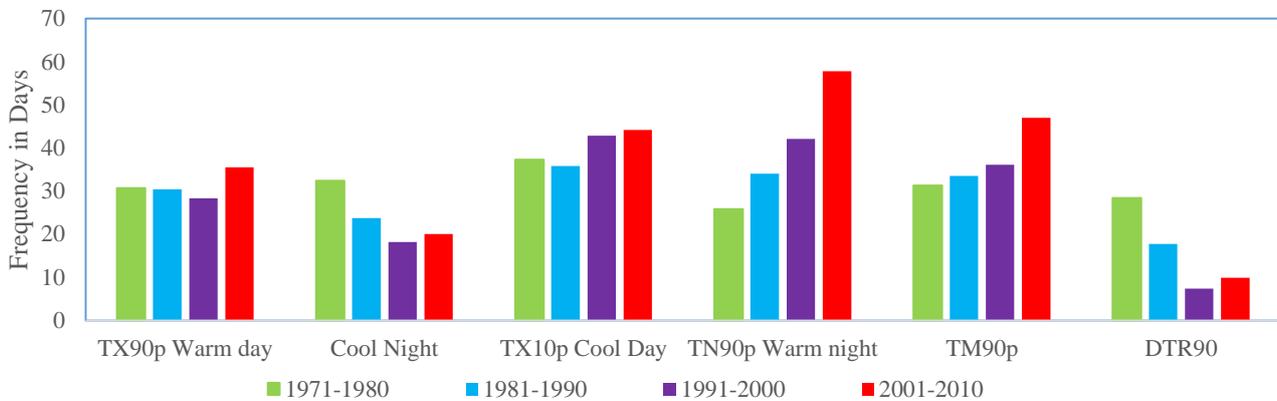

Figure 6. Decadal Variability of Relative Temperature Extremes

3.2.4. Annual and Decadal Distribution of Relative extreme Events

For relative measures of temperature events, six indices have been used, out of which IPCC has recommended four indices, namely Warm Days (TX90p), Warm Night (TN90p), Cool Nights (TN10p), Cold Days (TX10p); and apart from this, Tmean90p and DTR90p have also been used here to find out whether the extreme mean temperature values and extreme diurnal values changed over the time period or not, as those are also important temperature parameters. Significantly increase trend of warm nights has been recorded at Alipore with R^2 value of 0.49 (fig. 5).

The selected dataset have been suitably divided into four decades like 1971-1980, 1981-1990, 1991-2000 and 2001-2010. Different indices behave differently throughout the study period. It has been found that warm days and warm nights both of the urban observatories shows an increasing values (Fig. 6). The frequency of cool nights have not increased, while a gradual decreasing trend of cool nights, has been observed. On the other hand, a little increase of the cold days frequency has been noticed at Alipore. It is interesting to note that from all of the four parameters, positive change of the warm nights has been marked in other cities of India and World.

3.3 Precipitation extremes

Like temperature extremes, precipitation extremes of Kolkata has also been computed here (table 4 and fig. 7 a-d). Precipitation extremes of different parts of the world, changed differently, where most of the cases an increase of the PE has been examined, while others remain decreasing trend.

Table 12 Precipitation Extremes of Kolkata

Variable	Min	Max	Mean	SD	Kendall's tau	p-value	Sen's slope	Decadal Trend

3.3.1. R*1Day, R*5Day

One day Maximum Precipitation (R*1Day) and consecutive five days extremes precipitation (R*5Day) trend show an increasing trend with decadal increasing trend of 2.06mm/ day and 2.69mm/day respectively but the trend is not statistically significant.

3.3.2. Daily heavy to very severe Precipitation

Daily Heavy to severe precipitation of Precipitation greater than 20mm, 70mm, 120mm shows almost no trend with a slight decadal change of respected precipitation extremes lies from 0.11-0.15mm. No statistical significant trend has been observed at Alipore.

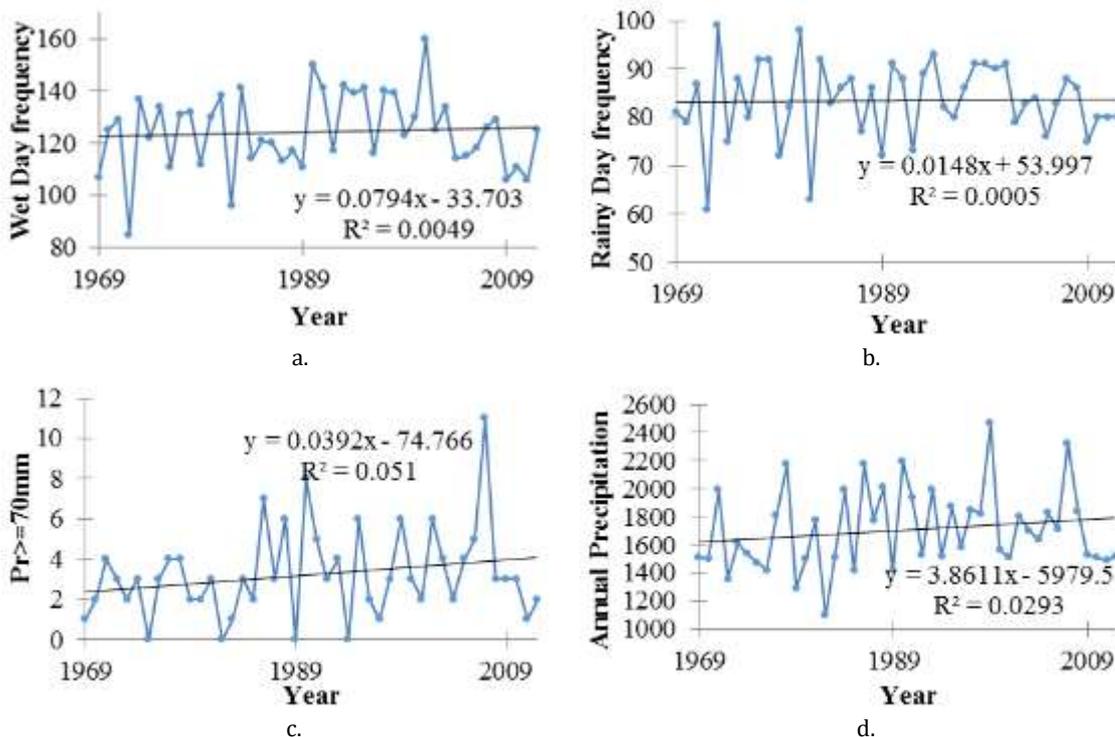

Figure 7. Precipitation Extremes of Kolkata: Wet Days frequency (a), Rainy Day Frequency (b), Heavy Precipitation Day (Pr>=70mm/day) frequency (c) and Annual Precipitation (d)

3.3.3. Wet Days Frequency and Rainy Days Frequency

Wet Days frequency (Pr>0.01mm/day) and Rainy Days frequency (Pr>2.54mm/day) are also good indicators for precipitation extreme analysis. Frequency of wet and rainy days remain unchanged throughout the time periods. Seasonal wet days frequency of the post monsoon seasons shows significant increasing trend with 3.89mm/decade, while other seasons remain unchanged with a decreasing trend of wet days frequency in monsoon seasons (-2.89mm/decade) has been noticed.

3.3.4. Simple Daily Intensity Index (SDII)

Simple Daily Intensity Index of the precipitation is increased with 0.68 mm/day. Although like other precipitation indices, trend of SDII also shows an insignificant trend.

3.3.5. Contribution 99th Percentile and 95th percentile of precipitation (R99P and R95P) and percentage contribution to total wet days (R99PTOT and R95PTOT)

R99P and R95P shows insignificant increasing trend of 1.29mm/decade and 1.85 mm/decade respectively, while R99PTOT and R95PTOT found to be insignificantly changed over the time period at the rate of 5.68% and 5.0% respectively.

A slight decreasing trend of the total annual precipitation (-0.57mm/decade), has been recorded while R95Percentile, R99Percentile remain no changed.

3.4 Trend of the Relative Humidity in Kolkata

Relative humidity is also an important parameter of the climate and its variability also plays a significant role on both physical elements such as Climate and other process and Human Being also. But, compare to temperature and precipitation, a little work has been carried forward by the researchers on RH, most of result shows a decreasing trend of the RH (Akinbode, Eludoyin, & Fashae, 2008; Jayamurugan, Kumaravel, Palanivel, & Chockalingam, 2013; Liu, Zhang, Zhang, & Wa, 2015; Yao, Zhao, Wang, Wang, & Zhang, 2016; Russo, Sillmann, & Sterl, 2017; Chang, 2017), While few study shows increase of RH (Chau & Woo, 2015; Desai, Patel, Rathi, Wagle, & Desai, 2015; Coffel, Horton, & Sherbinin, 2018). Here, RH at 8.30 am and 5.30 pm of Indian Standard Time (IST) has been analyzed. The results (table 5 and 6) show that, average RH of all of the seasons shows significant increasing trend with winter (2.28 %), Summer (1.11%), monsoon (0.44%), post monsoon (1.80%) and overall annual (1.45%) RH at 8.30 am, while winter (2.25 %), summer (0.73%), monsoon (0.31%), post monsoon (1.25%) and overall annual (1.14%) RH at 5.30 pm respectively. While RH 75 percentile days (RH75P) and 50 percentile days (RH50P) of RH in different seasons at 8.30 am shows an alarming rate of increasing trend with maximum trend has been noticed in the post monsoon season with 13.77% (RH75P) and 12.28(RH50P) while at 5.30 PM, pre monsoon and monsoon RH shows a decreasing trend while post monsoon season has recorded significant increasing trend.

4. CONCLUSION

The changing nature of the climate of any city is a very prominent feature all over the world, as increasing trend of TNA is three times greater in the northern hemisphere than southern hemisphere due to predominance of landmass (Karl, 1993; Ji, 2014). Hence a city located in the northern hemisphere may face faster rate of positive temperature change in recent times and in upcoming future also. The IPCC predicts that world urban agglomeration will experience a minimum of 2°C warming excluding UHI effects, compare to the pre-industrial level, and it may rise a minimum of 2.5 °C in some urban centers in 2025 and this rise of the temperature may also exceed 4°C by the end of this century as per the Representation Concentration Pathway (RCP) 8.5 scenario. LST of the Kolkata shows an increasing trend in both summer and winter seasons. Annual, seasonal and monthly TXa, TNa and TNx also show increasing trends in Kolkata, whereas the TXx is not increased. Annual and decadal trend of Relative TIs increased throughout the time period and the alarming rate of increasing trend of warm nights has been noticed which were also seen by Rahimzadeh, et al. 2009; Kothawale, et al. 2010; Revadekar, 2010; Jain, & Kumar, 2012; Dashkhuu, et al. 2015; Oza, & Kishtawal, 2015; Zhang, et al. 2017 on their studies. DTR of Kolkata has been decreased very much. On the other hand, trend of PIs did not show any significant increasing or decreasing change, only wet days frequency in the post monsoon season shows an increasing trend with 10% significance level. In urban areas, due to increase in temperature, precipitation not increased which also found by (Ali & Mishra, 2017) on their work. On the other hand, RH has been increasing at a very alarming rate and the change has been very significant in most of the cases with the p value <0.0001. Increasing trend of RH in the night has more compare to day time, and TXa, TNa, TM also shows increasing trend which leads to more value of the heat index, which amplifying the heat stress (Russo, Sillmann, & Sterl, 2017). Increase of summertime of the RH may lead to more morbidity in urban areas (Chau & Woo, 2015).

ACKNOWLEDGEMENT

We would like to thank the Centre for Scientific and Industrial Research (CSIR), Ministry of Earth Science, for funding on the research work of the first author as a Research Fellow, and the India Meteorological Department (IMD) for providing necessary meteorological data.

1080 STATUS OF MUNICIPAL E-GOVERNANCE IN INDIA: A NEW APPROACH OF EVALUATION

ABSTRACT

Innovation in Information and Communication Technologies (ICTs) is bringing the world to one's home. It is not only speeding up processes and communication, but also makes information available to every human being on earth, irrespective of one's location and profile. Rapid urbanization and scarcity of time is making ICT enabled mechanisms more and more effective. Managing the urban centres; be it a town or a metropolis; is becoming the toughest job for municipal administrators. Making the system of urban governance good is a major challenge for the contemporary world. India, being a developing nation is progressing towards the establishment of a transparent and accountable system of governance. Urban India is engulfed by multifaceted problems relating to environment, economy, administration, society and polity. Technology is making the urban affairs E-savvy. The ICTs are crucial to foster economic growth and facilitate pro-citizen development. E-Governance provides the opportunity to streamline the functioning of Urban Local Bodies (ULBs). While providing opportunity to urban administrators to disseminate information, collect tax, registrar birth/death, provide licenses; also making it easier for the citizen to convey their opinion, lodge complaints, access services from home and participate in developmental activities of their neighbourhood. Since the system of electronic governance is multi-dimensional, it can't be gauged apparently by considering only a few factors. This study is therefore a systematic effort to evaluate the municipal E-Governance of some selected Indian ULBs, through a set of newly constructed indices like Institutional E-governance Index, Participatory E-Governance Index, Social E-Governance Index, Financial E-Governance Index, Environmental E-Governance Index and Citizen centric E-Governance Index. The gaps in the level of urban E-Governance in India with that of the other countries are also identified. The methodological framework of this study focuses on the different dimensions of urban management. Since websites are the mirror of functions and functionalities of any organization, the in-depth municipal website survey forms the database of this study. These website-based E-Governance evaluation indices involve unique analysis in the sense that it deals with the actual service delivery interface that the common people deal with. Rigorous evaluation of municipal E-Governance portrays an overall satisfactory performance of the ULBs. It is also observed that in general the ULBs tend to follow a similar pattern in all the indices. Large urban centres and metropolis exert overwhelming dominance over the smaller towns and cities. While, the performance of Pune and Madurai is the best in citizen-centrism of municipal E-Governance; Port Blair and Diu occupies the bottom of the table. Though the overall performance of the Indian ULBs is satisfactory, but it portrays a wide gap in general outlook and approaches of urban E-Governance of the global economic giants. This systematic endeavour spotted that the municipal E-Governance in India is oriented to satisfy the minimum needs of people and maintain regular municipal enterprises; but ULBs of developed countries are motivated to promote and holistic upliftment of standard of living of their citizens. The Indian ULBs should therefore concentrate upon improving efficiency of pro-people E-Governance.

1167 THE GEOGRAPHY OF POLITICAL IDEOLOGIES IN SWITZERLAND**Daniele Mantegazzi**Istituto di Ricerche Economiche, Università della Svizzera italiana, via Maderno 24, CH - 6900 Lugano, email: daniele.mantegazzi@usi.ch**ABSTRACT**

Income-sorting processes and partisan-sorting forces are hypothesized to be interrelated phenomena leading to the clustering of people having similar levels of income and political ideologies. This paper determines the predominant political ideology of each Swiss municipality and examines whether there is any spatial concentration of political ideologies. The contribution of this research is that it proposes a new way to capture social interactions, based on the geographical concentration of political ideologies, and, following the literature on “the geography of discontent”, it shows that these concentrations are correlated with income and income inequality.

Classification codes: O18, O43, P48, R1**Keywords:** Political ideologies, Economic geography, Spatial cohesion, Geography of discontent**1 INTRODUCTION**

Geographical sorting processes are phenomena that many societies all over the world have been experiencing for centuries, usually leading to the clustering of population based on socio-economic, religious or ethnic characteristics. Following the economic literature, individual income level plays an important role in sorting processes. On one hand, income could represent a constraint in the residential decision of people, as already formalized in the bid-rent theory (Fujita, 1989, based on the pioneering work of von Thünen, 1826 and Alonso, 1964), and, on the other hand, as already highlighted by Tiebout (1956), people prefer to live close to other people who are similar to themselves, also in terms of wealth. From an alternative perspective, in the political science literature there has been an increasing interest in the phenomenon of partisan sorting, which analyzes whether individuals are nowadays more geographically sorted according to their political preferences (Bishop, 2008; Abramowitz, 2010; Abrams and Fiorina, 2012; Tam Cho et al., 2013). Moreover, the literature on voting behavior highlights how individual socio-economic characteristics are important predictor of political preferences (Meltzer and Richard, 1981; Rueda and Stegmueller, 2014). This implies that people sorting themselves based on socio-economic characteristics are also expected to share similar political ideologies. Hence, various sorting processes are hypothesized to cluster people with analogous socio-economic characteristics and similar political preferences. This is closely related to recent findings on the importance of economic geography and regional differences in terms of economic welfare in explaining how people vote. The results of the Brexit referendum represent a key example, clearly showing that the level of local economy was an important driver, even after carefully controlling for individual characteristics (Los et al., 2017). This has led to the term “the geography of discontent”, referring to the spatial distribution of discontent in a country, reflecting inequalities between regions in terms of economic welfare. Hence, as already highlighted by O’Laughlin et al. (1994), the spatial dimension is extremely important and needs to be considered.

The aim of this paper is to propose a new definition of spatial cohesion, representing a new way to capture social interactions, based on the geographical concentration of political ideologies. More specifically, this paper contribute to the existing literature by empirically identifying whether there is any spatial concentration of political ideologies in the context of Switzerland and determining the spatial extension of these concentrations. Moreover, following the argument of “the geography of discontent”, this study analyzes whether this clustering of political preferences is correlated with income and income inequality. The analysis focuses on Switzerland, which represents a very interesting case because it practices a semi-direct democracy, which allows having a rich dataset on many referenda, which is independent from short-term, candidate-related and party-related factors.

Following Hermann and Leuthold (2003), this paper analyzes the results of 312 federal referenda between 1981 and 2017 at the municipal level. This study identifies Hermann and Leuthold (2003)’s three dimensions representing the Swiss political ideology space and expressing the following political beliefs: left vs. right, liberal vs. conservative and ecological vs. technocratic. Additionally, on each of these three dimensions, this paper empirically assesses the existence of spatial concentrations of Swiss municipalities sharing the same political ideology. This result is particularly interesting because it shows that the various sorting processes leading to the concentration of people sharing similar political preferences extend beyond municipal borders. Finally, based on these results, this research finds significant differences in the level of income and income inequality of Swiss municipalities, depending on their belonging to a political ideology cluster. This result contributes and further supports the findings and claims of other scholars, related to the concept of “the geography of discontent”, according to which economic geography is particularly important in understanding how people vote.

The rest of the paper is organized as follows. Section 2 presents a review of the related literature. The third and fourth sections describe the methodology and the database adopted for this research, respectively. In section five the results are presented and discussed, and the last section concludes.

2 LITERATURE REVIEW

Clustering processes refer to the geographical aggregation of people, usually sharing a specific characteristic, and are often the result of spatial sorting phenomena. Spatial sorting refers to the redistribution of population groups into different neighborhoods in both urban and non-urban areas (Kawachi and Berkman, 2003) and is a key characteristic of many cities and nations across the world (Bailey et al., 2017). In fact, for centuries societies have been experiencing processes of spatial sorting, typically based on socio-economic, religious or ethnic characteristics. Economists, among others, have been studying this phenomenon for many decades. Already in the classic framework of the bid-rent theory (Alonso 1964; Beckman, 1969; Muth, 1969; Mills 1972 based on the pioneering work of von Thünen, 1826), as shown by Fujita (1989), the price for real estate, changing with the distance from the city center, shapes the residential choices of various income groups within a society, generating income sorting. In this setting, spatial sorting is the result of different willingness to pay for different income classes. Another growing body of literature in economics links sorting processes to social interactions (Schelling, 1971; Clark, 1991; Fossett, 2006), where residential decision are driven by individual preferences for the neighborhood composition. In particular, people prefer to live in places in which other people are similar to themselves (McPherson et al., 2001; Musterd et al., 2015). The idea that people with similar preferences cluster in particular municipalities is the focus of another important stream of literature in economics, which goes back to Tiebout (1956), where, in a fiscal decentralized setting, people sort themselves according to their preferences to achieve an efficient provision of local public goods. This model has then been extended to analyze the important role of differences in income in explaining sorting processes (Ellickson, 1971; Westhof, 1977; Ross and Yinger, 1999; Schmidheiny, 2006). Hence, various theoretical frameworks analyze and give possible explanations of those sorting processes which can be found in many contexts all over the world.

From a slightly different perspective, in the political science literature, there has been a growing interest in the phenomenon of partisan sorting and there is currently a large debate on whether individuals are nowadays more sorted according to their political preferences. As highlighted by O’Laughlin et al. (1994), the spatial dimension is extremely important and needs to be considered in order to fully understand the political forces underlying this phenomenon. This is particularly relevant whenever the political power is partially decentralized (such as in a federal political system), given that various political institutions and political ideologies within the same country can generate different political contexts. Various studies find that, in the last decades, there has been an increase in the geographic polarization of voters (Kim et al., 2003; Bishop, 2008; Abramowitz, 2010; Wing and Walker, 2010; Tam Cho et al., 2013; Kinsella et al., 2015; Lang and Pearson-Merkowitz, 2015). The potential causes of this geographic polarization of voters are partisan migration, generational replacement and the fact that parties are more polarized, making it easier for voters to identify themselves with a party (Vegetti et al., 2017). Bishop (2008) argues that a potential drawback of this sorting process is that homogeneous communities might encourage extremism by ignoring differing opinions. In contrast with these results, other authors find that voters are nowadays no more geographically sorted than in the past and minimize its importance (Glaeser and Ward, 2006; Levendusky and Pope, 2011; Abrams and Fiorina, 2012; Strickler, 2016).

The vast majority of the studies analyzing the phenomenon of partisan sorting and polarization are based on presidential election in the US. As highlighted by Abrams and Fiorina (2012), data based on presidential elections are weak, because they are the result of short-term, candidate-related and party-related factors. Moreover, it is difficult to capture the complexity of the distribution of political ideologies with a single manifestation of the personal political preference, occurring only once every four years.

Additionally, the literature on voting behavior finds that socio-economic characteristics, such as income and the degree of income inequality, determine voting outcomes and are important predictors of party choice, at the individual level (Meltzer and Richard, 1981; McCarty et al., 2008, Rueda and Stegmueller, 2014).

Hence, different sorting processes are, on one hand, hypothesized to cluster people with analogous socio-economic characteristics, in particular with similar levels of income, and, on the other hand, group people sharing political preferences which are very much alike. At the same time, according to the literature on voting behavior, people sorting themselves based on socio-economic characteristics are also expected to share similar political ideologies. The implication is that income- sorting processes and partisan-sorting forces are likely to be interrelated phenomena, leading to the clustering of people having similar levels of income and political ideologies. This is closely related to recent findings on the importance of economic geography and regional differences in terms of economic welfare in explaining how people vote, in particular when the vote is used as a “mean of protest”. In particular, the results of the Brexit referendum, in which voters were asked whether they wished to leave or remain in the European Union, represent a key example, clearly showing that the level of local economy was an important driver (Los et al., 2017; Chen et al., 2018; Crescenzi et al., 2018). In fact, people in regions with lower levels of income who perceived to have suffered from modern globalization were more likely to vote “leave” than those from areas with higher levels of income (McCann, 2018). This has led to the term “the geography of discontent”, referring to the spatial distribution of discontent in a country, reflecting inequalities between regions in a country.

This paper contributes to the existing literature by proposing a new definition of spatial cohesion, based on the geographical concentration of political ideologies. In particular, the aim of this research is to empirically identify whether there is any spatial concentration of political ideologies in the context of Switzerland in order to determine in a new way the existence of social interactions, and determine the spatial extension of these concentrations. Moreover, following the argument of “the geography of discontent”, this study analyzes whether this concentration is correlated with income and income inequality.

Switzerland represents a very interesting case because it has strong institutions, it is a federal republic with highly decentralized political power and, at the same time, it practices a semi-direct democracy, in which Swiss citizens directly vote on various issues. More specifically, any constitutional change needs to be approved by a mandatory referendum. Furthermore, an optional referendum can be demanded for any change in the Swiss law decided by the federal parliament⁵⁶. Additionally, any Swiss citizen may propose a popular initiative to introduce amendments to the federal constitution⁵⁷. The outcome of any vote is legally binding. Approximately, Swiss citizens vote four times a year and the most frequent topics on which they vote are healthcare, taxes, social welfare, drug policy, public transport, immigration, political asylum and education. The availability of referendum data allows overcoming the limitations of presidential election data mentioned above, and better determining the spectrum of political ideologies of voters. In particular, given that Swiss citizens directly express their opinion on various issues, the information available is independent from short-term, candidate-related and party-related factors. Moreover, the political preference is manifested several times every year. Hence, unlike the analyses on presidential elections or the Brexit referendum, this study simultaneously considers the results of several referenda, capturing the underlying long-term structure of political ideologies.

3 METHODOLOGY

The analysis presented in this study proceeds in three phases. The first step is to identify what is the political ideology of each municipality in Switzerland. Second, a spatial cluster analysis is performed in order to determine whether and where there is a significant geographical concentration of political ideologies. Finally, some tests are carried out to analyze whether the level of income and income inequality of municipalities belonging to different political ideology clusters are significantly different.

The first task is to establish the political ideology of each municipality. To do so, this study follows Hermann and Leuthold (2001; 2003), by considering the federal referenda collected at the municipal level in Switzerland and performing an exploratory factor analysis on them. The underlying idea is that the referenda are the observed outcome of fewer independent and unobserved dimensions characterizing the political ideology space. This hypothesis is supported by qualitative and quantitative considerations related to the data used. In particular, from a qualitative perspective, several referenda concern the same (or at least very similar) topic. One can therefore expect that the outcome of referenda on similar topics are highly correlated because are driven by the same underlying political preference. Indeed, from a quantitative perspective, the distribution of referenda shows that they are spatially associated, indicating that the variance of the referenda exhibits similar patterns. In order to maximize the explained variance, the exploratory factor analysis is performed with VARIMAX-rotation.

The results of the factor analysis allow extracting the statistical relationship among the referenda in order to determine the underlying unobserved factors. However, as highlighted by Hermann and Leuthold (2003), in order to meaningfully interpret them and identify the related ideological content, a qualitative interpretation of the specific political objects is needed. The combination of the factor analysis with the qualitative inspection of its results allows finding the dimensions representing the Swiss political ideology space.

In the second step, in order to measure the degree of geographical concentration of the political ideology, a spatial cluster analysis is performed. Following Kim et al. (2003), Darmofal (2008), Wing and Walker (2010) and Kinsella et al. (2015), this study computes the vector of Local Moran's I statistic (Moran, 1948; Cliff and Ord, 1981; Anselin, 1995) for each factor identified in the previous phase. The Local Moran's I statistic associates a vector of observed values of a specific variable with a weighted average of the neighboring values and compares the real distribution with random spatial distributions, in order to capture significant spatial pattern. In particular, this analysis is able to establish whether a municipality has a significantly high (low) value on a specific factor and is surrounded by municipalities with high (low) values on the same factor, or whether the value of the municipality is not significantly high or low. Hence, this analysis allows determining if and where there is a significant geographical concentration of the different typologies of political ideologies identified with the previous step.

Finally, following the social capital argument, the analysis focuses on empirically testing whether there is any evidence suggesting that there are significant differences in the level of income and income inequality of municipalities belonging to different typologies of political ideology clusters. The aim of this exercise is to follow the recent literature on the "geography of discontent" in order to verify whether the claim that economic geography is particularly important in understanding how people vote is valid even in the Swiss context, by simultaneously considering the results of several referenda, capturing the underlying long-term structure of political ideologies. To do so, Kruskal-Wallis tests are performed (Kruskal and Wallis, 1952). Similar to ANOVA, this test is used to verify whether the distribution of a specific variable is significantly different between more than two independent groups. However, differently from ANOVA, the Kruskal-Wallis test does not require the assumptions of homogeneity of variance between the groups and the normality of residuals. The result of the Kruskal-Wallis test indicates whether there are significant differences among the groups, however, it does not provide information regarding which pairs of groups are significantly different. Hence, this final phase is extended by computing the Dunn's test (Dunn, 1964), which is a post hoc pairwise multiple comparison suitable to deepen the analysis after a rejection of the Kruskal-Wallis test. In order to account for the fact that multiple

56 Any change to the Swiss law is subject to referendum if a minimum of 50'000 Swiss people have signed an official request to do so within 100 days.
57 In the case of a federal popular initiative, a vote is organized if the promoter collects at least 100'000 signatures from Swiss people within 18 months.

comparisons are conducted at the same time, Dunn's tests are performed with the Benjamini-Hochberg procedure (Benjamini and Hochberg, 1995).

4 DATA

This research analyzes the results at the municipal level concerning all the 312 federal referenda between 1981 and 2017. This information is obtained from the section Politics, Culture and Media of the Swiss Federal Statistical Office (FSO)⁵⁸. In particular, the factor analysis performed in order to identify the political ideology of each Swiss municipality is computed on the yes-share of all the 312 federal referenda considered⁵⁹. In order to compare and combine the data in terms of geo-political unit, all the referenda are based on the 2017 municipal definition of the FSO, which includes 2240 municipalities.

As explained above, the most frequent topics on which Swiss citizens vote are healthcare, taxes, social welfare, drug policy, public transport, immigration, political asylum and education. In order to capture changes in the political ideology of each municipality through time, the factor analysis is computed on different time-subsamples of the whole dataset. In particular, the first subsample considers all the 65 referenda between 1981 and 1990, the second subsample takes into account all the 106 referenda between 1991 and 2000; the third one contains all the 82 referenda between 2001 and 2010, and the fourth subsample considers all the 59 referenda between 2011 and 2017. As the results show, given that the Swiss population periodically votes on the same topics, the factor analyses computed over different time-subsamples generate factors which are built in a very similar way, allowing comparing the results from different periods.

To perform spatial analyses, there exist different specification of the spatial dependence matrix, W .

In order to take into consideration the impact of the extremely uneven topographical context of Switzerland⁶⁰ on the actual distance between two municipalities, this study considers a spatial weight matrix based on the inverse travel time between the centroids of the municipalities. Travel time data are provided by the Swiss Federal Office for Spatial Development and consider the trip by car in minutes. To keep the spatial analysis at a local level, after examining the distribution of distances between Swiss municipalities, a cutoff is imposed at a distance of 20 minutes travel time. Moreover, following the spatial econometric literature (Anselin, 1988; Kelejian and Prucha, 1998; LeSage and Pace, 2009), the W matrix has been standardized, such that each row sums to unity.

In the final part of this research, the aim is to test whether there are significant differences in the economic welfare level of municipalities belonging to different typologies of political ideology clusters. In particular, this study considers the median income and the Gini coefficient of the income distribution of each municipality. All these variables are obtained from the Swiss Federal Tax Administration. The analysis is done for each of the four time-subsample and the reference year for the economic welfare variable is the first year of the considered period⁶¹.

5 RESULTS AND DISCUSSION

This section first presents the results of the exploratory factor analysis and describes the identified dimensions of the political ideology space. Subsequently, the results of the spatial cluster analysis are shown. Finally, the discussion ends focusing on the results of the tests, which aim at verifying whether there are significant differences in the income level and income distribution of municipalities belonging to different typologies of political ideology clusters.

Factor analysis

In order to be consistent with the existing literature on the identification of the Swiss political ideology structure, this study follows Hermann and Leuthold (2003) and performs a factor analysis⁶² for each period identifying the same three unobserved factors they found. These three factors are able to capture between 55 and 60% of the overall variance of all the referenda, depending on the period considered. This indicates that the majority of political ideologies in Switzerland can be represented by three main dimensions. In order to give a meaningful interpretation to the resulting factors, the analysis considers from a qualitative perspective the ideological content of the referenda building them.⁶³

Considering the most important referenda building factor 1 in the period 1981-1990, factor 3 in the period 1991-2000, factor 2 in the decade 2001-2010 and factor 1 in the period 2011-2017, it emerges that they are based on topics related to the protection of the workforce (e.g. the popular initiative on shortening working hours in 1988, the popular initiative for a flexible retirement age in 2000, or the popular initiative for a minimum wage in 2014), the welfare state (such as the amendment to the federal law on aged and bereaved insurance in 1995, the popular initiative "Health has to be affordable" in 2003, or the popular initiative for a basic income in 2016), and the national security policy (for example the popular initiative for a Switzerland without army and a comprehensive policy of peace in 1989, the popular initiative for a voluntary civilian peace service in 2001, or the popular initiative on the abolition of compulsory military service in

58 It is possible to download the municipal-level results of Swiss referenda at the following webpage:

<https://www.bfs.admin.ch/bfs/de/home/statistiken/politik/abstimmungen/stimmbeteiligung.assetdetail.3362356.html>

59 The factor analysis is able to account for the fact that the wording of referenda on similar topics could be inconsistent, by giving positive or negative factor loadings.

60 Switzerland is characterized by flat areas and regions with very high mountains.

61 For the third period, data on median income and Gini coefficients are not available for the year 2001. Hence, information for the year 2003 are used instead.

62 The results of the factor analysis are reported in Appendix A.

63 The final factors are built considering all the votes with a factor loading of at least 0.5 (in absolute terms).

2013). Hence, as in Hermann and Leuthold (2003), these factors represent the “Left-Right” dimension of the political ideology space. In particular, these factors are capturing the debate between those who are in favor of the welfare state, the protection of the workforce, personal freedom and pacifism on one hand (i.e. with a left-wing perspective), and on the other hand those that have more propriety-oriented values, support the military strength and entrepreneurial freedom (i.e. with a right-wing perspective).

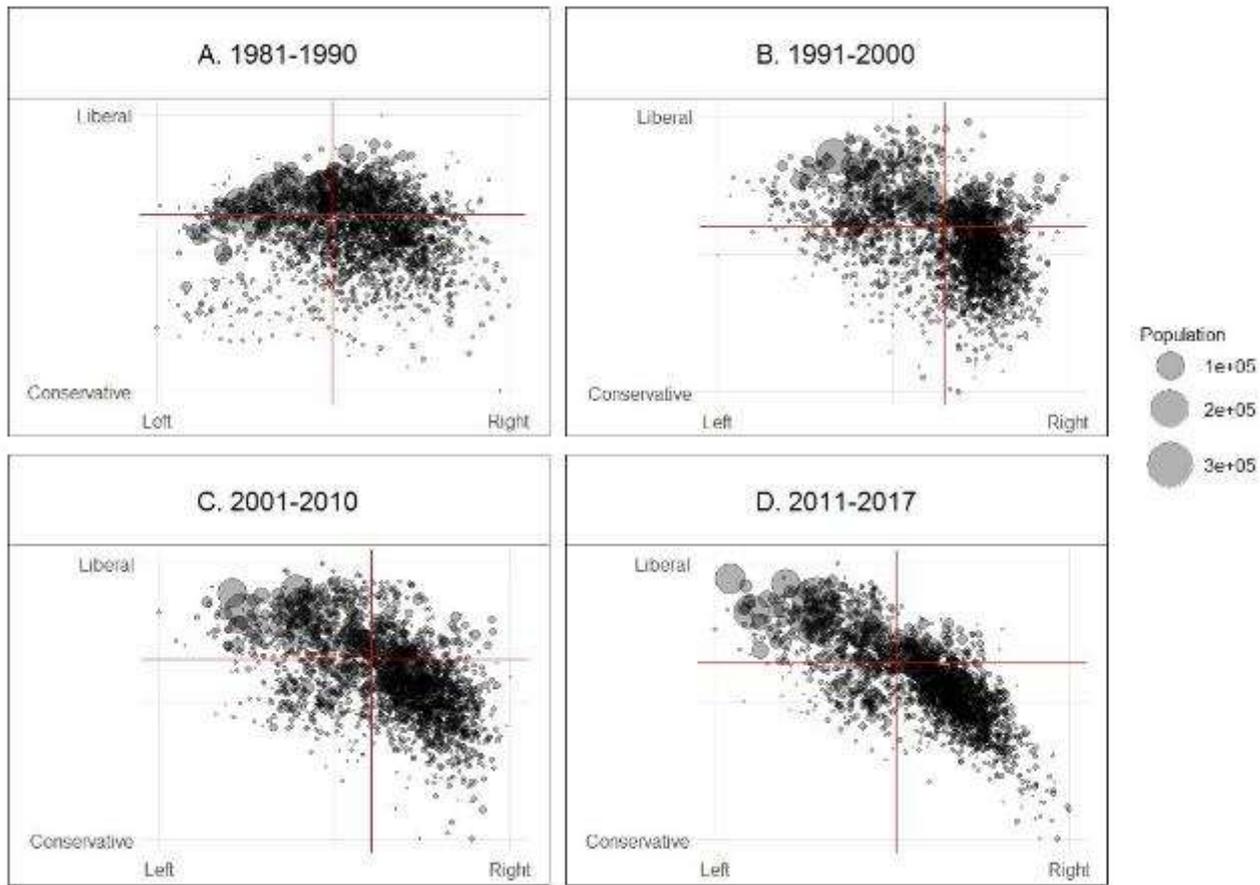

A different dimension of the political ideology structure of Switzerland is represented by factor 3 in the decade 1981-1990, factor 1 in the period 1991-2000, factor 1 in the decade 2001-2010 and factor 2 in the period 2011-2017. Analyzing the main referenda contributing to the construction of these factors, it appears that they link to topics related to foreign integration (such as the federal decree for a review of the procedure for naturalizing young immigrants in 1994, the popular initiative against the construction of new minarets in 2009, or the popular initiative against mass immigration in 2014), liberal economic policies (e.g. the federal decree on joining Bretton Woods in 1992, the popular initiative for Switzerland to join the United Nations in 2002, or the federal decree on extending the agreement on free movement of people to new countries of the European Union in 2005), and regulatory modernization (for example the federal law on government and administrative organization in 1996, the federal decree on a new Swiss Federal Constitution in 1999, or the federal decree on the non-introduction of public initiatives in 2009). Also in this case, the results are in line with those of Hermann and Leuthold (2003), in fact, these factors express the “Liberal-Conservative” dimension of the political ideology space. In particular, this dimension is representing the debate between those who support the opening of the country, are in favor of liberal economic policies and the modernization of institutions (i.e. with a liberal attitude), and those who are more skeptical towards changes and the opening of the country, prefer to preserve the existing regulations and mistrust the political and economic elites (i.e. with a conservative attitude).

Finally, the third dimension of the Swiss political ideology space is captured by factor 2 in the decades 1981-1990 and 1991-2000, and factor 3 in the periods 2001-2010 and 2011-2017. This dimension is based on topics related to traffic (e.g. the popular initiative “Stop the concrete - for a limitation on road making” in 1990, the popular initiative for the protection of the alpine region from traffic in 1994, or the popular initiative on lowering the urban speed limit to 30 km/h in 2001), and environmental protection (such as the federal decree on varying tolls based on engine power or mileage in 1994, the federal decree on providing enhanced legal protection for animals in 2010, or the popular initiative for the introduction of a tax on non-renewable energy in 2015). These factors represent the “Ecological-Technocratic” dimension identified by Hermann and Leuthold (2003). More specifically, this dimension expresses the debate between those who support the protection of the natural environment and are in favor of policies reducing the negative impact of human activities on nature (i.e. with an ecological attitude), and those who believe that the natural environment should be transformed to create more security and comfort, and used to generate technological progress (i.e. with a technocratic attitude).

The results of the factor analysis show that the political ideology of Swiss municipalities can be represented in a three-dimensional space, in which the three independent axes express the following political debates: left vs. right, liberal vs. conservative and ecological vs. technocratic. Figure 1 shows the political ideology position of Swiss municipalities on two of these three dimensions, for each considered period. In particular, the horizontal axis expresses the “Left-Right” dimension, while the vertical axis maps the position of each municipality on the “Liberal-Conservative” dimension⁶⁴. Each dot represents a municipality, and the size of the dots indicates the dimension of the municipality, in terms of inhabitants in the first year of the considered period. The red lines show the overall national position on these two dimensions. This graphical representation allows highlighting the following two remarks. Firstly, in the first two decades the positions of Swiss municipalities are spread on all four quadrants, however, in the last two periods (in particular in the last one) the political ideology positions of Swiss municipalities are mainly concentrated in the “Left-Liberal” and “Right-Conservative” quadrants. Hence, this first graphical representation highlights a phenomenon of increasing polarization that is characterizing the Swiss political ideology space. Moreover, to better capture political preferences and the underlying political forces, it is important to consider more than a single political dimension, which, additionally, should be independent from short-term, candidate-related and party-related factors. Secondly, by simultaneously taking into considerations both these dimensions and the size of each municipality, in terms of number of inhabitants, it emerges that the position on the political ideology space is also a manifestation of the rural-urban divide. In fact, in line with Hermann and Leuthold (2003), cities and bigger municipalities are mainly positioned in the “Left-Liberal” quadrant, while smaller and rural communes are mainly found in the “Right-Conservative” quadrant.

Figure 1 – The political ideology position of Swiss municipalities

⁶⁴ The two-dimensional graphical representation is preferred to the three-dimensional one because easier to interpret. The choice of the two dimensions to consider is based on their importance in explaining the overall variance of political preferences, as indicated from the results of the factor analysis.

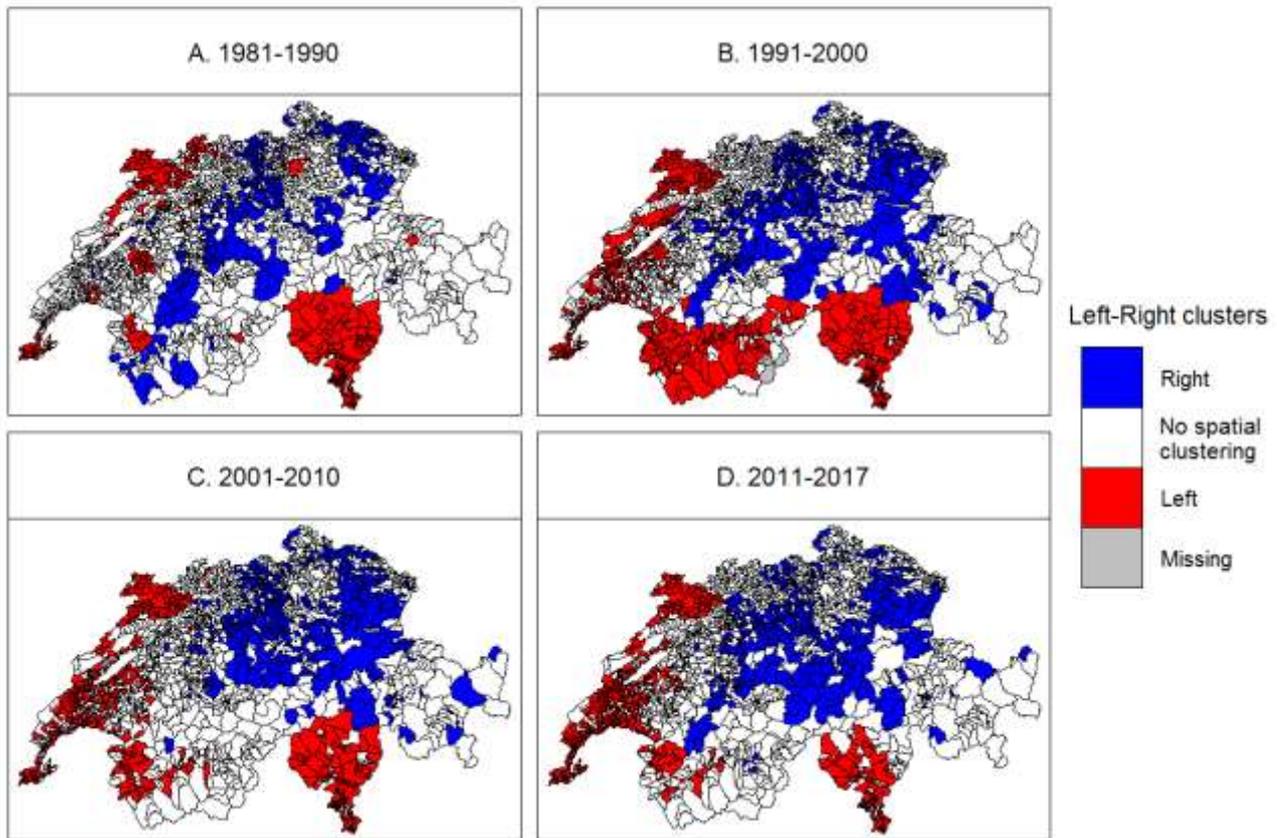

The identification of the political ideology of Swiss municipalities allows continuing the analysis with spatial cluster methods in order to empirically assess the degree of geographical concentration of political ideologies.

Spatial cluster analysis (Local Moran's I)

Following Kim et al. (2003), Darmofal (2008), Wing and Walker (2010) and Kinsella et al. (2015), the second phase of this analysis applies spatial cluster analysis to identify whether and where the political ideologies of Swiss municipalities are geographically concentrated. In particular, local Moran's I statistics for each of the three dimensions determined with the factor analysis are computed and then plotted in order to visualize the spatial pattern of significant concentration of political ideologies.

Figure 2 plots the results of the local Moran's I statistics for the "Left-Right" dimension as a set of significance maps for the four different periods. Municipalities exhibiting significant spatial clustering of the right-wing political ideology are shown in blue, while those belonging to a significant geographical concentration of the left-wing political ideology are colored in red. This graphical visualization clearly illustrates that the "Left-Right" dimension of the Swiss political ideology space is characterized by geographical concentrations of municipalities with similar political preferences. More specifically, in line with the results of Hermann and Leuthold (2003), right-wing municipalities are predominantly clustered in the rural areas of the German speaking part of Switzerland, i.e. the center and north-east parts.

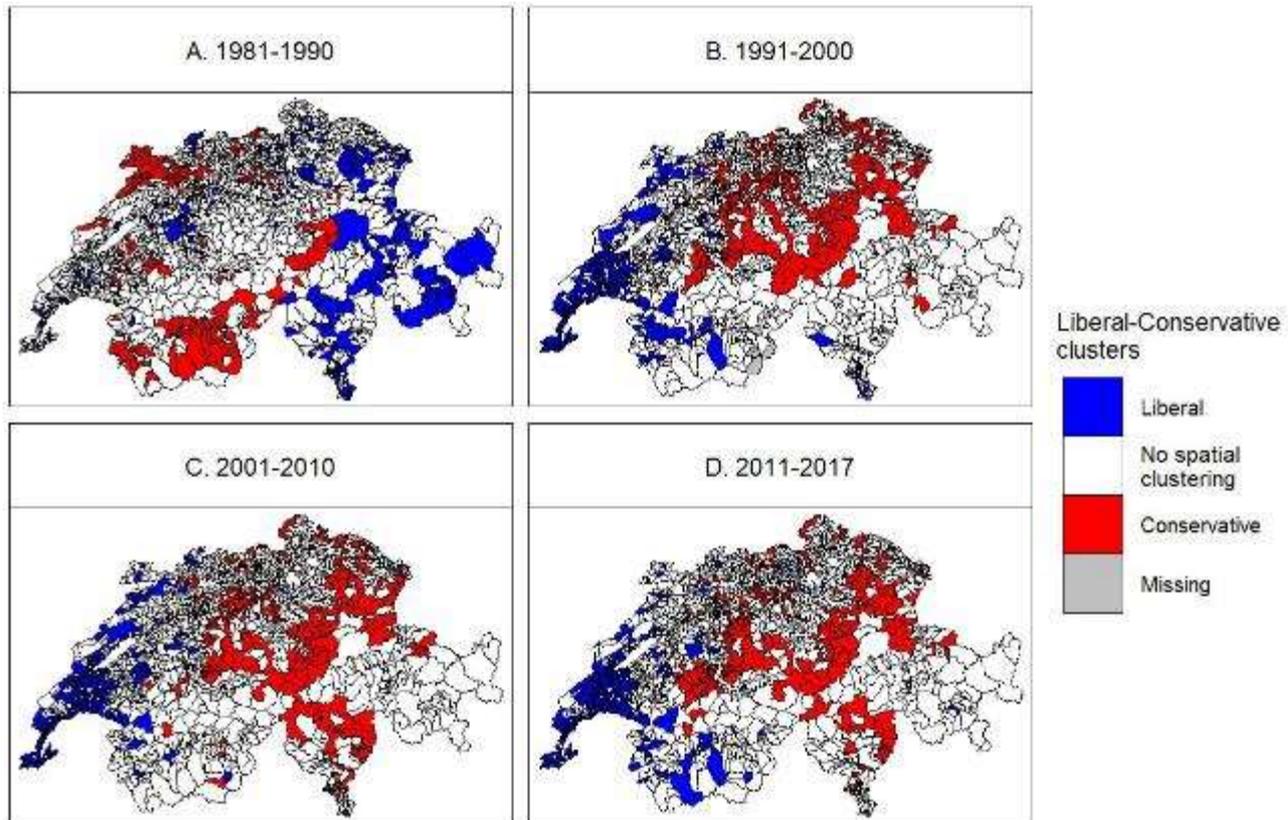

Figure 2 - Local Moran's I statistics for the Left-Right dimension

Additionally, left-wing municipalities are mainly concentrated in the Italian and French speaking part of Switzerland, i.e. in the south and in the west parts, respectively. The results also show that through time there has been some minor changes. More specifically, the geographical concentrations of right-wing municipalities are increasing in the central part of Switzerland, while the ones concerning left-wing municipalities are increasing in the western part of Switzerland and decreasing in the south, after an increase in the second period.

The results concerning the spatial cluster analysis on the “Liberal-Conservative” dimension of the Swiss political ideology space are shown in Figure 3. In this case, municipalities marked in blue belong to significant geographical concentrations of communes with a liberal political preference, while those colored in red are municipalities exhibiting significant spatial clustering of the conservative political ideology. The first consideration emerging from this graphical visualization is that geographical concentrations of political ideologies occurs also on the “Liberal-Conservative” dimension. More specifically, liberal municipalities are mainly clustered around the Swiss central-western cities and in the French speaking part of Switzerland. On the other side, the conservative municipalities are mainly concentrated in the rural areas of the German and Italian speaking parts of Switzerland, i.e. in the east and in the south-east, respectively.

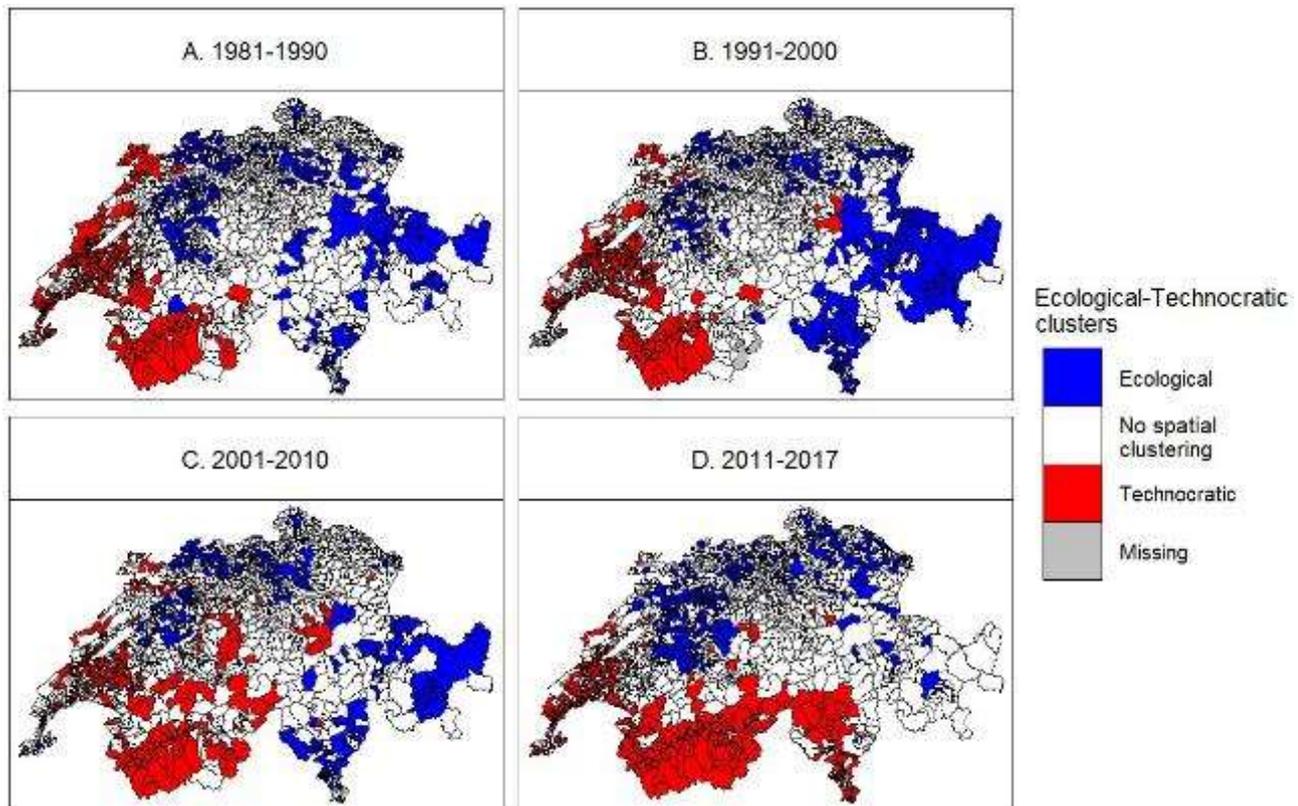

Figure 3 - Local Moran's I statistics for the Liberal-Conservative dimension

Considering the temporal evolution of the geographical concentrations of political ideologies along the “Liberal-Conservative” dimension, it clearly emerges that the first decade shows different patterns than the other three periods. As highlighted by Hermann and Leuthold (2003), this can be explained by the fact that the debate between liberals and conservatives in Switzerland became significantly important at the beginning of the nineties, when the discussion concerning the relationship between Switzerland and Europe started.

Finally, Figure 4 maps the results of the cluster analysis on the “Ecological-Technocratic” dimension of the Swiss political ideology space. Municipalities belonging to a significant geographical concentration of the ecological political ideology are colored in blue, while communes exhibiting significant spatial clustering of the technocratic political ideology are marked in red. Even in this case the results show that there are geographical concentrations of municipalities with similar political preferences. Ecological municipalities are mainly concentrated close to the big cities of the German speaking part of Switzerland (i.e. in the center and north-east parts) and in the rural areas in the east and south-east. On the contrary, technocratic communes are predominantly clustered in the rural areas of the French speaking part of Switzerland (i.e. in the west). The temporal perspective allows determining that the geographical concentrations of ecological municipalities have decreased, in particular in the rural areas in the east and south-east part of Switzerland. Moreover, the spatial concentrations of technocratic municipalities have increased in the south, but diminished in the north-west.

Figure 4 - Local Moran's I statistics for the Ecological-Technocratic dimension

Overall, the results of the spatial cluster analysis highlight that along all the three dimensions characterizing the Swiss political ideology space there are geographical concentrations of municipalities with similar political preferences. The geographical representations of these results show that the “Left-Right” dimension is characterized by many and wider clusters, while the “Liberal- Conservative” dimension is defined by fewer and narrower concentrations. Hence, it seems that there are stronger sorting and polarizing effects along the “Left-Right” axes and weaker along the “Liberal-Conservative” one, with the dimension related to the “Ecological-Technocratic” debate somewhere in between. These results are particularly interesting because they show that social interactions, captured as the geographical concentration of political ideologies, extend beyond municipal borders and further support the importance of analyzing these clusters.

Kruskal-Wallis and Dunn tests

The results discussed above indicate that Switzerland is characterized by geographical concentrations of political ideologies along various dimensions. As mentioned above, partisan-sorting processes are expected to be interrelated with income-sorting processes, implying that these phenomena are likely to lead to the clustering of people having similar levels of income and political ideologies. This hypothesis is also supported by the literature on “the geography of discontent” (Los et al., 2017; Chen et al., 2018; Crescenzi et al., 2018) as well as the one on voting behavior (Meltzer and Richard, 1981; McCarty et al., 2008, Rueda and Stegmüller, 2014). Hence, the final phase of this analysis aims at empirically verifying whether there are differences in economic welfare among municipalities belonging to different clusters of political ideologies. In particular, Kruskal-Wallis tests are performed on the median income and the Gini coefficient of the income distribution of each municipality, to verify whether the distribution of these variables are significantly different among municipalities belonging to different aggregations of political ideologies and that do not belong to any cluster. These tests are carried out for each dimension of the Swiss political ideology space and for each period previously considered, separately, and are reported in Table 1, Table 2 and Table 3, along with the median value of the considered variables for each cluster of municipalities. Additionally, Dunn’s tests are performed in order to exactly identify which pairs of groups are significantly different. Given that multiple tests are carried out at the same time, these tests are corrected with the Benjamini-Hochberg procedure⁶⁵.

Considering the “Left-Right” dimension, the results, as reported in Table 1 and in Tables B.1 and B.2 of Appendix B, indicate that the clusters of left-wing and right-wing municipalities are characterized by significant differences in the distributions of both median income and the Gini coefficient of the income distribution, with the exception of the decade 2001-2010 for median income.

Table 1 – Results of the Kruskal-Wallis tests on the “Left-Right” dimension

⁶⁵ The results of the Dunn’s tests are reported in Appendix B, along with the median value of the considered variables for each group of municipalities and for each period.

	1981-1990	1991-2000	2001-2010	2011-2017
Median income	$\chi^2(2) = 55.1$ p < 0.001	$\chi^2(2) = 125.3$ p < 0.001	$\chi^2(2) = 0.8$ p = 0.66	$\chi^2(2) = 62.8$ p < 0.001
Median “Left”	32’500 CHF	44’350 CHF	54’967 CHF	61’800 CHF
Median “Not Significant”	34’000 CHF	48’050 CHF	56’000 CHF	59’550 CHF
Median “Right”	32’250 CHF	48’500 CHF	55’925 CHF	56’600 CHF
Gini coefficient of the income distribution	$\chi^2(2) = 75.1$ p < 0.001	$\chi^2(2) = 23.6$ p < 0.001	$\chi^2(2) = 11.3$ p < 0.001	$\chi^2(2) = 113.0$ p < 0.001
Median “Left”	0.317	0.329	0.316	0.360
Median “Not Significant”	0.308	0.316	0.310	0.336
Median “Right”	0.290	0.318	0.310	0.328

By taking into account the median income for each cluster, it is not possible to find a clear pattern showing which cluster of political ideology is associated with higher (lower) values of median income in the four considered periods. On the other hand, the results indicate that municipalities belonging to a geographical concentration of a left-wing political ideology are characterized by a significantly higher Gini coefficient of income distribution, when compared to those with a right-wing political ideology, showing that there is a higher demand for left-wing policies where there are higher degrees of income inequality. Hence, these findings indicate that groups of municipalities with a significant left-wing ideology are characterized by significantly higher degrees of income inequality, in line with the findings of the literature on voting behavior (Meltzer and Richard, 1981; McCarty et al., 2008, Rueda and Stegmüller, 2014).

Table 2 – Results of the Kruskal-Wallis tests on the “Liberal-Conservative” dimension

	1981-1990	1991-2000	2001-2010	2011-2017
Median income	$\chi^2(2) = 105.0$ p < 0.001	$\chi^2(2) = 97.4$ p < 0.001	$\chi^2(2) = 335.6$ p < 0.001	$\chi^2(2) = 314.1$ p < 0.001
Median “Conservative”	30’775 CHF	45’650 CHF	52’200 CHF	54’200 CHF
Median “Not Significant”	33’600 CHF	47’125 CHF	55’800 CHF	59’150 CHF
Median “Liberal”	34’850 CHF	50’050 CHF	62’500 CHF	68’400 CHF
Gini coefficient of the income distribution	$\chi^2(2) = 157.9$ p < 0.001	$\chi^2(2) = 140.5$ p < 0.001	$\chi^2(2) = 120.0$ p < 0.001	$\chi^2(2) = 203.0$ p < 0.001
Median “Conservative”	0.279	0.304	0.297	0.317
Median “Not Significant”	0.304	0.322	0.311	0.337
Median “Liberal”	0.335	0.338	0.331	0.371

Focusing the attention to the “Liberal-Conservative” dimension, the results, as indicated in Table 2 and in Tables B.2 and B.3 of Appendix B, show that among the clusters of liberal and conservative municipalities there always are significant differences in the distributions of both median income and the Gini coefficient of the income distribution.

Moreover, both the median income and the Gini coefficient of the income distribution in clusters of liberal municipalities are in each period significantly higher than those of municipalities that do not belong to any cluster, along this dimension, and even higher than those of municipalities linked to a conservative cluster. Therefore, these results show that clusters of municipalities with a significant liberal ideology are characterized by significantly higher levels of economic welfare as well as significantly higher degrees of income inequality.

Finally, considering the “Ecological-Technocratic” axis of the Swiss political ideology space, the results, as reported in Table 3 and in Tables B.5 and B.6 of Appendix B, indicate that the clusters of ecological and technocratic municipalities are characterized by significant differences in the distributions of both median income and the Gini coefficient of the income distribution.

Table 3 – Results of the Kruskal-Wallis tests on the “Ecological-Technocratic” dimension

	1981-1990	1991-2000	2001-2010	2011-2017
Median income	$\chi^2(2) = 31.1$ p < 0.001	$\chi^2(2) = 13.7$ p < 0.001	$\chi^2(2) = 58.3$ p < 0.001	$\chi^2(2) = 7.1$ p = 0.03
Median “Ecological”	34’700 CHF	48’000 CHF	58’000 CHF	58’400 CHF
Median “Not Significant”	33’050 CHF	47’400 CHF	55’925 CHF	59’400 CHF
Median “Technocratic”	33’117 CHF	45’938 CHF	53’150 CHF	60’300 CHF
Gini coefficient of the income distribution	$\chi^2(2) = 26.9$ p < 0.001	$\chi^2(2) = 128.7$ p < 0.001	$\chi^2(2) = 37.0$ p < 0.001	$\chi^2(2) = 195.9$ p < 0.001
Median “Ecological”	0.311	0.343	0.323	0.327
Median “Not Significant”	0.302	0.313	0.308	0.333
Median “Technocratic”	0.315	0.318	0.307	0.373

In addition, both the median income and the Gini coefficient of the income distribution in clusters of ecological municipalities are significantly higher than those of municipalities belonging to a technocratic cluster, with the exception of the last period, which, interestingly, shows opposite results. Hence, between 1981 and 2010, clusters of municipalities with a significant ecological ideology are characterized by significantly higher levels of economic welfare as well as significantly higher degrees of income inequality. However, in the period 2011-2017 the reverse is true, i.e. clusters of municipalities with a significant technocratic ideology have a significantly higher median income as well as significantly higher degrees of income inequality.

Overall, these results clearly indicate that there are significant differences in the level of income and income inequality of Swiss municipalities, depending on their belonging to a political ideology cluster. These findings seem to support the hypothesis that partisan-sorting processes are interrelated with income-sorting processes and contributes to the literature on “the geography of discontent”, according to which economic geography is particularly important in understanding how people vote.

6 CONCLUSION

This paper proposes a new definition of spatial cohesion, based on the geographical concentration of political ideologies, which represents a new way to capture social interactions. The application of spatial cluster analysis empirically assesses the existence of spatial concentrations of Swiss municipalities sharing the same political ideology. This first result is particularly interesting because it shows that social interactions, captured as the geographical concentration of political ideologies, extend beyond municipal borders and further supports the importance of analyzing these clusters. Moreover, this result is valid for all the three main dimensions characterizing the Swiss political ideology space, expressing the following political beliefs: left vs. right, liberal vs. conservative and ecological vs. technocratic. Additionally, these findings seems to indicate that there are stronger clustering effects along the “Left-Right” axes and relatively weaker along the “Liberal-Conservative” one.

Moreover, a second important finding of this paper indicates that the geographical distribution of the clusters of political ideologies are also a manifestation of the rural-urban divide as well as the cultural divides among the different linguistic regions of Switzerland. In particular, geographical concentrations of left-wing municipalities are mainly located close to cities and in the French and Italian speaking parts of Switzerland, while clusters of right-wing municipalities are predominantly found in rural areas and in the German speaking part of Switzerland. At the same time, spatial concentrations of liberal municipalities are mostly situated close to cities and in the French speaking part of Switzerland, whereas clusters of conservative communes are mainly located in rural areas and in the German and Italian speaking regions of Switzerland. Additionally, clusters of ecological municipalities are predominantly found around cities and in the German speaking part of Switzerland, while agglomerations of technocratic communes are mostly located in rural areas and in the French speaking region of Switzerland. Moreover, the evolution of such divides between 1981 and 2017 seems to suggest that the Swiss political ideology space is characterized by a phenomenon of increasing polarization.

Thirdly, this study finds significant differences in income levels and income inequalities among Swiss municipalities, depending on their belonging to a political ideology cluster. More specifically, clusters of left-wing municipalities are characterized by significantly higher degrees of income inequality, when compared to aggregations of right-wing municipalities. At the same time, the results indicate that clusters of liberal communes have a significantly higher median income and a higher degree of income inequality, compared to concentrations of conservative municipalities. Moreover, with the exception of the period 2011-2017, clusters of ecological communes have a significantly higher median income and a higher degree of income inequality, compared to concentrations of technocratic municipalities.

Hence, these findings indicate that clusters of communes with a similar political ideology group either urban municipalities with relatively high levels of income and high degrees of inequality (as in the cases of left, liberal or ecological clusters) or rural communes with relatively low levels of income and low degrees of inequality (for the cases of right, technocratic or conservative clusters). Interestingly, the empirical evidence does not show any political ideology clustering of “privileged” communes (i.e. with high levels of income and low degrees of inequality), nor “left-behind” municipalities (i.e. with low levels of income and high degrees of inequality).

In conclusion, besides identifying the political preference of Swiss municipalities, these results highlight the importance of the geography of these political ideologies, and, in particular, of their spatial concentration. This result contributes and further supports the findings and claims of the literature on “the geography of discontent”, according to which economic geography is particularly important in understanding how people vote. These findings are particularly interesting because they emerge from a study simultaneously considering the results of several referenda, capturing the underlying long-term structure of political ideologies, which is independent from short-term, candidate-related and party-related factors. The existence of differences in economic welfare among municipalities belonging to different clusters of political ideologies implies that future research should consider this new definition of spatial cohesion in order to understand how and why different concentrations of political preferences are associated to different levels of welfare.

APENDIX A – RESULTS OF THE FACTOR ANALYSES

Table A.1: Factor scores for the period 1981-1990

Vote	Factor 1	Factor 2	Factor 3
Federal decree on the popular initiative for gender equality (counter-proposal)	0,72	0,31	0,2
Federal decree on the popular initiative the protection of consumer rights (counter-proposal)	0,67	-0,13	0,36
Federal decree on prolonging the federal finance order	0,01	0,01	0,62
New federal law on foreigners	-0,42	-0,05	0,39
Amendment to the Swiss penal code	0,2	-0,43	0,49
Popular initiative for the prevention of abusive prices	0,76	0,24	-0,06
Federal decree on the popular initiative for the prevention of abusive prices (counter-proposal)	-0,47	0,11	0,22
Federal decree on changes to fuel tax	0,36	-0,1	0,58
Federal decree on the constitutional article on energy	0,18	-0,4	0,28
Federal decree on the revision of nationality law in the Federal Constitution	0,18	-0,08	0,67
Federal decree aiming at facilitating certain naturalizations	0,21	-0,14	0,49
Federal decree on introducing tolls for heavy goods vehicles	-0,07	0,71	0,24
Federal decree on introducing tolls for national routes	0,21	0,62	0,41
Popular initiative for a real civilian service based on a proof through demonstration	0,79	0,06	0,17
Popular initiative against the abuse of bank client confidentiality and bank power	-0,15	0,8	0,03
Popular initiative against slashing the national soil	0,15	0,67	0,05
Popular initiative for a future without further nuclear power plants	0,62	0,09	-0,05
Popular initiative for a secure, parsimonious and ecologically sound energy supply	0,59	0,09	-0,12
Popular initiative for an effective protection of maternity	0,05	0,55	0,57
Federal decree on the constitutional article on broadcasting	0,29	0,11	0,76
Popular initiative for the compensation of victims of violent crimes	0,76	-0,17	0,11
Federal decree on abolishing primary school fees	-0,31	0,17	0,78
Federal decree on abolishing the government contribution to healthcare spending	-0,35	0,07	0,76
Federal decree on education fees	0,84	0,01	-0,08
Popular initiative on extending paid leave	-0,48	0,01	0,59
Popular initiative "right to life"	-0,11	0,34	0,74
Federal decree on abolishing the cantonal share of profits from banks' stamp duty	-0,02	0,28	0,76
Federal decree on the taxation raised from the sale of spirits	-0,07	-0,07	-0,41
Federal decree on the abolition of grants for the self-supply of breadstuffs	0,43	-0,38	0,5
Federal decree on the popular initiative to co-ordinate the start of the school year (counter-proposal)	0,78	-0,22	0,32
Federal decree on giving small and medium enterprises an advantage in cases of innovations	0,78	-0,25	0,16
Amendments to the Swiss Civil Code	0,51	-0,51	0,11

Popular initiative to ban vivisection	0,07	0,66	0,24
Federal decree on joining the United Nations	0,68	-0,03	0,43
Popular initiative on culture	0,18	0,16	0,3
Federal decree on the popular initiative on culture (counter- proposal)	0,62	0	-0,04
Popular initiative on vocational education	0,68	-0,15	0,09
Federal decree on the domestic sugar economy	-0,34	-0,51	-0,09
Federal decree on the popular initiative for the protection of tenants (counter-proposal)	0,42	0,58	0,38
Popular initiative for a just taxation of truck traffic	0,62	0,22	0,24
Amendments to the federal law on asylum	0,75	0,16	-0,17
Federal law on the residence and settlement of foreigners	0,67	0,14	0,42
Popular initiative for the people's co-determination of military expenditure	-0,36	0,08	0,12
Federal decree on the voting system for popular initiatives	-0,19	0,04	0,29
Federal decree on the Rail 2000 project	0,56	0,39	-0,06
Popular initiative for the protection of fens	0,59	0,17	0,26
Amendment to the federal law on health insurance	0,45	-0,07	0,41
Federal decree on the constitutional principles behind a coordinated transport policy	0,2	0,66	0,4
Popular initiative on lowering the retirement age to 62 for men and 60 for women	0,84	-0,02	-0,06
Popular initiative against real estate speculation	0,19	0,47	-0,25
Popular initiative for the shortening of labor time	0,57	0,38	0,06
Popular initiative for limiting immigration	0,85	0,08	0
Popular initiative for nature-oriented farming and against animal factories	0,34	0,73	0,08
Popular initiative for a Switzerland without army and a comprehensive policy of peace	0,75	-0,04	0
Popular initiative on introducing 130 and 100 kilometers per hour speed limits	0,27	-0,78	-0,16
Popular initiative "Stop the concrete - for a limitation on road making"	-0,05	0,91	0,02
Popular initiative for a highway-free countryside between Murten and Yverdon	-0,11	0,91	0
Popular initiative for a highway-free Knonauer Amt	-0,02	0,87	-0,01
Popular initiative for a highway-free area between Biel and Solothurn/Zuchwil	0,1	0,85	0,01
Federal decree on viticulture	-0,29	-0,37	0,51
Amendment to the federal law on the organization of the federal judiciary	-0,11	-0,67	0,11
Popular initiative to phase out nuclear power	0,61	0,27	-0,05
Popular initiative to stop the construction of any new nuclear power plants	0,52	0,27	0,28
Federal decree on the constitutional article on energy	0,69	0,1	-0,05
Amendment to the federal law on road traffic	-0,06	-0,78	0,15

Table A.2: Factor scores for the period 1991-2000

Vote	Factor 1	Factor 2	Factor 3
Federal decree on lowering the voting age to 18	0,04	0,74	-0,04
Popular initiative on promoting public transport	0,48	0,08	-0,15
Federal decree on reorganizing the federal finances	0,08	0,62	0,26
Amendment to the military penal code	0	0,35	0,44
Popular initiative for a financially bearable health insurance	-0,17	0,73	0,21
Popular initiative for the drastic and stepwise limitation of animal experiments	-0,38	0,49	-0,26
Federal decree on joining the Bretton Woods system	0,12	0,76	-0,07
Federal law on contributing to the Bretton Woods system	0,17	0,72	0,09
Federal law on water protection	0,23	0,67	0,2
Federal decree on the popular initiative against the malpractice of gene technology on humans (counter-proposal)	0,32	0,61	0,2
Federal decree on creating a civilian service alternative to military service	0,46	0,6	0,02
Amendments to the Swiss Penal Code and the Military Penal Code on sexual integrity	0,86	-0,05	-0,08
Popular initiative for the recovery of our waters	0,86	-0,07	-0,1

1503 REGIONAL DISTRIBUTION OF FEDERAL TRANSFERS AND EXPENDITURE IN INDIA

ABSTRACT

Intergovernmental fiscal transfers for ensuring horizontal fiscal equity are well established in the federal systems. In the presence of significant regional disparities in India, the central government engages in large intergovernmental transfers to the poorer states for horizontal fiscal equalization. Despite this, the role of central government in addressing interstate fiscal disparities has been not measured comprehensively. Other than the intergovernmental transfers to state governments, the central government also directly spends on health, education, rural development, and various subsidies. All these central expenditures, bypassing the state budgets, have implications for regional redistribution and horizontal fiscal equalization. This paper prepares estimates on a long felt gap regarding the availability of data on central government's transfers and spending at the state level. Using these estimates, we examine progressivity of multiple channels of central transfers and spending; and their impact on horizontal fiscal equalization in India.

1673 450 YEARS OF PORTUGUESE COLONIALISM IN INDIA: MISSIONARIES, EDUCATION, GENDER GAPS

Alexander Lehner⁶⁶

University of Bologna, E-Mail: alexander.lehner@unibo.it

ABSTRACT

This paper explores the persistent role of colonial heritage for economic development using different types of geographical regression discontinuity design (GRDD) estimations. It gives a deep rooted explanation for the emergence of gender roles and provides one possible explanation for the economic catch-up of Goa after its liberation. The empirical strategy exploits peculiarities of the history of the colonisation of Goa. It was conquered by the Portuguese in 1510 and uninterruptedly held until 1961. I argue that persistent effects of these activities, in which the Catholic missionaries played a key role, can be seen up until today in terms of sex-ratios and the gender gap in education as measured by literacy rates. I use an old border that doesn't exist any more since almost 250 years between the so-called Old & New Conquests as my identification device. In the former parts the colonisers forbade sati, polygamy, childhood marriage, and gave women property rights at an early stage. Furthermore the missionaries brought structured education. My analysis, carried out on a village level, provides strong evidence that the early Portuguese colonial activities were the cause of (geographically) sharp within differences that are still measurable today. The analysis of multiple censuses over time suggests that there has been within-Goa convergence and that gaps are washing out. Furthermore I find tentative evidence for a horizontal diffusion throughout villages: also the Hindus within the Old Conquests exhibit systematically higher sex-ratios and lower educational gender gaps. From a methodological perspective I point out the weakness of certain GRD estimations that have been applied in Economics so far and propose a more transparent and rigorous way in which results could be reported in the future; thus potentially also speak to the literature that deals with the so-called "statistical crisis in science" (see e.g. Gelman and Loken, 2014).

Keywords: Geographic Regression Discontinuity Design (GRDD), Colonialism, Religion, India, Portuguese Empire, Gender Gap, Female Empowerment.

1 INTRODUCTION

The Indian state of Goa, once the capital of the mighty Portuguese seaborne empire, was one of the poorest parts in all of South Asia at the time of the liberation from its colonisers in 1961. After receiving heavy transfers and infrastructural investments from the Indian government it managed to transform itself into what is essentially the most prosperous state in present day India⁶⁷. The picture is similar when it comes to the position of women in society: Goa is on top according to the most important indicators⁶⁸.

A more detailed investigation of the matter through the use of census data at a fine-grained level⁶⁹ reveals that those aggregate phenomena are to a substantial extent driven by four talukas (sub-districts) within Goa, all of which happen to have experienced a different colonial history than the other seven talukas.

Only by considering the various examples of failed development investments throughout the last decades, especially in Africa, Latin-America, and other parts of South Asia, the Goan case appears to be a worthwhile one to study. In addition to the overall economic success, it is crucial to understand the drivers for female empowerment which were mostly confined to specific parts. In numerous studies that examine the strong correlation between women empowerment and economic development, it is typically not clear in what direction the causation goes and whether the interrelationship is self-sustaining [Duflo, 2012; Doepke, Tertilt, and Voena, 2012]. In the history of Goa I identify several early "treatments" regarding the improvement of the position of females in society. These pre-date the experience of economic development by several hundred years and thus allow me to take a much stronger position on the causal link from the improved position of women towards economic prosperity.

The general economic success might be partly driven by the whole uniform Portuguese institutional setting (the civil code of 1871 - based on the Code Napoleon - who is still in place up until today): Goa for example is still the only state so far in India which has a uniform civil code that applies uniformly to all people, independent of religion or gender. This

⁶⁶ Please be aware that this is a very preliminary draft. Some figures, graphs, and several pieces of the text are still missing.

First and foremost I want to thank my academic supervisor, Matteo Cervellati, for his guidance and continuous support. So far I benefited from extensive conversations with Oded Galor, Nicola Gennaioli, Mara Squicciarini, Robson Tigré, Rocío Titiunik, Romain Wacziarg, Andrea Weber, and David Weil. I received very helpful comments from Ankush Asri, Stephen Broadberry, Jean-Paul Carvalho, Siddharth Chandra, Rui Esteves, Margherita Fort, Paolo Masella, Giovanni Prarolo, Anand Swamy, Eric Tagliacozzo, Felipe Valencia, seminar participants at the University of Oxford (Nuffield, Graduate Seminar Series), the Spring Meeting of Young Economists 2017, Michigan State University, CESifo Munich, EHES 2017 Tübingen, ASREC Europe 2017, the University of Bologna, and the Macro Lunch at Brown University.

⁶⁷ In terms of local GDP and HDI numbers as reported by the Planning Commission of the Government of India and several other indices of social progress.

⁶⁸ The Gender Vulnerability Index (GVI) 2017 by Plan India, or the National Family Health Survey 4 (NFS) from 2015/16 when it comes to the sex-ratio, female (access to) education, household bargaining power and domestic violence. According to the District Level Household and Facility Survey 4 (DLHS) from 2012/13 by the Ministry of Health the number of married women below age 18 in Goa went down to virtually zero. The same holds true for the number of induced abortions.

⁶⁹ Village and town level data from the Village Census Abstract and the District Census Handbook of Census India.

paper does not draw strong conclusions on that, but rather focuses on variations within Goa due to the presence of a "quasi experimental" econometric identification device that was an outcome of its peculiar historiography.

After being the first European power to round the southern tip of Africa in 1497, the Portuguese establish the capital of their subsequent thalassocracy in the Indian Ocean, the so-called *Estado da Índia*, in Goa in 1510. From then on it is uninterruptedly ruled for 450 years and thus makes it the longest constantly colonised piece of land in younger human history. One unique feature of the Portuguese colonisation strategy in the Indian Ocean was that they, unlike the Dutch or the British with their trading companies, interacted with the autochthonous people. Intermarriage of their soldiers with Hindu women was encouraged in order to create a loyal local population. Furthermore efforts were made to convert the populace to Catholicism. For that matter they were always accompanied by monks and priests which belonged to specific religious orders. The Franciscans and the Jesuits became the two most important players in the early colonial history of Goa. They built churches, a college, set up a network of parish schools, introduced structured education, and even brought the printing press.

Moreover the Lusitanians significantly altered the position of women in society: sat¹ and polygamy were forbidden and early childhood marriage was curbed. Furthermore women were granted property rights and could thus inherit from then on. This was conditional upon marrying a Christian and thus served as an additional incentive to convert. It has to be noted that these things were obviously not undertaken out of philanthropic motives. It was what the Portuguese believed to be a superior way of organising society, which they more or less successfully imposed on Goans. Further it should be noted that the early colonial years have been marked by tremendous hostility towards the Muslim population, which were preceded by hostility from the Bahmani Muslims towards the local Hindus prior to the European arrival. Around 1780 the Portuguese, albeit being economically and militarily already very weak, managed to extend the territory of Goa by the aforementioned seven sub-districts, the so-called *New Conquests*. At approximately the same time the Jesuits get forbidden and expelled due to exogenous events in Europe. A bit later, in 1839, all remaining religious orders get forbidden. Furthermore the people of the *New Conquests* were guaranteed religious freedom because the colonial government could not afford to pick up a fight with the landowning upper caste Hindus in those newly gained territories. It is thus ensured that the early missionaries did not carry out activities of any sort in those new dominions.

It is this historical "quasi experiment" alongside this border, which does not exist any more since 250 years, between the *Old-* and *New Conquests* that I use as my econometric identification device in order to apply a Geographic Regression Discontinuity Design (GRDD).

These estimations reveal that the gender gap in literacy rates jumps by around 4 percentage points on average in 2011 when the line is crossed. All other fundamentals that could drive economic activity, including several "placebo outcomes", stay constant at the same time. The discontinuity is thus driven by something unobservable which I trace back to Portuguese colonial activities. The same analysis carried out on the 1991 census⁷⁰ reveals that effect is twice as big and the within Goa gaps and disparities are much higher. Thus Goa underwent a within convergence process during its periods of economic growth: the poorer parts were catching up with the more prosperous *Old Conquests*, but the gaps alongside the old within border are still geographically sharp and measurable up until today. In addition the sex-ratio and the female literacy rate itself show a much more pronounced drop when one steps out into the *New Conquests* which did not experience missionary activities.

Furthermore, as later will become clearer, the historical quasi-experiment that I am exploiting allows me to potentially also tell apart what the long-term effects of differential cultural and institutional "treatments" are and how they interact. Something that is still not well understood by economists, as has been recently argued by [Alesina and Giuliano \[2015\]](#). My setup additionally allows me to draw tentative conclusions on the evolution of gender norms, which potentially deepens the understanding on how cultural norms and beliefs could change and evolve throughout time. I argue that a shift in the attitude towards women in the 16th century, both within village communities and the respective households, lead to the evolution of a different set of gender norms. These norms persisted locally and are the reason why educational gender gaps are lower and sex-ratios are higher in the parts that were colonised early. These places experienced the aforementioned "double-treatment": exposure to schools and structured education, and the early alleviation of the position of women in society. Especially in the context of a sub-continent which is still plagued by gender inequalities, even after decades of efforts to equalise females, this could serve as an important historical lesson on which one could rely.

For my econometric analysis, in order to potentially isolate causal effects, I redraw aforementioned abandoned border and use it to create a Geographic Regression Discontinuity Design (GRDD). I carry out different sets of estimations: a specifications in "naive" distances, specifications in polynomials in longitude and latitude [as famously put forward by Dell, 2010], and the more state-of-the-art implementation of what is called a GRD with a two dimensional score that allows me to uniquely pin down the location of every village in space and estimate heterogeneous treatment effects alongside the border [see Keele and Titiunik, 2015]. This would be equivalent to a "classical" RD [Imbens and Lemieux, 2008] with two running variables [Imbens and Zajonc, 2011].

I find that the 2011 gender gap in education as measured by the difference in literacy rates is around 4 percentage points higher in the *New Conquests*. This effect is substantial, given that the average literacy gap across Goa is around 8 percentage points. The magnitude of the effect that I identify at the cut-off is almost as high as the one from running a

⁷⁰ Which is the first one after Goa was upgraded from a Union Territory together with Daman and Diu to a state in 1987.

regression with just one dummy variable that indicates whether a village is in the Old-/New-Conquests. Furthermore the number of women per 1000 men is around 80 higher in the villages just on the inside of the old border as compared to those that are just on the outside.

The methodological contribution of this paper is that I implement the supposed ideal way to carry out geographic RDs [as suggested by Keele and Titiunik, 2015] in a more complete way: I show that the other specifications that were put forward so far in the economics literature may lead to spurious conclusions in my settings. I cannot make substantial claims on outcome variables such as the female labour force participation. Those seemed to be robust in the specifications in "naive" distances and with polynomials in longitude/latitude, but when I apply the more demanding RD estimation with two running variables at each border point, there seems to be too much heterogeneity alongside the boundary in order to infer clear effects, i.e. the point estimate keeps changing its sign

In order to further improve spatial RDs, I argue that we just have to stop to discard a clearly identified and visualisable feature within our data: space. Just by making use of simple spatial interpolation techniques such as kriging we could present the analysed data in a way that puts the reader immediately in a position to infer whether there is an actual jump alongside some specified border or not.

Through an extensive historical narrative, the analysis of historical census data, and the verification of numerous "placebo outcomes", I try to convince the reader that the root of these differences lie in the early improvement of the position of women and the early exposition to organised education in the Old Conquests. I also argue that these cultural values not only were transmitted vertically throughout generations, but also horizontally within village communities. The latter is elicited by the fact that the distribution across space of the educational gender gap and the sex-ratios for Hindus, which constitute the main religious group in contemporary Goa, is systematically different in the Old Conquests as shown by non-parametric statistical tests (higher sex-ratios and lower literacy gaps). It thus seems that effect that I am describing is not something that stems from "being Christian".

Very recent sociological research argues, that religion played an ambiguous role in the early-modern onset of Portuguese colonialism, as compared to other cases where religion is highlighted as a strong marker and maker of cultural difference [Henn, 2014]. This stems mostly from the fact that in Goa, things seem to be somewhat molten together: Christian converts kept a lot of Hindu practices up until today (e.g. the dowry system, clothing, ...). I am trying to convince the reader, that even though Hindu and Christian culture seems to be somewhat molten together, what mattered most for contemporary economic outcomes was the common historical experience of those families and villages in the Old Conquests. I thus connect to the broad literature of long-term comparative development by providing a deep rooted explanation for Goa's success and its geographic gender disparities. My study argues that, albeit having no clear measurable impact during early stages apart from the differential sex-ratios, the historical experience turned out to be important once education became widely available after the liberation in 1961. A certain set of beliefs towards education and the status of women was conducive for the appreciation of education and made people more likely to send their kids to school. This effect through missionaries on education was already shown to be important in the Latin American context by Valencia Caicedo [2014] and Waldinger [2017]. The additional feature of the Goan context is the second part of what I call a "double treatment". Female literacy were rising fast in the Old Conquests, while a lot of villages in the New Conquests still had female literacy rates of below 50% up until the 1990's.

Broadly speaking I am contributing to the strand of literature that tries to link historical events to contemporary economic outcomes, emphasising the importance of history for economic development, as e.g. summarised by Nunn [2009, 2014b] or more recently by Michalopoulos and Papaioannou [2017]. Within this sub-field, the present study tries to assess the long-term impacts of colonialism in the specific context of the Portuguese seaborne empire [the historical seminal study still being Boxer, 1969] and the Indian Ocean trade. Contributions focusing on Asia in this respect almost exclusively study the impact of Britain's influence in India [Banerjee and Iyer, 2005; Iyer, 2010; Gaikwad, 2015]. Recently there is some work that tries to assess the long-term impacts of Protestant missionaries in the territories of the British East India Company [Mantovanelli, 2013], and of colonial educational investments therein [Chaudhary and Garg, 2015]. Supposedly one reason why not much attention was paid so far to Lusitanian legacies, was that the Portuguese empire was a "forgotten empire", amongst historians and even more so amongst economic historians up until recently [Marcocci, 2012, p. 33]. Arguments, explanations and a description of the development in the field of Portuguese "overseas history", including a summary of the 2003 e-JPH debate are described in detail by Ferreira [2016].

Unlike, e.g. Acemoglu, Johnson, and Robinson [2002] or Bruhn and Gallego [2012] I am not comparing supposedly good and bad colonial policies in order to assess their long-term effects. My study aims to deliver an assessment of the interaction of colonial policies, which implicitly aimed more at a shift in beliefs and values, and the presence of Christian missionaries. The general rules on how property was taxed or economic activity took place were pretty much homogeneous throughout all of Goa.

More specifically I am contributing to the very recent literature on the long-term effects of (Catholic) missionary orders. Studies on Africa and India generally focus on protestant missions: e.g. Cag'e and Rueda [2016] point out the positive impact of the printing press that was present in protestant missions in Africa & Nunn [2014a] documents the beneficial impact of protestant missions on women in Africa. Woodberry [2004, 2012] documents the strong correlation between e.g. educational attainment and the presence of Protestant missions. This is the first work that specifically tries to assess the impact of Catholic missionaries in Asia within this highly localised "Goan-setting" that heavily reduces the concern of omitted variable problems. Since I also can clearly distinguish the area of influence of the two main orders, the

Franciscans and the Jesuits, before their expulsion at least, this work can be seen along the line of what Valencia Caicedo [2014] and Waldinger [2017] are doing in Latin America by comparing the differential impact of the different orders. Waldinger [2017] claims that the mendicant orders had a more beneficial impact on contemporary economic conditions in Mexico and Valencia Caicedo [2014] underlines the heavily beneficial impact of the Jesuits in the Guaraní area in contemporary Paraguay, Argentina & Brazil. Having a clear geographic distinction between Jesuits and Franciscans, my setup also allows me to draw the tentative conclusion that the Jesuit imprint was felt stronger and lasting longer. The areas where the Jesuits were historically active today have the highest sex-ratios and still the highest shares of Christians. This is corroborated by the fact that they became the virtual overlords of Goa throughout the 16th and 17th centuries [Borges, 1994; Velinkar, 1984]. Albeit the average literacy rates being a bit lower in the former Jesuit districts, the jump at the border towards the New Conquests is much more pronounced (apart from the few points that deliver point estimates with reversed signs).

From a methodological point of view I am pointing out potential weaknesses of the common RD specification put forward by Dell [2010], which has been increasingly popular recently. This relates to recent work on the “statistical crisis in science” [most famously described by Gelman and Loken, 2013, 2014]. Especially what they call a “garden of forking paths” or “researcher degrees of freedom” potentially applies to geographic RD’s in general. Simply by increasing the number of potential outcome variables on both sides of a geographic cut-off, one increases his probability of finding a statistically significant jump. Thus the danger of running into false positives is very high. The two solutions that I propose will alleviate these concerns tremendously.

2 HISTORICAL BACKGROUND

2.1 Geography

The contemporary Indian state of Goa, lapped by the blue expanse of the Arabian Sea in the west, admeasures an area of only around 3700 square kilometres and is located mid-way on the west coast of India. Technically its around 120km long coastline is part of the Konkan Coast, to its south the Malabar Coast begins. Goa stretches out to a width of about 60 kilometres in an east-west direction and extends to a length of about 105 kilometres from north to south. To the east, Goa (and the whole Konkan) are separated from the Deccan highlands of Karnataka, the neighbouring state to the west and south, by the mountain ridge of the Western Ghats. Thus from the outset it can already be seen that my study focuses on a geographically very restricted area that allows me to hold constant important features of first nature geography such as climate, soil quality, and the like. Consequently a potential omitted variable bias is not that much of a concern.

Politically the state is divided into two districts and eleven sub-districts, so-called talukas: Pernem, Bardez, Bicholim, Tiswadi, Sattari, and Ponda being part of North Goa; and Mormugao, Salcete, Sanguem, Quepem, and Canacona being part of South Goa.

Goa enjoys a salubrious, sub-tropical, monsoon type of a climate with alternating wet and dry seasons.

Linguistically it belongs to the Konkani-speaking region that reaches from Thane in Maharashtra, the neighbouring state in the north, to Mangalore in Karnataka in the south. The current population comprises about 1.2 million people of whom 65 percent are Hindus, 27 percent Christians, and 6 percent Muslims according to the 2011 Indian Census. It stands out from its neighbors’ culture by apparently European that is, Portuguese, features in its architecture, folklore, and cuisine. Generally this is true mostly for specific parts of Goa, namely in the so-called *Old Conquests*, as will become clearer later.

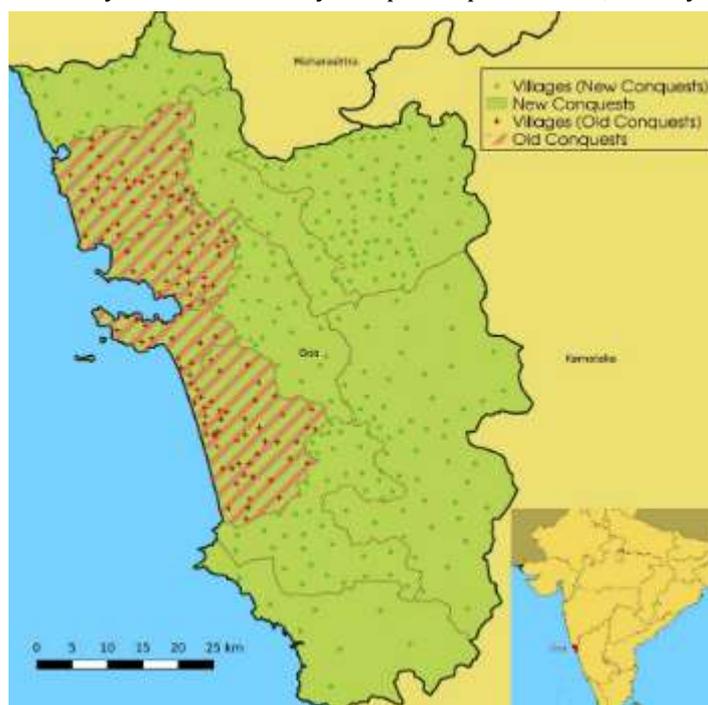

Figure 1: The location of Goa on the Indian west coast.

2.2 Portuguese Conquest

The Portuguese were the first foreign power to arrive and the last one to depart from the sub-continent of India, their 450 year long stay thus marks one of the longest uninterrupted periods of colonisation in history. The lusitanian adventure in the Indian Ocean starts in 1498 when Vasco da Gama lands in the port of Calicut with the famous first sentence *"We are looking for Christians⁷¹ and spices!"*. Later, in 1510, Alfonso de Albuquerque captured the Islands of Goa (its territory roughly equivalent to today's taluka of Tiswadi) from the Sultan of Bijapur. By 1543, the Portuguese had annexed the adjoining lands of Bardez in the north and Salcete (including today's taluka of Mormugao) in the south. These three territories have been designated as *Velhas Conquistas*, the Old Conquests.

It soon became the capital of the Portuguese *Estado da Índia* and rose to one of the world's most magnificent cities of the 16th century. It became an important trading post that connected China, Japan, the Moluccas (the famous "Spice Islands") and India with Europe. It was also referred to as *Goa Dourada*, the golden Goa, and supposedly was comparable in size to the major cities in Europe back then [Srivastava, 1990]. The extensive prosperity was caused by trade, mainly with spices, and was facilitated by naval superiority. For which the foundation was essentially laid by Henry the Navigator and his successors in the 15th century. They managed to prevent the secrets of the demanding maritime navigation in the Indian Ocean from spreading to other European nations for around 100 years, up until the Dutch traveller and later secretary to the viceroy in Goa, Jan Huyghen van Linschoten, copied all the information and published it in his *Itinerario* in 1596 [see e.g. ?]. Due to this catch-up in knowledge by the ascending Dutch provinces, the Portuguese quickly lost their pre-eminence in the Indian Ocean around 1600. Their entrance with the newly formed East India Company, the so called Vereingde Oostindische Compagnie (VOC), marked the beginning of a sharp decline of the whole Portuguese seaborne empire in general, and of its capital Goa in particular.

One of the distinct features of the Portuguese colonisation strategy was their zeal to convert the local populace to Christianity, and their enmity towards Muslims. Mass conversion campaigns were flanked by the destruction of temples and mosques. In Goa the result was an exodus of Hindus and Muslims, of which the former were by far the biggest religious group, and a rising number of Christians who soon became the overwhelming majority. The village communities, the so-called *Gaunkaris* (or *Comunidades*), around which economic and social life was organised were typically left in tact. The only requirement was that taxes and tributes were collected by the *Gaunkars* and transferred to the viceroy in Goa.

The key feature of the Portuguese colonising "strategy" as opposed to all other European colonisers was, that they always encouraged their men to intermarry with local, in this case Hindu, women. The aim was to generate a local populace which is loyal to the colonial government and thus reduce the potential for uprisings and revolts. Upon marriage with a Portuguese *soldado*, which made him a *casado* then, women were granted property rights. Thus their position in society was strengthened and they could inherit in case their husband died. Prior to that women were typically burned on the pyre of their dead man (sat'i). This clearly served as an additional incentive for local females to convert.

2.2.1 The Portuguese Trading (Colonising?) System

The state government in Goa was a macrocosm of that of the other areas and forts⁷². Each had a captain, usually assisted by a "vedor da fazenda", other minor officials such as clerks, and more important the factor, who supervised the royal trade in the area. There were also various clerics, a judge, and in the larger areas a municipal council. The object of all these forts and captains was to enable the Portuguese to achieve several economic aims. These may be listed as: a monopoly of the spice trade to Europe, a monopoly on the trade between various specified ports within Asia; the control, direction and taxation of all other trade in the Indian Ocean; private trade, done on their own behalf by most Portuguese living in Asia [Pearson, 1988].

Most of the official positions ensured high revenues to their holders. Distinction between public and private funds supposedly must have been blurred. The bulk of the officials' salary came in the form of several privileges and perquisites, such as the right to collect a certain tax⁷³ [Pearson, 1988]. Since they got rewards into their own pockets, they somehow had an incentive to extract. Probably one of the sources for the corruption that is described as endemic in numerous historical records [e.g. Boxer, 1969]. The biggest chunk of the state revenue was derived from customs duties.

Generally speaking, instead of exploiting the comparative advantage of their Cape-route in the East India trade and to supply Europe with as much spices as possible, they focused on taxing the already existing Indian Ocean trade and extracting as much as possible from the local (mostly Muslim) traders that operated between the Moluccas (the so-called "spice islands"), Malacca (close to nowadays Kuala Lumpur) and the Red Sea. Their lack of manpower⁷⁴ and the notorious inefficiency of the Portuguese colonial system can be viewed as the root cause of its later downturn.

One important implication of all this for my present study on Goa is that the respective colonial rulers never really were interested in developing the hinterlands or making meaningful public investments, at least not until the eve of the 19th

⁷¹ Prester John was thought to be in India at that time, plus they had evidence that the early apostles converted Indians already 1500 years ago.

⁷² In total the Portuguese empire comprised of XX forts in year XXYX [Boxer, 1961]

⁷³ The posts were seen as property from which the holder expected to make a profit, and thus they were willing to pay much more for a lucrative post than for one with few opportunities for pickings, even if the status of the latter was higher than that of the former. In a sale of 1618 more than twice as much was paid for the post of judge of the Goa customs house as for the captaincy of the whole city for example.

⁷⁴ The whole *Estado da Índia*, from Mozambique to Nagasaki, never had more than 10.000 soldiers [Boxer, 1969].

century. Portuguese "interference" happened almost exclusively through the Catholic missionaries, above all the Franciscans and the Jesuits.

2.2.2 Decline of the Seaborne Empire

As already indicated, a sharp decline of the whole seaborne empire set in at around 1600, when the rapidly ascending trading company of the Dutch Provinces, the VOC, entered the Indian ocean. Throughout the 17th and 18th centuries, the Portuguese thalassocracy was deprived of almost all its strongholds. Albeit the Dutch made two serious efforts to capture Goa, it constantly remained under Portuguese control.

Goa's customs revenues fell by almost one half between 1600 and the 1630s. Estimates of the value of her sea trade, based on these customs figures, show a decline from 2,700,000 cruzados in 1600 to 1,800,000 in 1616/17, 1,400,000 in 1635, and a minuscule 500,000 by 1680 [Pearson, 1988]. Goan capitalists vanished as the economy deteriorated. Additionally the Portuguese crown devoted its meagre resources mostly to Brazil for it was generally always higher valued than the possessions in the east.

It seems that there was a rise of country trade in the later sixteenth century as the *carreira* to Portugal declined.

One of the leading historians of the field, Malyn Newitt, suggests people to take care on the differentiation between the different periods. they have been different and must thus be treated differently Newitt [2005]. I would argue that, when we read the history of Goa, we need to do likewise.

2.2.3 The New Conquests of Goa

In 1763 the Portuguese were able to capture Ponda from the Marathas (Jesuit loan?, na das war gg defense Marathas?). In 1764 Sanguem, Quepem, and Canacona were placed under Portuguese jurisdiction because of an invasion by Hyder Ali. During hostilities between the Bohsles and the Raja of Kolhapur, the Portuguese took advantage of the situation and captured Pernem, Bicholim and Sattari and annexed them to Goa. By 1788 the modern territorial boundaries of Goa had been chalked out. The new parts were termed as the *Novas Conquistas* (New Conquests). They extended the area of Goa to the north, south and east; the Old Conquests make up about 785 square kilometres, the New Conquests a little under 3000. The latter were little valued at the time, but it was here that large deposits of iron ore were later exploited. By the end of the eighteenth century Portuguese India consisted of this enlarged Goa, and a moribund Diu and Daman⁷⁵.

The attitude towards the autochthonous population was by far not as hostile as it was during the 16th century in the Old Conquests. The locals were even guaranteed religious freedom. What is more, the main proponents of the proselytism in the 16th century, that is, the religious orders, were not present anymore: the Jesuits were expelled in 1759 and all other remaining orders were forbidden in 1835 [de Souza, 1990, p 107].

Goa remained Lusitanian until the 19th December of 1961, when the Indian Army drove out the colonisers with Operation Vijay. Thus Goa today marks the territory of the longest-held European colony in all of Asia, if not the world.

2.2.4 Why could the Portuguese rule uninterruptedly for 450 years?

In the early days of Lusitanian presence, their main opponents were the different Indian empires which were far superior by almost any means to the Portuguese (and most certainly to all other European powers at that time as well), except for naval technologies and strategies. All of those Indian empires were land based entities and their rulers didn't care too much about the coastline. The trade in the Arab Sea and the Indian Ocean was carried out by several trading guilds, most of which were of Muslim faith, since hundreds of years prior to the arrival of Europeans. Since the Portuguese Seaborne Empire was meant to be a trading empire with coastal outposts scattered around the world, a so-called thalassocracy, there was not much conflict of interest with the autochthonous ruling classes of the south Asian subcontinent in the first place.

⁷⁵ The Portuguese lost the extensive lands and quite prosperous town of Bassein to the Marathas in 1739; the New Conquests were somehow seen as a sort of compensation for the losses in the north.

Figure 2: The expansion of Goa

Later on, when the British became the overlords of India, they had little intention to conquer the small remaining Portuguese parts due to the strong ties of Portugal to the English crown. Catherina de Braganza married Charles II (part of her dowry was Mumbai, or Bom Bahia as the Portuguese called it). Later the Methuen treaty makes Portugal essentially a British trading puppet.

2.3 Christianity

From the historical introduction so far it is not hard to tell, that the *Estado português da Índia* in its early days during the 16th and early 17th century⁷⁶ was more or less a theocratic entity. During this time, its state machinery was fully geared towards the needs of evangelisation. Later on, as their seaborne empire and the Portuguese state itself were continuously declining, they lost their zeal for proselytisation. From the 16th century on, Goa, which before had experienced the presence of Hindu and Muslim rulers alike, was now subjected to probably the most dominant themes of Portuguese imperialism: christianisation and acculturation.

Especially the Muslims of Goa were exposed (has tradition in POR, think of Ceuta) to harsh brutality. In the first place, the Hindu majority enjoyed independence in order to remain a certain degree of local support. There is a "conversion-by-conviction-or-by-coercion debate" of how much the christianisation efforts harmed the local population of Goa and how cruel they were [see e.g. [Kamat, 1999](#), p. 42 for a discussion].

2.4 The Role of Women

Generally speaking, the Portuguese tried to change as little as possible when they arrived. They deliberately left the economy in the hinterland, which was organised on a village level, as much in tact as possible in order to e.g. maintain a stable tax base. This was especially true for the *New Conquests*, once they were acquired. The colonial government needed these pieces of land for agricultural purposes and thus didn't want to interfere with the Hindu land-owning class. Certainly one of the reasons why people in those parts that were acquired around 1780 were guaranteed complete religious freedom.

The few main "interventions" they tried to make regarding customs in the Goan society actually specifically concerned females.

Discrimination against women was (and still is to some extent, it has to be remarked) apparent in several ways on almost the entire sub-continent of south Asia: early childhood marriages, polygamy, the interdiction of remarriage, the prohibition of property rights (girls could thus not inherit from their families or passed away husbands), sati (a practice

⁷⁶ It is important to distinguish between the different, in some respects distinct, periods of the Portuguese thalassocracy when it comes to analysing the respective historical narratives as [Newitt \[2005\]](#) strongly emphasises.

where the widow is burned alive on the pyre of her husband)⁷⁷, and infanticide⁷⁸ (since the 1970's rather feticide). [Da Silva Gracias \[1996\]](#), Chapter 1, draws an extensive picture of the status of women in Indian society at the time of the Portuguese arrival.

Upon his arrival, Afonso the Albuquerque issued the so-called *Politica dos Casamentos*, a mixed marriage policy between his men and native women. He incentivised this by endowing those couples with cash, a house, cattle, and land [see e.g. [Da Silva Gracias, 1996](#); [Kamat, 2000](#)]. These Portuguese soldiers were then referred to as *casados*. The main purpose, it is said, was to create a "white" identity in the *Estado* and to develop a community which is loyal⁷⁹ toward the Portuguese. Intermarried women, which had to convert to Christianity, thus could suddenly claim all the privileges of a born Portuguese.

Also upon their arrival, the Portuguese immediately forbade practices that supposedly appeared barbaric to them: the tonsuring of widows and the practice of sati. Later on polygamy (1567) and childhood marriages were also forbidden (sati was abolished in the *New Conquests* only in 1884). Whether all those laws were effectively serving their purpose at the time they were implemented must be questioned. The historical narrative suggests that people tended to continue with traditional practices. But it has to be acknowledged that there existed at least written laws that tried to curb the discrimination against women at a very early stage. Also in the sixteenth century, women were granted the right to inherit property of their *husbands and fathers in the absence of sons. These things generally affected only Christian women since the Portuguese had no real hold on the Hindu village communities. They had influence on the Christians though via the well-established net of churches and parishes that was set up by the Catholic orders.*

All those measures of course were designated to serve one purpose: Christianisation. Women were provided with incentives to convert to Christianity. Furthermore Hindu widows and orphans were only entitled to the property of their ancestry in case they converted. Regarding the *New Conquests*, Hindu women were only permitted at the end of the 19th century to opt out of their Hindu law and seek justice under Portuguese law.

Later on the Portuguese civil code of 1867, which was extended to the colonies in 1869, regulated all the above mentioned things more clearly and formally and further improved the position of (Christian) women. The code was uniform for all citizens, irrespective of caste or sex. It guaranteed equality of the sexes with respect to property, protected the interests of widows and it contained laws concerning the family. Hindus generally were subject to the so called *Codigo dos Usos e Costumes* (in the *New Conquests* it was promulgated in 1853). When Portugal became a republic in 1910, the civil code was further expanded, e.g. by the possibility to annul or divorce a marriage.

Albeit socio-religious customs prevented women to a large extent from taking advantage of all these legislations, it cannot be stressed enough that their sheer existence and partial exertion were a major achievement, brought about at a comparatively very early stage in history.

2.4.1 The Dowry System

Dowry, as practised in India, is an amount of money, property, ornaments and other gifts that the family of the bride has to pay on the occasion of the marriage to the bridegroom or his family. Though dowry is prohibited by law in India, it is widely practised. Since most marriages in India are arranged by the families, dowry is decisive in finding a suitable bridegroom. Moreover, in practice, dowry is not a onetime payment, but the husband and his family continue to expect and demand money and other gifts from the wife's family, the denial of which leads to a lot of tension and violence. Consequences of dowry include female foeticide, discrimination against girls, late marriages for many girls, unsuitable matches for girls, lowering of women's status, breakdown of marriages, increase in mental diseases, increased rate of suicide and impoverishment in poor and middle class families and so on.

It could be argued that the sheer religious differences across the *Old-* and *New-Conquests* would explain the differences in female literacy rates and the educational gender gap that I observe across the old Border which doesn't exist anymore. The implicit driver for the preference for males being the dowry system. This can be rejected since the Christians, albeit partly adopting Portuguese culture, still kept many ancient Hindu practices. One of them being the dowry system [see e.g. [Ifeka, 1989](#); [Hickman, 2007](#); [Kumar, Kiran, and Gone, 2013](#)].

2.4.2 Education of Women

It has to be mentioned that in early times the education of women was generally neglected. Only some girls of upper strata were exposed to home schooling. If females benefited at all at early stages from Portuguese and missionary's interventions from an educational point of view, then the historical narrative again strongly suggests that this exclusively was the case for the *Old Conquests*. In this process the Catholic church played a significant role, although the precise motives and channels being somewhat opaque, scholars agree on the importance of the church in this respect [[Neill, 1985](#); [Xavier, 1993](#); [Da Silva Gracias, 1996](#); [Emma Maria, 2002](#)]

2.4.3 Women and the Church

⁷⁷ Even though it must be noted that the ban on sati was temporarily lifted in the 16th century due to pressure from the population.

⁷⁸ Albeit there are no records on female infanticides in Goa, it is reported that daughters on average were treated worse than sons. They were breastfed for shorter periods and were also later on poorer fed. Male children were also provided with better medical care as well since they were regarded as an asset according to social customs. Thus the disease survival rate of boys was reported to be higher [[Da Silva Gracias, 1994](#)].

⁷⁹ n.b.: the British, on the other hand, typically discouraged marriage (or even interference) with the local populace.

As already mentioned, Catholic missionaries played a significant role in the process of raising the status of women in the Goan society. Numerous letters and decrees display the concern of church officials towards the plight of women. Through their ability to influence the government substantially, several achievements have to be ascribed to their efforts. Especially when it comes to the ban of polygamy and the encouragement of widow remarriages.

Around the turn towards the 17th century, the church started to set up several homes that served as shelters for women. At around the same time the first nunnery was started in the city of Goa. Colonial government forbade the *satī*. They also passed laws to allow Hindu widows to marry again. They also requested the king to impose strict punishments on those who violated the rules of monogamy.

Goan women in general could (officially) opt out of an unhappy or undesirable marriage from 1910 on [Da Silva Gracias, 1996, p. 144].

"It must be admitted that unlike other religions, Christianity gave their women due respect and position which was an impetus for others to reform their society. The Christians were neither treated as chattels nor were they treated as properties. They were not treated as door-mats but as human beings with rights and privileges. They enjoyed the proprietary rights, they were consulted in all matters of importance, they attended all functions and so on. The position which the Christian women enjoyed was in fact a matter for envy for non-Christian women. Even the Hindu reformists in the later years, became fervent advocates to criticise the disparaged position of the Hindu women. The Portuguese themselves were instrumental to improve the position of non-Christian women through several state laws in the 17th and 18th centuries." [Xavier, 1993]

"Christian missionaries were the first to put women on the agenda of Indian social reform and drew attention to the low social status of women. They felt that education alone would help them to oppose things like sati, female infanticide, child marriage, and enforced widowhood." [Basu, 1993]

"Historically, the Portuguese have displayed a deep concern for women's rights and their egalitarian sense has reflected itself in the people of Goa. One can see this in the equal access to education and the resultant freedom to choose a full time profession, the increase in the age of marriage and the Portuguese Uniform Civil Code, later called the Uniform Civil Code which gives the daughter an equal right to her father's inheritance and property." [D'Costa, 2007]

"The State and the Church played a significant role in upgrading their [the Women's] position. The Portuguese rule seemed to have made a difference to the status of women. As a result the conditions of women in Goa were far better than their counterparts elsewhere in India." [Da Silva Gracias, 1996]

Generally speaking, scholars agree that there are several root conditions that need to be met in order to begin with the empowerment of women in India: the abandonment of polygamy, early childhood marriage, *sati* and the permission for women to possess property and be able to remarry as widows [see e.g. Khanday, Shah, Mir, and Rasool, 2015]

2.5 Goan Catch-up & Development after 1961

Since the Portuguese government was not willing to give up on Goa, the Indian government decided to take it over by force. Operation Vijay can be described as a success in the sense that the number of casualties was very low and the later transition towards "normality" took place comparatively smooth. Especially when one takes into account that the territory was ruled for 450 years by a European power.

Fact is that Goa back then can be described as one of the poorest regions in India: the number of schools was very low and education was tailored towards an elite that was close to the colonial government, only less than 5% of the villages had electricity, and so forth.

Once the Indians took over, transfers in form of infrastructural investments were flowing from the government in Delhi. This was especially true for the construction of primary and secondary schools [Varde, 1977; Malvankar, 2015]. As the later census data suggests, these investments were highly successful and were one of the reasons for Goa's immense catchup. One thing that has to be thought of here is that this is not the usual outcome when we look back at the history of development aid and infrastructural investments in structurally weak areas. The effect of decades of foreign aid in numerous countries across all continents has to be described as mild at best. This holds also true for different parts of India, mostly in its North. So why could Goa be so different?

This study shows that the aggregates in terms of educational improvement (as measured by literacy rates, both for males and females) were in the beginning driven by the *Old Conquests* of Goa, and that the other parts only started to catch-up in the 1980's and 1990's. I try to convince the reader that one of the main reasons for this phenomenon lies in Goa's differential history. Due to the penetration of those four districts that are "Missionary Goa" by monks and priests for centuries, even in remote villages, people became familiar with the concept of structured education and potentially also saw the returns to it, even without being able to participate by themselves. This is what I would describe as a "taste for education" that becomes important once schools become widely available and accessible for children of all backgrounds. Out of a similar reasoning this also differentially contributed to female education. Since the position of females were alleviated by a bundle of "rules" early on (regarding *satī*, polygamy, childhood marriage) and these diffused intergenerationally throughout time, families were much more likely to also send their daughters to schools, once the Indian government made them available.

It should be mentioned here already that the government did not preferentially treat the *Old Conquests*. This is crucial to point out, otherwise one might conclude that the effect that I am describing stems from differential infrastructural investments that eventually made those parts more prosperous. Rather the opposite was true: it was obviously known

that the *New Conquests* did worse on average, especially the parts in the hinterland, thus it was aimed to harmonise the regions and the *New Conquests* received more rather than less investments from the time on when the Maharashtrawadi Gomantak Party, representing lower castes and social classes, came into power in 1962.

Table 1: An overly simplified sketch of the two historically distinguishable parts of Goa.

Historical Narrative - A Quick Overview	
Old Conquests	New Conquests
<ul style="list-style-type: none"> Conquered in 1510 (Tiswadi) & 1543 (Bardez, Salcete/Mormugao) Experienced the heydays of the Portuguese <i>Estado da Índia</i> where the so-called "golden Goa" had supposedly up to 100.000 inhabitants Network of parishes/schools from early days College(s) [printing press] Sati, polygamy, early childhood marriage curbed from early 16th century on Women can inherit and remarry already in the 16th century 	<ul style="list-style-type: none"> Acquired in peculiar ways in different stages around 1780 No "early" economic impetus since the Portuguese thalassocracy was already at the bottom when these parts were acquired Missionaries never enter Structured education arrives late Polygamy and early childhood marriage ubiquitous until the 20th century. Laws improving the position of women being implemented from late 19th century on
<ul style="list-style-type: none"> Uniform civil code of 1871 (still in place makes Goa the only state so far in India which has a uniform civil code, applying to all people across religions, female and male) From 1961: uniform investments from Indian government (schools, electricity,...) 	

3 DATA

The main arguments of the present study are based on 1991 and 2011 Indian census data. The respective Village Census Abstracts contain the number of males/females for each village/town, whether they are literate, and if they participate in the labour force. This allows me also to compute a sex-ratio for each unit of observation, not by age-cohorts though.

From the so called District Census Handbook (DHCb) I obtain village/town-level data that I use as control variables in some specifications (number of doctors and nurses, number of primary schools). My sample then consists of 70 towns and 335 villages in contemporary Goa. In a next step I geolocalise all villages and towns via a tool called [India Place Finder \[Mizushima Laboratory, 2013\]](#)

For robustness checks I employ nightlight data from the DMSP-OLS program which have been shown to correlate highly with regional economic activity [[Croft, 1978](#); [Elvidge, Baugh, Kihn, Kroehl, and Davis, 1997](#); [Chen and Nordhaus, 2010](#); [Henderson, Storeygard, and Weil, 2012](#)]. Geographic information (i.e. the respective shapefiles) on the location of borders and (sub-)districts has been obtained from the [Project \[2016\]](#) which was cross-checked with exactly georeferenced maps and numerous historical sources, all of which are cited throughout the paper. An important note of caution for the implementation of GRDDS in general is, that the widely used data on sub-national units and their border from the [GADM project \[GADM, 2012\]](#) are not precise enough for a full fledged GRD design.

Historical information on the location of churches and parishes in the 18th century (before the expulsion of the missionaries) come partly from [Borges \[1994\]](#) and [Gomes \[2003\]](#). A map of the location of Jesuit "sites" in Salcete and contemporary Mormugao & Tiswadi from [Borges \[1994\]](#).

For descriptive statistics (share of religious groups, etc) I use data from the so called A-Series from the 2011 census. I unfortunately cannot observe the literacy broken down for each religious group for villages, only for towns. The latter information is then used for the non-parametric statistical tests in table 6.

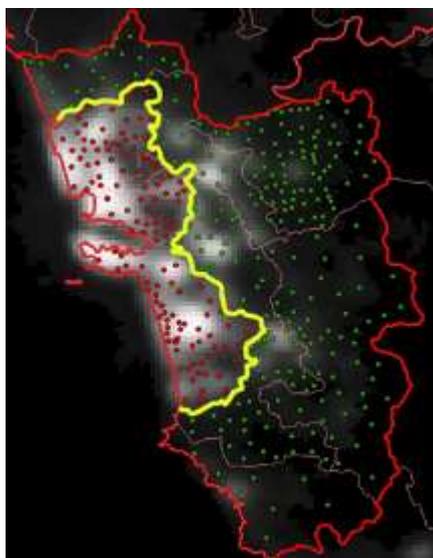

Figure 3: Goa at night in 2013 with all villages and towns; red dots demarcate the ones in the Old Conquests ("Missionary Goa")

4. ECONOMETRIC SPECIFICATIONS

Generally speaking, the living standards in Goa are higher than in its neighbouring states. This average "Goa-effect" is e.g. observable in higher literacy rates for both males and females. Digging a bit deeper into the data, it is also easy to identify average differences between the *Old Conquests* and the *New Conquests*, this suggests that there is also something like a "within-Goa-effect". The historical narrative, which was outlined in detail in [Chapter 2](#) and summarised in [Table 1](#), strongly suggests that these differences are due to the different degrees of Portuguese colonial penetration and missionary influence.

In order to improve upon these plain correlations and to try to potentially isolate causal effects, this set-up, displaying a historical quasi-experiment, lends itself especially well to the use of a specific type of a *Regression Discontinuity Design* (RDD): a spatial- or geographic RDD (GRDD). In general, the "classical" RDD type of research design has tremendously gained popularity throughout the last years [as e.g. summarised by [Lee and Lemieux, 2010](#)]. This is largely due to the potentially high credibility that is attributed to it. One of the strengths of RD designs is, that a known treatment assignment rule exists and is enforced. The GRDD differs from a standard RDD when it comes to the cut-off that splits units into treatment- and control-groups. It is argued that such a geographic cut-off, usually a border of any kind, occurs in an as-if random fashion. GRDD designs, such as the one in the present study, fall short of some of the premises of an ideal RD design. Since I do not have geo-referenced individual data, it is impossible for me to get observations arbitrarily close to the boundary. Thus GRDDs in general rely on "ignorability assumptions" within a certain band around the border. Thus many, if not all, will fall short of the RD ideals that were outlined in the "classical" RD literature. Nevertheless it has been demonstrated that such a set-up can lend itself especially well to provide convincing evidence about causal effects when carried out carefully by the researcher [[Keele and Titiunik, 2015, 2016](#); [Keele, Lorch, Passarella, Small, and Titiunik, 2017](#)].

The reason why in this study an RD is the ideal tool to isolate causal effects is the geographical heterogeneity of Goa in the East-West direction in terms of market access. The villages (and towns) on the coast are on average more prosperous due to tourism (trade), whereas the villages in the hinterland suffer from their remoteness. The villages alongside the abandoned border that I use as my RD identification device on the other hand are highly comparable in fundamentals as the balancing checks in [Table 5](#) show. By just looking at villages very close to each other on either side of this border, jumps in terms of literacy and sex-ratios cannot be explained by observables and thus need further investigation. As was already indicated, I am tracing these discontinuities back to the long-term exposure of differential historical experiences.

In order to point out the differences in the estimated effects but also to depict the evolution of the GRDD literature⁸⁰, being mostly restricted to Political Sciences and Economics, on its path towards more credible empirical analyses of geographically heterogeneous effects, in the present study I am carrying out my empirical analysis in three different ways in order to flesh out potential pitfalls and weaknesses. These are essentially all possible ways that have been applied in the literature so far:

1. A spatial RD in "naive" distances, ideally estimated non-parametrically through a local linear regression, identical to classic RD's (e.g. [[Michalopoulos and Papaioannou, 2014](#); [Eugster, Lalive, Steinhauer, and Zweimu"ller, 2017](#)]).
2. A polynomial-in-longitude/latitude specification including covariates for a certain band around the border (e.g. [Dell \[2010\]](#); [Becker, Boeckh, Hainz, and Woessmann \[2016\]](#); [Oto-Peral'ias and Romero-A'vila \[2017\]](#)).
3. A GRDD (following the nomenclature of [Keele and Titiunik \[2016\]](#)) which resembles a two-dimensional RD that is estimated non-parametrically at every point of the cut-off. For the time being this clearly resembles the "gold-standard" in spatial RD settings (so far only applied by [Keele and Titiunik \[2015, 2016\]](#); [Keele et al. \[2017\]](#)).

In the Economics literature, especially the sub-field that tries to link historical events to contemporary economic outcomes, the second specification in which the outcome variable is regressed on a dummy variable whether the unit was treated or not and a set of control variables (including polynomials in longitude and latitude that control for the position), seems to be the most popular one.

The methodological difficulties that arise in those spatial settings were clarified by [Keele and Titiunik \[2015\]](#). They further show that their ideal GRDD designs lead to identification of local treatment effects at the cut-off under a two-dimensional continuity assumption [thus generalising [Hahn, Todd, and van der Klaauw, 2001](#)]. They also point out the potential problems arising with GRDD designs and other spatial RD set-ups in general. All of them will be discussed and addressed within the present study. An essential difference to "classical" RD's with two forcing variables, individual points at the boundaries of GRDD's have a clear interpretation.

I second their critique and take their approach one step further and propose a way to consistently visualise the heterogeneous treatment effect alongside any RD-border (this is what I call a GRDDseries)⁸¹. Furthermore I argue that all investigated outcome variables should also be visualised by simple spatial interpolation techniques such as Kriging. This will give the reader a feeling of the spatial dimension of the data generating process. The two techniques combined, I

⁸⁰ I restrict all my discussion to the - generally more credible - subset of studies wherein experiments are based on adjacent areas.

⁸¹ I am especially grateful for extensive in-person feedback on this by Roc'io Titiunik herself.

assert, would allow us to identify false positives that any technique that reports one homogenous treatment effect for the full border might deliver.

4.1 Discussion of GRD Identification Issues

One potential problem is that the continuity assumptions needed for identification will hold less often in geographical settings because agents may sort around the boundaries and thus undermine the design's validity.

Another issue could be so called compound treatments. In the context of historical applications, this could be additional events or policies that affected the region that is subject to study in exactly the same geographical dimension.

4.2 Naive Distances

This simpler version of a spatial RD uses the perpendicular distance of each observation to the boundary as its score for the estimation. This geographically "naive" measure of distance ignores how the units are spatially distributed since the shortest distance towards the border does not determine the exact location in the two-dimensional space [ass e.g. pointed out in [Keele and Titiunik, 2015](#), p. 137].

This specification allows to estimate an average effect which will mask considerable heterogeneity along the border. Yet, as I will show, this type of analysis is capable of delivering a quick intuition of what the data can potentially tell. Especially when it comes to the visualisation of this set-up with a "standard" RD-plot.

In this setting units around a narrow band around a border are assumed to be valid counterfactuals. This design may mask underlying heterogeneity and thus may not allow to evaluate the plausibility of the needed identification assumptions. A naive GRD design is still appropriate in some circumstances, e.g. when the boundary of interest is short and defines a homogeneous region. Technically it is only fully valid when treatment effects are constant at all boundary points $b \in \mathcal{B}$.

Ideally such specifications are measured non-parametrically via local linear regressions as is state-of-the art in "classical", ideally with data driven robust confidence intervals as suggested by [Calonico, Cattaneo, and Titiunik \[2014\]](#). As already mentioned before, such estimations are capable of delivering information about an average effect alongside the full cut-off, which can be very misleading about the actual effect that is subject to study as I will demonstrate in [5](#). Yet, as I would argue, such estimations can reveal important information about a certain underlying pattern in the data to the researcher.

4.3 Polynomial Specifications

In some applications where observable characteristics are different on both sides of the cut-off, it might be reasonable to control for those observables in order to still be able to obtain meaningful results. Estimation though has to be carried out by means of a parametric adjustment method or by a matching estimator as e.g. suggested by [Keele, Titiunik, and Zubizarreta \[2015\]](#).

The next specification that I bring to the data uses an RD polynomial that contains geographic information within a standard regression framework as proposed by [Dell \[2010\]](#) and also implemented by [Becker et al. \[2016\]](#) and [Oto-Peralías and Romero-A'vila \[2017\]](#):

$$y_{ib} = \alpha + \gamma \times \text{MissionaryGoa}_i + f(\text{geolocation}_i) + \mathbf{x}'_i \beta + \phi_b + \varepsilon_i, \quad (1)$$

where y_{ib} is the outcome variable of interest for village i on border segment b . MissionaryGoa_i denotes a dummy variable that equals 1 if the village is inside the old, non-existing border and was exposed to early Portuguese colonial rule and missionary influence. $f(\text{geolocation}_i)$ represents the RD polynomial which is supposed to control for smooth functions of geographic location and is going to take on varying forms across different specifications. Finally, vector \mathbf{x}_i contains a set of control variables and ϕ_b represents a set of boundary segment fixed effects. With the latter geographic treatment effect heterogeneity is meant to be captured. This might be desirable in some settings, but the obvious drawback is that this approach masks the heterogeneity that potentially is capable of delivering deeper insights into the problem at hand. A GRD clearly improves upon that by delivering a point estimate at every point of the border, and overcomes the arbitrariness in the choice of the number and location of border segment fixed effects.

Another drawback is that there are no clear formalised suggestions for the bandwidth selection in such an estimation procedure as were put forward for non-parametric methods [[Imbens and Kalyanaraman, 2012](#); [Calonico et al., 2014](#)].

4.4 GRD (two running Variables)

Discuss [Imbens and Zajonc \[2011\]](#) and [Papay, Willett, and Murname \[2011\]](#) basics. These were brought into a geographic context by [Keele and Titiunik \[2015\]](#). Therein they develop in detail their so-called GRD. The difference is, that the comparability of treated and control units need not occur in a certain band around the geographic discontinuity, a border in most of the cases. The effect in this type of setting is measured at *any* point of the border. One of the huge advancements is therefore, that one can obtain heterogeneous treatment effects alongside the border. [Keele and Titiunik \[2015\]](#) suggest to visualise results than with an average treatment effect curve that is measured alongside the whole length of the discontinuity which is subject to study. I further propose a way how to depict those estimates graphically on a map.

All estimated with [Calonico, Cattaneo, and Titiunik \[2015\]](#); [Zubizarreta and Kilcioglu \[2016\]](#)

In order to account for spatial correlation, a non-parametric estimation method, which by now is standard in the "classical" RD setting in any case, is to be preferred.

One drawback when it comes to the data-driven selection procedures that select specific bandwidths for the estimation [Imbens and Kalyanaraman, 2012; Calonico et al., 2014], that they in some cases are not capable of dealing adequately with sparse boundary points where there are no observations close to the border.

To sum up, the effect identified in a GRDD is not a point estimate but a line of treatment effects along the whole cut-off, displaying the magnitude of the heterogeneous effect at each point. As compared to "classical" RD's with two forcing variables, here the heterogeneity has a clear interpretation. In essence this can be highly valuable since geographic patterns in the results would potentially affect the interpretation of the results.

5. SPATIAL REGRESSION DISCONTINUITIES

5.1 Average Effects

Before we move to the spatial RD's, the following tables should give the reader just a coarse feeling of what the data looks like. The units of observations here are already the towns and villages that are then also used for the GRD; 141 of which are in "Missionary Goa" and 246 are located in the *New Conquests*. As described in detail already before, the latter were not exposed to the Christian monks and priests and women were formally made equal to men only with the Portuguese civil code of 1871. Given that Goa up until today is the only state in all of India with such a legal institution that equalises all people, irrespective of gender or religion, the late 19th century could still be described as remarkably early.

Column 1 in Table 2 shows that the villages in the *Old Conquests* have on average a 6 percentage points higher literacy rate in 2011. The intercept reveals that the average outside is around 75%.

Looking at the literacy gap, i.e. the female literacy rate subtracted from the male literacy rate, the observed gender discrepancy is approximately half the size in "Missionary Goa". Those parts of Goa also have on average 54 females per 1000 males more as Table 4 reveals.

Table 3: Average effects (OLS with dummy)

	Dependent variable:			
	Literacy rate 2011

5.2 Balance Tests and Pre-Treatment

One important condition that needs to be satisfied when it comes to RD estimation in general is that before the "treatment" there was no effect observable across the considered response variables. In my setting this turns out to be literally impossible since during the 15th century no data was recorded and detailed quantitative historical records in general are non-existent. I thus have to rely on historical narratives. The point is best made by simply presenting a quote from a Goan history book:

Table 4: Average effects (OLS with dummy)

Note: *p<0.1; **p<0.05; ***p<0.01

"Their country had never enjoyed the same unity that it has had since the Portuguese conquest in 1510. Before that date, the different districts belonged to different kings and different kingdoms, so that Goa, as we know it now, was never one country. Its various parts have been welded into one whole, [...]" [?]

Due to the constant conflicts between the Hindu Vijanaghara empire and the Muslim Bahmani sultanate, the border changed several times in non-systematic ways within the territory of present day Goa. It is thus outruled that anything of significance happened right across or alongside the abandoned border that I consider for my GRDD design.

Table 5 shows that the villages I am comparing on both sides of the border are highly comparable in size, population, and the number of households. It is thus outruled that any observed effects are spuriously driven by comparing big with small or urban with rural villages. From the comparable household size it can also be inferred that the observations are approximately comparable when it comes to socio economic factors.

What is more, so-called features of first nature geography such as climate, rainfall or the quality of soil are equally comparable. A quantitative analysis is not reported due to the fact that there is no variation within the data. The border

only stretches only around 40 km north-south, and those values are typically reported on gridded datasets with a larger scale.

Table 5: Balancing Checks

5.3.2 Polynomials in Longitude/Latitude

This specification, put forward by [Dell \[2010\]](#), is usually preferred within the Economics literature. It is well suited to report an average treatment effect alongside a given border. But as we will see later with e.g. the female labour force participation, it could be misleading in some circumstances and produce false positives. As the more detailed visualisation in form of the GRDDseries shows, this is due to strong effects that occur locally and drive the average effect. The spatial interpolation exercises then visually confirm that there seems to be in fact no "action" in terms of this variable at the RD border.

Table 6 shows the average treatment effects for all considered outcome variables. The estimations are robust towards all potential bandwidths.

Table 6: Polynomial specifications with controls & border segment FEs

5.3.3 GRDD (2011)

In this section I employ the technique proposed by [Keele and Titiunik \[2015\]](#) which measures the RD in space by considering a two-dimensional score as running variable and push it one step further by carrying out this estimation for each point of the border. The figures should be read as follows: the plotted lines represent each point on the discretised RD border (500m distances inbetween) and its point estimate including a 90% confidence interval. The color indicates whether the estimate is significant at the 10% level or not. The version of the GRDDseries below displays the estimation of the identical specification, only with a forced selection radius of approximately 20km. This is just to increase the precision of the point estimates by forcing more observations into the estimation. Since a triangular kernel which weighs each observation in the regression by its distance to the respective boundarypoint is used, this should not be much of a concern. Since the bandwidth selection of the CTT algorithm is not very meaningful in some cases when one has to deal with sparse observations, I decide to drop each estimation where less than 10 observations were chosen on each side of the border. This is arbitrary, but estimations with 20+ observations arguable make more sense than ones with five or ten.

These resulting GRDDseries provide the reader with a transparent visualisation of the heterogeneous treatment effect across the whole border.

Figure 5.3.3 shows the main specification under scrutiny. The signs of the point estimates essentially never change their sign. Due to the small sample size the confidence intervals do overlap with zero quite often, but the majority of the point estimates at least gets significant once the algorithm is forced to select more observations.

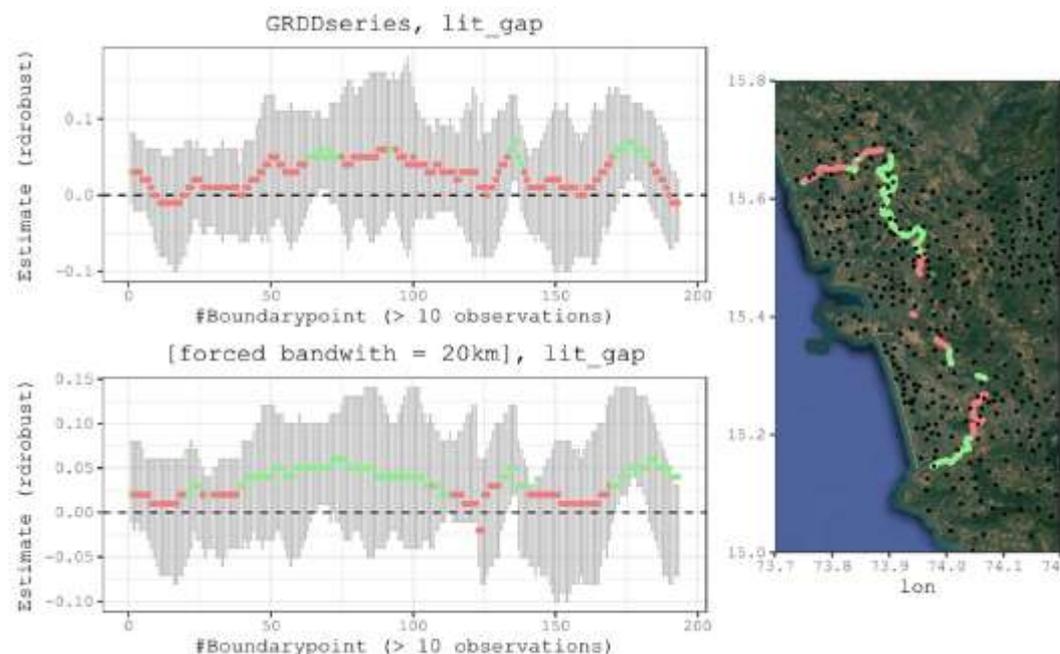

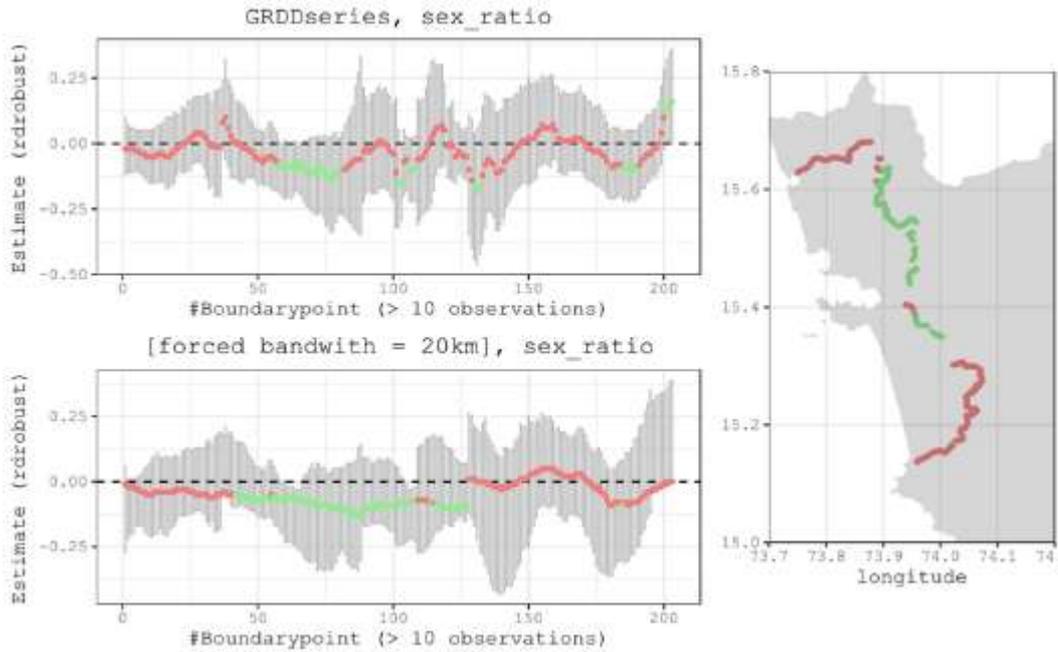

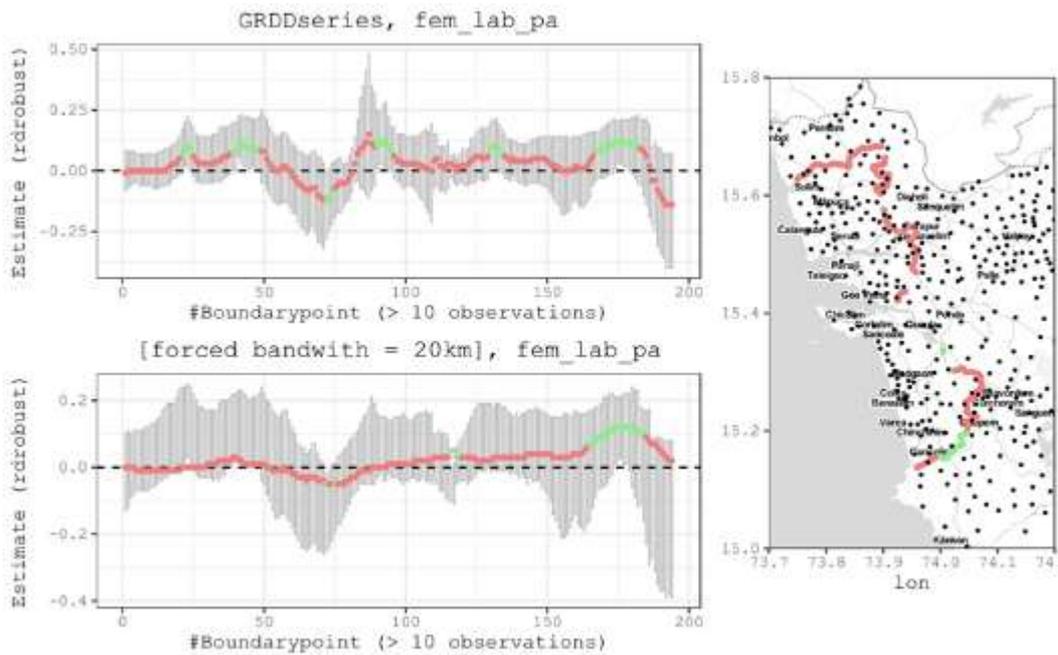

Figure 5: GRDDseries and spatial visualisation of the literacy gap in 2011

5.3.4 GRDD (1991)

The exercise describe above is repeated in the same manner on the census from 1991, which is the first one after Goa became a full state of India. Before it was organised as a so-called Union Territory together with the other former Portuguese colonies Daman & Diu and the censuses were reported differently. Only from 1991 the reporting was carried out on the village level that I need for my RD estimations.

The estimations reveal that the observed jumps were around two times the size in 1991 as compared to 2011, which indicates that there was a convergence process taking place that seemingly harmonised the regions within Goa.

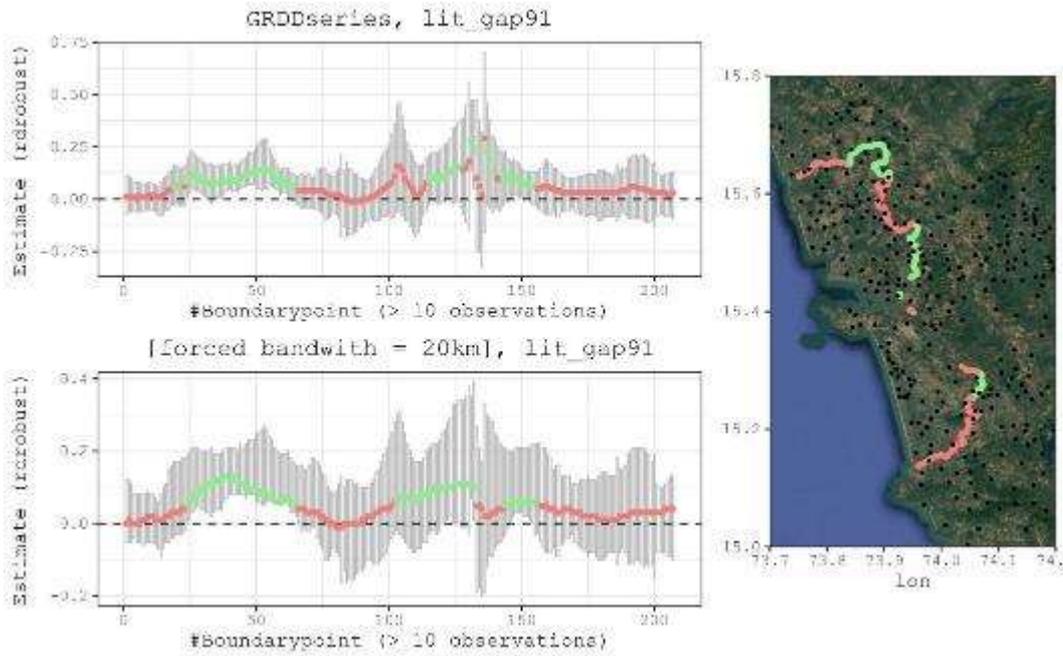

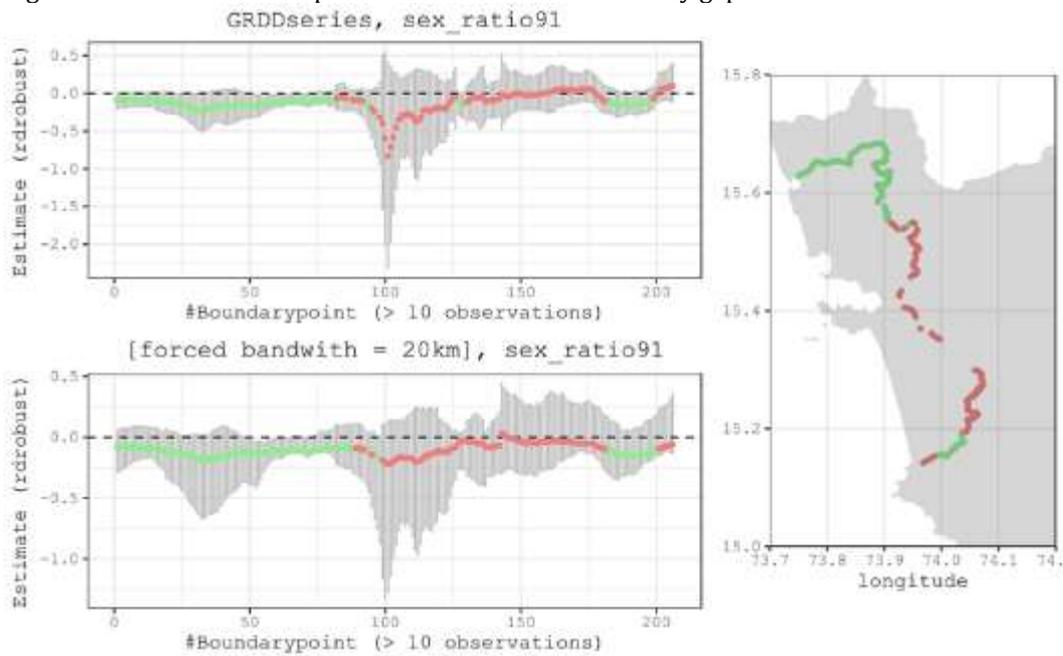

Figure 6: GRDDseries and spatial visualisation of the literacy gap in 1991

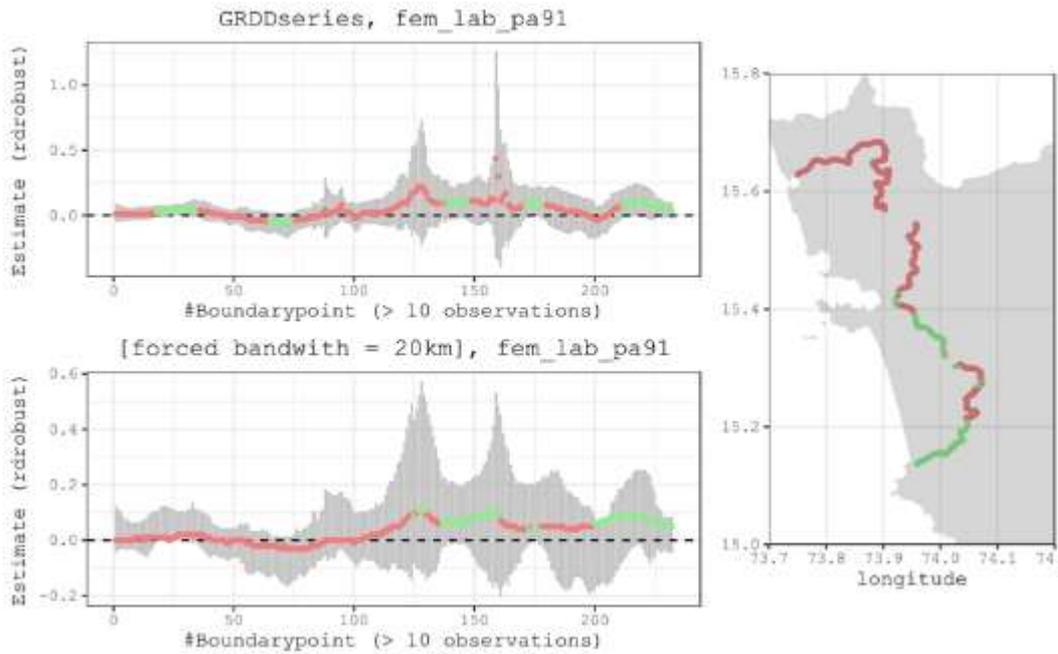

Table 7: Polynomial specifications with controls & border segment FEs (ATE in 1991)

These results are based on a 3km bandwidth.

5.3.4 Spatial Interpolation - Kriging

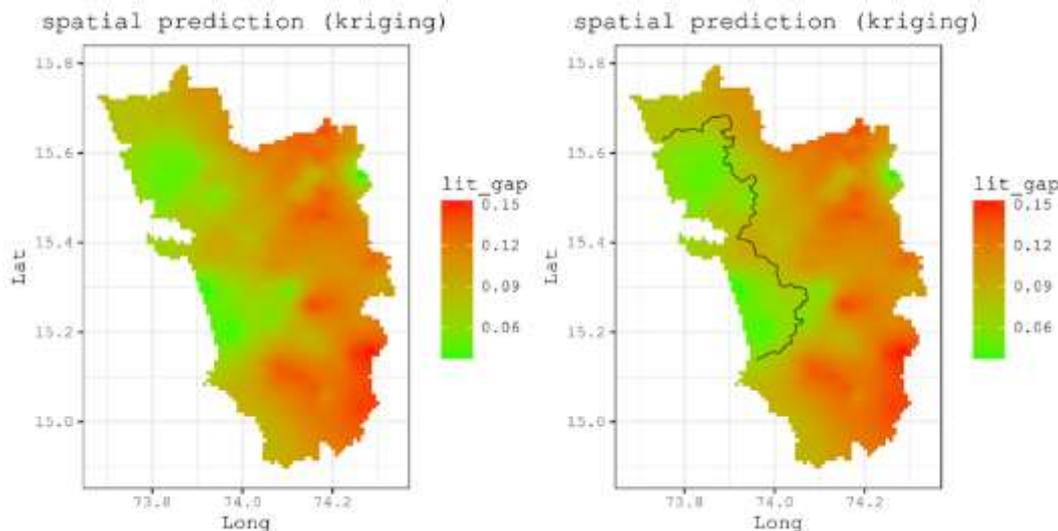

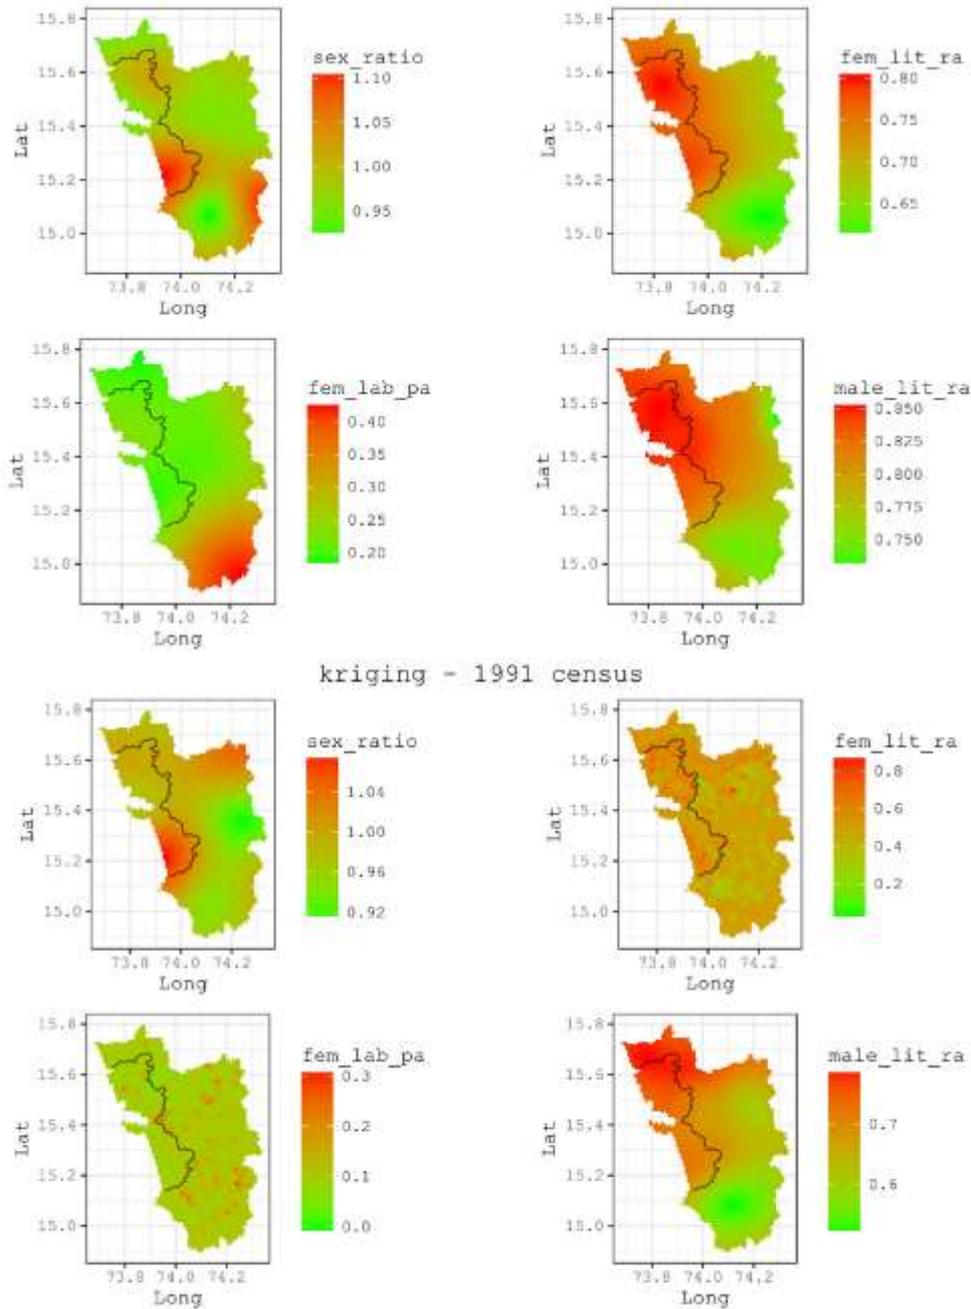

Figure 7: Spatial interpolation, village level 2011

5.4 Falsification Tests

In this subsection I try to convince the reader of the robustness of my results and provide deeper analyses of whether the results so far can be interpreted as a genuine effect of the historical Portuguese presence on (female) education and sex-ratios in Goa. They aim to rule out that the identified effect reflects other things such as selective expansion, in which case the results may reflect pre-existing differences.

5.4.1 Different Bandwidths

All "classic" GRD specifications are robust towards different bandwidths ranging from 1 to 10km. This can also be visually inferred from the pictures of the spatial interpolation exercises. For the GRDDseries specifications this is not relevant in any case, since the algorithm by [Calonico et al. \[2014\]](#) does data-driven bandwidth selection by itself.

5.4.2 Pseudo Borders

When the border is moved in both directions and the estimation carried out on those fictional lines, all of the relevant specifications lose significance. This can also be inferred visually from the spatially interpolated pictures.

5.4.3 Intermediate Step: Colonial Census of 1851

One might argue that the observed effects are an artefact of something that happened after the Portuguese had left, or was due to something that was not caused by their presence. I thus analyse the recently digitised Portuguese colonial censuses starting from 1776 which were recently digitised by a group of economic historians [[de Matos, 2013, 2016](#)]. The first one which is reported on a village level and is thus compatible with how I carry out the analysis is from 1851. For all of those data-points I know in which district they are, and thus whether they are within the *Old-* or *New Conquests*.

The exact location of the villages is almost impossible to obtain since the names changed multiple times over the years and some villages were merged with each other. An RDD on this dataset is thus not feasible. But as figure 8 demonstrates, in order to make the point it suffices to report a simple descriptive statistic. It plots the histogram of the sex-ratio for each village and demonstrates firmly that the one's in the "treated" districts are far off from the ratios in the other villages. It is thus safe to argue that the effect I was talking about was already in place before the Indian government took over and even before Portugal moved away from being a monarchy.

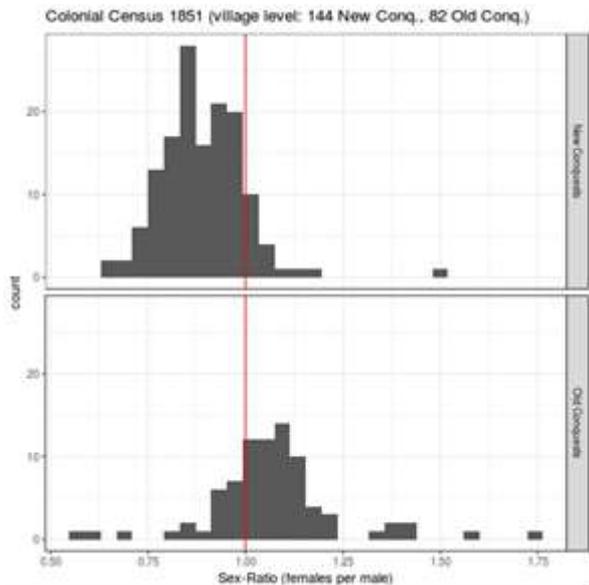

Figure 8: Sex-ratios at the village level in 1851.

5.5 Placebo Outcomes

7 CONCLUSION

This paper has put forward a deep rooted explanation for the emergence of gender roles by examining the effects of the long-term presence of Portuguese colonisers in the Indian state of Goa. They, inter alia, significantly altered the position of women in society at a very early stage in history. In addition they interfered culturally by introducing what I call a "taste for education": their accompanying missionaries set up a network of churches, parishes with schools and even set up a college and brought the printing press. After the sharp downturn of the Portuguese thalassocracy in the 17th century, also the Goan economy was in a continual decline up until its liberation. Interventions by the late Salazar dictatorship to boost economic growth only masked deep structural problems and appeased the urban upper classes. When the Indian government took over in 1961, only a few villages had electricity and the number of schools was low. Once schools and a broader infrastructure became widely available throughout all of Goa, the catchup process, initially driven by iron-ore mining in remote areas and the port in Mormugao, began.

A more disaggregate analysis reveals that this process was experienced differently by parts of Goa that are referred to as the *Old Conquests*. These territories were colonised in a different period and experienced an entirely different colonial reign: Catholic missionaries spread the word of Christ, built schools within their network of parishes even in the most remote places, and thus induced something that I would describe as a "taste for education". A further cultural intervention in the 16th century regarded the position of women in society: sati, polygamy, and early childhood marriage were forbidden. Additionally females received property rights upon conversion to Christianity (in the 19th century women of all religions formally received property rights due to the Portuguese civil code which was based on the Code Napoleon).

The heavy aggregate increase in male and female literacy rates from 1961 was driven by the four districts of the *Old Conquests*. Once education became available, boys and girls were sent almost equally to schools. In the *New Conquests* female literacy rates began to increase significantly only during the last two or three decades. This mechanism also manifests itself in the sex-ratios, which were historically always heavily male biased in the *New Conquests* (which is e.g. shown by the colonial census of 1851 in figure 8). In the *Old Conquests* they were always significantly above 1 and only began to fall slowly from 1961 onwards, mostly probably driven by migration⁸².

In order to isolate causal effects and to show that the observed patterns were actually driven by the early Portuguese "interventions", I make use of the spatial interpretation of a technique from causal inference called Regression Discontinuity Design (RDD). This allows me to compare villages and towns on either side of this border which has no meaning any more since 250 years in a close-to-random manner: as the balancing checks showed, they are highly similar in size, population, household composition, and features of first nature geography such as rainfall, soil quality and the like. Also anything that regards the infrastructural treatment by the Indian government from 1961 on was shown to be comparable when it came to the placebo checks (number of schools, doctors/nurses, medical coverage).

The last concern could be that those outcomes are driven by economic activity or the prosperity of villages in general. The only way to verify this at the disaggregate level is to look at light emissions measured from outer space by satellites which has been shown to proxy very well with local GDP [Henderson et al., 2012]. These light data exhibit no jump alongside my RD-border. What is more there is also no observable difference in the slope of the respective fitted lines, thus also a kink RD design does not exhibit significant coefficients⁸³.

Having applied the method of elimination on all thinkable observables, I am thus confident to conclude that the observed differences were driven by the only thing in which the villages and towns differ(ed): their differential "cultural" experiences in the distant past which were induced by the Portuguese presence.

The alleviation of the position of women in society and especially within the households throughout the 16th century led to a cultural shift and to the emergence of a different set of gender norms on a sub-continent which historically was always plagued by discrimination towards females. Albeit the jump in the observed gaps in education (as measured by the male & female literacy rate differences) between the two territories shrank from around eight percentage points in 1991 down to 4 percentage points in 2011, they are still observable today. The sex ratios on the other hand do not exhibit

⁸² See e.g. the Goa Development Report 2011 by the Planing Commission of India

⁸³ The latter might be more appropriate in general since light does not exhibit jumps by nature but fades out continually. If there was something systematically different on both sides of the border, we should observe different first derivatives, i.e. slopes, on either side of the border.

such a convergence pattern. The villages just inside the old border that I use as my identification device have around 80 women more for each 1000 men.

That I am not describing something that is driven by the distance of the villages to the coastline can also be visually inferred from the spatial prediction techniques (kriging) that I used in chapter 4.4: the literacy gap is four to five percentage points almost uniformly across the *Old Conquests* without any observable gradient.

Aside from the spatial RD estimations I find evidence that there was diffusion of attitudes towards women within communities (as summarised in table 6): Hindus in the towns of the *Old Conquests* - on aggregate - exhibit systematically different sex-ratios and educational gaps than their counterparts in the *New Conquests*. The effect that I am describing throughout this paper thus does not seem to be entirely driven by "being Christian".

All in all, the results lead me to tentatively conclude that the early colonial experience in the form of a cultural treatment seemed to be more important than the uniform institutional and legal treatment that all Goans - independent of gender and religion - experienced from the 1871 civil code on. Compatible with this would be the interpretation that the infrastructural investment, pretty much uniformly received from the Indian government, was just more effective in the *Old Conquests* in the long-run. In order to semantically frame it in terms of the current frontier of the long-run development literature: it thus could be the case that what matters most is the interaction of "culture" with institutions and infrastructure, and that none of them alone are sufficient conditions for economic prosperity [Alesina and Giuliano, 2015].

From a methodological point of view I showed that the geographic RD representation by Dell [2010] might lead us to spurious conclusions under certain circumstances. In order to alleviate this problem, I argue that we just have to stop to discard a clearly identified and visualisable feature within our data: space. Just by making use of simple spatial interpolation techniques such as kriging we could present the analysed data in a way that puts the reader immediately in a position to infer whether there is an actual jump alongside some specified border or not. I then put forward a simple way in which one could visualise the methodology proposed by Keele and Titiunik [2015]. The two-dimensional RD estimations for every point alongside the discretised border can be both plotted in form of a "GRDDseries" and at their respective position in space at a map; visualised next to each other. In case the RD estimates change signs multiple times and the coefficients are insignificant most of the time, the researcher then probably has to conclude that the response variable under inspection does not exhibit a jump at the cut-off. Of course these procedures demand a lot from the data, but if we want to meet the high standards of the so-called "credibility revolution in applied Economics" also for spatial RD estimations, we should start to implement them.

1153 COMPARISON OF THE PERFORMANCE OF SPECIAL ECONOMIC ZONES (SEZS) IN THE PHILIPPINES**Arianne Dumayas**

Faculty of Economics, Chuo University

ABSTRACT

Economic zones have been a top development strategy for many developing countries. Most countries have started implementing economic zone strategy as an effort to liberalize the economy, capture foreign investments, and increase exports. As the economies march towards liberalization, the underlying goals of these economic zones have consequently transformed from mainly export-oriented to technology and innovation-oriented zones. Furthermore, the management of zones have changed from government-initiated or government-operated to public-private partnership or purely private. Like other countries, the earliest form of economic zones in the Philippines are free trade zones and export processing zones. Special economic zones in the Philippines also started as solely government-led and managed zones but eventually, the participation of private sector was allowed in 1995. As of 2016, the number of economic zones stood at 348 zones and majority of these zones are developed and managed by the private sector. While the number of economic zones has continuously increased, the performance of these economic zones, particularly at the disaggregated level, has been rarely examined. This study aims to contribute to a better understanding of the performance of selected economic zones in the Philippines. This study seeks to identify which zones performed better than others. This study also aims to examine whether development of more private economic zones and IT Parks and Centers have any impact on the performance of existing public economic zones. To compare the performance of selected economic zones, this paper devises a performance index calculated based on three commonly identified static measure of outcome: investment, exports, and employment. The dynamics of the performance is analyzed based on three trends: long-term trend (base period of 1995-2000 or 2001-2005 vs. latest period 2011-2015), latest trend (2006-2010 vs. 2011-2015), and comparison of long-term and recent performance. The long-term trend shows that public economic zones have declined, while IT Parks and Centers have expanded significantly. The recent trend indicates resurgence of all public economic zones and continuous growth of most IT Parks and Centers. The comparison between long-term and latest performance reveals two categories of zones: zones which performed consistently well and zones which have deteriorated steadily. The zones with consistent better performance are mostly private manufacturing economic zones and IT Parks and Centers. On the other the hand, the zones with decaying performance are mostly manufacturing economic zones located in areas with huge number of established economic zones.

1. INTRODUCTION

Economic zones are often instituted to attain various development goals such as industrial development, regional development, infrastructure development, knowledge-transfer and spillovers. Economic zones also come in different names and forms such as industrial agglomeration, industrial parks, technology parks, and export processing zones. Many countries have started implementing economic zone strategy as an effort to liberalize the economy, capture foreign investments, and increase exports. As the economies continue forward into liberalization, the underlying goals of these economic zones have consequently evolved from mainly export-oriented to high technology and innovation-oriented zones. Furthermore, the management of zones have changed from government-initiated or government-operated to public-private partnership or purely private.

Like other countries, the earliest form of economic zones in the Philippines are free trade zones and export processing zones. As early as 1923, there were already proposals to convert existing ports to free trade zones, but this did not push through until the late 1960s (Castro, 1982). The Philippines would later embark on three main stages of economic zones development: government-led EPZ from 1970-1994; private sector-driven special economic zone (SEZ) from 1995-1999; and Information Technology(IT) industry-centered SEZ from 2000-present. The first export processing zone is established in Mariveles, Bataan in 1972. Additional public economic zones were established in the following years: Baguio City Export Processing Zone(BCEPZ) in 1980 and Mactan Export Processing Zone(MEPZ) in 1979, and Cavite Export Processing Zone(CEPZ) in 1986.

For more than two decades, the development and operation of economic zones lies solely on the government, however significant policy shift has occurred with enactment of Special Economic Zone Act of 1995. This act allowed the participation of the private sector in the development and management of economic zones. The act also modified the prevailing export orientation of the first-generation economic zone as it allowed firms to engage in non-export activities. Furthermore, in addition to traditional manufacturing activities, incentives were expanded to other activities such commercial/trade services, utilities and facilities, and real estates. In 2000, amendments were made to Special Economic Zones act to encourage and support the investments in information technology(IT) through the establishment of IT Parks/Buildings and offering incentives to IT enterprises. During this time, the IT and business processes outsourcing(IT-BPO) have just started to gain traction and government have started to take notice of its potential so appropriate incentives and support were extended to this industry. Subsequent board resolutions were approved to establish additional types of economic zones and activities: Medical Tourism Park/Center (2006), Retirement Ecozone Park/Center (2006), Tourism Economic Zones (2012), and Agro-Industrial Economic Zone.

As of 2016, there are 348 economic zones that are actively operating in the Philippines. A huge majority of these are private economic zones and IT Parks and Centers. The current Duterte administration is actively pursuing the plan to

establish special economic zones in every province and city and region nationwide (Mercurio,2017). The Philippines Economic Zone Authority have recently approved the establishment of five special economic zones in Tawi-Tawi, the southernmost island in Mindanao (Campos, 2017).

While there seems to be unwavering enthusiasm towards the development of additional special economic zones in the Philippines, the performance of these economic zones, particularly at the disaggregated level, has been rarely discussed. Manasan (2013) reviewed the performance of export processing zones and special economic zones and pointed out both positive and negative experiences. The establishment of Philippines Economic Zone Authority (PEZA) has been lauded to be successful not only in increasing investments, exports, and employment but also in creating in good investment climate through its one-stop-shop model. On the other hand, special economic zones are found to have weak backward linkages and huge number of firms are involved in low-technology and low-value added activities.

This study aims to contribute to a better understanding of the performance of selected economic zones in the Philippines. This study seeks to identify which zones performed better than others. This study also aims to examine whether encouraging more private economic zones and IT Parks and Centers have any impact on the performance of existing economic zones. This paper aims to provide answers to the following questions: How do selected economic zones perform in terms of investment, exports, and employment from 1995-2015? Are there any variations in performance across economic zones? Which zones are performing better? What is the impact of promotion of private economic zones and inclusion of IT Parks and Centers on the performance of public economic zone?

To analyze the performance of selected economic zones, this paper devised a performance index calculated based the three commonly identified static measure of outcome: investment, exports, and employment. The study computes indices for four periods (1995-2000, 2001-2005, 2006-2010,2011-2015). The paper analyzes the dynamics of the performance based on three trends: long-term trend (base period of 1995-2000 or 2001-2005 vs. latest period 2011-2015), latest trend (2006-2010 vs. 2011-2015), and comparison of long-term and recent performance. Moreover, this study also ranks the performance of zones during the four periods.

This paper is organized as follows: Section 2 provides a review of related literature; Section 3 presents the methodology; Section 4 discusses results of the research; Section 5 summarizes and concludes the paper.

2. REVIEW OF RELATED LITERATURE

Special Economic zones are commonly defined geographic area with differentiated rules and regulations from the national territory which are commonly instituted to attract investments, promote exports, and generate employment (Carter and Harding, 2011; Baissac, 2011). Special economic zones come in various forms which includes export processing zones free zones, free ports, foreign trade zones, export processing zones, trade and cooperation zones, and economic technological development zones (Baissac,2011).

Over the past years, special economic zones have evolved, specifically, in terms of zone objective, incentives, structure, location, and ownership (Aggarwal,2010). In terms of objective, establishment of SEZ have developed from facilitating trade and generating employment to fostering high-skilled and high-technological activities, stimulating economic activity, and diversifying export composition. The incentives within SEZs have also evolved from traditional tax-related incentives to various incentives such as infrastructure, services, industrial policies, labor policies, and corporate taxation. The structure of SEZs have also advanced from stand-alone industrial estates to integrated industrial townships. The economic activity within SEZ have also evolved from trade-oriented and labor-intensive to capital intensive to high-technology intensive SEZ. The location pattern of SEZs also changed from areas that are located near the port areas to various parts of the country with the aim of integration with host economies. The ownership and management of SEZ started as government-created and management but starting from 1980s, privately-developed and managed zones have emerged.

The inclusion of private sector in the development of management of economic zones can be attributed to both push and pull factors (Farole,2011). The push factors include difficulty for many countries to cover the associated costs of economic zones and need to revitalize failing economic zones programs. The pull factor involves the opportunity to profit for the private companies from real estate ventures and services to the firms. The first private economic zone is established in Dominican Republic in 1969 and this model was followed by other Latin American countries such as Costa Rica, El Salvador, Honduras, Nicaragua, Guatemala, and Colombia (Farole, 2011). Asian countries like Thailand, Philippines, and Vietnam have initiated private economic zones from 1990s. The number of private zones in developing and transitioning economies have increased from 25 % of zones in 1980s to 62 % in 2007 (FIAS, 2008).

The comparison of efficacy of public economic zones over private economic zones or vice-versa is a highly debated topic, although anecdotal evidence shows that private SEZs are likely to be more effective (Baissac, 2011; FIAS, 2008). However, no comprehensive empirical analysis has been conducted to address this question. Private economic zones might have successful business operation but offer limited or negative economic contribution. On the other hand, public economic zones may fail to deliver profit but provide socio-economic impact.

Assessing the performance of economic zones is often difficult and context-specific. To evaluate the success of economic zones, a framework based on the outcomes of the objectives can be outlined(Farole,2011). The framework identifies two types of outcomes: static and dynamic. Static economic benefits are relatively short term and pertains to outcomes when economic zones are used as instruments of trade and investment policy. The static economic benefits are often measured through the following indicators: employment, foreign-direct investments, foreign exchange through exports, and value-

added. Meanwhile, dynamic economic benefits include non-traditional economic activities, hard and soft technology transfer, the encouragement of domestic entrepreneurship, and the promotion of economic openness.

3. DATA AND METHODOLOGY

This study adopts a methodology similar to Tantri (2011) in evaluating the performance of seven economic zones in India. Tantri (2011) constructed two different types of indices: general profile index and trade performance index. The general profile index included indicators such as geographical area, total exporting units, concentration of units, employment, and investment. The trade performance index is calculated based on total exports, total imports, net foreign exchange earnings, value addition of SEZ, per capita exports, share in total exports and import of SEZs, sectoral concentration index, geographical concentration index, import intensity of exports, compound annual growth rate of exports and imports, and growth rate of exporting units. Both indices were computed for five different time periods from 1986-2008. The changes in performance of zones over the past years are evaluated in two ways: first, comparing the ranking of each zone for the latest available year over the rankings of zones in base year; and second, ranking of each zone for the latest available year.

Due to limited data availability, this paper only constructs performance index and not general profile index. This paper devises a basic performance index based on three static measure of outcome: investments, exports, and employment. The study computes indices for four periods (1995-2000, 2001-2005, 2006-2010, 2011-2015). In contrast to Tantri (2011), this study covers 35 zones which are already operating between 1995-2005. These zones are divided into three groups: 1st group or public zones which are in operation before 1995; 2nd group or economic zones which started functioning in 1995-2000; and 3rd group or economic zones which began operation from 2001-2005. This study chooses to expand the number of zones to help identify the impact of policy changes, particularly, with the expansion of private economic zones and inclusion of IT Parks and Centers. The paper analyzes the dynamics of the performance based on three trends: long-term trend (base period of 1995-2000 or 2001-2005 vs. latest period 2011-2015), latest trend (2006-2010 vs. 2011-2015), and comparison of long-term and recent performance. In addition to this, this paper analyzes performance of zones based on their ranking in the four periods. The evaluation of performance of zones over the past years in based on absolute value of index and ranking. This paper uses indicators sourced directly from PEZA.

Indicators were transformed into index using the min-max formula below:

$$Y_t = \frac{(X - X_{min})}{(X_{max} - X_{min})}$$

Where X is the actual value of the indicator, Xmin is the minimum value in the series, and Xmax is the maximum value in the series.

The indicators were given equal weights in computing the performance index using the formula below:

$$PI = \left(\frac{1}{3}\right) \sum_{t=a}^e Y_t$$

The composite index value for each zone ranges from zero to one. The closer the index value to 1 signifies good performance. This paper also identifies the statistical significance of the variations in performance of zones using one-way analysis of variance (ANOVA). ANOVA is commonly used to established whether there are any statistically significant differences among the means of independent groups.

4. RESULTS AND DISCUSSION

4.1 SEZ in the Philippines

In the Philippines, Special Economic Zones or ecozones are defined as selected with highly developed or have the potential to be developed into agro-industrial, industrial tourist/recreation, commercial, banking, investment, and financial centers (PEZA, 1995). There are 5 types of special economic zones: industrial estates or manufacturing SEZ, export processing zones (EPZ), free trade zones, tourism ecozones, and IT Parks/Buildings. The development of these economic zones aims to generate exports, create employment, and encourage investments, particularly foreign investments. Moreover, the establishment of special economic zones in suitable and strategic locations aims to drive a sound and balanced industrial, economic and social development of the country (PEZA, 1995).

The economic zone development strategy in the Philippines have undergone three main transition: government-led EPZ (1970-1994); private sector-driven SEZ (1995-1999); and Information Technology (IT) industry-centered SEZ (2000-present). The first phase of economic zone development (1970-1994) began in late 1960s. RA 5490 or Export Processing Act in 1969 legislated the creation of the Mariveles, Bataan as the first free port zone. Three more public EPZ were inaugurated in the following years: Baguio City Export Processing Zone (BCEPZ) and Cavite Export Processing Zone (CEPZ) in 1980, and Mactan Export Processing Zone (MEPZ) in 1986. The second phase (1995-1999) of economic zone development started with the enactment of RA 7916 or the Special Economic Zone Act of 1995. The act enabled the private sector to participate in the development and management of economic zones. The act also expanded incentives to firms who firms engaging in non-export activities such as commercial/trade services, utilities and facilities, and real estates. The third phase (2000-present) of economic zone development commenced in 2000 when amendments were made to Special Economic Zones act to encourage and support the investments in IT industry through the establishment of IT Parks/Buildings and provision of incentives to IT enterprises.

The number of economic zones has increased from 2 in 1970s to 348 in 2016 (Figure 5). There is a remarkable increase in number of economic zones from 1996 after private-sector was allowed and incentives were given to IT industry. Majority of the established economic zones from 2000s-present are IT Parks/Buildings.

Figure 1. Cumulative Number of Economic Zones

Source: author’s construction based on Philippines Economic Zones Authority (PEZA) statistics

As of July 2016, there are 348 special economic zones that are operating in the Philippines and additional 145 zones are being developed (Table 1). Almost 70% of active economic zones are IT Parks/Centers and around 20 % are manufacturing SEZs. IT Parks/Centers also constitute the largest number of planned economic zones.

Table 1. Active and Planned Economic Zones

Types of Economic Zones	Active	Planned
IT Parks/Centers	234	104
Manufacturing Economic Zone	72	29
Agro-industrial Economic Zone	21	6
Tourism Economic Zones	19	6
Medical Tourism Parks/Center	2	
Total	348	145

Source: author’s construction based on Philippines Economic Zones Authority (PEZA) statistics

There is a massive number of private economic zones in the Philippines (Table 2). Except for economic zones that are managed by PEZA or by local government, almost all economic zones in the Philippines are developed and managed by private sector. PEZA currently manages four manufacturing economic zones: Baguio City Economic Zone, Cavite Economic Zone, Mactan Economic Zone, and Pampanga Economic Zone. Bataan Economic Zone is formerly under PEZA but was converted into Freeport Area of Bataan (FAB) in 2009 through Republic Act 9728 (AFAB, 2009). FAB is managed by the Authority of Freeport Area of Bataan (AFAB), a government-owned and controlled corporation.

Table 2. Type of SEZ Management

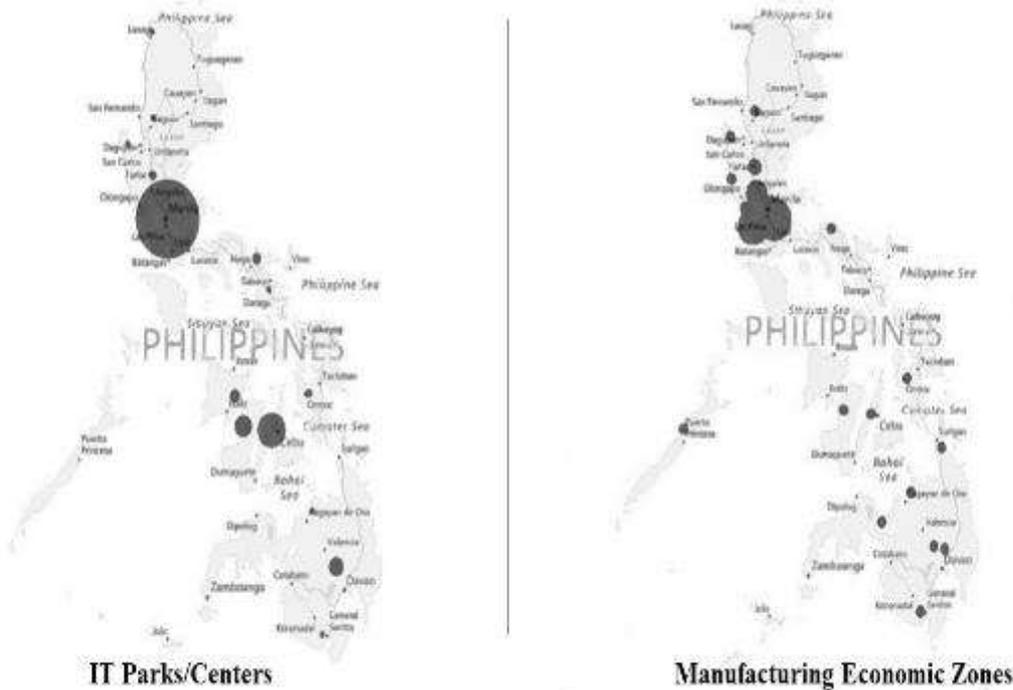

Type of SEZ	Public	Private
IT Parks/Centers	6	228
Manufacturing Economic Zone	9	63
Agro-industrial Economic Zone	1	20
Tourism Economic Zone	0	19

Source: author’s construction based on Philippines Economic Zones Authority (PEZA) statistics

Meanwhile, the ownership or management structure within private SEZ varies. The developers of IT Parks/Centers are involved in the management of multiple number of IT Parks/Centers. The developers of IT Parks/Centers also happen to be the top real estate companies in the Philippines such as Robinsons Land Corporation, SM Prime Holdings, Ayala Land Inc., and Megaworld Corporation. On the other hand, developers or operators of manufacturing SEZ typically operate single zone, except for Carmelray Industrial Corporation and Laguna Technopark Inc.

While balanced development is one of the key aims of economic zone policy in the Philippines, economic zones are clustered in few areas in the country. IT Parks/Centers and Manufacturing SEZ tend to concentrate in few and relatively developed areas of the country. More than half of IT Parks/Centers are located within Metro Manila (Figure 2). While several IT Center/Parks have chosen to locate in secondary or tertiary centers of Cebu Negros Occidental, Davao Del Sur, Laguna, and Iloilo. More second and third tier cities are being geared up to host IT Centers/Parks through Next Wave Cities (NWC) Program. The NWC program is a joint effort by both government and public sector: Department of Science and Technology- Information and Communications Technology Office (DOST-ICTO) and IT Business Process Association of the Philippines (IBPAP).

Figure 2. Location of IT Parks/ Centers and Manufacturing Economic Zone

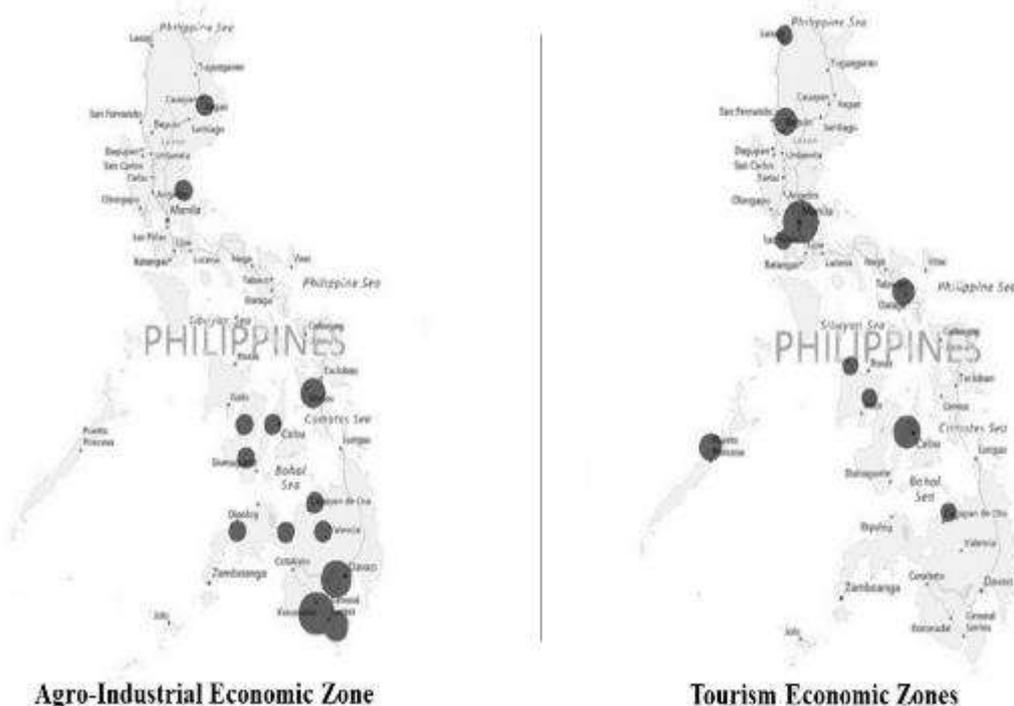

Source: author’s construction based on Philippines Economic Zones Authority (PEZA) statistics

Meanwhile, manufacturing SEZ are heavily concentrated in Southern Luzon, Metro Manila and Central Luzon (Figure 2). Southern Luzon was developed as highly-industrialized region under the Calabarzon Project in 1990s. Under this project, massive infrastructure projects such as superhighways, ports, and industrial estates were constructed in the five Southern Luzon provinces of Cavite, Laguna, Batangas, Rizal, and Quezon. Meanwhile, a few manufacturing zones are dispersed in other regional growth centers of Cebu, Baguio, and Davao.

Agro-industrial SEZ and Tourism SEZ are relatively scattered across the country. Agro-industrial economic zones are mostly located in Mindanao island or Visayan island (Figure 3). Tourism SEZ are dispersed in different locations but a couple of zones are in Metro Manila, Cebu, and Palawan.

Figure 3. Location of Agro-industrial Economic Zones and Tourism Economic Zones

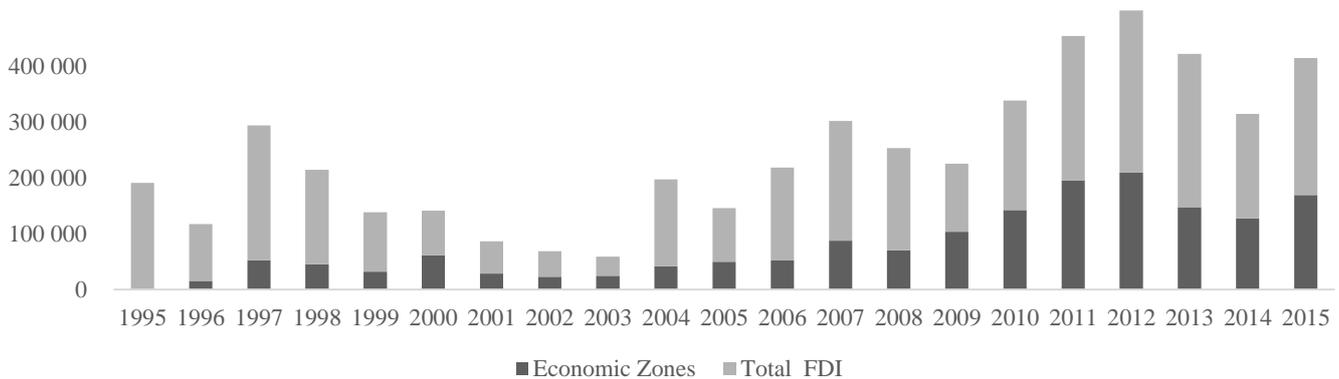

Source: author’s construction based on Philippines Economic Zones Authority (PEZA) statistics

4.2 Performance of Economic Zones: National Level

The flow of foreign direct investments (FDI) at the national level have undergone a boom-bust cycle with significant decline in 1999-2003 (Figure 4). Nevertheless, the amount of FDI have increased from 1995-2015. The erratic flow of FDI is often attributed to unstable political situation in the country. For instance, the 2001-2003 period which had the

lowest level of FDI coincides with the overthrow of Estrada administration due to corruption charges and succession in power of Arroyo administration who was also frequently smeared by political scandals. The impact of economic zones in generating FDI was minimal in 1995. However, in conjunction with increasing number of economic zones, the share of FDI coming from economic zones has significantly risen. Economic zones generate 69% share of the national FDI in 2015.

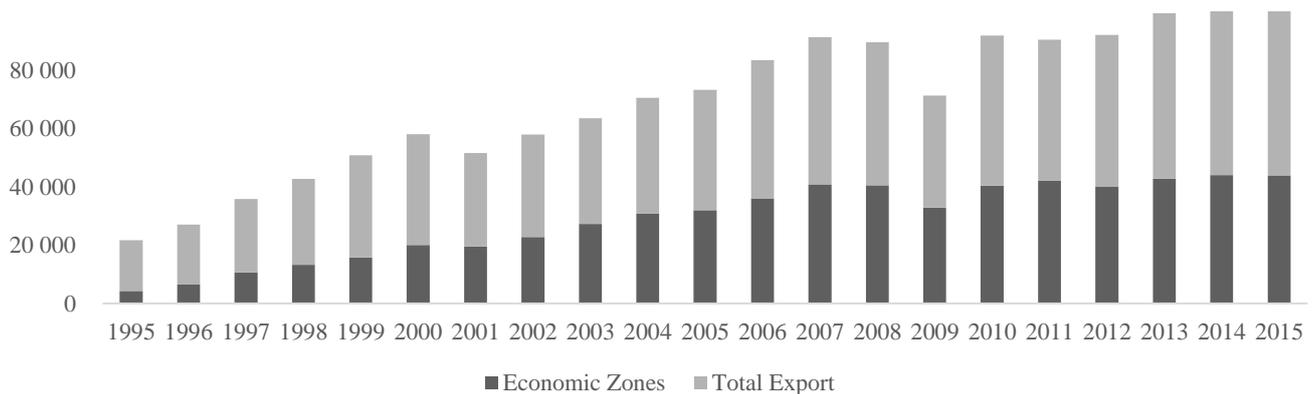

Figure 4. Total Flow of FDI and Share from Economic Zones (Million PHP) 1995-2015 (Nominal Values)

Source: author’s construction based on 1995-2015(PEZA); total FDI (PSA)

In contrast to flow of FDI, the value of exports has been expanding consistently from 1995-2015(Figure 5). The slight dip in exports in 2001 coincides with political instability after the ouster of Estrada administration. The value of exports had also fell in 2009 after the global financial crisis of 2008. The share of exports from economic zones was already relatively substantial at 25% in 1995. The impact of economic zones in exports has prominently increased over the past 20 years. Economic zones have become the most dominant source of exports in the country with 75% share in 2015.

Figure 5. Volume of Total Export and Share from Economic Zones (Million USD) 1995-2015 (Nominal Values)

Source: author’s construction based on 1995-2015(PEZA); total FDI (PSA)

The number of employment generated at the national level has been gradually increase from 1995-2015(Figure 6). However, this growth in employment lags significantly behind rapid population growth. Moreover, despite recent strong economic growth of 6-7% annual gross domestic product(GDP) increase, unemployment rate of 5-6% remains the one of highest in Southeast Asia region (ASEAN Secretariat, 2017).

In contrast to investments and exports, the impact of economic zones on employment generation is relatively weak ranging from 1%- 3% share. The plausible reason behind the marginal effect of economic zones on employment is the analysis only included data on direct employment. The data on indirect employment is incomplete and difficult to estimate so it was not considered in the analysis.

4.3 Evaluation of Performance of Economic Zones: Disaggregated Level

The selected economic zones in this study have relatively diverse characteristics (Table.3). There are 4 zones which belong to 1st group or public economic zones; 11 zones which fall under the 2nd group or zones which began operation between 1995-2000; and 20 zones which are under 3rd group or zones which started functioning between 2001-2005. In terms of type, 29 zones are industrial or manufacturing economic zones and 5 are IT Parks/Centers. In terms of corporate ownership, majority or 20 economic zones are 100% Filipino and the rest are joint-partnership with foreigners. The top foreign investor in Japan. The selected zones are in different areas, but majority are concentrated in few areas: 9 zones in Laguna, 8 zones in Metro Manila, and 5 zones in Cavite. The land area of selected economic zones varies widely. The biggest economic zone in terms of land area is Bataan Economic Zone with 1733.37 hectares and smallest zone is Summit One Office Tower with 0.25 hectares.

Table 3. Key Characteristics of Selected Economic Zones

Group	Economic Zones	Type	Management	Corporate Nationality	Province	Area(Has)
1	Baguio City Economic Zone	Manufacturing	Public	100% Filipino	Benguet	116.25
1	Bataan Economic Zone	Manufacturing	Public	100% Filipino	Bataan	1733.37
1	Cavite Economic Zone	Manufacturing	Public	100% Filipino	Cavite	278.51

3	Summit One Office Tower	IT Parks/Centers	Private	100% Filipino	Metro Manila	0.25

Source: author’s construction based on Philippines Economic Zones Authority(PEZA) statistics

The performance indices of the 1st and 2nd group of zones are calculated at four different time periods, while the 3rd group of zones are estimated at three different time periods (Table 4). The calculated performance indices vary across zones and time periods. To test variation in performance across zones, one-way ANOVA is conducted (Table 5). The result confirms that there is statistically significant in performance index across different zones

To examine the dynamics of the performance of the zones over the years, the study analyzes three different trends: long-term, recent, and consistency of performance. First, the long-term trend which compares average performance in the base period (1995-2000 or 2001-2005) and latest period (2011-2015) is analyzed. Second, the recent performance based on 2006-2010 and 2011-2015 is evaluated. Third, the consistency of performance based on the two earlier analysis is examined.

Table 4. Performance Index: 1995-2000

Group	Economic Zones	1995-2000	2001-2005	2006-2010	2011-2015

The analysis of the long-term trend of economic zones performance reveals some interesting patterns (Table 6). The performance of 1st group or public economic zones has declined from 1995-2015. The zone with biggest decline in performance index is Bataan Economic Zone with -53% decline. On the other hand, Baguio City Economic Zone and Mactan Economic Zone managed to limit the drop to -3% and -9% respectively. More than half of economic zones under the 2nd group have also experienced weakened long-term performance. On the other hand, most of the zones under 3rd

group have experienced better performance. The zone with largest improvement in Northgate Cyberzone with 3141% increase. The decline in performance of many earlier zones suggests the existence of competition from newer zones. While competition may result to decline in performance of some zones, it is eventually beneficial, especially for firms and employees. The expansion in number of zones offers higher chances of finding zones that can meet their requirement. Moreover, some companies prefer to deal with private zones than government office to avoid delay and corruption (Farole, 2011). Subsequently, the increase in number of economic zones and firms can lead to additional job opportunities and higher exports and investments. As illustrated in the case of the Philippines, the growth in number of economic zones corresponds with increase in number of firms, investments, export, and employment.

Table 6. Performance Indices (Base Period vs Latest Period)

Improve		Decline			
2	First Cavite Industrial Estate	82%	1	Baguio City Economic Zone	-3%
2	Laguna Technopark - SEZ	34%	1	Bataan Economic Zone	-53%

Source: author's construction based on Philippines Economic Zones Authority (PEZA) statistics.

The analysis of the recent performance of economic zone denotes improvement of the performance of the many economic zones, notably, public economic zones and IT Parks and Centers (Table 7). The performance of public has grown impressively with notable increase from Bataan Economic Zone with 51% and Baguio City Economic Zone with 29%. The reorganization and conversion into a Freeport Area of Bataan in 2009 possibly bolstered the performance of Bataan Economic Zone. Meanwhile, zones under 2nd group have mixed performance with 6 zones having better performance and 5 zones with worsening performance. Most zones from 3rd group experienced improvement of performance. Overall, there are more zones with better performance than worsening performance in recent period. This improvement of performance of many zones coincides with the overall economic growth in the Philippines. In 2010-2017, the Philippines achieved average GDP growth rate 6.4% (Felipe and Estrada, 2018). Alongside with impressive economic growth is significant expansion of IT-BPO industry, whose contribution to GDP has increased from 2.4% in 2005 to 5.4 % in 2014 (Natividad, 2015).

Table 7. Recent Performance (2006-2010 vs 2011-2015)

Improve		Decline			
1	Baguio City Economic Zone	29%	2	Carmelray Industrial Park I	-33%

The comparison of the performance based on the long-term performance and recent performance denotes consistency of some zones, either consistent improvement or persistent decline (Table 8). None of the public zones had consistent performance. Meanwhile, in the 2nd group, 4 zones are found to have constant better performance and 5 zones with steadily worsening performance. In the 3rd group, 12 zones are identified with consistent good performance and 3 zones are found to have constantly deteriorating performance. Almost all IT Parks/Centers have consistent better performance, and this reflects the continuous growth of IT-BPO industry. On the other hand, zones with constantly deteriorating performance are manufacturing economic zones. Apart from Leyte Industrial Development Estate, zones with constantly deteriorating performance are in provinces with substantial concentration of economic zones which again suggests presence of competition.

Table 8. Analysis of Consistency of Performance

To further extend the analysis, performance indices of economic zones are also ranked. (Table 9). In the first period (1995-2000), Laguna Technopark-SEZ occupied the top spot, while the first generation of public economic zones, Cavite Economic Zone, Mactan Economic Zone, and Baguio City Economic Zone, ranked 2-4 spot. In the second period (2001-2005), the top 3 economic zones have retained their position, while Gateway Business Park and Light Industry & Science Park I moved to the top 5. In the third period (2006-2010), the top 2 zones have maintained their ranking; Gateway Business Park have moved up one place; and Mactan Economic Zone have reentered the top 5. In the fourth period (2011-2015), the top 2 zones held on their previous spots; First Philippine Industrial Park climbed up to top 3; and public economic zones, Mactan Economic Zone, and Baguio City Economic zone, occupied top 4-5 spot.

Table 9. Top 10 Zones

Rank	1995-2000	2001-2005	2006-2010	2011-2015
1	Laguna Technopark - SEZ	Laguna Technopark - SEZ	Laguna Technopark - SEZ	Laguna Technopark - SEZ
2	Cavite Economic Zone	Cavite Economic Zone	Cavite Economic Zone	Cavite Economic Zone

Source: author’s construction based on Philippines Economic Zones Authority(PEZA) statistics

In contrast to earlier analysis which shows IT Parks have improving performance, the ranking shows that manufacturing economic zones continue to deliver more significant outcomes. The dominance of manufacturing economic zones is no surprise as it is more capital and labor-intensive than IT Parks and Centers. The ranking confirms that performance of public zones has declined from 1995-2015. Nevertheless, with exception of Bataan Economic Zone, all public economic zones managed to be top 10 in all four periods. Baguio Economic Zone, Cavite Economic Zone and Mactan Economic Zone continue to play a significant role and deliver strong outcomes. The relatively strong performance of these public economic zones signifies resiliency against competition from private economic zones. The relative success of these public

economic zones can serve as useful guide for the government's plan to build more public economic zones. In the case of Cavite Economic Zone, good location and strong support from the local government drive its growth (JICA, 2004). Cavite is in Southern Luzon or Calabarzon region wherein massive infrastructure projects were pursued to accelerate the industrialization. The local government of Cavite has also been active in inviting investors. The case of Mactan Economic Zone highlights the importance of transition of economic activities (Moran, 2011). Mactan Economic Zone began with low-skilled intensive industries such as garment, shoes, and toys but gradually shifted to middle-skill intensive industries such electronics, machinery and medical equipment. The case of Baguio Economic Zone also emphasizes the significance of the transformation of economic activities from low-skilled industry of garment to high-skilled industries of IT and electronics (Moran, 2011). Furthermore, the development of Baguio Economic Zone was steered by an anchor firm, Texas Instrument.

5. SUMMARY AND CONCLUSION

This study presented some key characteristics of economic zones in the Philippines. Economic zones are defined as selected with highly developed or have the potential to be developed into agro-industrial, industrial tourist/recreation, commercial, banking, investment, and financial centers. IT Parks/Centers constitute the largest number of operating and planned economic zones. The development and management of economic zones are dominated by private sector. Majority of economic zones in the Philippines are private economic zones. The geographical distribution of economic zones demonstrates distinct patterns. IT Parks/Centers and Manufacturing SEZ tend to concentrate in few and relatively developed areas of the country. Meanwhile, Agro-industrial SEZ and Tourism SEZ are relatively scattered across the country.

This study analyzed the dynamics of the performance of selected economic zones in the Philippines. The analysis shows the varying performance of the selected economic zones. While the dynamics of the performance is diverse, certain trend can be identified. First, the analysis demonstrates the declining performance of public economic zones which implies the existence of competition. Second, the analysis also denotes that consistent improving performance of IT Parks/Centers which signifies the continuous expansion of IT-BPO industry.

Meanwhile, the analysis based on ranking indicates that while IT Parks/Centers are constantly performing better, the contribution of manufacturing economic zones remains substantial. This finding is predictable as manufacturing economic zones are more capital and labor-intensive. Moreover, while the public economic zones performance has declined over the years, they continue to deliver significant outcomes. The experiences of the relatively successful public economic zones can serve as rich source of guide for the government plan to develop additional public economic zones.

While this study provides useful insight about the dynamics of performance of selected economic zones, some areas needs to be further investigated. First, as the study points out the possible existence of competition among economic zones, it would be meaningful to further examine the mechanism or structure using models of spatial competition. Second, as the study only provides description of the variation of the performance, it would be worthwhile to analyze the determinants of varying performance. Third, as economic zones are probably one of the most popular spatially-focused instruments, it would be valuable to analyzes the importance of host location whether zones in more developed areas perform better than those in less-developed regions.

1292 PUBLIC SPACE OF KOLKATA: AN EVOLUTIONARY HISTORY**Binay Krishna Pal**Research Fellow (Ph. D.), Dept. of Geography, University of Calcutta, Kolkata, India (Email: binaygeo@gmail.com)**INTRODUCTION**

The Public space has become one of the most important parameters to understand a modern city and its character. As it is the space between peoples' two exclusive territory, it shapes the public lives, their imaginations and actions through becoming a container of public gathering, discussions and participation. Public space is the produced space of peoples' action and integration (Carr, 1992). It is defined as the material and social interactions that characterises the use of that space within the non-exclusive realm of the city (Brown, 2006). It is a space of peoples' mind which although has physical limit but limitless in thinking thus by legitimate activities of the collective over a space. The public space is transformative process of people want, needs and desires. (Slater, J. J. 2004). The defining characteristics of public spaces are- proximity, diversity and accessibility (Goheen, 1998; Zukin, 1995). Public space, being a '*third space*', has played an important role in shaping up urban landscape and rendered a praiseworthy service to nurture human creation. Actually it tries to rationalize the common interest by giving a space to diverse groups to interact, assemble and understand the issues of public interest and policies influencing their lives. There is a tendency towards the decrease of public space for political establishment, whereas increasing focus is on creation of exclusive-premium public space for consumption. Therefore, the democratic-interactive spaces have been transformed to a space of commerce and consumption and too some extent surveillance and police control. Cases of encroachments by real estate developers and commercial entities are found in various parts by changing the natural landscape into a cultural one. The symbolic presentations of the public space have to be taken seriously, as it is approaching towards the sphere of *consumptive hedonism*. In Kolkata, historically the public spaces were framed to cater the leisure and luxury of the Britishers where the native community space was hardly imagined and emphasized. Although people have created and utilized some spaces as common spaces to nurture their wellbeing and interpersonal contact. The practices through urban ecological process have formed distinct neighbourhoods spatially. Post-independence the trend toward the utilization and freedom over public spaces can be called a paradoxical phenomenon where the people were encouraged to maximally enjoy the space limiting to defiant attitude towards authority. In the era of globalization and post globalization, public spaces have been experiencing the same scenario where the previous nature of being considered as the means of leisure and entertainment has been transforming to private clubs, gated multi-complexes, surveillance controlled shopping malls which has not only been barring the people to accomplish a relation with the nature but also disturbing the urban-social fabric. The exclusive public spaces are provided to particular economic groups of people neglecting the role of the state in maintaining traditional urban common space; majority of people has become accustomed with it since a long time. Hence the various public spaces have been emerged as the container of assemblage of various groups of people using common parks, playgrounds, markets etc. Such an attitude of various groups of concerned populations has entitled them as one of the creators of public space. On the other hand, the roles of planners in sculpting public space also deserve a special mention.

Jacobs (1961) was one of the pioneer in urban public space studies. According to him: "Cities have the capability of providing something for everybody, only because, and only when, they are created by everybody." Mitchel (1995) traced police brutality over the conversion of peoples Green Park in California with nexus of UC Berkeley administration and State for a golf club. The values of public space are often celebrated and promoted in the urban studies literature. Public space is represented as a forum that encourages mingling and encounters between people of different classes, races, ages, religions, ideologies, and cultures (Berman, 1986; Harvey, 1992) and as such serves as a breeding ground for mutual respect, political solidarity, tolerance, and civil discourse (Walzer, 1986). The significance of public space to the practice of politics has also been advanced by other political theorists and geographers (Soja, 1989; Young, 1990; Lefebvre, 1991; Ruddick, 1996; Mitchell, 2003; Staeheli and Mitchell, 2004). The existence of spaces and forums to which everyone has access is seen to be critical to the practice of politics: "In such public spaces people encounter other people, meanings, expressions, issues, which they may not understand or with which they do not identify. The force of public demonstrations, for example, often consists in bringing to people who pass through public spaces those issues, demands, and people they might otherwise avoid. As a normative ideal, city life provides public places and forums where anyone can speak and anyone can listen" (Young, 1990). Habermas (1991) explains "public sphere"- a place between private individuals and government authorities in which people could meet and have rational-critical debates about public matters. His work roots in classical antiquity, feudalism and its crisis and emergence bourgeois democracy in Europe. He claims at the initial period of democracy, the societies needed open spaces for the growth of market through political establishment and participation and strengthening capitalism. Now the capitalist crisis of new invention and search for new prime space for market set up for more consumption looking upon the common space once created for bourgeois class's interest. So, here is the need for restricted or reduced public space. The 'privatisation' of public space has been pointed to and criticised in recent literature on American cities (see for example Davis 1990). Argument over expansion of public space emerged from cases of Scandinavian and Chinese cities, where people's expressions are manifested for group's demand and rights as well as daily activism, group-ism Mahadevia (2015). This paper's major objective is to explore the transformation of public space in the city from pre-Colonial period to the present by assessing the evolution of perceptions of public space by planners from different periods. There are underlying agents, shape design the space how it represents itself over a period of time. To analyse and get diverse dimension different time frames have been taken

into account. The city has plenty number of dichotomies over the space and time. This study tries to look into that aspect too.

MATERIALS AND METHODS

This study aims to explore the socio-spatial dynamics of transformation of urban public space, hence take the documentation of archival records which includes publication by the municipality, various authors worked on Kolkata. Newspaper reporting and content analysis is one of the most important dimensions of research. The city space has been represented by various authors of literature through their literary explanations and peoples' narratives. Sometimes literature has modern day social network is also important dimension and tool of research. Now a day many people particularly living in the urban space expressing their likes and dislikes over the social media platform. Takings snaps of their expressions over a period a time on Google Maps and Facebook enrich this study. Spatial analysis tool used in GIS also used to understand the scenario of distribution of parks in different neighbourhoods. The study takes into account experts opinion about their understanding of transformation of public space over the period of time and space. Tracing social transformation is always a nebulous process unlike political and economic change (Sinha, 1978). This study incorporates areas specifically of Kolkata Municipal Corporation (KMC), whenever there are related aspects these has been taken into consideration. New areas have been incorporated into the domain of Municipal Corporation.

INFRASTRUCTURAL PUBLIC SPACE

The traditional public spaces are transforming by the impulse of market expansion. Erstwhile the open market is transforming into surveillance controlled malls, private clubs, exclusive space of assembling and activities (Choudhury, 2017). However, the access, one of the major factor towards the fulfilment of criteria of public space is away to attained. With the unusual and continuous structure of footpaths make inaccessible for the elderly, children and disables, lack of space for pedestrians due to hawking on footpaths people have to take risk to walk on the street. Lack of public toilets and awareness of the people the streets are sometimes unhygienic.

From the infrastructural point of view, public space of any city can be classified into following major types, but not limited to it:

Roads: Roy (1986) has categorised the roads as follows: 1) On the name of Kings and Lords, for e.g. Raja Nabakrishna, Raja Rajballav, Darpanarayan Thakur, Baishnabcharan Seth, Nilmani Mitra, Harighosh, Banamali De etc; 2) On the name of famous people belonged to another province, like- Hujurimal, Rustamji, Umichand etc.; 3) Common people belonged to different populations, like- panchi dhopani, panchu khansama, Akhil Mistri (mechanic), Ramhari Mistri (Carpentar), Chidam Mudi, Ramakanta Mistri (Carpentar), Shyama Bai (women dancer) etc. 4) On the name of various market, like- Boubazar, rajabazar, Shyambazar, Radhabazar, Teritibazar etc. 5) On the name of garden, like- Kalabagan, Peyarabagan, Horitukibagan, Hatibagan etc., 6) On the basis of trees, like- Nebutala, Jhawtala, Nimtala, Taltala etc. 7) On the basis of various caste, ethnic group and their occupation, like- Kolutola, Gowaltuli, Koshaitola, Kumortuli, Uripara, Dhopapara etc. 8) On the names of family or village goddess, like- Chitpur, Gobindapur, Shibtala, Panchanantala etc. and 9) Self Manifested/ Luminous Roads like Serpentine lane, Crooked Lane, Cork Scrue Lane etc. (Roy, 1986). Thus the city has given a space to nomenclature of streets of the people from the different strata of society. It's a very interesting thing that the name of people from sub-altern category was put on street just beside the famous peoples' name. Although the small roads and lanes were named from the lower strata people, the large and famous streets were named on the basis of famous people like, Mahatma Gandhi Road, Chittaranjan Avenue, Acharjya Prafulla Chandra Road, Jagadish Chandra Bose Road (Jwardar, 2003: 26). Now the name of roads and neighbourhoods are influenced by the name of a person, the locality known for its service as well as corporate push to make a known place in the name of their brand. Example can be cited from Exide More (More is a crossing or a nodal point of transport and shops) which has been popularised with the Exide company, a premier heavy battery maker, Ruby More a leading private hospital located near Cosba Etc. Kolkata's roads constitute about 15.2% (9km² out of 62km²) of its total area (UN-HABITAT). The cities of developed nations are characterised by 22%-36% of its street area. Increasing population had required new roads and transport networks.

Footpath: One of the important public space in some of the streets (College Street, Esplanade, Shyambazar, Gariahat etc.) are occupied by the temporary hawkers leads to access barrier of pedestrians. (Pal, 2014). The contest over the utilisation of streets has led to many controversies as several forced displacements from the streets were executed in different periods. Many areas of the city like Gariahat, College Streets have narrow footpaths due to occupancy of the vendors.

Parks: Parks constitute one of the important aspects of public spaces. The parks can be classified according to their size and functions. The concentrations are found mostly in the Central and south-central Kolkata. North & North-central Kolkata really lacks in number and size of parks (Fig-1). People from various parts of the city stated that accessibility, safety are some of the important issue as many parks allow some narrow entry, many places have lack of proper lightening. There are several conflicts over the encroachment on the parks by illegal construction. The morning walker and nearby residents opposed construction of concrete structure in 2017 on Rabindra Sarobar, one of the largest park in south Kolkata.

HISTORICAL TRANSFORMATION OF KOLKATA'S PUBLIC SPACE

Kolkata, has its roots in colonial rule went through various stages of transformation under various authorities. There are many debates whether the city is planned or not. The Formation of Calcutta Improvement Trust in the year 1912 was thought as the benchmark towards managing the urban space and problems (Gupta, 1993). Public space at that time was

not exclusively demarcated and planned. However, the phases of evolution and transformation of public space can be described in the following chronological periods:

- *Colonial (1700-1947)*: a large area of public spaces was designed to cater the need of entertainment and security purposes for the Britishers; e.g.- Maidan was planned to use as a battle ground. Other community spaces were least emphasised, the number of well-maintained parks, square were a few in number. Democratic spaces were hardly imagined and practiced. Although at the later stage, when the educated native emerged to be the new generation of Kolkata and Bengal many places were chosen for street activities, possession, play to display anguish and exploitation by the Britishers (Mitra, 1982). Two parts of Kolkata, British dominated south and native dominated north was uniquely different in terms of representation of space. The British swore by clean, well ventilated and spacious public spaces whereas the Indian dominated was filth, small spaces. There were also differences of designs and motives towards limiting the native space in terms of their utilitarian and maximum use (Choudhury, 2017).
- *Post-Independence (1947-1965)*: Initial period was seen as a vibrant character where people and various political parties used spaces in multiple dimensions like- playground, small markets, dedicated space for democratic gathering and possession. Some of the very popular movements like Food Movement, Land Reform Movement were popularised through varied street activities like street drama, wall art, cultural programmes, stage protests etc.
- *Naxalite Regime (1965-1977)*: This regime is characterised by the perpetuated fear by radicals which started in the northern part of the state, a small village Naxalbari of Darjeeling. (Punwani, 2009; Doner, 2011). Berman (1982) suggested, urban life has been vital in shaping visions of a better world and the attending imagery. Implicit in his and their accounts is the assumption that a bourgeois modernity would be desired and would emerge, as 'traditional' patterns and associations, affective ties and 'backwards' institutions, especially caste and gender discrimination, were left behind. However, in the view of these middle-class men, while the colonial city was on the way up, the post-colonial city for a long time did represent this desire, but fell short in terms of the fulfilment of such modernist visions. In this version of the 'idea of India' (Khilnani 1997), modernity gets unstuck in a narrative within which partition and independence reversed the processes that brought the middle-class within the orbit of utopian urban imageries, and while the post-independence period saw Delhi and Bombay flourish in the new nation, Calcutta lost most of its lustre as cosmopolitan communities left, investment fled and thousands of refugees flocked into the city. The city not only lost investment, but the city public space was full of fear from the police as well as from the extremist radical forces.
- *Leftist Regime (1977s-1990)*: Although the initial phase the public spaces were seen as the urban common property resource. At the later stage the public space has been the means of controls where democratic rights violated for the greater political establishment. Many protesters were accused and sentenced in the name of maintenance of law and order. Public spaces specifically serving cultural, and literary practices happen were emphasised by creating Nandan, Academy of Fine Arts, Madhusudan Mancha, where frequent cultural occasion organises. (Choudhury, 2017).
- *Neo Liberal Regime (1990s onwards)*: Public spaces in Kolkata is still vibrant, while there are some restrictions to use it as an extreme political platform. The Infrastructure has improved a lot, but there are still lags for the different abled and elderly people. The creation of Open Theatre in Alipore and beautifying various spaces like Street Corners, Bus Stands, Parks are happening. There is increasing number of public space which are excluding the diverse peoples' access in terms of their wealth now a day. Emerging shopping malls, entertainment parks, private coffee shops are excluding the erstwhile nature. Although the old tradition is still there, new private or exclusive public space are running parallel.

The traditional public spaces are transforming by the impulse of market expansion. Erstwhile the open market is transforming into surveillance controlled malls, Private clubs etc. With the contemporary trend of expansion of exclusive public space like malls, gated complexes, private clubs barring the essence of public-ness of public space. The colonial legacy of racial bias still persists in Kolkata's public spaces by the segregation of various social groups on the basis of age, community, religion etc. (Kaviraj, 1997).

ANALYSIS AND DISCUSSION OF PRESENT SITUATION

Since the middle of eighteenth century Kolkata started to congregated and become an urban space from erstwhile hamlets. Hawlwel, the then Zamindar of native town, divided different localities for different group or caste of people as the existing social hierarchy did not allowed people to live in same place intermingled. The segregation was done on the basis of occupation or social status of different groups of people as even the people belonged to lower status did not associated themselves with the people of lower caste or status than them. To avoid chaos and disruption of social stability it was created. In that time many higher caste or higher status and economically well off people had come to Kolkata from the surrounding villages to keep themselves safe from *Bargi attack* (Maratha invasions of Bengal). In 1937 a storm destructed almost all the houses, which were mostly non-concrete houses. That incidents led to the construction of new concrete permanent structure houses. In the same time people had come to Calcutta from Satgaon and Hooghly as the ports were destroyed or abandoned. After the construction of Fort Willum, Portugese, Dutch and Armenians also came to live in Calcutta, all these led to population increase and make it a compact city (Joardar, 2003).

The tradition of segregation was not only experienced in the arena of residential or neighbourhood segregation, but in the economic sphere. The first municipal market was established in 1874 as the New Market exclusively for the Britishers in the of the British Town of Kolkata, i.e. Dharmatala. Later many municipal market was set up, but they did not get such importance as the New Market got (Sur, 2014). Chaudhuri (2017) identified public spaces of Kolkata are going through transformation by contest among various stakeholders and participation by the users. As Ahmed Says, "by 1974 there were 186 markets within the Calcutta metropolitan area; most markets are the purview of a religious or ethnic community, and are the business centre of that community. Markets in North Calcutta are run by mostly Hindu communities; the Bara bazaar has historically been home to the traders and money-lenders of the Marwari caste, and the Park circus area has Muslim meat markets. Entering a market is not simply a commercial enterprise, but allowance into the world of a specific community. The city is composed of many quarters, described as "mohulla" or "parah." (Ahmed, 1995).

West Bengal Bangla Academy each year conducts Little Magazine Fair at Nandan, Rabindra Sadan premises. But in 2018 they have announced to shift the fair at the premises of West Bengal Bangla Academy Premise at Salt Lake City Centre. Around 150 little magazines have refused to apply for the fair in the Salt Lake citing cosmopolitan and consumer cultural practices and lack of readers due to problems of transportation. Little Magazine Union Platform (Little Magazine Sommonwoy Mancha). According to the Editor of a Bengali Bi-monthly Journal Ekak Matra and One of the member of that Union has identified it as the attack on the sphere of critical thinking where the artists, authors and readers can directly interact each other.

Public Space as democratic space: The city is considered as a vibrant one in terms of its political culture and practices. Issues which are sometimes cultural, religious and social becomes political as the mobilisation of social groups would led to benefit in the election. Hence the public space of Kolkata in terms of politics is highly competitive. Although the city is seeming to provide a level playing field for political exercise there are some controversies like imposing 144 of Indian Penal Code in the College Street which bans all kinds of gathering to safeguard the academic sphere surrounding (Ekak Matra, 2017). Although critics including eminent human right activist, Sujat Vadra identify this action as the attack on the practices of activism and state control of space to silent the voice of dissent.

Public Space towards safeguarding rights of access of children, women, elderly and disabled: Feminists scholars have questioned the subjectivity of the gender and other social groups of people in the sphere of public space. The existing cultural notions and patriarchal set up creates barrier to the women entering the public sphere. The physical infrastructure most of the time restrict the access to the women particularly pregnant, elderly people, children and the disabled. Beside the physical access, social or economic access of the public space is matter of concern. In the beginning of this year, 2108 the West Bengal Govt. has decided to allow to run autos by women drivers through initiating pink auto on a particular route of Tollygunge. But that move was protested by the men auto drivers citing the effect on their business. They also questioned the need of women in this particular sector. (Banerjee, 2018).

Public Display of Affection: Urbanisation has always been gendered biased in the developing countries as the mode of production depends on the patriarchal system. Until the 1960s the city has seen a conservative tradition of maintaining secret on the affection like love or sexual expression. The situations are changing very fast since the enlightenment period and influx of global modern culture. Still publicly display of affection become issue. In a very recent phenomena of April, 2018 a couple have been harassed and thrashed as they were hugging and kissing in the metro rail compartment publicly (India Today, 2018).

The Debate over accessibility by citizen's vs right to the city of encroachers: The city space is debated over the right of people, as 'whose city' in the arena of 'right to the city' concept. The Bengal Famine in 1943 has produced migration of village poor and occupation on the streets of Kolkata. The food movement also resulted into many violent protest in the city of Kolkata. Post partition and Bangladesh freedom movement in 1971 was marked as the influx of illegal migrants and occupation over the streets and footpaths of Kolkata. Operation Sunshine in 1996 to vacate the illegal vendor or occupants of the footpaths was one of the important incident of conflict over the right of footpaths and public space. (Chatterjee, 2004).

Street and Religious Public space: The streets of Kolkata are full of religious practices includes temporary rock goddess to small temples. Shibram Chakraborty, one of the famous satirist prose writer has identified that the ritual of Shani Puja (Saturn) is the result of fear among the citizen (Chakraborty, 1947). He exposed the then situation of religion and fear over public life, which is reflected on the public space.

CONCLUSION

This research aims to explore in details the critical dynamics of socio-spatial transformation of spaces used by people and controlled by the authority. From the above discussions, it can be attributed that the public space and public sphere of Kolkata was not a simple and linear aspect to conceptualise. Its transformation was carried out by various agencies vis-à-vis public policies, which sometimes helped people to enjoy earnestly and otherwise detrimental to exercise their rights. Economic state of the state guided by the country has determined the inclusivity of the space. The dichotomy of citizens' right to access versus the right to the street dwellers now a day major issue to be sorted. This will indeed be useful for the future planning for a sustainable community life that is increasingly "inclusive" and "participatory".

1551 AVAILABILITY OF BASIC AMENITIES IN CENSUS TOWN AND STATUTORY TOWN: A STUDY ON WEST BENGAL, INDIA

Sandip Mondal

Centre for the study of Regional Development

1 INTRODUCTION

The longstanding metrocentric research orientation in the urban and regional research arena heavily incorporated the world cities as a unit of analysis, focused only on the large financial center. The traditional urban research in India also experienced 'academic bias' towards metro cities Gill (2013) (what is academic bias). But the urban experience of India in this early decade attributed by the growth of small and medium town influenced by the tremendous growth of census town shifted the focus from 'metrocentricity' towards small town (Scrase, Rutten, Ganguly-Scrase, & Brown, 2015).

We are living in an "urban age" where for the first time in history, more people are living in cities than the countryside (Mcguirk, 2010). On the perspective of India's urban transition, for the first time, the absolute increase of urban population is more than the rural counterpart (R B Bhagat, 2011). But the dynamics of urbanisation depends on the definition of urban area and the varied narratives about the conception of "urban" which lead to the problems of a universal definition of urban area. The government of India uniquely defined the urban area endowed by the administrative conception which is known as statutory town as well as by functional conception which is known as census town. The statutory town are those which have a municipality, corporation, cantonment board or notified town area committee, etc. These towns are notified under the law by the state/UT governments and have local bodies like municipal, corporations, municipalities, municipal committees etc. without any consideration of their demographic characteristics (RGI, 2011). The census town are those settlement unit which have a minimum population of 5000, a density of population at least 400 persons per sq. km. and at least 75 percent of male main working population engaged in non-agricultural pursuits (RGI, 2011).

In this early decade India as well as West Bengal experienced an unprecedented growth of census town contrary to the stagnating growth of statutory town. The total number of new census town in West Bengal is 537 which is highest in India followed by Kerala. The reclassification of rural areas into census town contributes 66% to the urban growth for West Bengal for 2011. Out of 537 new census town, the number of town having a population less than 20000 are 517 containing 72.4% of the population. This kind of urban transition interested me to take the state as a case study for studying of the quality of service provisions and household quality of living in census town of West Bengal.

As the urban population and income are rising, the demand for major services such as water, sewerage, environment treatment, low-income housing is increasing five to seven-fold in cities of all type and in every size (Planning Commission, 2012). The responsibilities of providing those basic amenities lie to the urban local bodies. The central difference between the census town and statutory town is their governance status where statutory town is governed by its local urban body and the census town by the village panchayat. The village panchayat itself is funded from the rural development ministry and mainly dependent on the scheme of the central and state government. But the panchayat status may not be enough for the census town for providing basic services which is quite different in nature. On the other hand, statutory town can generate tax and non-tax revenue for undertaking planning and development of the municipal area (Kundu, Bagchi, & Kundu, 1999). In this perspective, the major objectives of the study is to know the difference in availability of basic amenities between the census town and statutory town. Whether the administrative status of census town and statutory is a matter of fact for availing basic services is an arena of inquiry in this study.

2 CENSUS TOWN AND CHANGING NARRATIVES ON URBANIZATION IN INDIA

The unprecedented increase in census town challenges the several viewpoint on conventional urbanisation in India. The growth of census town discards various preconceptions about urbanisation which associate urbanisation with migration, municipalities with urban areas, villages with agriculture and cities with manufacturing (Mukhopadhyay, 2012). These census town emerges as the in-situ transformation of village mainly by the agricultural to non-agricultural workforce transformation without having little role of migration mainly governed by the rural panchayat. By challenging the popular conception about stagnating and unproductive smaller town, the census town emerges as an economically vital settlement in India. These dynamics of census town also opposing the traditional concept of urbanisation by urban sprawls through the in-situ transformation of village into an urban area (Jenkins, 2012).

One of the important aspects of the census town is its spatial dynamics. Contrary to the previous experience, a significant proportion of census town emerge beyond the metropolitan influence (Guin & Das, 2015; Pradhan, 2013). One of the interesting thing portrayed by various scholars that spatial transformation or land use of the statutory town is not confined within its administrative boundaries (GSURR, 2015a). Even the probability of becoming census town is not unidirectional where the transformation of village and census town can be of both ways (Sidhwani, 2014). Generally, the village transforms into census town by the shifting of the agricultural worker to the non-agricultural sector. But, on the contrary, the opposite transformation can also happen by the shifting of the workforce from non-agricultural to the agricultural sector.

The growth of census town is a debatable part in the academic arena. Kundu (2011) coined the term "census activism" where the census town is growing due to the discretionary power of the census official. But Guin & Das (2015), argued

that this unprecedented growth of the census town is not due to the census activism, but due to the distress driven sectoral diversification of the rural economy. The agricultural distress in the rural areas forced to the shifting of labour into the non-agricultural sector. But Samanta (2013) put her argument in an opposing manner by arguing that the agricultural surplus and the consequent movement of surplus from farm sector to non-farm sector led the shifting of the workforce to the non-agricultural sector.

3 CONTESTATION FOR ADMINISTRATIVE STATUS IN THE CENSUS TOWN

The scholars in the academia have contesting articulation about the pros and cons of having rural panchayat in census town. The rural panchayat itself have no specific institution for improvement of infrastructural facilities and basic amenities in census town, contrary to the statutory which is better equipped to provide the basic infrastructure and services to the citizens (Samanta, 2013b). Even the haphazard growth of building areas, degradation of local environment due to increased industrial activities, and land acquisition issues will be easy to handle by the statutory body.

On the other hand, the census town can avail various schemes and government funding from the state and census government (Sivaramakrishnan, 2011). Except this, they can lose the attraction of industry, which now a days have more interest to set up in the rural areas (Anuja, 2012). Even it is not always necessary to set up urban local bodies for own resource generation and supply of services where the panchayat can be creative by raising various types of revenues (Anuja, 2012).

At the local level, various types of socio-political interests e.g. tax structure, service provision, access to basic services, land regulations, interests of certain social groups augment the complexities of classification from census town to statutory town (GSURR, 2015b). Usually, the residents of census town go against the urban status because of giving a higher level of tax for the urban service provisions. But this situation is not universal, where sometimes people are ready to pay tax if they get proper services (Jenkins, Anuja & Gadgil, 2012). The various packages for rural areas like MGNREGS, IAY, etc. provoke people to stay under rural governance as the accessibility to this scheme mainly available for those who live under the panchayat body. The class and caste dynamics also played a key role where the low caste and class are against the urban status by which they will lose the rural schemes. On the contrary, the wealthier wards are in support of the municipality by which they want to get affordable access to basic amenities, water, sanitation, solid waste management, etc. (GSURR, 2015b). Sometimes the administrative status is framed in a local elite framework where local politicians and businessmen who have better connections to the higher level governments have a good deed for an urban status.

State machinery also plays an important role in the contestation of providing of urban status. According to the 74th constitutional amendment, local bodies have to prepare their own development plan and generate their own resources (Bhagat, 2005). But the actual classificatory power from rural to urban administration vested on the state machinery (Bhagat, 2005 ; Sivaramakrishnan, 2011). This has created anomalies in the classification from rural to urban, where sometimes state government do not have any will to devolve power to the local bodies for keeping control over the essential facilities like sanitations, water, town planning, etc. (Roche, Mathew, & Yusuf, 2013). Even sometimes, state machinery becomes pro-urban status because of showing the high urbanization scenario in the state. In the case of Tamilnadu, the municipalisation was boosted by the state government with the impressions of becoming of most urbanised state in India (Bhagat, 2005).

4 PERSPECTIVE ON BASIC AMENITIES AND POLICY IMPLEMENTATION IN CENSUS TOWN

There is limited research on the condition of basic amenities in census town due to the academic bias towards metrocentricity. There is no macro level study on the provisions of services to the census town except some case study and report. The recent researches mainly focuses in the small urban local bodies, but the census town and their condition of basic services is beyond the scope of this study. Even, the research on rural studies, conventionally, did not include the census town in their research arena. Most of the research on the basic services highly engaged into showing the systematic decline of basic amenities from metro cities to small town. In case of the distribution of the service like electricity, there have no difference between census town and statutory towns (GSURR, 2015b). In the study on Singur, Samanta (2014) argued that due to the limited financial resources to provide better infrastructure and services, the overall condition of water supply, sanitation and roads is very poor. The level of infrastructure and services in the census town, they are far from the required by an urban area.

There are various types of complexities in implementing government policy in the census town because of its rural governance. The JNNURM scheme cannot be applied to the census town because it is ruled by rural panchayat (Khan, 2014). Though the 74th constitutional amendment has shaped the third tier of governance, the smaller urban local bodies are unable to perform most of the specified functions (Khan, 2014). The small town is hardly better than the rural areas regarding basic amenities e.g. electricity, sanitation and clean drinking water (Bhagat, 2013). Government have declared RURBAN mission which has a huge potentiality for the census town as well as small town (Nair & Sethi, 2014). The issues of the peri-urban areas and census town and disparity among various settlement could be solved by the mission (Nair & Sethi, 2014). Even the PURA scheme cannot be implemented to the census town for boosting the rural administration (Bhagat, 2013).

5 OBJECTIVES OF THE STUDY

From the above background, it can be summarized that the census town is a contesting space in terms of its politics and governance. Multiple stakeholder are contesting each other for or against the statutory status in the census town. Even

some government policy cannot be implemented to the census town because of its rural government. Even most of the research highly concentrated on metrocentric work flowing the persistence neglects towards small town. So, this study tries to contribute to the above research gap by showing the existing condition of basic amenities in census town and statutory town. So, the major objectives of the study is to contribute the above debate by finding out the existing gap in basic amenities between the census town and statutory town

6 DATA AND METHODOLOGY

This study have been done harnessing the houselisting and housing data at the census town and statutory level of the census of India of 2011. The difference in basic amenities between the census town and statutory town have been shown through a unique line diagram. The maximum covergae of household of any amenities in a census town or statutory town is 100 percent. So, the 100 percent have been divided into ten equal interval and for each division, the percentgae of census town and statutory town.

Table 1: Percentage of census town and statutory town in each division of household coverage

Coverage of household of any basic amenities	Percentage of Census town	Percentage of statutory Town
0-10 %	↓	-
10-20% to 90-100%	↓	-

Source: Author’s own

Then the line diagram has been drawn by putting the division of coverage of household in X axis and the percentage of census town and statutory town in the Y axis. Then the up- bars and down-bars have been put into the line diagram where the white coloured up-bars are showing the proportion of census town are better than the statutory town, on the other hand, the black coloured down-bars are showing the proportion of statutory town better than the census town.

Three major amenities have chosen for showing the difference in availability between the census town and statutory town i.e. water, sanitation and electricity. The following indicator have been taken for water, sanitation and electricity-

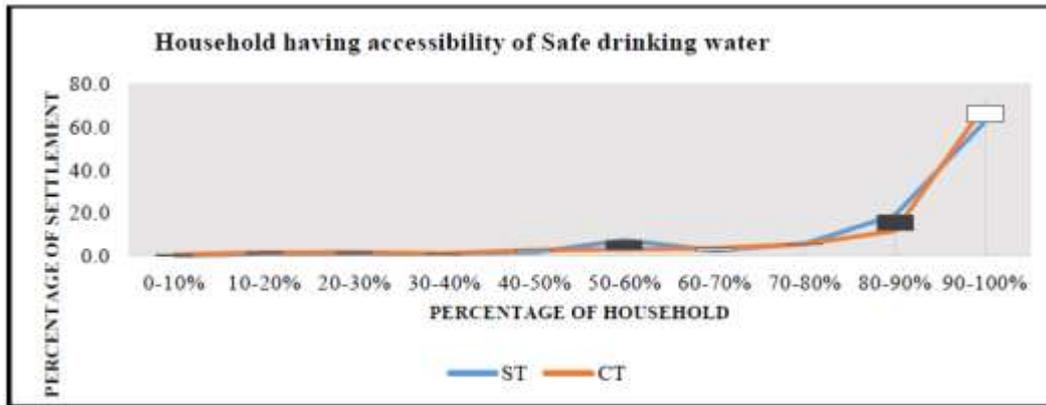

- a) Water: Percentage of household having access to safe water and percentage of household having tap water from treated
- b) Sanitation: Percentage of household having latrine within premises and percentage of household having closed drainage for waste water outlet
- c) Electricity: Percentage of household having accessibility to electricity

The population size of census town and statutory town and their availability of basic amenities also studied. But it is a difficult task to divide the census town and statutory town because Only 14 census town has population more than 30000 population, and only 15 statutory town have a population below 30000 population. So, scatter diagram have used to show the basic amenities and size class division of census town and statutory town

7 DIFFERENCE IN BASIC AMENITIES BETWEEN CENSUS TOWN AND STATUTORY TOWN

The improvement of the governance structure at the local level is a necessity to ensure the provision of basic services to the citizens. One of the critical concern were raised in the ninth five year plan about the ever increasing gap between the demand and supply of basic services (Planning Commission, 1997). Though the challenges of providing civic amenities in the urban area is multifaceted, most of the scholar emphasizes on the three elements e.g. drinking water, sanitation and electricity (Shaw, 2007). Safe drinking water have multidimensional influence in improving quality of living, reducing incidence of disease and deaths, cutting off health expenditure etc. *Safe drinking water here refers to the of sum of the variable of source of drinking water from tap water from treated sources, covered well, hand pump and tube well/borehole.* The percentage of household having accessibility to safe drinking water for the census town and statutory town is 88.05 percent and 86.41 percent respectively (Table C3A1). But There don’t have any significant disparity between the census town and statutory town in terms of household accessibility of safe drinking water as both the line of census town and statutory town overlap each other (figure 3.10).

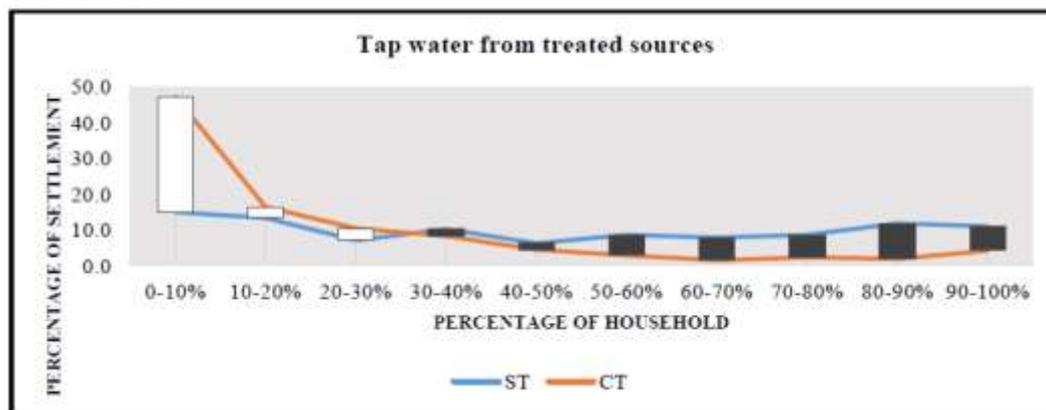

Figure.1: Comparison between census town and statutory town in household having accessibility to safe drinking water

Source: Census of India, 2011.

One of the major source of safe drinking water in the urban area is through tap water system. The coverage of household with tap water system is a reflection of the state intervention directly or through the local government (A. Kundu, 1993). So, the lower participation and capability of the governance influence the coverage of the population through tap water system. The percentage of household covered by tap water from treated source in the census town and statutory town is 21.28 percent and 47.91 percent (Table C3A1). But when it is coming for the individual town unit, it is showing that there is no clear cut division between census town and statutory town. Some proportion of census town is well performed than the statutory town as well as some proportion of statutory town is well performed than the census town (Figure 3.11)

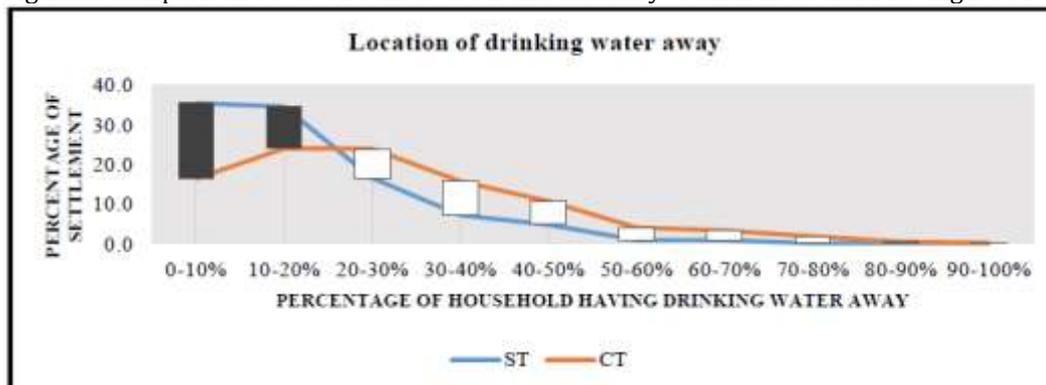

Figure.2: Comparison between census town and statutory town in household having accessibility to tap water from treated sources

Source: Census of India, 2011.

Location of drinking water have important implication from governance perspective and economic status of household. Provision of drinking water within the premises designate the economic status of the household in some extent. On the other hand, the location of drinking water away from the premises indicates the government intervention in providing drinking water to the household. But the availability of drinking water have important implications for more gender empowerment as girls and women are used to fetch water for household and they will get relieve if it became available to the premises (Das & Mistri, 2013). It is showing that the 26.62 percent of household of census town and 16.81 percent for statutory town use to get water from away to premises. From the figure 3.12, the white up-bars indicates that census town have more concentration of household having location of drinking water away from the premises. In that context the laggard economic condition of household in census town leads attract the government attention on the supply of drinking water.

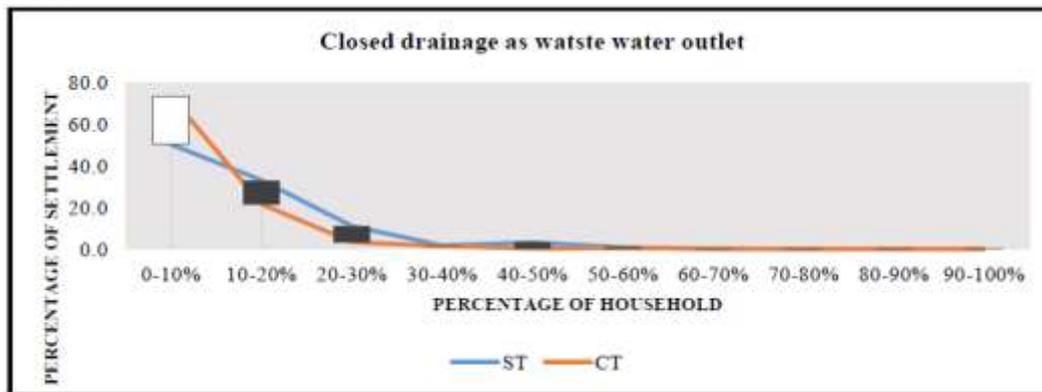

Figure.3: Comparison between census town and statutory town in household having location of drinking water away

Source: Census of India, 2011

Sanitation sector is one of the important sector where government intervention is very much necessary. In India, there is a problem of open defecation. It is revealed in the census of India in 2011 that one in two people in India use to defecate in open space. The latrine facilities within the premises conceals the effort of the peoples at sanitation. The public latrine and the latrine away from the premises indicates the government effort on sanitization (Shaw, 2007). The percentage of household having latrine within the premises for census town is 70.73 percent and for statutory town is 82.73 percent. The percentage of household having flush latrine in statutory town is 60.32 percent and in census town it is 31.73 percent. This indicates that the modern type of sanitation facilities is available in the administratively important towns. But the percentage of public toilet have only 2.94 percent for census town and 3.83 percent for statutory town. This also reveals that there is minimum governance intervention in the sanitation sector.

Figure 4: Comparison between census town and statutory town in household having closed drainage for waste water outlet

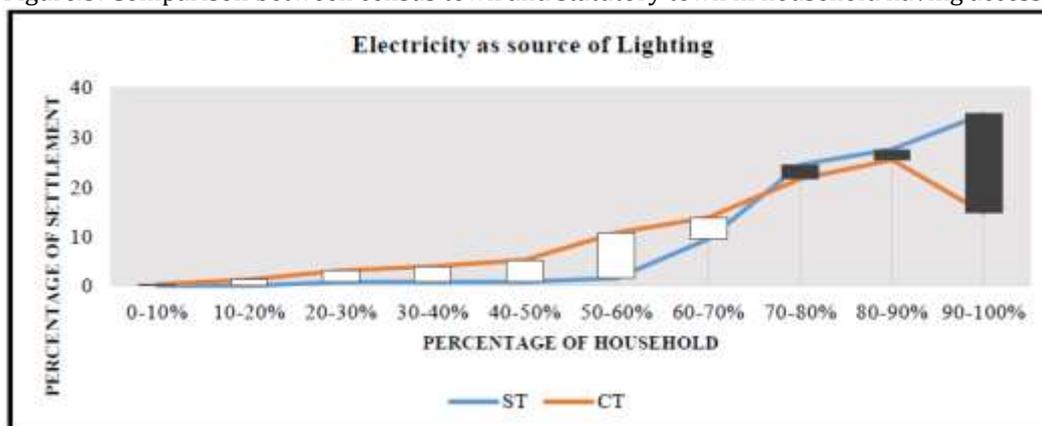

Source: Census of India, 2011.

Closed drainage for waste water is an important effort of the local bodies where the construction and functioning of the drainage lies on the local governance. The micro environment of the local area depends on the sewerage and drainage system which have important health implications. Among the others, closed drainage is hygienic as well as good for health (Haque, 2016). The percentage of household having closed drainage system in census town is 7.57 percent, on the other hand it is 12.46 percent for the statutory town (Table C3A1). When it is coming to individual level settlement unit, it is showing that there don't have much difference between the census town and statutory town in terms of closed drainage as waste water outlet. It is evident that there is minimal state intervention in sewerage system in urban area, albeit the statutory town is well performed than the census town.

The supply of electricity is a function of state government and the magnitude of availability replicates the priorities of the state government. One of the optimization of planners in India is the universal coverage of electricity in India (Planning Commission, 2013). The percentage of household having availability of electricity in census town is 71.38 percent and 82.56 percent in statutory town (Table C3A1). But some census town is well performed than the statutory town which replicating the asymmetrical functioning of the local bodies in providing electricity.

Figure.5: Comparison between census town and statutory town in household having accessibility of electricity

Source: Census of India, 2011.

Is size an important parameter?

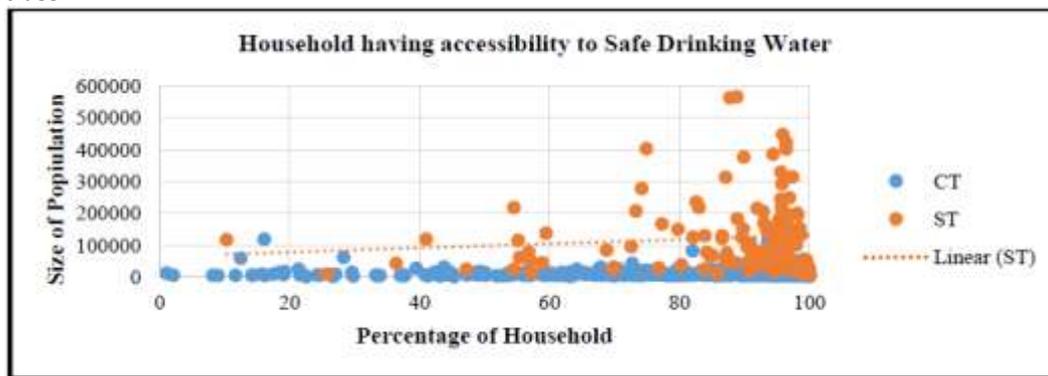

Size class division of town has an important implications for the provision of basic amenities in urban area. The provision of basic amenities in urban area follow a systematic decline according to size class division of town (Kundu et al., 1999; Bhagat, 2011 ; Shaw, 2007; Khan, 2014). The big city is well performed in terms of basic amenities and infrastructural development than the small city. The omnibus project JNNURM taken by the government for urban renewal have been suffused with complexities in resource allocation. Its UIG and BSUP scheme are for the allocation to big city, on the other

hand, UIDSSMT and IHSDP focused on the small town. But it is observed that the big city scheme UIG and BSUP got more resource allocation than the small town scheme UIDSSMT and IHSDP (Khan, 2014). Even in the small town UIDSSMT and IHSDP, the larger town have received more central assistance than the small town and cities. Above all, the JNNURM scheme cannot be apply to the census town because of its governance by the rural panchayat (Khan, 2014).

In this perspective, it is the central task to identify the size class bias in basic amenities in statutory town and census town. The statutory town is enriched with the municipal body for conducting any task relating to provisioning of basic amenities to the citizens. On the other hand, census town is non-statutory in its nature governing by rural panchayat. So, it's totally depend on the schemes of the state government and central government for providing basic amenities to people. Although by being an urban area in terms of its demographic and economic parameter, the JNNURM scheme cannot be applied to this space because of its rural governance.

Unlike the previous study, the role of size class division in census town and statutory town have been shown through the scatter diagram. The outcome is also similar like the previous one where it is showing that the size class division only works for the statutory town. There cannot be found the size class regularity in provision of basic amenities for the census town. It can be found that with the increase of population in the statutory town, there is also increasing provision of safe drinking water (Figure 3.17). On the other hand, there is no regularity with census town with their size in the provision of safe drinking water. Location of drinking water away indicates the inability of the household to install the tap water or tube well in their premises. On the other, most of the drinking water sources outside the premises are due to the government intervention in drinking water supply.

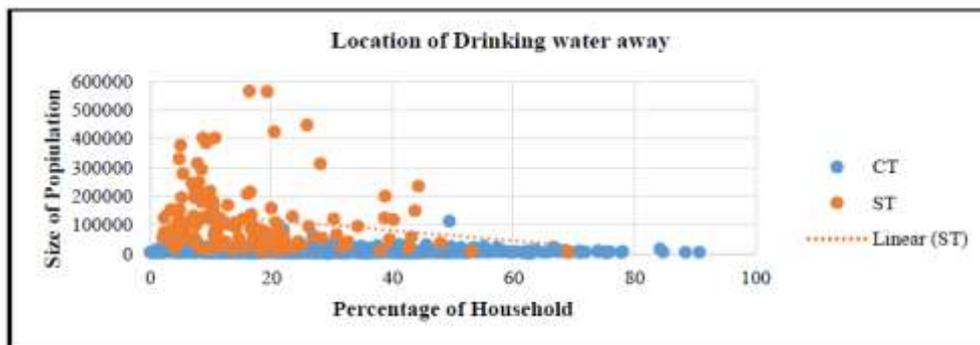

Figure.6: Distribution of household having safe drinking water in census town and statutory town according to their size class

Source: Census of India, 2011

The following figure demonstrate that the decrease of population of the statutory town, the number of household having drinking water away is increasing (figure 3.18). So, the household of small and medium size statutory town are mostly depended on the water sources away from their premises. Thus it can be argued that laggard economic condition of the small and medium statutory town may be responsible for the dependency on the household having location of drinking water away from their premises.

Figure.7: Distribution of household having location of drinking water away in census town and statutory town according to their size class

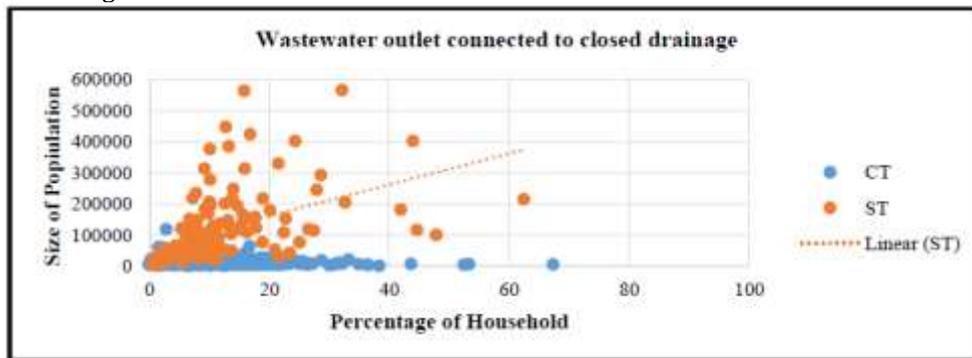

Source: Census of India, 2011

Wastewater outlet connected to the closed drainage have an implication for the microenvironment of the town and cities. The coverage of the household having connection to closed drainage depends on the functionality of the local bodies. From the below graph, it is showing that in the statutory town, with the increasing of the population size of the statutory town, the household having closed drainage increased (Figure 3.19). So, it can be argued that local bodies of the higher order cities have more capability than the lower order cities in managing the micro environment of the cities. Almost the similar findings can be found in case of electricity coverage of household (Figure 3.20). As the demand of electricity for household consumption more in higher order statutory towns, the government is also more engaged in supply the electricity to the citizens. But the local bodies of the lower order cities have less capability to provide the electricity connection. The higher order cities have more electricity connection than the lower order statutory town. The lower

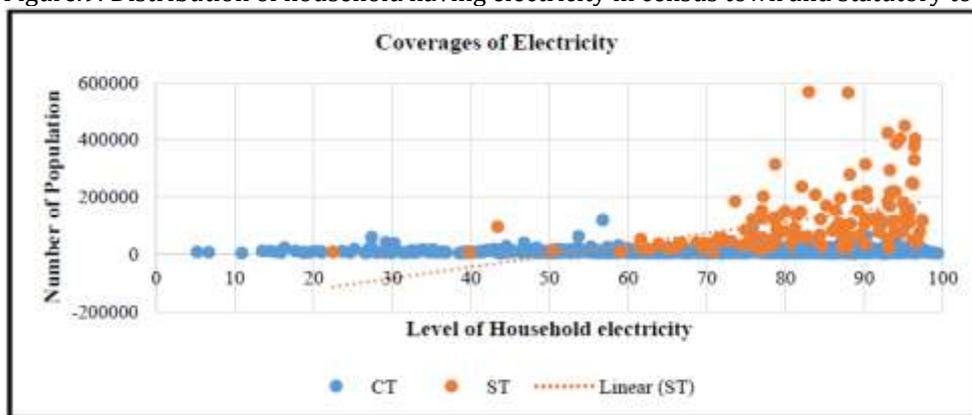

order statutory town fulfilled their demand by using fuel wood, coal etc. in place of LPG. So in a nutshell it can be concluded that the local bodies of the higher order statutory town have more capability than the lower order statutory town in providing the basic services to the citizens.

8 CONCLUSION AND POLICY IMPLICATIONS

The major objectives of the current chapter are the summarization of the empirical analysis, the policy implication by the empirical analysis, and suggestion for the further work. The complex urbanity of census town motivates to study the basic amenities and household quality of living of those settlement unit.

A quite different and insightful scenario can be found when the individual settlement put on a line graph. The various parameter of the housing shows that there is a blurred distinction between census town and statutory town. Regarding the household having good census house, it is noted that some proportion of census town better facility in getting basic amenities compared to the statutory town. Even a significant proportion of census town and statutory town is overlapped regarding their housing parameter, indicating the similar status between them. This scenario is true for the others variable like household having concrete roof, dwelling room four and above, ownership status as owned, census house as permanent, etc. The pattern of basic amenities and household quality of living in census town and statutory is showing almost the same pattern as like the housing pattern.

The pattern of disparity between census town and statutory town has been tried to analyse across size class division. As the range of population distribution between census town and statutory town is very high, scatter diagram have been used for showing the relation between size of population and housing parameter. The pattern is showing that there is no size class bias for the census town regarding housing. But the size class regularity is only maintained for the statutory town where the trend line is showing that there is a positive relation between the size of the statutory town and household having good census town. On the other hand, it is showing that with the increase in the population size of the statutory town, the household having dilapidate house is decreasing. Unlike the previous study, the roles of size class division in basic amenities and household quality of living in census town and statutory town have been shown in the scatter diagram. The outcome is also similar like the previous one where it is showing that the size class division only works for the statutory town. The size class regularity cannot be found in provision of basic amenities for the census town. Actually most of the census town are small in their nature, which in turn, does not create any class division in terms of housing. On the other hand, they are run by the rural panchayat which does not have any institution for improving the housing in census town. For that reason, the fate of the all census town remains same regarding housing and basic amenities.

A comparison has also been done with the census town and village regarding their housing, basic amenities and household quality of living. Unlike the census town and statutory town, regarding census house, basic amenities and

household quality of living, it shows that some proportion of village receives better amenities compared to the census town. On the other hand, some proportion of census town is well performed than the village. Even, a significant proportion of village has similar good census house as like census town.

The size class divisions of the village and census town and the distribution of basic amenities, housing and household quality of living have been shown in the study. In the previous study, it is already established that there is no pattern of availability of basic amenities with the population size of census town. But according to size class division of village showing that some housing and basic amenities parameter are actually decreasing with increasing size of the village. In the case of housing, the household having good census house and material of roof as concrete are decreasing with increasing size of the village. Even the household having accessibility to tap water from treated source, safe drinking water, the location of drinking water away from premises also decreases with village size. So, it can be asserted that the panchayat is unable to provide the service to the village when the population of the village tends to increase. So, at the policy level there need to empower the panchayat so that they can perform well in providing the service to the citizens.

The insightful findings of the above study leads to the recommendation of some argumentative proposition. First of all, it is the gradation of distribution rather than the crude division among census town, statutory town and large village. The hierarchical classification of Indian settlement system does not acquaint with the hierarchical distribution of housing and basic amenities. Though the statutory town has statutory body for improving the quality of living of the residents, still some proportion of census town is more progressive than the statutory town. Even some proportion of the statutory town has equal quality of living as like census town. This is questioning the functionality of the urban governmental institution in statutory town. In India, the urban local body is suffering from multiple shortcomings ranging from the poor revenue generation to limited people’s participation in decision-making. This is, however, not leading to any difference in the quality of living between census town and statutory town. So, there needs a radical reformation for improving the capability of the urban local body to provide quality services to the residents of cities.

A question about the nature of urbanity in urban space can be raised from the above study. One of the important attributes of India’s present urbanisation process is the “morphing of place” where in-situ village area is transforming into urban one by changing its demographic and economic characteristics. But the new census town is not acquainted with the statutory body for providing urban services to the citizens. So, there doesn't have much difference in housing, basic amenities index in census town and large village. As a consequence, the household quality of living in census town and village has only minimal difference. Sometimes, some villages receives better basic amenities compared to the census town in household quality of living.

Some policy level change is a necessary step towards solving the problems raised by the study. The micro level study at the individual settlement unit is showing that there is a gradation except for the clear-cut divide between the census town, statutory town and large village. But the broader policy perspective in India does not consider the complex settlement character regarding the provision of housing, basic amenities and household quality of living. The current policy experience in India is discretely binary regarding rural and urban. The findings of the study shows that some large village is well performed than the census town, as well as some census town are well performed than the statutory town. So, it is necessary to think about the level of development at the village, census town and statutory town and to implement a policy about them rather than rural-urban binary. So, the micro level study suggests that it is a time in the policy arena to shift from the approach of “one for all”.

The second strand of complexity found in the relative performance of urban local bodies and the utility of decentralisation. As some census town is well performed than the statutory town, the performance of urban local body as well as the rising academic judgment towards establishing urban governance in census town needs interrogation.. As some census town is prosperous even under rural governance, and some statutory town lagged behind census town even after urban local body, it is necessary to think beyond the establishing urban local bodies in census town.

Table C3A 1: Descriptive statistics of basic amenities of census town and statutory town

	N		Mean		Variance	
	CT	ST	CT	ST	CT	ST
Tap water from treated sources	783	127	21.28	47.91	650.81	966.47

1612 SOCIO-SPATIAL UNDERSTANDING OF INTER-RELATIONSHIPS BETWEEN CRIME SPACE AND GENDER: AN ANALYSIS OF MURDERS IN KOLKATA

Ratrita Pal

ABSTRACT

Space governs the occurrence, frequency and nature of crime. In fact whatever one does and how, varies with circumstances and settings. Thus nature of crime doesn't just exhibit spatial variation but also genetic variability in terms of causal, co-relational and co-happenstance explanation. The objective of this study was to find the locational variability of occurrence of murders in Kolkata using hot-spot analysis, the gender-based difference in victim-perpetrator/accused relationship and to find the different causes behind these crimes. According to NCRB, murder is the most prominent of all cognizable crimes in India with a growth percent of 7.39% (1953-2006). As a social menace it is of utmost concern as it affects human resource doubly, first it curbs a life and second it cages at least another per incident. Data was collected from Crime Records Section of the Detective Department of Kolkata Police for a period 2012-2015. Inferential statistics and different techniques from GIS platform were used to derive outcome and map it. While Tiljala, Jadavpur, Patuli, Burtolla and Entally police stations recorded maximum number of murders, male murders by male outnumber the other gendered victim-accused relationships. Female murders committed were more in the other categories than the 498-A cases. The reasons behind the murders also varied across the city. Of the various causes, previous grudge was found to be dominant in cases of both male and female murders. Blunt wounds, burns, hanging and sharp wounds were the major causes of death of the victims.

Keywords: Violent crimes, crime-space, gender-space, victim-perpetrator/accused relationship, hot-spot analysis

INTRODUCTION

'Crime' more often becomes an Abstract noun that generates fear, which often has greater impact than the actual events of crime (Evans & Fletcher 2000). Similarly, crime can simply be a complex as well as an organised event occurring in a particular spatio-temporal setting (Shaban 2008). On the other hand it is a social construction, where criminals are found as imminently social creations and are conditioned by a spectrum of social dynamics (P. L. Brantingham et al. 2008). It occurs when an offender, a victim and a law intersect in time and space (fig. 1); therefore a criminal activity is non-random in time and space consideration; rather it raises questions about the location and reasons for its location (Andersen 2006) along with a particular pattern.

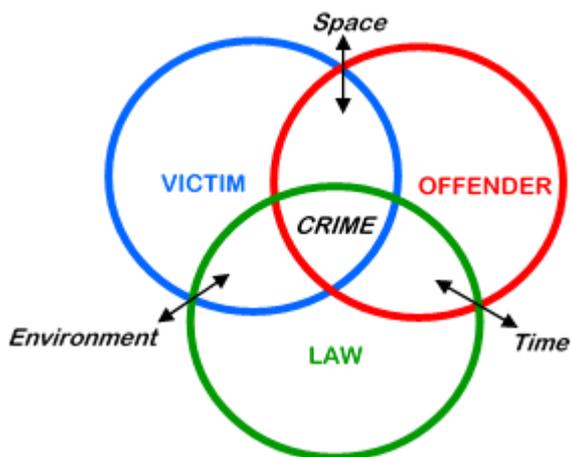

Fig. 1: Conceptual framework of Crime with a close location of space-time-environment setting

Theory of 'Crime pattern' maintains that criminal events occur in persistent, identifiable patterns with time and space dimensions (Brantingham & Brantingham 2013). The spatiality of these patterns are often less than and the fear they generate, thereby affecting significant aspects of daily life, which have been studied closely by human geographers who have examined the interactions between crime, space and society. There is a strong geographical tradition that has focused on mapping crime and explaining its spatial variation (Yarwood 2015). These patterns are temporally structured by routine humane social and economic activities; and are spatially structured by physical and social nodes, paths, and edges that constrain physical activity. They are shaped more deeply by the cultural, social, economic and physical backcloth that underlies any place of human habitation (Brantingham & Brantingham 1993, 2008).

The fact that people are not equally fearful of all places suggests that they understand that crime is not evenly distributed. Hence, the question regarding the 'where' is also an important element in an event of crime. Fear for a space largely depends on one's subjective evaluation of the neighbourhood and the quality of life offered by surrounding environment (Schafer et al. 2006). The perceptual component of crime affects how a landscape is perceived and eventually affects the way of life of the residents of the area, thereby forcing them to negotiate with their quality of life (Foster et al., 2013). The presumption of men's fearlessness coupled with aggressiveness and criminality often overshadows the fact that it the men who are more susceptible to violent crimes, in almost every part of the world. Masculine demand of public space

participation and performance put young men at greater risks of violent victimisation. Fear of violence in both men and women, however, is a function of economic marginalisation and racism (Brownlow 2005).

Crime mapping can be very conveniently considered as an indispensable aid to law enforcement, and has contributed in a significant paradigm shift in policing (Sharon 2006). For these reasons, its strategic implications are also worth considering, particularly the targeted policing of so-called 'hot spots' (Kydnis 2014). GIS plays a crucial role by facilitating the development of the timely and accurate visualization of crime for the combined use of police and concerned civilians (Getis, A. et al. 2000). It helps not only in targeted policing but also reduces socially negative reputation of a place by mitigating the fear of the residents and the commuters. GIS fuses geography with location-based information thereby allowing police personnel to plan effectively for emergency response, determine mitigation priorities, analyse historical events, and predict future events (Johnson 2002). Social Scientists have a responsibility not just to interpret the world, but to try and change it; cartography offers us a powerful tool for action research and a vehicle for promoting social justice (Kydnis 2014). Identifying the problematic zones might act as a feeder to find probable solutions. Since, most of crime mapping being retrospective (Groff & La Vigne 2002), planning for future requires efficient and accurate modelling based on assumptions. However, crime mapping of real time and place through linkages with GPS and Automated Vehicle Location systems can reduce the gap between crime events and crime analysis (Weisburd & McEwen 1997).

UNODC (United Nations Office on Drugs and Crime) reported a global average intentional homicides rate of 6.2 per 100,000 population for 2012 (in their report titled "Global Study on Homicide 2013") The study extensively reports on intentional homicides across the world. It reports on individual countries along with their region and sub region along with the year. The report suggests that homicidal rates are higher in the developed parts of the world. Among the south Asian countries, India ranks 4th with a homicidal rate of 3.21%

National Crime Records Bureau, India publishes an annual report Crime in India. A comparative analysis from 2011-2016 reveals that 'Crime against Body' has been steadily increasing in West Bengal, from 22nd rank in 2011 to 12th rank in 2016. However its crime-rate has always remained below the National Rate.

Table 1: Crime affecting body rate and incidence in India 2011-2016

YEAR	2016		2015		2014		2013		2012		2011

India Total	70.4		68.1		65.4		47.5		46.2		43.4	

(Source: Compiled by author from Crime in India, 2011- 2016)

The paper begins with stating the research problem and then setting out the objectives. It then attempts to give an account of the data sets and methodologies used. What follows is an examination of the overall scenario of the extreme crime i.e. *murders* in Kolkata Municipal Corporation, including its spatiality and temporality, followed by an elaborate discussions on the particular findings and there-after drawing a conclusion.

STATEMENTS OF PROBLEM:

Crime’s influence on daily life is way beyond than just the impact of an event of crime. Research suggests that crime is affected by multiple locational factors and hence it should be studied from sociological, psychological and even geographical approaches, since crime changes its nature from time to time, space to space and even person to person. Location and situation of the victims and accused along with their genders play the most crucial roles in a criminal incident, which adversely affect the quality of life. Here the query is whether there is a geographicality of the crimes committed and the gendered variation amongst them.

OBJECTIVES:

The objectives of this study are

- ✓ To measure the spatio-temporal variation of murders in Kolkata urban unit,
- ✓ To analyse the gender dimension of murders and factors associated with it.
- ✓ To examine the different motives behind these murders and the causes of death in these cases.

DATA AND METHODOLOGY

Data was collected from Crime Records Section, Detective Department, Kolkata Police, West Bengal from their monthly journal 'Crime Review' for the time period of January 2012 to December 2015. The rationale for selecting the time period is that the police jurisdiction areas have changed since 2011 and 2015 was the latest data available. Thereafter the data was sorted, tabulated, mapped and analysed according to their location, victim-accused relationship, causes of death, weapons used and motives behind these murders. Finally the hotspots of murders in Kolkata were identified based on the location of the crime cites.

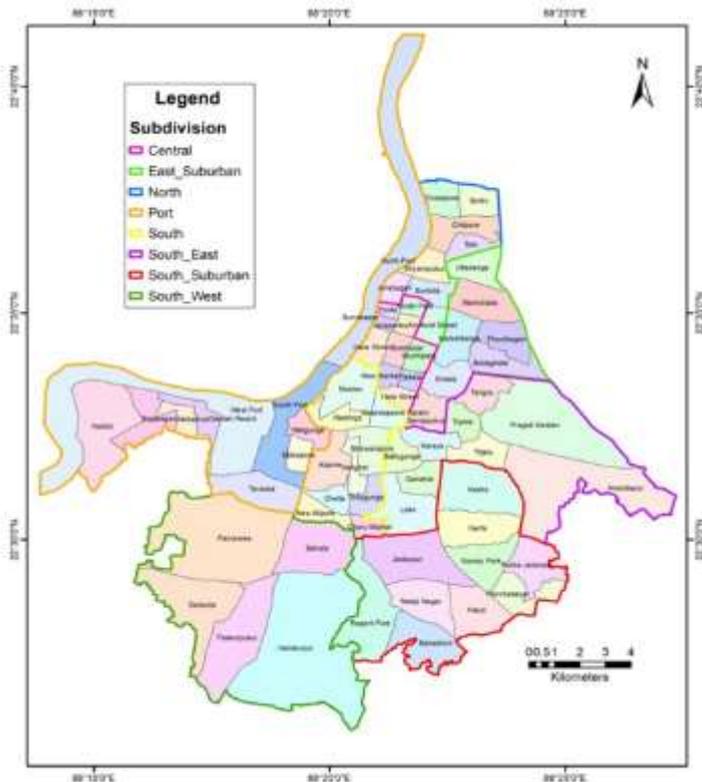

Fig. 2: Police Stations and Subdivisions under Kolkata Police Area, 2015

Criminology groups crime into three broad classifications: violent crime, property crime and nuisance/other crime (Ellis & Walsh 2000). Violent crime includes assault, fighting, hold-ups, homicide, robbery, sexual assault and stabbing. For this paper only murder cases were considered since the data is available only for reported crimes, where final investigation and judgement is yet pending. Geo-coding the point locations of these crimes can be potentially erroneous. Aside from the accuracy of geo-coding algorithms (Ratcliffe 2001) geo-coding can also result in not finding the addresses of point locations. In this case addresses were geo-coded using a website (<https://www.latlong.net>) which provided almost 98% accurate latitude longitude coordinates. These were verified using Google Earth and also field visits. However there were problems of no address records, no street names, or cites being very far away from the study area. Few cases have been left where only the decomposed dead bodies were recovered with ambiguity about the actual cite of murder. The geo-coded data was mapped using ArcGIS software (version 10.2.1). The data was mapped to identify the spots of murders along with gendered victim and accused relationship and incentives behind these incidents. A temporal analysis was also done using the 4 years data.

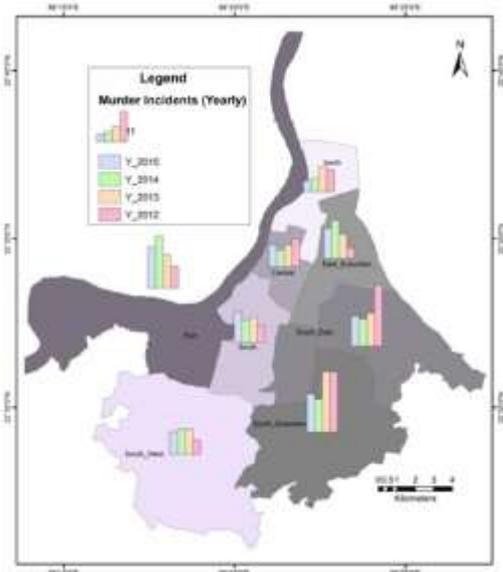

Fig. 3: Murders in Subdivisions under Kolkata Police, 2012-2015

RESULT & DISCUSSION:

The paper looks into the 69 Police Stations and 8 subdivisions of the Kolkata Police Jurisdiction. Data is recorded police station wise, in a chronological manner. IPC Sections, victim’s and accused’s age and gender, cite of crime, cause of death, weapons used and motive behind these incidents were data mined out of the cases’ brief fact. This data served as the

meta-data for the descriptive statistics where spatiality and associated attributes of these cases were mapped and analysed. Further geo-coding the addresses of the sites paved way for the hotspots identification.

(Source: Compiled by author from Crime Review of Kolkata Police, January 2012- December 2015)

SCENARIO OF EXTREME CRIME (MURDER) IN KOLKATA:

The study revealed that maximum murders happened in the police stations of Tiljala (21), Jadavpur (16), Patuli (13), Burtolla (12) and Entally (11). These fall under South East (1), South Suburban (2), North (1), East Suburban (1) subdivisions. The yearly occurrence of murders also reveals that the maximum reported murders occur in the South-East and South Suburban sub-divisions. These areas are the newer residential areas which has heterogeneous population along with high slum population. Moreover these are zones of heterogeneous land use, hence it can be deduced that these factor do have an impact on the occurrence of crime.

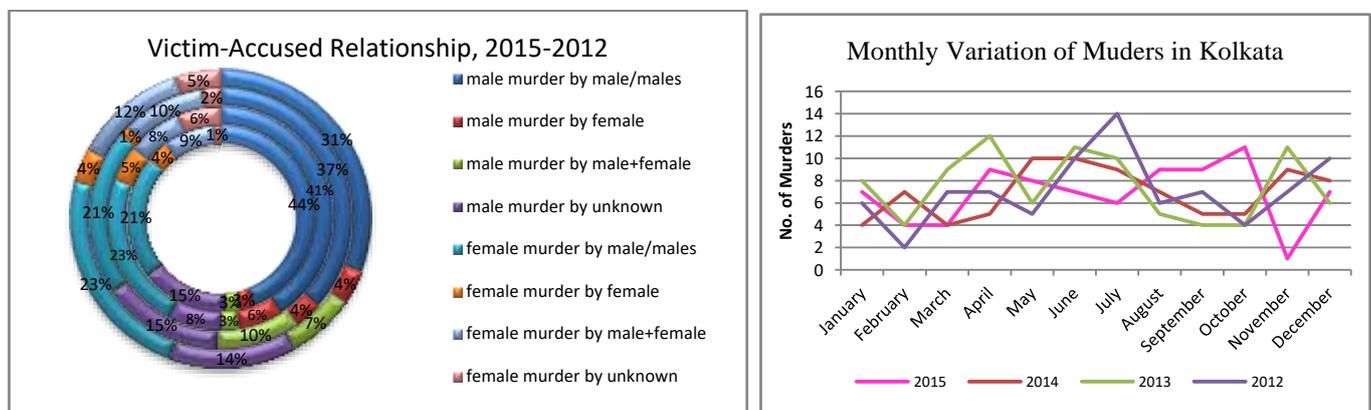

Fig. 4(a): Gendered Victim-Accused Relationship & (b) Monthly Variation of Murders in Kolkata 2012-2015

The gendered victim-accused relationship reveals that male murders by males dominate the crime scene of the Kolkata, which is understandable owing to the fact that males not only spend significantly higher time outside their homes and

also are more socially active in their localities. The next largest number of cases was under male murders by unknown, which comprised cases of death by drowning, hanging and in carnal rape. The number is followed by female murders by males, and though dowry and domestic violence cases come under this category, previous grudge was the major cause behind these murders. In fact the number of cases of female murders registered under Dowry Prohibition Act and Domestic Violence (27.55%) were outnumbered by other cases (72.45%) significantly. The monthly variation of the reported murders reveal that though the lines do not establish a very distinctive pattern, if we overlook 2015, the other three years show a fall in the murders in the months of February, May and September. They rise in April (Bengali New Year), July (rainy reason) and October-November (Durga Puja and other festivities). A superficial study suggests that extreme natural or social climate can have a relationship with incidents of crime.

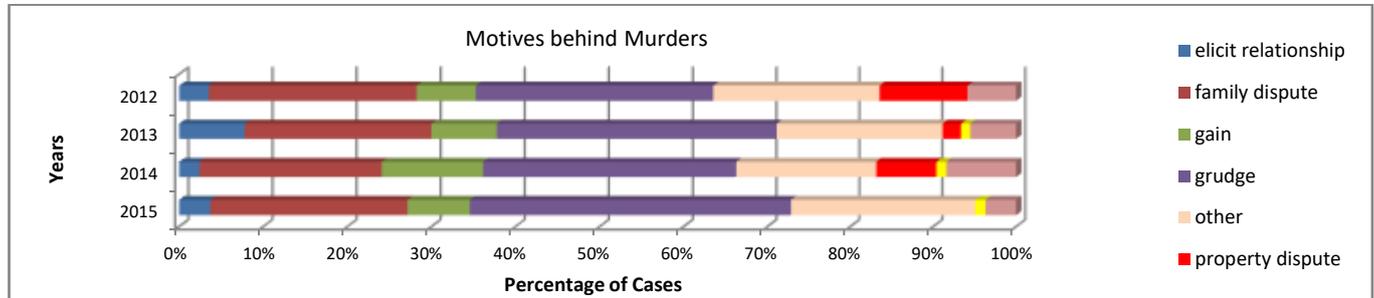

Fig. 5: Motives behind Murders in Kolkata 2012-2015

A study into the motives behind the murders showed that grudge is the most dominant reason followed by family and financial disputes. The murders due to elicited relationship had both male murders by female and female murders by male. It is interesting to see that whereas female murders by males had husbands killing their wives and their paramours, male murder by females had women killing their paramours. The murders under family dispute also include dowry and domestic violence cases, since these are cases that are still under investigation it has been clubbed under family dispute cases. Murders for gain are cases where murders are accompanied with theft (*dacoity* in local language). Geriatric crimes dominate this section. These cases were mostly from North Subdivision with a few from South Subdivision.

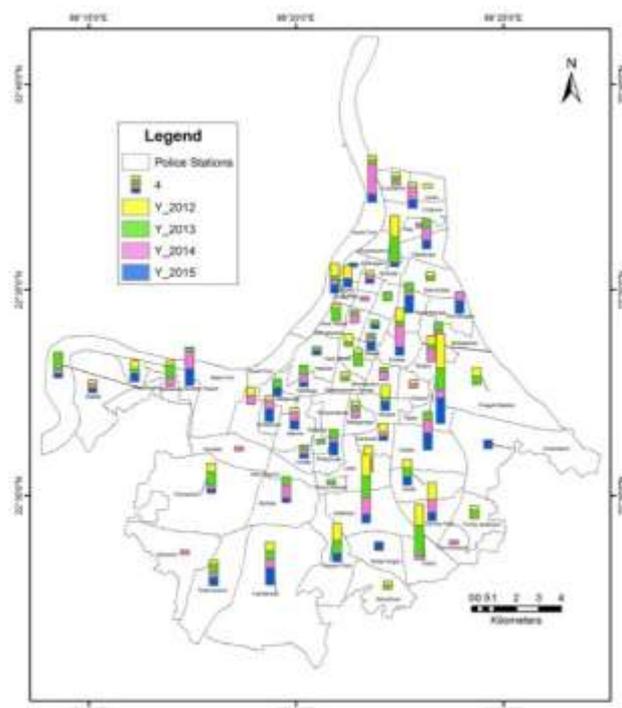

Fig.6: Yearly Variation of Murders in Kolkata 2012-2015

Murders are not just higher in certain subdivisions but also in particular police stations under these subdivisions. The bar charts (fig. 7) give a clearer picture of the inter-zonal and intra-zonal variations in the occurrence of murder incidents. The graphs reveal that though Burtolla recorded 4th highest number of murders during the study period it is the only police station of its subdivision to record such high values, hence murders are quite localised. It is almost a similar situation in the South-East Subdivision which has Tiljala Police Station. However, the East Suburban and the South Suburban subdivisions show that along with Entally and Jadavpur Police Stations respectively, they also have other police stations like Narkeldanga, Ultadanga and Patuli, Regent Park and Survey Park police stations, of the respective subdivisions, recording a moderate to high number of murders. A map (fig 6) helps to identify more clearly the spatiality of these murders.

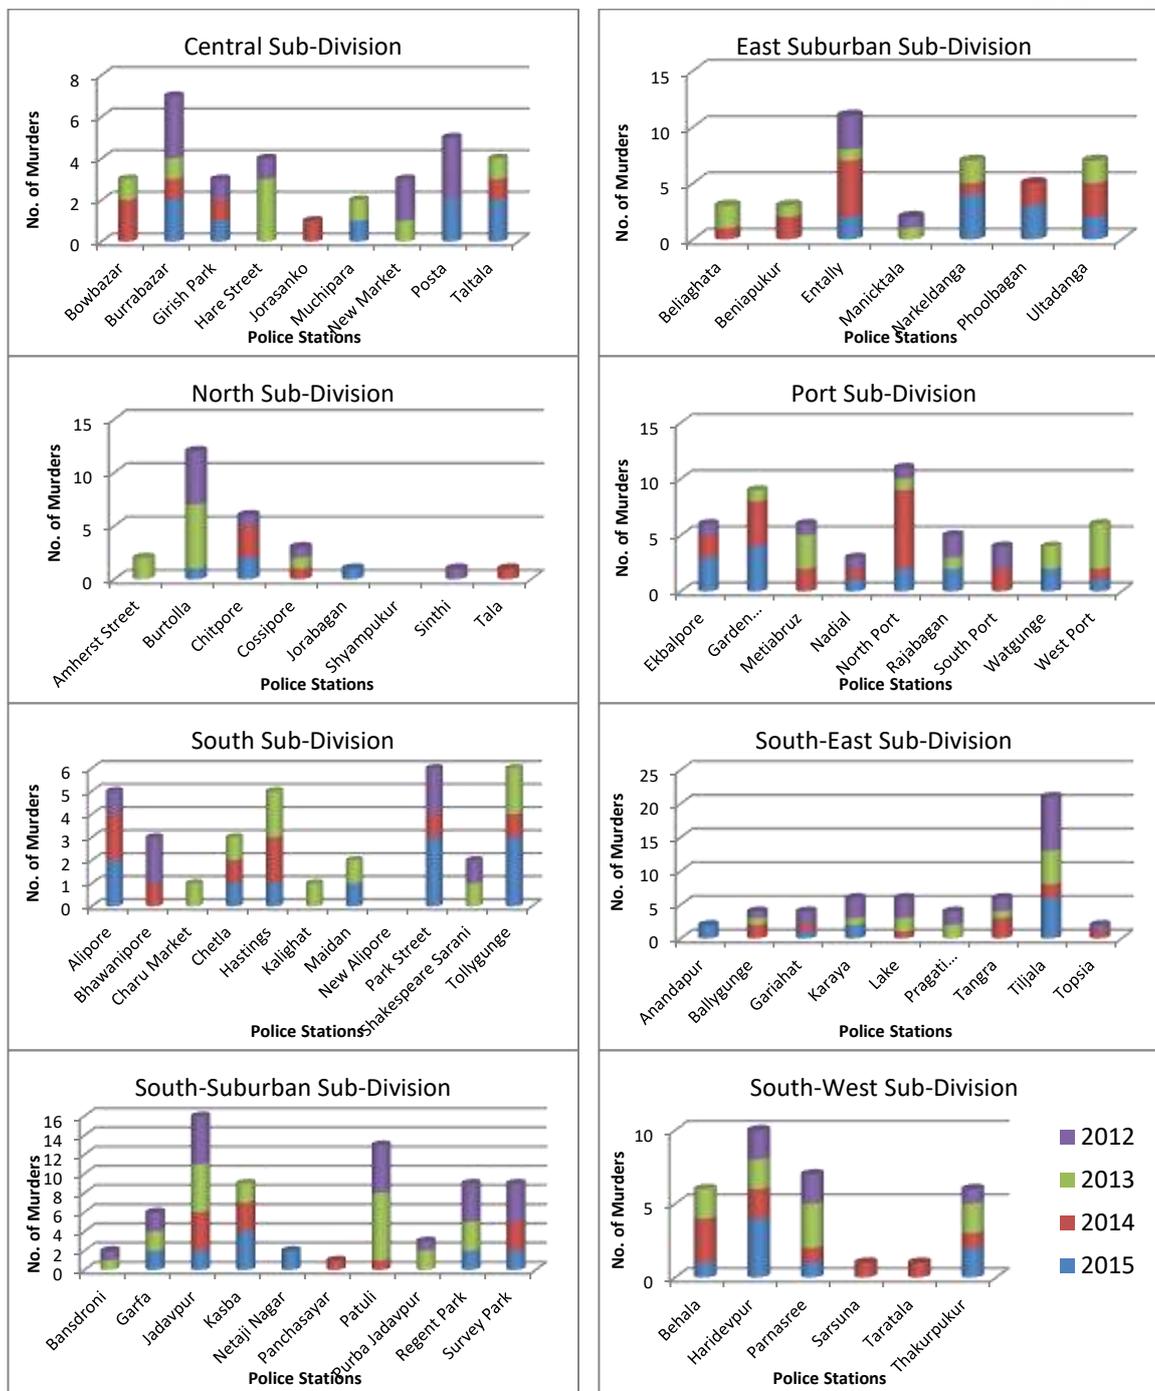

Fig. 7(a)(b)(c)(d)(e)(f)(g)(h): Subdivision-wise Yearly Variation of Murders in Kolkata 2012-2015

SCENARIO OF HOTSPOTS OF EXTREME CRIME:

Hotspots intervention not just supports reallocating existing resources into the treatment areas without incurring any additional costs, but generates both crime control gains and monetary savings relative to traditional policing methods. (Braga et al 2014). Hotspot analysis can be done at three levels:

- ✚ Place theories explain why crime events occur at specific locations. They deal with crimes that occur at the lowest level of analysis—specific places. Crime phenomena at this level occur as points, so the appropriate units of analysis are addresses, street corners, and other very small places, which are typically represented on maps as dots.
- ✚ Street theories deal with crimes that occur at a slightly higher level than specific places; that is, over small, stretched areas such as streets or blocks,
- ✚ At a higher level than place or street, neighbourhood theories deal with large areas. Two-dimensional shapes such as ellipses, rectangles, and other polygons are used on maps to represent crime phenomena at this level.

The most common method of "forecasting" crime in police departments is simply to assume that the hot spots of yesterday are the hot spots of tomorrow. The research on repeat victimization suggests that much more could be learned from further examination of the composition of hot spots and the extent to which repeat victimizations could be used to predict not just future victimizations, but future hot-spot areas (Groff & Vigne 2002).

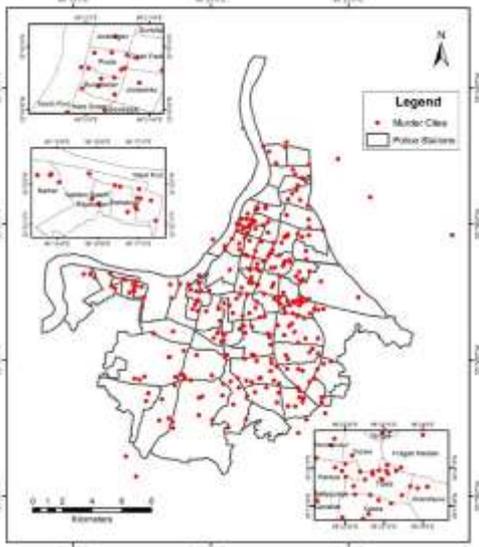

Fig. 8: Hotspots of Murders in Kolkata 2012-2015

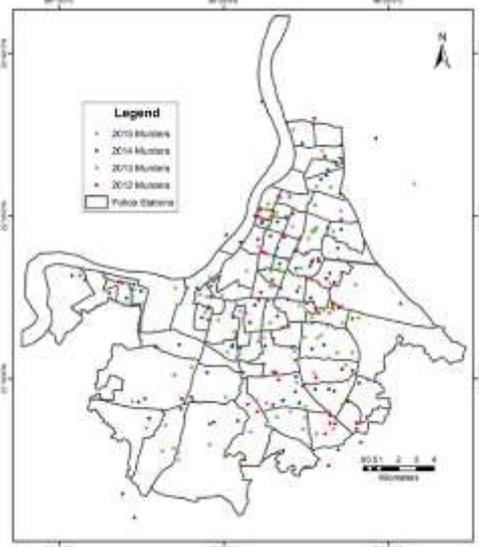

Fig. 9: Locations of Murders in Kolkata 2012-2015

The greatest advantage of Hotspot analysis in Criminological studies is that it identifies very particular spaces where a particular crime dominates. It is particularly a significant tool for Human and Social Geographers to identify the problematic spots in a neighbourhood and look redressal measures to improve the quality of daily life of people of the area and also who commute through the areas. This paper tries to identify the hotspots and describe their attributes only. Extensive field surveys, in-depth interviews and perception studies are required for identifying the locational factors influencing the event of crimes and for suggesting redressal measures.

Murders reported in the four study years (315 out of 340) were geo-coded on a map to find the clusters, and three were identified_ first in the Burtolla area, second in the Metiabruz area and the third in the Tiljala area. These areas were further zoomed and it was found that the murders are being committed towards the periphery of the police jurisdiction areas. Burtolla and Tiljala were identified as concentrated zones of murders in the general analysis sections, however geo-coding the murder-cites pointed another hotspot zone. Most of the incidents of the entire study area showed a higher occurrence towards the periphery of the police jurisdiction areas. Zones of higher incidence rate reports murders in all the four years; inconspicuous reporting is seen in areas of low incidence rates. A temporal analysis of even larger duration might depict starker change of spatiality with time.

To find the spatiality of murder victims and accused (fig 10(a) (b)) the variables have been clubbed into three categories, female (adult/juvenile/single/multiple), male (adult/ juvenile/ single/ multiple) and male + female (adult/ juvenile/ single/ multiple); however, an unknown category had to be kept for the accused. The maps revealed that city core or the Central subdivision is dominated by male victims and by male accused. The outskirts of the city or the suburbs also show a similar trend except for the north section where female victims outnumber males. The number of female victims is higher in the female category of victims, whereas it is higher in female + male category in the accused

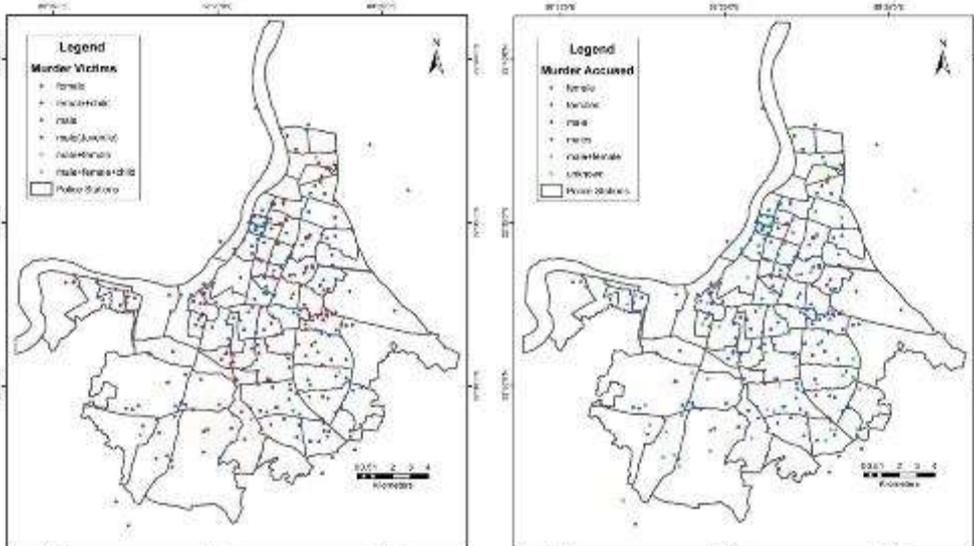

Fig. 10: Location of Murders in Kolkata 2012-2015 based on (a) gender of Victims; (b) gender of Accused

While geo-coding the murders with the motives (fig 11) behind them grudge though quiet dispersed yet was concentrated in the central part of the city including the East-Suburban, Central and South Subdivisions, whereas family dispute cases were spread all over the study area. Murders for gain were in the Eastern part of the city starting from South and South-Suburban to North and East Suburban. These are areas of old residential area with geriatric population and newer posh

areas. Murders due to elicit relationship is restricted to south Suburban and East Suburban subdivisions, with the only exception being Burtolla police station of North Subdivision.

To get a clearer picture of the gendered susceptibility to murder, data had been graphed at Sub-division level. It was seen that except in North and South East Subdivision male murders significantly outnumber female murders. Thus in Kolkata, men are at greater risks to being victims of violent crimes. Of the female murders in the North Subdivision the dominant motive is gain, and the victims are either single ladies or old women. Some property disputes had also led to female murders in this region. The reasons in the South-East Subdivision were quiet diverse however murders due family dispute (including Dowry Prohibition Act and Domestic Violence had a higher frequency.

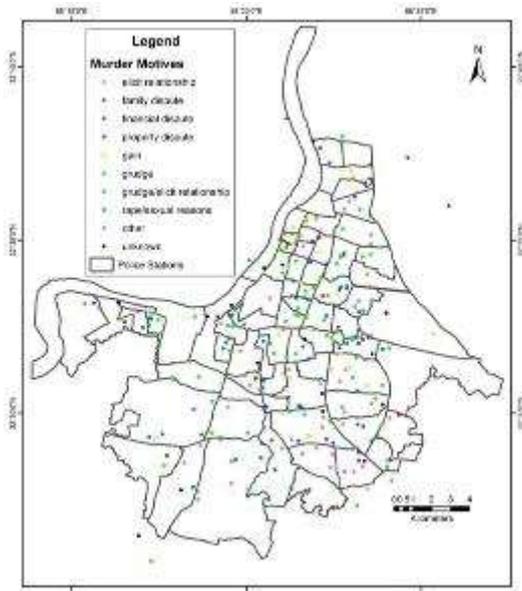

Fig. 11: Spatial Variations in Motives of Murders in Kolkata 2012-2015

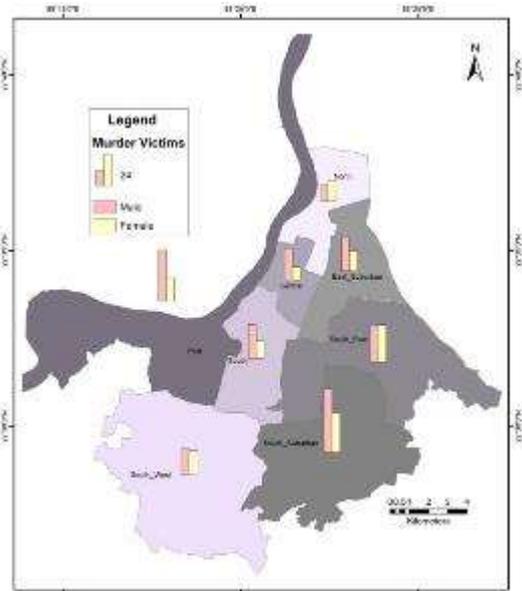

Fig. 12: Subdivision-wise gender of Murder Victims in Kolkata 2012-2015

MAJOR FINDINGS:

This paper looked into the murder-scenario of Kolkata during 2012-2015 and it was found that murder has both spatiality and temporality (monthly) variability. The heterogeneous diasporas of the various regions had an influence on the incidents. The causes behind cases varied from region to region, along with the gendered difference of victims and accused of the incidents in the study area. The gendered analysis revealed that male victims and male offenders outnumber the female victims and female offenders respectively and that female murders were less under 498-A category than other sections. As a matter of figures, 72.45% of female murders were cases without 498A, 304b or DPA (cases of dowry demand and domestic violence). Male murder by males was the dominant victim-accused relationship while grudge and family dispute were the major motives. Though causes of death and weapons used were not studied elaborately, blunt wounds, burns and hanging were the more frequent causes of death of the victims. An analysis into the various causes of death showed that most deaths were caused by blunt wounds (73), followed by burning (54), hanging (47), sharp wounds (44) strangulation (26) and drowning (20) out of the total 340 cases reported in Kolkata urban area. Hotspot Analysis based on 315 cases out of total 340 (cases left out due missing and incomplete addresses) was done on the study area, which resulted in the identification of three clusters, mainly at the Burtolla, Metiabruz and Tiljala areas. It also revealed that murders took place more on the periphery regions of the police jurisdiction areas. Extensive surveys, in-depth interviews are required to understand the importance of the socio-economic factors of the areas to completely understand the total geographicality of murders in the identified clusters.

1595 LOW REPAYMENT CAPACITY AND HIGH INDEBTEDNESS AMONG AGRICULTURAL HOUSEHOLDS IN INDIA: SUSTAINABILITY OF THE SECTOR AS A SOURCE OF LIVELIHOOD

Raya Das

PhD Scholar at CSRD, Jawaharlal Nehru University, New Delhi. Contact No. 8377983018. Email Id: raya78_ssf@jnu.ac.in

INTRODUCTION

Sustainable development of agriculture does not denote a particular way of production process, rather it compels the producers to think regarding the adaption of sophisticated approach that can maintain high yields and farm profits without undermining the resources on which agriculture depends (Pretty, 1997; Diao and Prett, 2010). Sustainability of the agriculture sector depends on the responsiveness of the large section of farmers towards the technological change of the production system and the ability to adapt them. Since, the Green Revolution, Indian agriculture has come a long way. However, the new production system, characterized by the usage of bio-chemical inputs, and mechanisation, is still facing challenges both in terms of accessibility and affordability of inputs by a large section of farm households. "The economic well-being of farm households depends on its resources, production and employment levels, and the ability of income to meet consumption, savings, and other household needs" (Mishra, 2007, p. 5). Marginal farm households with small investment stock are in a critical position due to the variability of income, and they are prone to detrimental effects of weather risk as well as market volatility. They occupy the lower-most strata regarding accessibility to resources, affordability of input expenses, less realization of the price of the commodity as well as the risk of agricultural production. The lack of institutional accessibility and property rights on land destitute this section and make it the most vulnerable segment of the production organisation (NCEUS Report, 2008).

Green revolution led advances in the sector could not bring inclusive and sustainable development due to inadequate policies and failure of institutional reforms in the country. Growth in output bypassed the economic wellbeing of the large section of farm households which overlooked the viability of the sector from the perspective of farmers' income. Primary focus on modern input usage to augment the productivity level undermines the response of local agro climate of the region as well as the resource base of the agricultural households regarding land, non-land resource and base of knowledge to adapt to changes. Lack of diffusion of information concerning judicious input usage brought changes in cropping pattern without focusing on the affordability of the farm households and resource availability. While at the aggregate level, the state may perform well, the situation of small and marginal farmers in agricultural developed regions needs targeted analysis to increase their capability to meet the expenses of increasing inputs and to earn a decent remuneration from the production process.

The trajectory of development path of Indian agriculture from a food shortage economy to a self-sufficient and surplus food production country has attracted much attention. But malnutrition, distress sale, uncertainty in production, bankruptcy, crop loss, and rural poverty are realities in the countryside which indicates the plight of the farmers. Increased news of farmer suicides further questions the viability of this sector as a source of livelihood. The economic situation of the farm households appears to be deteriorating and the viability of the sector as a source of income is under question mark. Poor remuneration from agricultural production process and absence of adequate alternative sources of income illustrate the growing agrarian crisis of Indian agriculture (Mishra 2008, Reddy et al., 2009). Hence it is immensely important to analyse the economic situation of the agricultural households across farm-size groups in a regional framework in accordance with the sustainability of the sector as a source of livelihood for them.

Keywords: Indebtedness, Repayment Capacity, Sustainability, Viability.

SCOPE OF THE STUDY

Agrarian distress is not a short-term event, rather it is a drawn-out process often symptomized by a situation in which farmers get trapped into indebtedness due to unviable expenditures and low repayment capacity. In this paper, we focus on the three major dimensions of economic situation, repayment capacity, extent of indebtedness and economic viability on the basis of Situation Assessment Survey of India 2012-13. Firstly, economic situation of agricultural households in terms of income, consumption and incidence and extent of indebtedness have been described across farm-size groups and regions. At the next level, k-means cluster analysis has been performed to delineate homogeneous economic regions by the repayment capacity and extent of indebtedness across farm size groups. Further determinants of economic viability⁸⁴ which depends on the repayment capacity status of the household, have been traced by Linear Discriminant Analysis across farm-size groups.

DATABASE

⁸⁴ Literature mainly focus on the economic viability of agricultural holdings (Adelaja, 2005), however there is dearth of study on economic viability at household level. India, as well as in other developing countries, the share of agricultural income is reducing especially for marginal and small agricultural households.

Hence, the question arises regarding the ability of total income which includes agricultural income and alternative income sources to generate surplus over consumption expenditure level.

The present study uses the dataset of 'Agricultural Situation Assessment Survey'⁸⁵ (hereafter SASAH) of the 70th round of NSSO unit level data for the year 2012-13 (Jan- Dec) to understand the dynamics of current production organisation of agriculture as the principal database. In this survey⁸⁶, detailed information has been covered on the receipts and expenses in farm and non-farm sectors at household level.

METHODOLOGY

Delineation of economic region on the basis of repayment capacity and extent of indebtedness has been done by k-means cluster analysis across farm-size groups. The basic premise of cluster analysis is to categorize N data points, each of D-dimensional, into groups of K clusters. The method assigns data points to a particular cluster in a way that minimizes the distance between intra-cluster data points while maximizing the distance between inter-cluster data points (for mathematical detail refer to section 9.1, Bishop,2007) This method has been used to target agricultural households on the basis of specific attributes to get an idea about their spatial distribution as well as class specific concentration.

$$J = \sum_{n=1}^N \sum_{k=1}^K r_{nk} \|x_n - \mu_k\|^2 \quad (i)$$

This objective function J is minimized in an iterative fashion performing the following two steps:

$$r_{nk} = \begin{cases} 1 & \text{if } k = \arg \min_j \|x_n - \mu_j\|^2 \\ 0 & \text{otherwise} \end{cases} \quad (ii)$$

$$\mu_k = \frac{\sum_n r_{nk} x_n}{\sum_n r_{nk}}$$

The above two steps are repeated until there is no change in the assignments.

Variables are fitted in the equation (i) and (ii) in both the cluster analysis for allotment of D dimensional data points into specific clusters. In the cluster analysis, N=79 and D=2.

At the next level, linear discriminant analysis⁸⁷ has been used to explain the gap between viable and non-viable agricultural households on the basis variables portraying the socio- economic attributes of the household and the production process across farm-size groups. The analysis has been carried across farm size groups with the assumption that the relative strength of discriminant coefficients significantly varies for the explanation of the distance between these two groups.

SECTION I

Economic Status of the Agricultural Households across Farm Size Groups and Regions

Economic status of the agricultural households considers the consumption expenditure pattern, repayment capacity and indebtedness⁸⁸ of the household. Lack of remuneration from farm income, the pressure of indebtedness, lack of opportunities outside agriculture and inability of policies to tackle the interest of the large section of farmers lead to deterioration of the situation of farmers. But the extent and intensity of distress varies across regions. Most of the incidence of agrarian distress concentrates in the states of Andhra Pradesh, Karnataka, Punjab, and Maharashtra in last decade due to volatility in income, lack of remuneration of income from cultivation, crop failure, huge indebtedness at the household level (Vyas, 2004; Suri, 2006). According to Shah's writing on agrarian distress, it is an artificial creation of the scarce situation where the trauma of pauperization pushed the farmer to the extreme position (Shah, 2012). The level of agrarian distress across regions is hereby discussed focusing on income, consumption, and indebtedness of agriculture households across regions and farm size groups.

⁸⁵ The survey used the interview method of data collection from a sample of randomly selected households and members of the household by stratified multi-stage design method. The survey used for the present analysis, has been covered the rural areas only. The information has been collected by NSSO in two visits to the same set of sample households. Datasets are merged to get the annual estimation of any continuous variable, wherever needed. Otherwise datasets are individually used for the analysis, mentioned in the specific section. For the binary variables, either visit 1 has been used or two visits have been dealt separately.

⁸⁶ This round did not keep 'land possession' as a compulsory criterion to be labeled as the agriculture household, but it puts a benchmark of generating a value of ₹3000 from agriculture with at least one person in the family self-employed in the agricultural sector as a principal or subsidiary status during last 365 days. Hence it includes landless agricultural households (regarding both owned land and operated land) who are dependent on agriculture other than crop husbandry as it takes into account all other agriculture allied activities, termed as agricultural production (SASAH, 2013).

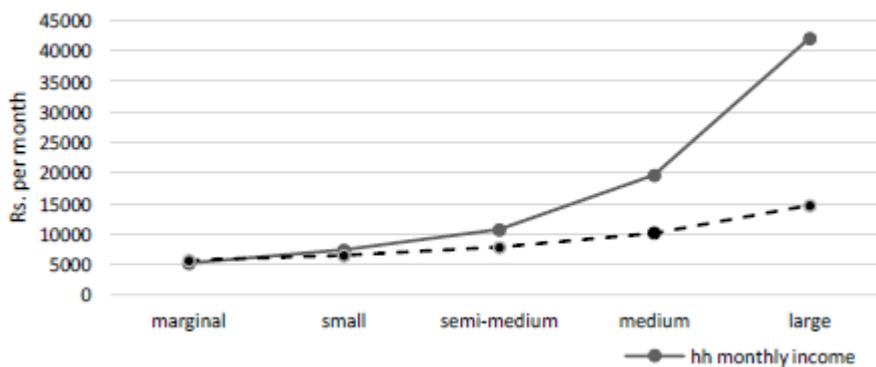

⁸⁷ It is a method of classification proposed by R.A Fisher in 1936. It has been conceptualized to differentiate between two target groups through the explanatory variables.

⁸⁸ Loans included borrowing in cash and/or kind (including hire purchases/credit purchase). Borrowings in kind are evaluated at current retail price prevalent in the local market in this survey. An advance payment received for forward delivery of goods also considered as loan. Cash loans taken for short period without any security are excluded.

At all India level average monthly income is estimated as ₹ 6426 per annum among agricultural households. Across all farm-size groups, Haryana (₹ 12,683 p.m.) ranks top, regarding total income⁸⁹ followed by Jammu & Kashmir (₹12,683 p.m.) and Kerala (₹ 11,888 p.m.). In contrast to that the lowest income per household is earned in Bihar (₹ 3,558 p.m.) followed by West Bengal (₹ 3,980 p.m.). Regarding consumption expenditure⁹⁰ per agricultural household, Punjab (₹ 13,311 p.m.) ranks first followed by Kerala (₹ 11,008 p.m.) and Haryana (₹ 10,637 p.m.) respectively. Whereas, consumption expenditure in rural agricultural households is the minimum in Odisha (₹ 4,307 p.m.) followed by Chhattisgarh (₹ 4,489 p.m.) and Jharkhand (₹ 4,721 p.m.) respectively.

The gap between income and consumption expenditure gets wider across farm-size groups at all India level. Marginal farms generate a negative economic surplus and are not able to earn sustenance level of income from the current production process. Whereas the situation is not so better for small farmers as well; both the curves are almost overlapping for this farm size group which further reveals their incapability of repaying the loan from the current level of income. The graph exhibits that difference between consumption and expenditure shows drastic difference between medium and large farms which elaborates the investment capacity of the large farms and dispossession of marginal and small farmers from the production process due to its inability to generate sustenance level of income.

Figure1. Net Income or Net Surplus across farm-size groups

Source: Calculated by unit level data from NSS quinquennial survey on SAS of Farmers in India 2012-13 Note: Monthly Net Income from all sources and consumption-expenditure data have been plotted at household (hh) level

Eastern states mostly generate a negative economic surplus over consumption expenditure. In West Bengal, the average spending per household is 1.28 times higher than the total income for the marginal farmers along with 51 percent incidence of indebtedness. Bottom 10 percent of agricultural households earn virtually nothing with negative net income; next 10 percent of agriculture households earn only ₹ 13,344 p.a. which is on an average ₹ 1,112 per month per household. Although in these states consumption expenditure is almost half of Haryana and Punjab; even that little amount cannot be afforded by these farmers resulting negative economic surplus with low-income level. But the extent and incidence of indebtedness are comparatively lower in eastern states resulting relatively less pressure of indebtedness among these households. Compared to other states, Punjab performs better regarding the level of income and consumption; but inequality concerning income-consumption is vast across farm size groups. 78 percent of income is spent on consumption expenditure for marginal farmers whereas only 27 percent of the income of large farmers' get used for consumption-expenditure due to the drastic gap in income level across farm-size groups [See T.1.]. Bottom 10 percent of income quantile earn ₹43,655 per annum with consumption expenditure level of ₹1,05,971 per annum as well as an extent of indebtedness of ₹ 45,022 per household. Similar to the situation of marginal farmers, large farmers have spent ₹2,58,662 p.a. on consumption-expenditure with ₹ 11,55,575 p.a. household income on an average. Haryana ranks first regarding total income level, but the distribution is highly skewed towards the upper end of the farm households. Total income of marginal farm households is ₹11,974 p.a. whereas the income of large farmers goes up to 1.4 lakhs per month [see T.1.].

The other highlighted states with agrarian distress are Andhra Pradesh; a closer view of the economic situation of the state reveals the depth of vicissitudes prevails in the state. Bottom 10 percent of agricultural households are running in the deficit from net income from all sources, in addition to that on an average ₹1,06,894 loan amount outstanding per household as on the date of survey. Marginal farmers of Andhra Pradesh and West Bengal belong to the similar position in terms of income, consumption expenditure level, however, the incidence of indebtedness is excessive among marginal farmers of Andhra Pradesh. 93 percent of marginal farm households are indebted with a mean value of ₹ 88,100 loan

89 Total income means Net receipt from all sources, calculated by deducting total expenses from total receipts for each source of income. Expenses included only the actual expenses incurred (out of the pocket expenses) for farm and non-farm business. Imputed expenses in respect of inputs out of home stock or out of free collection as well as receipt in exchange or borrowed were not considered for reporting expenses for the purpose of the survey. Income of the agricultural households from various other non-economic activities such as pension, remittances, etc. are not collected in the survey and not included in the average monthly income presented here.

90 The value of consumption out of purchase, value/imputed value of home produced stock, receipts in exchange of goods and services, gifts and loans and free collection are considered for working out the average monthly consumption expenditure in this survey

outstanding per household whereas the incidence of indebtedness among marginal farmers of Bihar and West Bengal are 38 percent and 51 percent respectively with much lower level of the extent of debt [T.2].

Micro level analysis of Vidarbha region in Maharashtra unearthed that the extent of debt is 3.5 times greater in households with agrarian suicide incidents compared to the non- suicide households (Mohanty et. al, 2004; Mishra, 2006; Mishra & Shroff, 2007). The less repayment capacity is due to shallow total income level along with higher dependence on income from the farm. Eastern part of Vidarbha region are in the 'advance stage of the agrarian crisis' (Mishra, 2006). Marginal farmer households of this region have a total earning of only ₹ 3,344 per month with 28 percent incidence of indebtedness compared to net income of ₹8,900 per month in the inland western region of Maharashtra. The incidence of indebtedness of Vidarbha region rises to 71 percent for the large farm households of the region. While, in Karnataka, due to the skewed distribution of irrigation facilities, inequality is distinct regarding farm income. Bottom 10 percent of the household earns ₹ 5,000 p.a. compared to ₹ 5,10,800 p.a. for the top decile of agricultural household. The state wise income, consumption-expenditure and indebtedness across deciles have been plotted to show the distribution across income deciles of agricultural.

Note: II=Incidence of Indebtedness (Percentage of indebted households), EI=Extent of Indebtedness (Average loan outstanding in ₹

'0000)

Source and Extent of Indebtedness

Concerning the credit supply, 70 percent agricultural household avails institutional loan whereas for small and marginal farmers it is 30 Percent on an average. Since 2005-06 institutional credit flow in agriculture has been increased at a high pace, still it is not able to reach to the small and medium farmers to reduce their vulnerability of indebtedness and dependence on money lenders. They are trapped in hereditary loans and gets forced to sell their land to repay. At all India level, 60 percent of farm households have access to institutional credit including bank, cooperative and Government whereas, 26 percent of agricultural households are still relying on professional money lenders. The dependence on the bank is distinct for large farmers, while small farmers are primarily dependent on informal sources of loan. Due to increased expenses on input, they are forced to lend, and the less accessibility to institutional loan is making them trapped with money lenders. The role of the bank as a lender is increasing, still, it is unable to capture the entire lending market. Regarding the source of indebtedness, the share increases from 25 percent for the landless agricultural households to 58 percent for small farms and it goes up to 70 percent for large farms. Concerning the amount outstanding, marginal farmers have a higher share of non-institutional loan whereas it gets reverse for small farmers and the the share of institutional loan increases across land owning classes.

Figure 2. Incidence of Indebtedness and Loan Amount Outstanding across Land Owning Classes

Source: Calculated by unit level data from NSS quinquennial survey on SAS of Farmers in India 2012-13

Note: Marginal land owners have been further divided into groups due to distinct difference regarding accessibility. Ownership of land is used to compare the asset and liability among agricultural households

SECTION II

Repayment Capacity of Agricultural Households across Farm Size Groups

Now, the analysis is forwarded to examine the repayment capacity of the household. Single- minded focus on indebtedness is not enough to describe the economic status of the household. While, repayment capacity is conceived as the amount of current net income over consumption expenditure of the farm household which examines the capability of the farm family to reimburse the loan amount from the current level of production (Barnard et. Al,2013). 'Repayment Capacity Sensitive analysis' has been used in Barnard's study to measure the degree of repayment capacity calculating by the given formula.

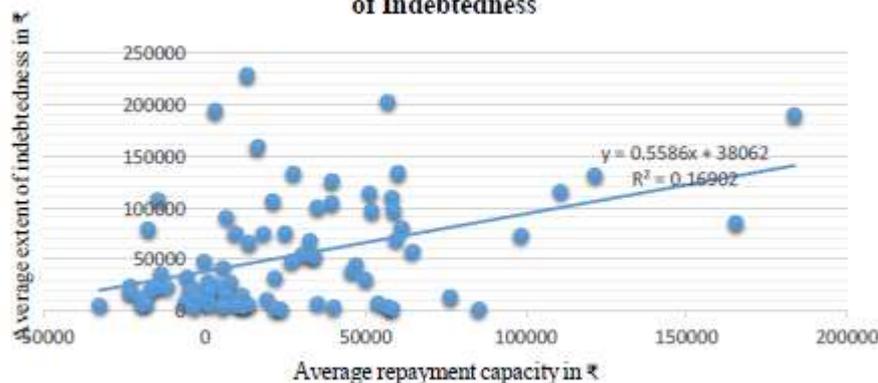

Repayment Capacity of the household=Net Farm Income from Operation + Non-farm income- Family Expenses

The present analysis deducts the family expenses from income from farm and non-farm to get an estimate of the repayment capacity of the household.

Thereby it is important to boost the repayment capacity to make the farm families capable of using loan to increase the production level rather than getting trapped in the vicious cycle of indebtedness. The region with a higher income level of large farmers can sustain greater extent of debt, but the situation is extreme for the areas with low-income level and high indebtedness. Thereby NSS-regions have been delineated by k-means cluster analysis for each farm size groups as well as across all farm-size groups to get broad pattern depicting economic situation of the agricultural households

- High Repayment Capacity with high indebtedness
- High Repayment Capacity with low indebtedness
- Low Repayment Capacity with high indebtedness
- Very low Repayment Capacity with low indebtedness

Figure 3. Relation between Repayment Capacity and Extent of Indebtedness

Source: Calculated by unit level data from NSS quinquennial survey on SAS of Farmers in India 2012-13

The scatter diagram reveals that there is no systematic relationship between net income of the household and the extent of the debt. Rather at NSS-region level, it forms some groups by these two variables. Thereby, cluster analysis has been performed to understand the economic status of the agricultural households regarding the repayment capacity and the extent of indebtedness. Centroid values of clusters [Table 6.7] exhibit that in regions of w1 cluster, net income and extent of indebtedness both are the maximum across all farm size groups. Entire Punjab, Western Haryana belong to cluster (w1) with high repayment capacity and low indebtedness whereas western parts of the country are mostly distressed under lower income and massive indebtedness (w3). Eastern regions have mean income in negative at NSS-region level with comparatively lower debt than western regions. This is the situation across all farm size groups; however, the situation varies across farm size groups. Cluster analysis on small farmers reveals that developed states (Punjab, Haryana) also belong to w3 cluster which is characterized by low repayment capacity and huge indebtedness. Hence, the economic affluence of agricultural household is not only region specific phenomenon; it concentrates in few hands of medium and large farmers of well-off regions. Regarding the cluster analysis only regions of Kerala comprises the high repayment capacity and low indebtedness cluster, whereas some pockets of regions of Western Maharashtra, Western UP are parts of cluster w2 (high repayment capacity and high indebtedness). Eastern and central regions have very poor repayment capacity along with lower indebtedness, while the North western regions and remaining southern regions have huge indebtedness with low repayment capacity.

SECTION III

Sustainability of Agriculture as a Source of Livelihood

The analysis demonstrates that farm income is not enough for the sustainability of the household in most of the states; thereby economic viability on the basis of agricultural income as well as of total income of the household is going to be considered in this section. The farm households are categorized into two separate groups by economic viability of the household. Net income from the household is calculated by net income from farm, livestock and off-farm wage income. The household is labeled as viable if the household generates a positive surplus from the current level of income⁹¹ over consumption expenditure (sustenance level); otherwise, the household falls into the group of the non-viable zone. Firstly, descriptive analysis has been carried out across states and farm size groups to understand the role of alternative sources of income as well as the capacity of farm business income to generate a positive surplus for the household.

The ability of farms to produce a positive surplus for the household increases across farm-size groups. In Punjab, 10 percent of marginal farm households have positive economic surplus depending only on farm income whereas it goes up to 77 percent of large farms. Adding up of livestock income increases the percentage share to 27 percent and 85 percent for marginal farms and large farms respectively, which reveals the importance of livestock income to generate positive surplus especially for the small and marginal farms. While in Haryana the percentage of viable households only by farm income is close to zero for marginal farms and 20 percent for small farms; the share goes up to 52 percent and 76 percent for semi-medium farm households and medium farm households respectively. Including income from livestock, the percentage of viable farm households rises to 19 percent for marginal farmers in the state. In the same way, the gap between the contribution of farm income and agricultural income is even higher than Punjab portraying the importance of the share of contribution of the livestock sector.

Due to high wage rate in both the states, the addition of wage share leads to the viability of 50 percent farmer households among marginal farms. The pattern also shows that marginal farmers are more reliant on wage income to become sustainable farm households whereas small farm households are more dependent on livestock share to earn surplus over consumption and medium and large farmers earn a surplus by farm income only. Rajasthan also portrays at similar

⁹¹ Annual income includes nonfarm business, livestock income and wage. These are measured by deducting the expenses from the value of output. The survey does not include data on remittances

pattern, but the capacity of farm income to obtain economic viability is substantially lesser in comparison to large farms of Punjab and Haryana; only 51 percent of farm household generate positive economic surplus and absence of alternative income sources the situation persists similar even after inclusion of the income from livestock and wage income. In Eastern states the situation is worse regarding the economic viability of the marginal and small agricultural households; West Bengal has only 3 percent of marginal farm households with a positive economic surplus from agricultural income whereas the share goes up to 19 percent only for the marginal farm families after inclusion of wage income. In contrast to that Kerala has 15 percent share of marginal farm households producing a positive economic surplus from agricultural income and it rises to 39 percent including the wage income due to the high wage rate.

The data on income composition shows a higher share of wage income for marginal farm households in Eastern states especially in West Bengal and Odisha; it is evident from the present analysis that the higher percentage of wage is not capable enough to produce a viable level of surplus over-consumption. In Jharkhand and Odisha, the situation is slightly better than West Bengal, with one-fourth of economically viable marginal farm households. The role of livestock income as alternative income source contributes a paltry amount in Eastern states resulting low economic viability for marginal and small farmers in these states.

In Andhra Pradesh out of estimated 33,097 large farm households only 21 percent are economically viable, and due to higher dependence on farm income, the level of viability is same after incorporation of wage earnings. 50 percent of farm households belong to the marginal farm-size group and out of that only 5 percent are economically viable by agricultural income, and it rises to 29 percent including wage income. Small farmers of Kerala perform better concerning both agricultural income viability and overall economic viability compared to other Southern states.

Source: Calculated by unit level data from NSS quinquennial survey on SAS of Farmers in India 2012-13

Note: Percentage of viable agricultural households has been calculated in these three selected category: farm income (FBI), farm income and livestock income (Agricultural income=AI), Agricultural Income and Wage Income (AI+Wg).

Linear Discriminant Function Analysis (hereafter LDA) has been performed to differentiate the economically non-viable and viable agricultural households by a set of variables and to measure the relative strength of these variables on the viability of the household. At the aggregate level, the explanatory variables provide a crude picture; hence regression has been focused on marginal and small farm size groups as well as across all agricultural households, dividing into viable and non-viable farm households to trace the variables which decide the viability status of the agricultural households.

$$Z = \sum_{i=1}^n L_i X_i \tag{i}$$

where,

$$Z = \bar{Z}_0 + \bar{Z}_1$$

Xi = Variables chosen to explain the causes of variation between two groups X1 = Land Owned in hectare (as an indicator of land asset)

X2 = Family Size (as in indicator of economic burden)

X3= Loan Outstanding per hectare (as an indicator of liability)

X4 = Share of livestock income (reliance on non-crop agriculture) X5 = Share of wage income (dependence on off-farm income)

X6 = Cost of cultivation per hectare (as an indicator of the intensity of input use) X7 = Per capital consumption expense (an indicator of standard of living)

X8 = Productivity (GVO per hectare)

X9 = Percentage of secondary above education (knowledge of farmer)

X10 = Percentage of area under HVC to GCA (as an indicator of cropping pattern) Li= L1, L2....., L10 (Coefficients or weights of discriminating variables)

Z-score (critical discriminant score) has been calculated by summing up the score of a mean of estimated Z0 (non-viable farms) and Z1 (viable farms).

Z0 and Z1 are obtained by multiplying the mean value of Xi with the specific coefficient and are added to get the individual score. If the individual has score fitting the equation (i) greater than Z the individual falls into economically viable farm household otherwise it belongs to non-viable farm household zone.

*' 1 percent, '**' 5 percent and '***' 10 percent significant level respectively

Table 2. shows the result of LDA analysis; the p-value for all the models is less than 0.05 depicting that the function is capable of discriminating between viable and non-viable farm households. Canonical Correlation results of the models illustrate that the set of variables are correlated with the set of discriminating groups at a significant level.

Table 3. Validation Results of Model

	Marginal	Small	All farm
Canonical Correlation	0.215	0.33	0.26
Likelihood ratio	0.953 (0.000)	0.886 (0.000)	0.932 (0.002)

Source: Calculated by unit level data from NSS quinquennial survey on SAS of Farmers in India 2012-13 (figures in parentheses are p values)

Model 1 examines the impact of discriminatory variables on viable and non-viable farmers among marginal farm households. It is observed from the discriminant coefficient that the share of wage income followed by ownership of land and area under high value cropped explain the maximum share of discriminating coefficient of viable and non-viable farm households.

A one standard deviation increase in the share of wage income leads to 0.593 standard deviation increase in the predicted value of viable farm households at statistically significant level. A one-unit increase in productivity level leads to 0.22 standard deviation increase in the predicted value of becoming viable farm households; it has the maximum share in discriminating distance among other variables. The mean productivity of viable farmers is ₹71360 per hectare whereas the productivity level is substantially low in non-viable farm household with a value of ₹ 46650 per hectare. In line with the positive relation between productivity and viability of farm household; it is also observed that cost of cultivation is inversely related to the viability of farm among marginal farm households.

Among all the farm size groups marginal farm households has the maximum relative strength of percentage of HVC to GCA to explain the higher predicted value of viable farm household. The mean percentage of area under HVC to GCA is 20 percent for viable farm household whereas it is 12 percent for the non-viable farm households. The mean difference in productivity between viable and non-viable farm household persist to be the same for the small farms; the mean difference is of ₹ 26395 per hectare. Regarding the demographic composition of the household family size is inversely related to the viability of farm households across all farm- size groups; individual models depict that family size has inverse relation till semi-medium farm size households whereas medium and large farms show the positive relationship with the viability of the household.

Mean value of the cost of cultivation per hectare is higher for viable farm household compare to non-viable farm household across all farm-size group, but according to discriminant function cost per hectare impacts the viability of household positively for marginal farms but it has an inverse relation to other farm size groups. A one-unit increase in standard deviation of cost per hectare brings down the predicted value of becoming viable agricultural household by 0.48 times and 0.39 times for small farms and semi-medium farm size group respectively. The relative strength of discriminant coefficient increases for large farms and a one-unit increase in standard deviation of cost per hectare reduces the predicted value of becoming viable agricultural household by 0.67 times.

At all farm size, level of education above secondary positively influences farm viability with discrimination coefficient value of 0.31; which depicts that one-unit increase in the standard deviation of above secondary education leads to 0.31 unit up-rise in the predicted probability of viable farm household. Per capita increase in consumption expenditure is inversely related to the viability of farm households excluding large farm size group. That means large farm households can afford a higher level of consumption expenditure per capita whereas higher expense per capita is an economic burden for other farm size groups and influences the probability of non-viable household.

CONCLUSION

The paper has examined the economic situation of agricultural households in India across farm size groups and regions. Indebtedness, itself is not disadvantageous for farming households. However, repayment capacity reveals the ability of the household to reimburse the loan taken. The economic situation of Andhra Pradesh reveals that Bottom 10 percent of the agricultural households are running in a deficit from net income aggregating all income sources with intense extent of indebtedness. Marginal farmers of Andhra Pradesh and West Bengal belong to a similar position in terms of income, consumption expenditure level but the incidence of indebtedness is acute among marginal farmers of Andhra Pradesh. Less repayment capacity in Vidarbha region is due to very low total income level along with higher dependence on income from the farm. Marginal farmer households have total earning of only ₹ 3,344 per month with 28 percent incidence of indebtedness compared to ₹ 8900 per month in the inland western region of Maharashtra. The study further investigated the determinants of the economic viability of agricultural households across farm-size groups at all India level. Regarding the viability of agricultural households, the share of wage income followed by ownership of land scores the maximum to differentiate viable and nonviable agricultural households for the marginal and small farmers. The analysis finds out that the share of alternative sources of income, income from livestock and the income share of wage, are distinct for bottom 40 percent of agriculture households across the states. In the Eastern states and Kerala, the bottom 30 percent of farm families have a higher share of wage income than income from the farm which indicates the moving out of farm families for other sources of earnings. However, in Eastern states, even including the wage income, marginal agricultural households are not able to meet their expenditure from the farm and nonfarm income. Alternative sources of income have an immense role in the betterment of the economic situation of the agricultural households. A frontal strategy to

raise wage income needs to be taken to ensure the economic viability of marginal and small agricultural households. The situation of marginal farmers even in agriculturally developed states is under crisis; however, livestock sector significantly supports these households to meet their consumption. Expansion of livestock sector, especially in Eastern states needs to be taken as an alternative strategy for the economic well-being of land-poor agricultural households.

1602 MIGRATION AND LABOUR MARKET: A CONTINUED CASE OF OCCUPATIONAL SEGREGATION AND CASTE DOMINANCE

Dipsita Dhar

INTRODUCTION:

The traditional theories of migration (Todaro, Haris, Stark) had introduced migration into a broadly rational framework where in reality it is an outcome of various social, cultural and economic construct. It is rather community or the identity, one individual immediately identifies with during making such decision that influences the mobility. This paper thus borrows the theoretical framework from Turton, Richmond and Van Hear and tries to place migration behaviour in recent Indian context where the migrants are considered as “purposive actors” in particular social, political and historical situations. Caste being one of the most crucial social order that controls the means of production and labour division, this paper will look how caste as a category influences migration. Caste is here not constrained as an identity only but apprehended as a “cultural capital” that enables some people to access skill in form of education and restrict rest from doing the same. At the same time it seeks to testify the claims of migration being an agency of social mobility through change in occupation.

The migration optimists from academia has often mentioned migration to be a window of opportunity which people from marginalised community use to escape from the traditional exploitative economic and social structure. Settling in a new place thus can be empowering in some sense as it gives a chance to rearrange the social relation and overcome the marginalisation. But in reality it is more likely it is the ‘marginalisation’ that gets rearranged in different form keeping the fundamental alienation and deprivation as it was. The study shows even after the migration the labour force remains highly segregated in terms of caste and gender, certain kind of occupation show the dominance of people from certain communities and though the occupation changes but the social strata or the class position remains unchanged. For example an agricultural labour from the rural area becomes informal labour with no assurance of future after migrating to urban area, there can be partial increase in purchasing power but the vulnerability remains constant. Those who could actually get mobility through migration are predominantly those who have some kind of privilege either in form of class or caste and sometimes both. So the people from lower caste who are also from lower class even after migration continue being as what Marxist say “reserved labour pull” and get further exploited. This paper thus tries to bring in the essence of vicious nature of labour exploitation and the social immobility of marginalised migrant labours in the present Indian context.

1. ENCOMPASSING CASTE CLASS AND MIGRATION:

“The distribution of economic and political power is central to the decision-making process at the individual and collective level. ‘Rational choice’ within a means-end schema, in which individuals maximize net advantage, is a special case rarely found in isolation from decisions which are influenced by direct coercion, manipulated opinion and value systems, the non-rational pursuit of transcendental goals and normatively oriented voluntaristic action.”⁹²

The idea that Richmond propagated had taken into account the complexity and the multicausal nature of the decision making. It essentially included the non economic factors which played significant role in determining the degree of autonomy an individual or a community can actually exercise even regarding the access to the strictly economic factors. The movement of people is no longer seen in a binary but in a continuum of different social processes. A step ahead the theory of **Van Hear** in the same line also had tried giving a holistic answer on why people migrate? Interestingly he took the effort of redefining the class as a universal category with inclusion of social and cultural factors embedding into it. He argued “class in itself and class for itself”.

“While once a mainstay of social science, class has lately been eclipsed in much of migration studies by consideration of other forms of social difference, affinity, and allegiance such as ethnicity, gender, generation, and lately religion. This article puts the case for renewing attention on the part class plays in shaping migration – particularly who is able to move and to where. It argues that the form of migration and ultimately its outcomes are shaped by the resources that would-be migrants can muster and that in turn the capacity to mobilize such resources is largely determined by socio-economic background or class. Drawing on Bourdieu, class can be conceived in terms of the disposal of different forms of capital – economic, social, and cultural. Having access to combinations of such capital shapes the routes and channels migrants can follow, the destinations they can reach, and their life chances after migration.”⁹³

Borrowing the conceptual framework from this above two, this paper will attempt to see the Indian migration trajectories putting the major on caste and how it actually shapes up the endowment of other capital forming distinguish class category which further controls the occupation choices and social mobility of individual or community.

In India Caste is one of the major social realities which cuts across different religion, due to the long history caste based society this further acts as a controlling factor in all most all aspect of life. It results in presence of endogamous social groups in which social position is hierarchically arranged and ascribed. The patterns of landownership and the distribution of occupational and educational opportunities remain very closely linked with caste in India. As a result, it

⁹² Richmond Anthony H.; Sociological Theories of International Migration: The Case of Refugees; 1988.

becomes a determining factor in determining access to economic, social and cultural resources. The caste system with its normative order differentiates the various segments within and between the castes. Although hierarchical and localized nature of caste system, its rigid rules, the strict adherence and the attachment to caste system along with its close knit boundaries tend to hamper spatial mobility. At the same time the caste system also pushes the process of migration by becoming the basis of social inequality and conflict. Caste system is the root cause of innumerable problems like differential values being attached to different castes, discrimination and tensions between the castes, differential resource distribution based on caste, exploitative economic categories along caste axis along with the exploitative social forms of relationship. All these are very closely linked with caste based migration. There are some studies that have shown the impact of caste on migration. They reveal that caste has a different effect on migration because different caste groups perceive migration differently and take decisions to move out accordingly. Their perceptions and motives of migration are regulated by the caste based socio-economic inequalities. For example if the caste position varies the perceptions and motives of migration also vary accordingly. Since social caste and economic class inequalities co-exist there is both the caste and class selectivity in migration. The study of Rajasthan villages by Kothari shows that the propensity to migrate is high in upper and lower caste groups.

This is confirmed by Yadav's study done in 1989 on the rural-urban migration in India. The upper caste migrants move to gain from migration while the lower caste migrants move for almost no gain. For instance after the partition of India the second wave of refugee influx and the social composition of that population had created a strong movement in Bengal named "Namasudra" movement under the leadership of Matua Sangh which precisely raised the discrimination the dalit refugees were facing by the state. It has been argued by historian Sekhar Bandyopadhyay that 64 in 'post-colonial West Bengal, the violence caused by partition and refugee influx led to a re phrasal on the idioms associated with victimhood, with less emphasis on caste and focusing more on the causes of migration and the struggles faced by the refugees' and hence, in spite of perpetuation of caste based discrimination, "caste" as an idiom of protest disappeared from public space.⁹⁴

Pradip Kumar Bose specifically hitting on the casteist nature of the state mentioned that the Namasudras had been the prey of calculative discriminatory responses of the Indian state which quite overtly followed a caste line vis-à-vis its rehabilitation policy. Unlike the upper caste Hindu refugees who were settled in and around the city of Calcutta, the Namasudra migrants were either resettled in the uninhabitable camps in districts of 24 Parganas, Nadia, Burdwan, Midnapur or Cooch Behar or deported mostly to inhospitable areas of Dandakaranya and Andaman Islands. Being utterly confused and disillusioned by the factionalism in its leadership on the eve of partition, and largely lacking the family/caste connections and other means to survive on their own, most of the Namasudra refugees had to depend on government relief schemes and hence were meticulously scattered in small pockets in different parts of India. In other words, the earlier organized dalit movement was effectively broken and the dalit refugees were strategically not allowed to unite.⁹⁵

In a study by **Danen Benbabaali** where she looked in to the specific mobility of Kammas from the Andhra Pradesh she showed, how the dominance over land has given the Kammas the opportunity to move from their native lands and take important jobs specially in the Southern Peninsular Cities and with active participation in politics and entertainment media helped them gaining power not only in undivided Andhra Pradesh in the leadership of Telegu Desham Party but also able to influence a decent number of mobilisation in Tamil Nadu, she described this whole assertion in social hierarchy with an important note on their physical mobility and coined this dominance as not merely "material hegemony" but as ideological too. ⁹⁶ **Deshingkar and Start** had argued in the line that the lower castes, due to the inaccessibility to land tend to migrate more than the other landowning castes.⁹⁷ The same argument was given by the scholars like Breman(1994) too. Tsujita and Oda while analysing the migration trend just like Danen had established the link between the landholding, caste hierarchy and the influence on migration decision, but quite contradictory to previous scholar had mentioned of a non linear relationship between these three. In earlier literature also Oberoy and Singh (1983), Van wey (2005) had found an "u" shaped relation between these. A study on the migration between US-Mexico found out an inverted "u" curve.

There had been ample number of studies on the relations of caste and migration, with contradictory claims. Where scholars like Khan, Mahapatra, Rajan and Mishra argued that the probability to migrate among the SC and ST is more than the rest, Shukla (2006), Kara (2006) and Bhagat (2010) argued the case reversely. Berman (1985) too argued in the later line and said there is over representation from the lower caste in the circular migration. Skeldon (2013) on the other hand brought in the class angle and stated that out of poverty people usually migrate but there can be situation where due to acute poverty people might be unable to move as well. Thorat (2005) inter linked exclusion, initial inequality and low economic growth as the cause of "chronic poverty" and migration as a tool to escape that. Ellis (2003) in the same line of thought referred migration as a "central livelihood strategy". Interestingly a study by Korra (2010) on the migration pattern in Andhra Pradesh didn't put migration into a simplistic caste binary but tried to focus on the intersctionality and variation where states "each upper caste house has one person migrating at urban areas, where rural to rural migration is common in Madigas and the other landless marginal agricultural labour".

As the caste hierarchy is traditionally directly related to the access to means of production specially the land, which too is an important factor while discussing the migration as land can be a source of livelihood which if is labour intensive tend to keep people grounded around the land, where as the income that land generates can also be an incentive for providing the capital to move. In an agrarian society landlessness too can result into the either of the condition where a person chose between staying back and moving out. Scholars like Belwal (2007) Khan (1986) Mahapatra (1998) and Lipton (1976) found out a negative relation between the land holding and outmigration, whereas a study by Yadav (1996) found showed land to be a potential supplier for initial capital to migrate.

There had been ample number of studies on the relations of caste and migration, with contradictory claims. RESEARCH DESIGN, DATABASE AND METHODOLOGY:

In order to get an empirical result the India Human Development Survey-II (IHDS-II), 2011-12 is used as a database which is nationally representative, multi-topic survey and includes 42,152 households in 1,503 villages and 971 urban neighbourhoods across India. Statistical tools such as regression model, co relation co efficient and cross tabulation and thorough analysis of literature available is used for better understanding of the subject.

Variables like Caste (ID13), Seasonal Migration (MG1), Education (ID18), Access to land(Landowned1) is used in the exact form that is given while surveying. The variable “Class” is defined as the quartile of total income to have a easier classification.

While defining the different type of occupation, some of them are clubbed together on the basis of nature of the occupation (formal-informal and according to the NATIONAL CLASSIFICATION OF OCCUPATIONS-1968) and classified to understand the social and economic mobility through occupational change.

Salaried: Architects, Engineers, Technologists and Surveyors, Engineering Technicians, Aircraft and Ships Officers, Life Scientists, Life Science Technicians, Medical and Technical Persons, Journalists Creative Artists, Composers and Performing Artists, Professional Workers, Elected and Legislative Officials, Administrative and Executive Officials, Financial Institutions, Working Proprietors, Working Proprietors, Directors, Managers and Related Executives etc.

Business and Service related: Merchants and Shopkeepers, Wholesale and Retail Trade, Manufacturers, Agents, Technical Salesmen and Commercial Travellers, Salesmen, Shop Assistants and Related Workers, Insurance, Real Estate, Securities and Business Service, Salesmen and Auctioneers, Money Lenders and Pawn Brokers

Domestic help and Petty service Provider: Hotel and Restaurant Keepers, House Keepers, Matron and Stewards (Domestic and Institutional), Cooks, Waiters, Bartenders and Related Worker (Domestic and Institutional), Maids and Other House Keeping Service Workers, Building Caretakers, Sweepers, Cleaners and Related Workers, Launderers, Dry-cleaners and Pressers, Hair Dressers, Barbers, Beauticians and Related Workers, Protective Service Workers, Service Workers. **Agricultural:** Farm Plantation, Dairy and Other Managers and Supervisors, Cultivators, Farmers other than Cultivators, Agricultural Labourers, Plantation Labourers and Related Workers, Other Farm Workers, Forestry Workers, Hunters and Related Workers, Fishermen and Related Workers. **Non agricultural:** Metal Processors, Wood Preparation Workers and Paper Makers, Chemical Processors and Related Workers, Spinners, Weavers, Knitters, Dyers and Related Workers, Tanners, Fellmongers and Pelt Dressers, Food and Beverage Processors, Tobacco Preparers and Tobacco Product Makers.

A thorough statistical analysis of secondary data, literature available and **Richmond Migration axis** is used for narrowing down the conclusion of the study. To see the change in the occupation the simple % calculation and to understand the factor affecting them cross tabulation is used. All the graphs and tables are calculated from IHDS data (2011-12) independently by the author.

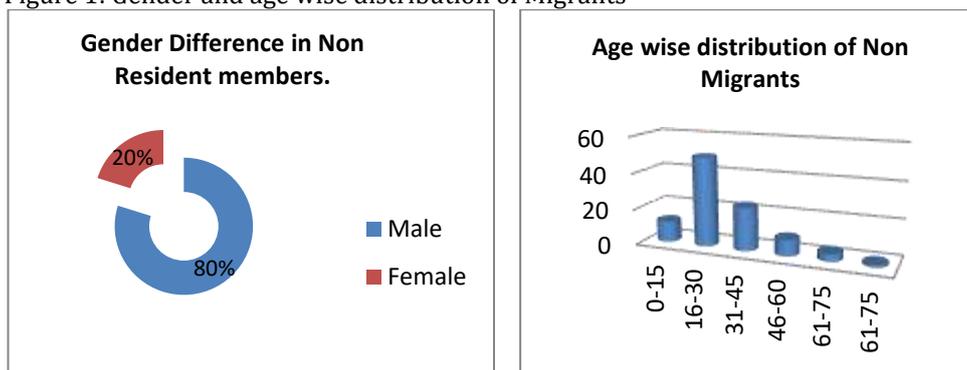

2. SOCIO CULTURAL FACTORS, POLITICAL ECONOMY AND MIGRATION IN INDIAN CONTEXT:

According to P. Sainath, the collapse of livelihood in the primary sector especially agriculture has been the major cause for the increase in migration. More than 240,000 farmers have committed suicides between 1995 and 2009 because of failure of our agricultural policies and has been a major reason for out migrations which he referred as ‘distress

migration'. The collapse of the agricultural sector in these regions thereby increasing unemployment, indebtedness, low wage rates etc become the push factors for seasonal migration in search of employment. In these conditions food twice a day, and the job availability throughout the year though at very low wage rates become the pull factors in migration in search of a better life (Srivastava and Ali, 1981; Rao, 1994; Rogali et al, 2002; Deshingkar and Start, 2003; Deshingkar and Grimm, 2005; and Deshingkar and Akter, 2009).⁹⁸

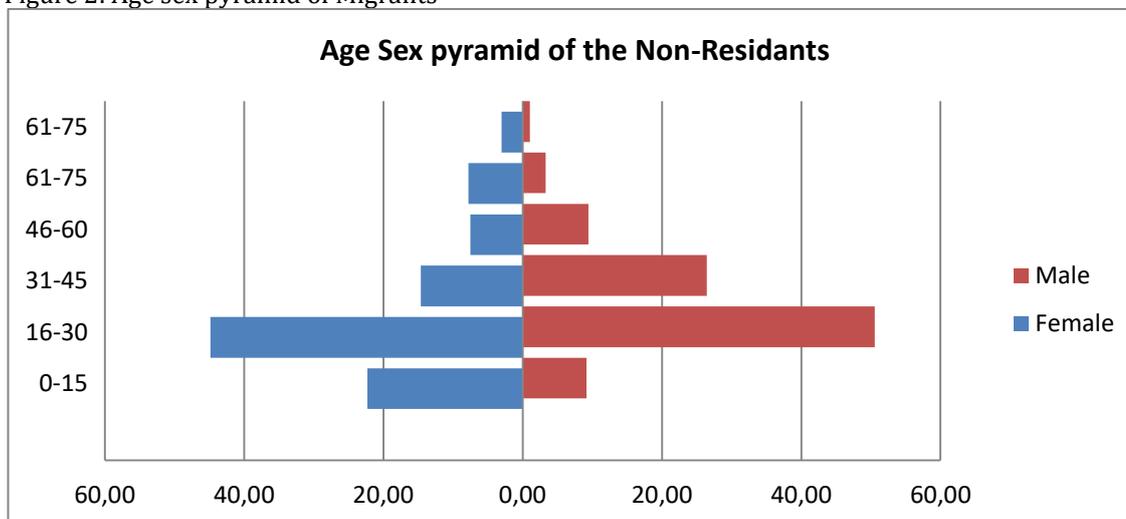

In IHDS survey, residents who are either born to the surveyed household or married to any individual of the household who no more stay with the current household are considered as the non-residents which includes husband/wife of any of the member who stay outside, the children of any of the member of the household who stay outside and parents of any children in the household who stay outside. These people can also be considered as out migrants to the respective households. The basic demography of them shows that there has been a gender bias in migration, where majority of reported migrants are male, which means the migration was mainly due to economic reasons (the mobility of women due to economic reason is still to be less likely in a country of Classical Patriarchy like India, Rao 2014)⁹⁹, it also mean that women of the family, who were married off are underreported. This reflects the gendered notion of how women are no more considered as a member of the family once married, also while “male moving out in search of job” are considered as an event worth mentioning the removal of women looks more naturalised thus not worth reporting.

Figure 1: Gender and age wise distribution of Migrants

Source: Computed from the IHDS data (2011-12)

Figure 2: Age sex pyramid of Migrants

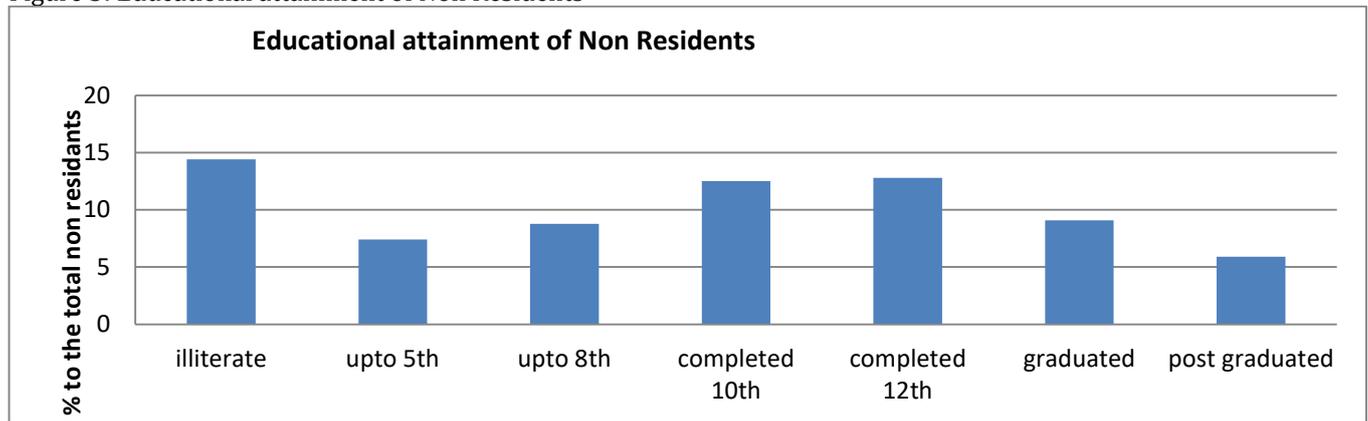

Source: Computed from the IHDS data (2011-12)

As expected among the migrants most of them are between the age group of 16 to 30 years, followed by people up to the age of 45, all most 70% of the NRs belong to the working age group and the rest in the dependent one. It is interesting to see that number of people under the age of 15, are largely men. Female migrants are mainly between the age group of 16 to 45 and collectively more than the men of the same age group. This trend follows up till the age of 60 and take reverse direction afterward. The woman moving after marriage can be reason for the bulge in middle part, also very few women are allowed to move alone in Indian society at younger age, but the same may not be applicable for the men of the same age. The urge for earning money and men as an agency to do that is widely common in India. Unlike the neighbouring Bangladesh India really didn't face what Elson and Pearson (1981) coined as the “nimble fingers” phenomenon, where there is deliberate effort from the state and the capital to “culturally legitimate the migration of young, single women from rural to urban areas” which indeed allowed them to be treated as a “docile, reliable, and low-paid reserve army” (Bagchi 2011, Ghosh 2002, Standing 1999).

⁹⁸ Parida Jajati Keshari, Madheswaran S ;HIGHER WAGES, COST OF SEPARATION AND SEASONAL MIGRATION IN INDIA.

⁹⁹ Rao Smriti ;Women and the Economy in India: Insights from the Data on Migration; December, 2014.

Figure 3: Educational attainment of Non Residents

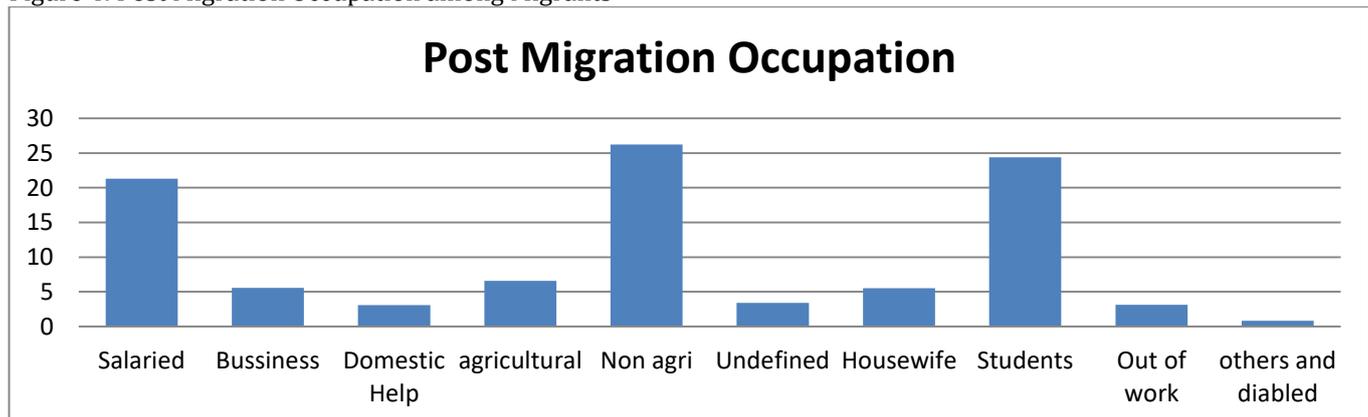

The data shows people on the move are majorly illiterate, but it dips down afterward. The migration stream picks up again after they pass class 5th and reaches a saturation point at people passing class 12th. There is a strong decline after this point which continues up till their post graduation. This is an indicator that generally people with higher education move less for long term than the rest, at the same time the rise in migrants educated up to secondary shows, some sort of educational acquirement empowers or provide basic skills to move as well. The people with higher educational attainment might get a job in place of their origin and thus take less part in migration.

3. CHANGE IN OCCUPATION AND FACTORS CONTROLLING MOBILITY

As this paper primarily look into the generational occupation change taking into account the caste dynamics, a statistical review of change in occupation is required. The followings are the particular caste wise break up of pre migration traditional occupation and the one they taken reportedly after migration.

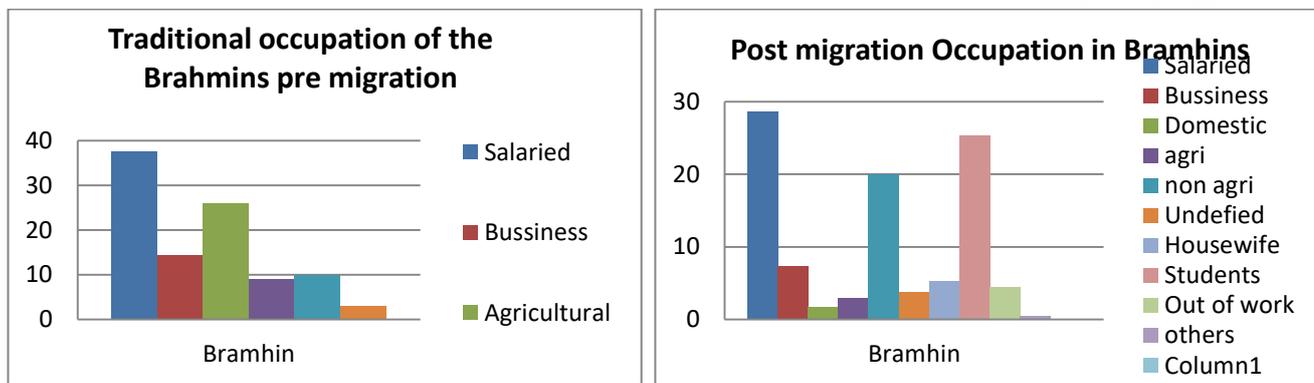

Figure 4: Post Migration Occupation among Migrants

Source: Computed from the IHDS data (2011-12)

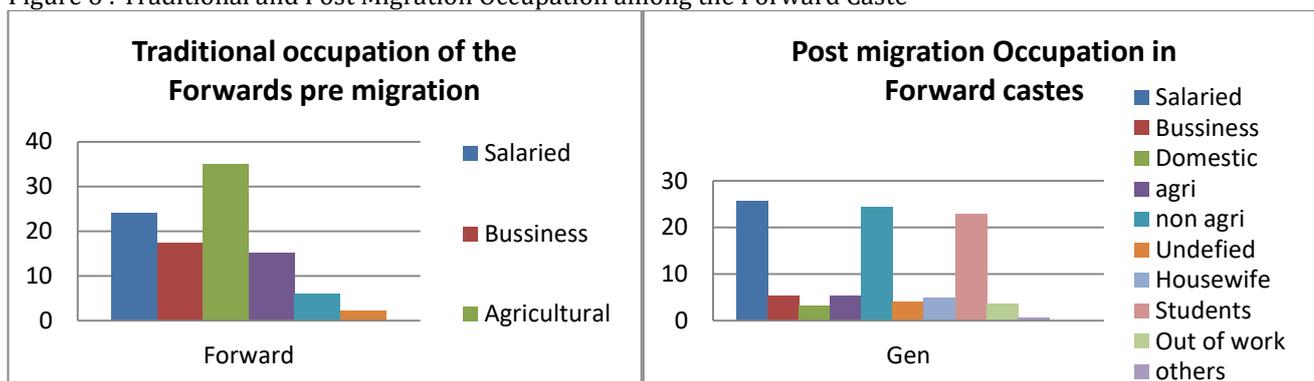

The graph above depicts majority of people after migration deploy themselves into three major activities; Non agricultural wage labourer, students and salaried services. The decrease in agricultural activities marks the rural-urban, intergenerational migration and shift in overall economic activity. The women who are married off or moving as their family move, come under the housewife category, and it is important to keep it in the occupational classification as in a patriarchal society domestic work done by the women of the family goes unnoticed as a labour input. Domestic help includes people who work as cook, cleaner, laundry owner etc, though in economic activities they might fall as service provider but in reality operate in a complete informal manner with unregulated low pay. Now if looked into the traditional occupation of the migrant family and current one in many cases there will be difference, and there will be many instance with no change in their occupation. But why some tend to get into a new job while others remain in same. In a country like India no socio-economic study can be done without taking into consideration the caste factors. If individual caste and its effect in occupation is measured, a theorisation can be formulated.

Figure 5 : Traditional and Post Migration Occupation among the Bramhins

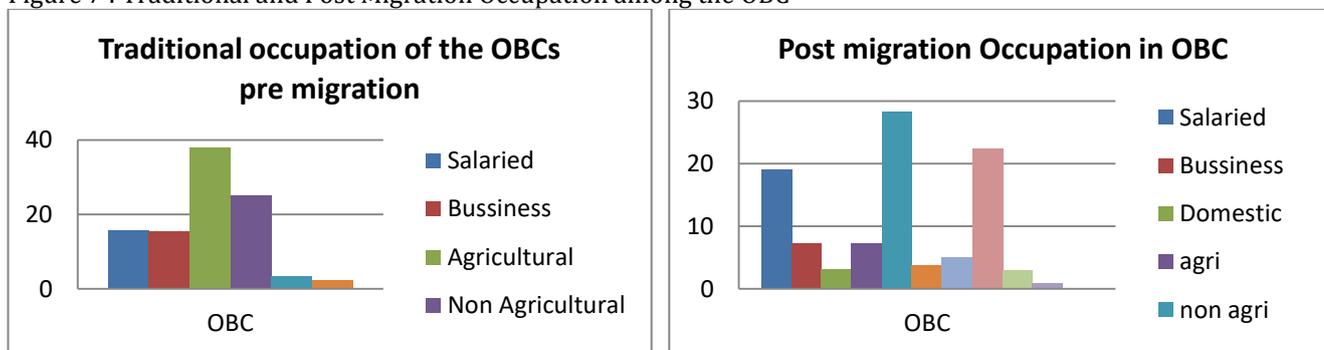

In case of Brahmins a significant chunk of people who are moving outside their houses are moving as students (25.41%), interestingly the primary dependency on salaried job remain unaltered. There has been an increase in the non agricultural labour force and a usual decline in the people involved in agricultural activity.

Figure 6 : Traditional and Post Migration Occupation among the Forward Caste

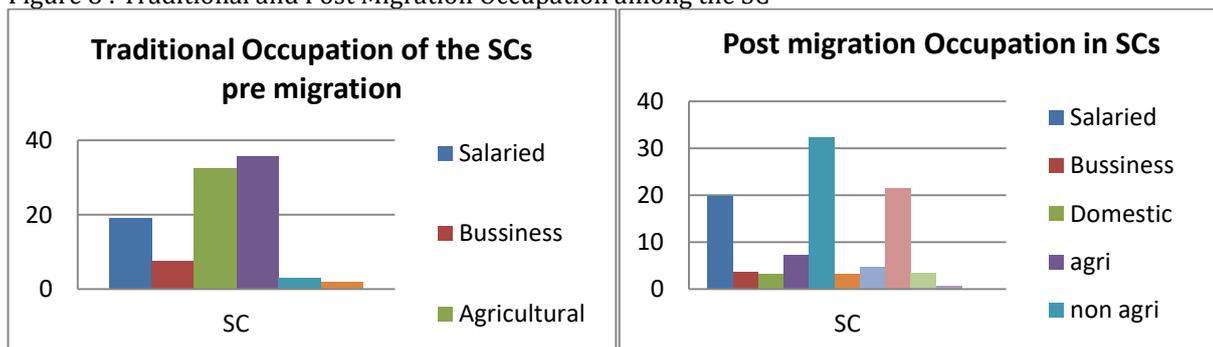

Among forward castes there is a clear shift from agricultural activity to salaried job after the migration, this is interesting and significant as unlike Brahmins, forward castes are traditionally feudal landlords or land owning class. The sweep in occupational choices after the migration shows the growing dependency on non-land activity which is induced by the agrarian distress and salaried job as a symbol of status upgradation.

Figure 7 : Traditional and Post Migration Occupation among the OBC

The occupational shift among OBCs happened majorly from agricultural to non-agricultural activities followed by salaried jobs. And over this point the caste groups can be differentiated. Where in upper caste the thrust remains on salaried job, in OBCs it gets consolidated in non-agricultural wage labour.

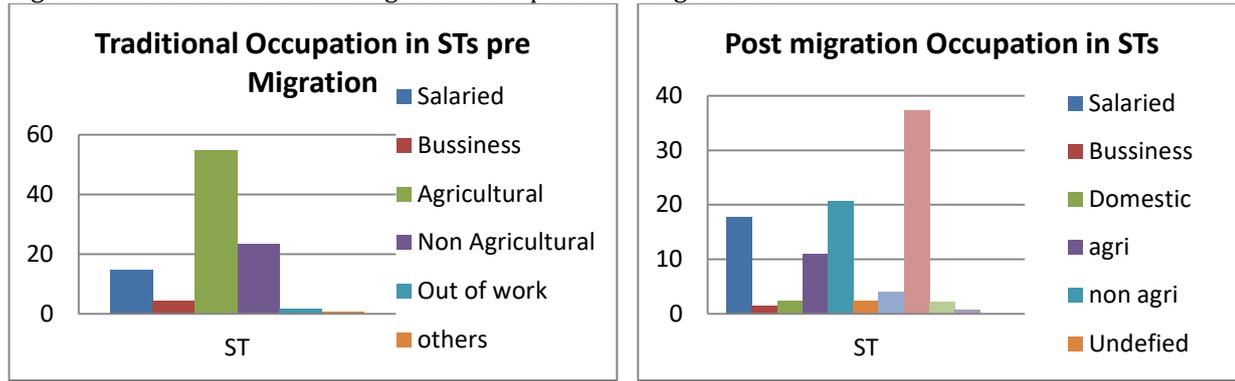

Figure 8 : Traditional and Post Migration Occupation among the SC

So it is basically the Scheduled population and the Brahmins whose traditional occupation becomes their current occupation even after the migration. The graph clearly shows the dependency on non agricultural wage labour remain

unchanged among the scheduled caste even after the migration. Percentage of salaried job also remains around 20% as it was earlier in the traditional occupation.

Figure 9: Traditional and Post Migration Occupation among the STs

The case of scheduled tribes is a bit different with a huge proportion students coming out of their natives, this can also be a result of the concentration of tribal in North Eastern region who anyway migrate to the metropolitans for the purpose of studying. Though their economic dependency remains largely same with a shift to non-agricultural activity, the proportion of salaried people also remains unaltered even after migration. Regional analysis in case of ST migrants will give a clearer picture of some of their regional variations.

So, the question comes why is that some castes after migration shift their occupation whereas others remain in the same. Now even a change in occupation cannot have a quantitative connotation to either be positive or negative. For instance a person who was traditionally in salaried job is a positive trait, where as a person who was earlier in agricultural activity if stays in agriculture even after migration may not be the same thing. On the other hand if there is a shift from the agricultural activity to salaried job this will be considered to a positive change, where as shifting to non agricultural wage labour won't be as it does not bring any fundamental change to the migrants. Often agricultural labourers come to cities and start working as a construction labour, though this bring changes in their occupation but creates marginal effect in their overall livelihood.

Table 1: caste wise distribution of post migration occupation

Caste	Salaried	Business	Domestic	Agricultural	Non Agri	Undefined
Brahmin	27.38	9.52	2.38	4.76	52.38	3.57
Forward	12.15	7.73	3.31	10.22	64.36	1.38
OBC	6.8	5.57	2.75	16.34	66.96	1.08
SC	3.81	4.03	1.96	20.7	67.43	1.31
ST	2.14	1.95	3.7	35.67	55.95	0.39
Others	8.33	16.67	16.67	4.17	54.17	0

The trend is presumable and clear, the upper caste especially that of the Brahmins remain almost 30% into salaried job which is much more than the 12% of the other forward castes. There is a heavy deployment of labour in the non agricultural activity all the castes contributing more than 50% of their labour force into it, OBC being the largest constituent of a whopping 66%. The most interesting part though remains in case of the scheduled tribe migrants where an astonishing 35% even after migration remain in the agriculture related activity. According to a report by planning commission of India, "Tribal's are engaged in various occupations like hunting, fishing, gathering of forest products, shifting cultivation to settled agriculture, rural crafts and artisans. A very few tribal groups are engaged in non-agricultural activities...tribal people migrated to the rural areas of Bihar, West Bengal mainly to work as agricultural labour (Mosse et al., 1997)."¹⁰⁰

Table 2: caste and Class wise distribution of people with no change in occupation type

Caste	1st Quartile	2nd Quartile	3rd Quartile	4th Quartile
Brahmin	13.35	18.79	24.22	43.63
Forward	16.4	21.08	23.96	38.56
OBC	27.33	25.94	26.45	20.28
SC	28.89	31.39	21.6	18.12
ST	53.87	25.1	10.42	10.62
Others	7.69	18.68	37.36	36.26

The interplay of class and caste shows, among the Brahmins and other forward castes that there is a trend of more people from the upper class to remain the same group of profession. In the previous section it was shown in both the castes, the percentages of people who are in salaried job remain almost unchanged. So the fact that people from upper class who

¹⁰⁰ Migration of Tribal Women: Its Socioeconomic Effects - An in-depth Study of Chhatisgarh, Jharkhand, M.P and Orissa; Planning Commission Government of India; October 2010.

remain in the same group of occupation are presumably those who are in salaried job. This stationary condition is a positive indicator where migration is not done as a part of survival strategy but progress or to maintain the status quo.

Whereas in case of OBC no unilinear trend is observed, till 3rd quartile there is a rise-low-rise pattern in people remaining in same occupation but when it reaches the 4th quartile it falls down. In case of OBC, the major occupation group which was equally important even after migration was non-agricultural wage labourer. This can be presumed that migrants remain in the same occupation are basically the wage labourer who defiantly will be in less number in the top most quartile.

The trend among the Scheduled Castes shows across the class realm people remain in the similar type of job, as the earlier graphs also showed. The occupation that remained almost same was the salaried one. Explanation to it can be even the salaried job that are taken up by the scheduled castes are low paid in nature, thus there is a concentration at second quartile which doesn't continued in upper two classes. But this explanation seems to be too generalised and to get an exact answer a more detailed study will be needed. The Scheduled tribes show a reverse pattern from that of the Brahmins, meaning concentration in the lower class group of people remaining in same occupation. As it was seen even in the case of seasonal migration a large section of them remain in agricultural activity even after the migration. The same condition might be occurring even for the long term migration as well. So, in case of tribals basically even after migration, the poorest remain in a condition with no drastic change in their living condition.

Table 3: Caste and Educational distribution of people with no change in occupation type

Caste	Illiterate	1 to 5th	5th to 8th	till 10th	till 12th	till graduation	post graduation
Brahmin	6.52	4.97	11.18	24.84	17.7	24.07	10.71
Forward	14.62	14.14	10.92	17.94	14.9	16.09	11.39
OBC	21.42	18.39	21.36	16.08	9.18	8.46	5.12
SC	20.73	18.55	19.81	20.96	9.97	6.78	3.19
ST	34.43	20.36	18.16	12.28	9.78	3.49	1.5
Others	23.08	10.99	5.49	39.56	5.49	8.79	6.59

Education proved to be important criteria for deciding whether to migrate or not and naturally this should be one of the major factors which decide the type of job of the migrant. There are basically two broad categories the first is a top heavy structure like that of Brahmin and partially the forward castes where migrants are mostly in salaried job like their ancestors and thus gather around the higher educational attainment if we move towards the second one, OBC, SC and ST the pattern gets reversed and more people gather around the low educational attainment. This is an important evidence to say that the lower caste people as semi or low skilled labour group even after migration engages in similar menial jobs which are mainly labour intensive.

Table 4 Caste and Land ownership among the Seasonal migrants.

Caste	marginal	small	semi medium	medium	large
Brahmin	81.28	9.83	5.4	2.96	0.54

The land relation and the Caste remain a mysterious case which does not show a prominent trend. The division across the caste line remains almost same, with SCs having least ownership towards the higher end the Forward Castes with highest number in the large landholdings. This can be related to the present context as historically the dalits didn't have the right to own land and mostly worked as labourer in upper castes' fields. Traditionally even the Brahmins too were not supposed to own land as they according to the Hindu rituals will be a devotee to God and survive through "begging" from the people but in reality that does not seem rally happen. Though lesser than the other forward castes, Brahmins too own significant amount of land. The case of Forward castes should be understood in the framework of traditional division of labour, forward castes include caste groups like Rajputs, Bhoomihars, Kayasthas which had been the feudal lords, and as land reform was not successful in most of the part of India the ownership over big landholdings still exist with the Forward castes.

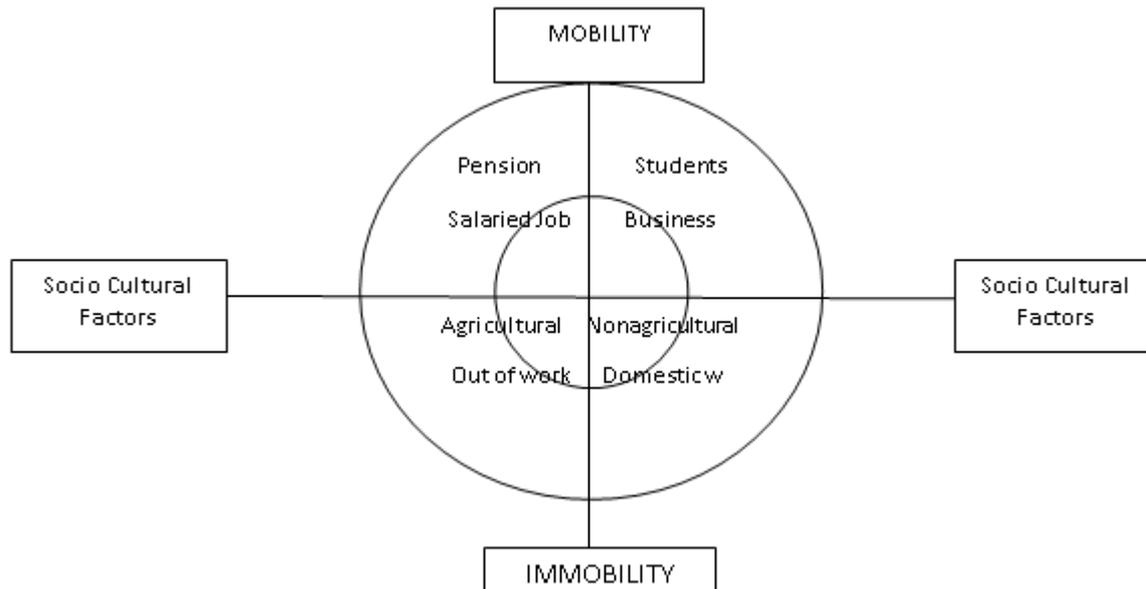

Table 5: Caste and Educational Attainment among the Seasonal migrants.

Caste	Illiterate	1st to 5t	5th to 8t 8th to 10	10th to 1	Graduates	Post Graduation
Brahmin	19.24	9.76	13.77 15.68	26.01	9.71	5.83

Caste groups just like class differences show clear control on educational attainment where the percentage of illiterate increases towards STs and number of post graduates and graduated decrease in the same line. Among the SCs and STs the migrants pursuing higher education is actually low, which further confirms the hypothesis of lower castes who are coming from, lower class with low skill migrate as a labour stock for further exploitation.

Now the question arises about the claims of migration optimists who have always advocated the need of spatial mobility in order to gain a social or economic mobility. The discussion above clearly points out that even after migration the “historically disadvantaged” communities remain in the tail of the existing structure, only those with a certain access to skill or cultural capital may succeed to go upstream. So there is a need to theorise migration as a tool to attain mobility, in order to reach that conclusion the theoretical framework of Richmond is borrowed. Richmond had successfully blended the spirit of sociological and social psychological theories on migration and the unrealistic boundary of economical and socio political binary was broken. His postulated Richmond Axis came up with a much more holistic and multivariate approach where the centrality of the argument was shifted to the exercise of “autonomy” from the voluntarily- novoluntarily debate. Though he classified the refugee movement along the axis of Reactive and Proactive refugee, the similar framework can be followed to map down the mobility and immobility of inter-state migrants.

The figure above shows the change in occupation from any other to Salaried Job, Business or moving as students should be considered as something that helps the migrant to get the mobility. The reason being the formality of the occupation, the fundamental change in the nature of occupation and an opportunity of skill development three of these respectively provide. Now the previous discussion had already showed that salaried job and business enjoys a higher proportion of upper class across the caste line and a large chunk of Upper castes as the occupants. This further shows those with a caste privilege, or even among the deprived caste one with a better of class position that enables them to acquire skill in form of education can really avail the mobility in true sense. On the other hand agricultural labour, non agricultural labour and domestic labour being the alternate occupation which is largely run as an informal sector, with little or no assurance of the future. The analysis showed that the lower class across the caste groups either have not changed their occupation or changed from the first one to the later two. This again brings into the strict caste dominance in occupational segregation even after a spatial dislocation of migrants from their earlier societal structure.

So it can be said mobility through migration is a complex process of existing power structure, caste induced political economy and differential endowment of cultural capital, to which a individual or a community responds to. The one with higher cultural capital tends to use the political economy of migration in his or her favour by moving up with a better job and greater stability, whereas the other one with lesser endowment remain immobile or get marginal mobility by staying in same or similar occupation even after the migration.

FINDINGS:

- Migration is clearly influenced by caste, class, land ownership and educational attainment. Among the migrant’s lower castes, lower class, marginal land owner and illiterates are large in number.
- Caste becomes an important factor but even within a single caste does not reciprocate homogeneously, with upper class and higher education even those from the same caste behave very differently in taking decision about migration.
- Migrants mostly change their traditional occupation after the migration a strong stream seen where most people move from agricultural activity to non agricultural activity let it be salaried job or wage labour.
- In Long term migration change in occupation is dominated by the individuals caste, class education etc. The data shows Bramhins and upper castes who were in salaried job even before the migration stay in the same group of occupation. They maintain their social position through and after the migration. The scheduled tribes too remain in the same

occupation but that in mostly either as agricultural labourer or sometimes as non agricultural wage labour. Even after the migration they fail to achieve an upward social mobility and gets trapped into the destitute. The SC's and specially the OBC showed a higher mobility in the occupational structure. This is important to see that OBCs are in many cases the dominant or the preponderant communities with much acquired political power in recent times which is also reflected in this case. The SC's on the other hand though preponderant still hardly come across as dominant but there had been individual upliftment among them specially those who could avail reservation. Even among the dalits with a traditional occupation of salaried job, continue to be in salaried job after their migration but the proportion of such cases are much lesser than that of the upper castes.

4. POLICY RECOMMENDATION AND A WAY FORWARD

Agricultural distress had been a major reason of seasonal migration and even the people with agricultural activity as their traditional activity tend to migrate more for long term and change occupation into varied non agricultural activities. So across the class and creed the low return in the agricultural sector had pushed people to move from their native. In order to have a check on this upsurge in migrational stream corrective measure should be taken by the government, where pesticides seeds should be taken back from the hands of corporate as the increasing price of this basic material had summed the total cost production so high that earning profit for the small and medium farmers becomes next to impossible. A more regulated market control and peasant facilitating Government intervention should be promoted to revive agriculture and keep people to their origin. Now it is true that migrant labourers had been exploited badly both in terms of social and economical terms but at the same time migration is also a survival strategy for the rural poor who are dominated by the OBCs and other lower castes. To ensure that these huge portion of working population do not remain unskilled, low paid and socially stigmatised, the labour laws had to be reformed. Those who are working as contractual labour in mostly unorganised sector in the "periphery", should be provided with basic minimum wage, defined working hour and social security like other jobs. The over representation of scheduled communities, illiterates and marginal land owner in the migration stream shows the multiple vulnerability that the migrants of India are open to, now these can be only addressed with a proper implantation of welfare policies, reservations in government and private job and a real life adaption of "education to all" goal. As it is proven the higher skilled who may be emancipated due to the caste hierarchy, class position and the already gathered cultural capital after migration tend to be in a better position which do not repeat for those who lag this and remain in the same loop of destitute, thus migrating without the skills or capitals really not going to bring any sustained change among the downtrodden.

5. CONCLUSION

Migration as a survival strategy is important for the people across the different mosaic of identity. Almost in all the cases discussed here show the people from the lower class in all caste categories tend to move more than the economically better ones. India with a huge bulk of poor population thus has considerable number of people who are migrating inside the country. The table 4.1 shows that these poor people are also mainly from the rural areas, table 4.5 which gives an idea about their traditional occupation which shows that a majority of workers who are dependent on land, tend to move more than the those who are not bound with land. The agricultural distress that had been quite consistent in India just after the green revolution where marginal farmers had fallen prey to the neo-liberal market economy and rather than improving their position they had to migrate out both from their native land as well as their traditional occupation. Now who are this people, who work in fields or as labourers? The occupation diversification along the caste lines show that the backward communities, SCs and STs are the ones who are more into labourer jobs, where as the upper castes concentrates themselves more into the salaried services and business. This also brings into the fact that it is the lower castes and the backwards that are in process of moving continuously. But as the hypothesis says even among them the attainment of skills which have been considered here as education, plays a vital role. The data shows that in all the caste groups except that of the Brahmins, migrants are those, who either illiterate or have only finished their primary education. Only the Brahmins show an interesting trend where even their top most educated section tends to migrate more than the other castes.

- The lower class from all the caste attains no or minimum education and even after migrating they remain in low paid low-skilled jobs. The nature of their migration is substantial in nature and though receives a marginal change in the wages but in totality do not experience any drastic change through migration.
- Among the upper castes the education attainment ratio is much more than the lower castes, though among the other forward castes the negative relation with migration and education remain same. But the rise in migration among educated Brahmins is the only exception from the general trend. This indicates to the fact that unlike the other castes Brahmins also engage in migrations for jobs which require higher skill and well paid as well. So, the Brahmins who are traditionally into salaried job tend to escalate their occupational status by moving out.
- Even after generational change in the occupation there is no substantial change in the social or economic position of the migrant labourers. Only those who have acquired or been born with certain cultural capital can use migration as process of mobility as they engage in occupations which are more formal in nature where as the rest remain immobile due to their "lag" in skill. The occupational diversification remains completely segregated on the caste lines even after the migration taking place.

1427 INFORMAL WORK AND THEIR WORKPLACES: SPATIALLY SEGMENTED LABOUR MARKET FOR SLUM DWELLERS IN KOLKATA

Tania Debnath

Centre for the Study of Regional Development, Jawaharlal Nehru University, New Delhi. Email Id: tanya.debnath@yahoo.in

ABSTRACT

Spatial segmentation of the labour market within the metropolitan is observed globally. In India it is not only compartmentalised on gender, caste, ethnic lines but also geographically segmented by the creation of spatially disjointed markets. The present paper argues that the labour market for informal workers is segmented into smaller labour markets separated by commuting (home-work) distance. Hence, the present paper has two objectives. The first is to map spatially fragmented labour market of smaller scale within a big metropolitan market. The second objective is to understand the determining factors (age, gender, social and religion groups, migration status, educational qualifications, employment types and residential locations) for home-workplace distance.

The present paper is based on case study of labour market in Kolkata. This paper is based on data collected from field survey of 1500 households located in 6 different slum clusters. The quantitative focus is on the variable like employment pattern, workers characteristics and human capital, commuting pattern (home-workplace distance) taken from the survey. For the present study, only workers with fixed workplaces are considered. This is only to reduce the complexity in conceptualising spatial labour market boundaries.

In the study it is seen that the average commuting distance (home-workplace distance) of workers are much shorter than the metropolitan-wide scale. This is true for all the locations surveyed. Often the employment field around these 6 localities (residential areas) are non-overlapping. It is indicating towards the fact that the workers in the informal employment are spatially constrained. It creates small, segmented highly localised markets within the metropolitan city. Workers in central localities travel much shorter distance compared to non-central localities. It is seen that women's spatial access is more constrained compared to men's. Similarly the self-employed workers have much spatially confined markets compared to regular and casual wage workers. The home-workplace distance increases with increasing level of education.

Keyword: Informal worker; Metropolitan labour market; Spatial segmentation, Kolkata

1 INTRODUCTION

Intra-metropolitan spatial labour market research has gain scholarly attention in the west (Hanson & Pratt 1991; Hanson & Pratt 1995; Parks 2004; Ellis et al. 2007; Wright et al. 2010). These scholars have advocated the presence of local labour market finer in scale compared to metropolitan-wide scale. The disadvantaged groups of workers tend to have lack of spatial mobility and tend to be more affected by the local employment structure. Disadvantaged groups like women (Madden 1981; Hanson & Pratt 1995), racial minorities (Kain, 1968; cited in Houston, 2005), immigrants (Ellis et al. 2007; Wright et al. 2010), low wages and lower level of skill possessions tend to be more affected by the intra-metropolitan spatial differentiation.

In developing countries, the labour market is often segmented into formal and informal sector. Indian economy is dominated by informality and informal employment occupies a large share in urban areas (Mittra 2004). Informal work is characterised by low wages, lack of security. Workers in this type of employment are generally lack in skill possessions. It is often argued that labour market is segmented along the caste, gender and ethnic line (Mittra 2006; Banerjee & Bucci 1995; Banerjee 1983). In India it is not only compartmentalised on gender, caste, ethnic lines but also geographically segmented (Gupta & Mittra 2002; Shaw & Pandit 2001). Both of these studies are focused on the low income groups and workers in informal sector employment. Gupta and Mittra (2002) mentioned that low income workers tend to work closer to home because of high transport costs. Shaw and Pandit (2001) mentioned the need to further analysis of the informal sector workers spatial segmentation.

The present paper argues that the labour market for informal workers is segmented into smaller labour markets separated by commuting (home-work) distance. Hence, the present paper has two objectives. The first is to map spatially fragmented labour market of smaller scale within a big metropolitan market. The second objective is to understand the determining factors (age, gender, social and religion groups, migration status, educational qualifications, employment types and residential locations) for home-workplace distance.

The present study has been divided into four sections. The first section builds the theoretical background for the study. The second section discusses the study area, database and methodology. The third section is dedicated to delineate the 'employment fields' of the workers in various study locations. The fourth section tries to understand the role of worker's socio-economic characteristics in shaping their commuting distance.

2. OVERVIEW OF LITERATURE

Space and Metropolitan labour market

Often the metropolitan labour market is considered as one single labour market or frictionless space. Many regional geographers tried to understand that the metropolitan area is comprised series of local labour market separated by

journey-to-work. The main aspect of spatiality of labour market is home-workplace relationship. Hanson and Pratt (1992) mentioned that the local labour market is created through dynamic dependencies between home and workplace. Because the home-work distance indicate the physical access to labour market which determines the segmentation of labour market. "At the intra-metropolitan (neighbourhood) scale of analysis, in contrast, the spotlight tends to fall on the districts where work is performed in relation to the neighbourhoods where workers reside" (Wright et al. 2010, p.1037). The home-workplace link is the central criteria for intra-metropolitan spatiality research.

Spatial accessibility plays important role in the development of many theories like '**spatial mismatch hypothesis**', '**gender and space**' and '**immigrants and spatial niche creation**'. 'Spatial mismatch hypothesis' is to understand the disadvantages faced by inner city African-American residents in job access due to sub-urbanisation of low skilled jobs. It was proposed by Kain (1968) (Houston 2005; McLafferty & Preston 1992). This explains how the inner-city residents cannot access the sub-urban jobs due to high commuting cost. On the other hand, 'immigrant's spatial niche' theory focuses on the role of residential segregation, spatial distribution of jobs and spatial accessibility in creation uneven distribution of immigrant's occupational niche creation (Ellis et al. 2007). Ellis et al (2007) and Wright et al. (2010) found the role of spatial proximity in the creation of ethnic niche. Again 'gender and space' focuses on women lesser commuting distance due to gender related segmentation, household responsibility etc. (Hanson & Pratt 1991; Hanson & Pratt 1995; Madden 1981).

The main themes of these three theories are that these theories tried to explain the intra-metropolitan spatiality of labour. All these three theories have mentioned repetitively that metropolitan area is not a frictionless space, rather the friction of distance creates differential outcome for different groups of workers. Even the space and information is closely related. The information flow about work is related to spatial proximity and vice versa.

Different theories have emphasised that the dimension of local labour market varies for different workers depending on their residential distribution, access to social network and commuting pattern. Madden (1981) mentioned women's shorter travel to work and mainly emphasised on the role of household-responsibilities for their spatial entrapment. Again Hanson and Pratt (1995) have found that women who are in female-dominated occupations and have small children tend to commute even shorter distance compared to other women. 'Spatial mismatch hypotheses' on the other hand gave emphasis on residential location on the commuting pattern of the workers. In US cities, scholars have noted that the inner city residents have to commute longer distance for low-wage jobs due to sub-urbanisation of jobs (McLafferty & Preston 1992). Most of the studies have focused on the disadvantaged groups such as minorities, women, less-educated workers, workers in low-paid jobs. This is because these workers face issues related to spatial accessibility and social accessibility.

Hence, it seems that the metropolitan labour market is not frictionless rather creates its geography through the distributive pattern of residence and workplaces.

Indian labour market and informal employment

In developing countries, urban labour market is dominated by informal employment. In case of informal employment (both wage and non-wage sector), general education is very low. The low skilled worker's job search range is much smaller than a skilled or educated worker (Simpson, 1987). As the informal workers are less in educational qualification and skill possessions, their search field is limited. In general workers in informal employment rely on their social ties for job search. As knowledge is space bound which can lead to concentration of workplace. Contact based rural-urban migration often leads to settling of migrants to the area where their peer groups are. Contact based employment leads to choice of same workplace as well where their peer group members work. Hence they end up choosing work closer to their residential areas. hence labour market is segmented physically (Gupta & Arup 2002). Village based solidarity exists in slums (Racine, 1990). Women and informal employment is highly interlinked. Majority of women are engaged in various kinds of informal activities. Engagement in home-based work can also be seen in the light of spatial entrapment for women (Soni-Sinha 2011).

Most of the research on informal sector employment in case of India is focused to understand the nature and characteristics of this sector (Marjit & Kar 2009). But there are very less research on space and labour market outcome for India. On the intra-urban variation of employment outcome of low-income rural migrants, Gupta and Mitra (2002) and Mitra (2004) mentioned the role of neighbourhood proximity based choice of employment may cause intra-urban spatial variation in employment. But the further question arises that whether these workers tend to have workplaces in the same zone where they reside? Are these workers are really spatially constrained? Shaw and Pandit (2001) tried to answer this question by mapping worker's residence on the basis of their workplaces. They covered only one industry for the analysis. But the accurate home-workplace spatial relationship for informal workers in general is not established. Hence, there is good scope for research in this field.

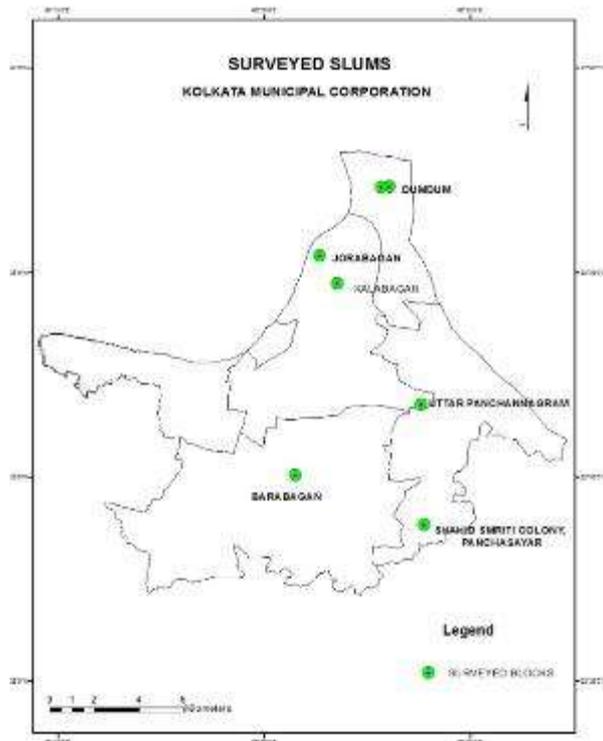

3. THE STUDY

The present study is based on Kolkata Municipal Corporation, a metropolitan city in the eastern part of India. Kolkata is an old city established in the British period. "Calcutta (former name of Kolkata) was the product of an economic and political process imposed from outside India" (Banerjee 1990, p. 89). The city was created by British and all the economic and infrastructural developments were took place by them. The downfall fall of once prosperous city started in 1960s. Since late 1960s, the formal sector employment slowed down in West Bengal. The industries started closing down. Hence the then Left Govt in power have promoted informal sector to provide employment to the poor people (Sarkar 2006).

The informal sector employment provided a living for the poor and helped them to escape unemployment (Banerjee 1990).

Kolkata is also known as the city of despire. The widespread of poverty, slums are situated here and there. The slums of Kolkata are result of huge immigration from neighbouring states like Bihar, Uttar Pradesh and Orissa. The in-migration created a social and cultural mosaic. As creation of job in organised sector is very less, the workers tend to rely on caste and language based social ties for job search. Hence the labour market is segmented in the line of caste, language, ethnic line (Bose et al, 1990). Even the residential areas are segregated on the basis of caste, language (ibid.). In this situation there is a strong possibility of the creation of geographically segmented labour market.

Map 1: Surveyed Location in Kolkata Municipal Corporation in different land use zones

Source: Collected from field survey, Jan-Dec, 2016

The present study is based on a survey conducted on slum dwellers from different parts of the city. Majority of the workers reside in slums of Kolkata are engaged in various kinds of informal work or engaged as informal employee in formal sector. Generally the informal sector is linked with slum residents. Generally slum dwellers' economic problem is linked with their employment structure i.e. bulk of them engaged in low productive informal segment of tertiary activities such as trade, transport and commerce compared to manufacturing sector (Mitra, 1990). Hence the slum dwellers were chosen as target group.

In this study, the residential neighbourhood is chosen as study unit to capture the occupational variety of workers. Hence the delineation of local labour market is done on the basis of the concept of 'employment field' or job search areas of workers from their residential areas (Vance 1960). The segmentation of local labour market is conceptualised as employment fields smaller than city scale and separated from each other.

Six blocks of slum clusters located in different parts of the city were surveyed. The rationality between selections of location in various parts of the city is to capture the impact of economic agglomeration in the creation of spatial labour markets. Jorabagan and Kalabagan are located in the central part of the city, which is very near to Central Business District of Kolkata. Mitrabagan and Noongola, Dumdum Road area is located in the northern parts of Kolkata. Again Barabagan is located in the southern part of Kolkata. On the contrast two peripheral locations Uttar Panchannagram and Shahid Smriti Colony, Panchasayar is located in the eastern and south-eastern part of the city.

Central Locations: Jorabagan area is located in the central part of Kolkata. This part of Kolkata is dominated by various kinds of *Bazaar* economy (markets of wholesale and retail trade), mixed residential areas with small household industries and commercial centres mixed with residential areas. *Bara Bazaar* (one of the central commercial market in Kolkata) is located within 1 km distance from the neighbourhood. Bara Bazaar and surrounding commercial area provide numerous opportunities for the slum dwellers. It is spatially connected with various bus routes, Circular Railway, and Metro services. The residents of Jorabagan slum cluster is a mixture of Bengali and Non-Bengali Hindus. Majority of the Non-Bengali population are chain migrants from neighbouring states like Bihar, Uttar Pradesh and Orissa. They have a fixed rented room in this area, where the migrants come generation after generations. Though there are migrants who migrate with their families.

Kalabagan is also located in the central part of Kolkata. It is located within 1 km distance from *Barabazaar*, College Street, Raja Bazaar. In these areas there are numerous opportunities in wholesale and retail and petty trading activities, small size manufacturing units of metal and shoe manufacturing. This locality is well connected by various public transports like Metro services, bus and tram services.

Non-central Older Locations: Mitrabagan and Noongola (Dum Dum Road) slum area is located in the northern part of Kolkata. This slum cluster is old, and established before independence. This area is dominated by the various industries, hence the slum areas was put up for industrial workers. Due to continuous closing down of the factories in this area, this area has left with few industrial units and mainly surrounded by residential neighbourhood. This area is connected with bus routes. Dum Dum railway station and Metro station located within 1 Km from the surveyed blocks. The surveyed clusters were dominated by Bengalis. A considerable number of Non-Bengali families are present in this area. But most of the families are old migrants or second generation migrants. This slum area is has generally better in amenities and housing compared to other surveyed region. Generally all the slums located in this region have better amenities compared to other slums of Kolkata.

Barabagan slum cluster is located in the crossing of Prince Anwar Shah Road and Deshapran Sashmal Road. This cluster is an old residential area. According to the residents of that area, this cluster is 70-80 years old. It faced deconstruction in the time of expansion of Prince Anwar Shah Road. In terms of communication, it has easy access to road as well as sub-way Metro connectivity.

Peripheral Locations: Uttar Panchannagram is located in the eastern periphery of Kolkata. It is a newly settled area which is established around 40 years ago. The eastern periphery of Kolkata is rapidly changing in last two decades. The eastern periphery has a major connectivity route Eastern Metropolitan Bypass which connects the northern and southern parts of Kolkata. The surveyed slum cluster is located besides the E M Bypass. It is dominated by Bengali migrants from Bangladesh and southern part of West Bengal. There are a considerable number of Non-Bengali migrant populations residing in this area. In this area, it is seen that women's participation in labour market is higher compared to central and northern locations.

Shahid Smriti Colony, Panchasayar is located in the south-eastern periphery of Kolkata. It is basically rehabilitation colony, supported by Left Govt. This cluster is 36 years old from the time of survey. Some of the residents were living in nearby slum before the creation of this colony. But this cluster is dominated by Bengali Hindus who are migrants from the southern districts of West Bengal. Here, the participation of women in the labour market is noted highest amongst the four surveyed locations.

Database and methodology

The paper is based on a field survey conducted in Kolkata (January-December, 2016) of above mentioned six residential blocks. The starting point of the research is to identify the 'employment fields'¹⁰¹ of different groups of workers. In the household listing survey of the survey locations, the information about their socio-economic characteristics, employment characteristics, and details about workplace is collected. Hence information about 6 locations from various parts of the city, about 1500 households, about 2469 workers are collected. Among these surveyed 2469 workers, 1557 workers have fixed workplace/s. Hence, the present study is focused on these 1557 workers.

The variety of work pattern will let us understand how different occupations have impacts on spatial dimension of labour market. The quantitative part of the survey is focused on variables like employment pattern, workers characteristics and human capital, commuting pattern (travel-to-work distance) taken from the survey. The qualitative part is focused on the perspective of selected worker to understand underlying causes. A section of workers from each location were selected for qualitative survey. The rationale behind the qualitative survey is to understand the socio-economic and behavioural process behind the spatial behaviour of economic actors.

Mapping the spatial labour market:

Some workers have fixed workplaces where others don't have any fixed workplace. Generally self-employed service related workers and casual wage labourers have no fixed places of work. Some of the workers have a region where they work. This is particularly true for the mobile vendors, self-employed service provides, worker in public transport etc. The present study has included the workers with fixed workplaces only. Workers can have one or multiple fixed places of work. In case of multiple workplaces, the average distance is considered. Workers with no fixed place of work are excluded from the present analysis.

Home-work distance: Home-workplace distance is the central idea regarding the studies of 'local labour market' and especially intra-metropolitan labour market analysis. Studies regarding home-work distance used different methods. Some have considered straight line distance from home and work, where others preferred considering the travel route. Due to lack of information straight line distance between home and work is considered in the present study. In case of multiple workplaces, the average distance is taken as the home-workplace distance. The distance has been calculated using Arc-GIS software. Worker's workplaces have been demarcated on the basis of Google Earth High Resolution Imagery 2009-10.

Least Square Regression Analysis has been performed to explain the travel distance of the workers with the help of various socio-economic, employment and locational characteristics of the workers. The home-workplace distance has been used

¹⁰¹ Coined by Vance 1960 which denotes the regions to which workers goes for work from a particular residential area.

as the dependent variable. On the other hand among supply side variables workers personal and human capital variables such as age, year of education, marital status and migration status are used. Among social characteristics, social group and religion are used. Among the employment related variables, type of employment, industry and occupation has been used. Among the locational variables, the dummy for each location has been used. The locations are used to indicate the city structure in the determination of workers home-workplace distance.

4. CHARACTERISTICS OF THE INFORMAL WORKERS IN DIFFERENT LOCATIONS

General Characteristics of the workers surveyed

This present section tries to set the background for the further analysis. In this section, location wise socio-economic characteristics of the workers will be discussed. The rationale behind this is to understand the pre-market factors which affect the employment outcome as well as the commuting behaviour of the workers.

Table 15: Characteristics of the informal workers in surveyed slum cluster

	Central Core		Older Non Central		Peripheral		Total
	Jorabagan	Kalabagan	Dumdum	Barabagan	Uttar Panchannagram	Panchasayar	
Mean Age	39.01 (12.301)	35.15 (12.865)	40.29 (11.057)	36.67 (11.921)	37.34 (10.485)	36.62 (11.264)	37.61 (11.802)
Mean Year of Education	6.27 (4.262)	4.15 (4.480)	8.22 (3.624)	6.59 (4.214)	5.37 (4.356)	4.13 (4.240)	5.82 (4.433)

Source: Collected from field survey, Jan-Dec, 2016

Note: the figures in parentheses are denoting the standard deviations.

The mean ages of the workers varies between 35 to 40 years in all the six locations, in Dumdum the mean wage is highest (40.3 years) where in Kalabagan it is lowest (35.15 years). In terms of year of schooling it is seen that average year of schooling for the sample is 5.82 years. Dumdum has highest average year of schooling (8.22 years) where Shahid Smriti Colony, Panchasayar has lowest average year of schooling (4.13 years). Most of the workers surveyed are currently married (74.5%). The percentage is highest for Shahid Smriti Colony, Panchasayar (81.7%), followed by Uttar Panchannagram (80.5%). The percentage of married workers are lower for Kalabagan (63.0%), followed by Dumdum (71.9%) and Barabagan (72.5%). In case of religious distribution of the localities, it is seen that all the localities have one dominant religion. Jorabagan, Dumdum, Uttar Panchannagram and Panchasayar are solely Hindu dominated neighbourhood, where Kalabagan and Barabagan are solely Muslim dominated neighbourhoods. In terms of social group compositions, it is seen that share of scheduled tribe (ST) population is negligible in the sample. Majority of the workers surveyed belong to lower social status (either SC or OBC) (68.72%). In the Hindu dominated neighbourhoods like Jorabagan (41.4%), Uttar Panchannagram (60.0%) and Panchasayar (77%) have high share of Scheduled Caste population. The share of SC population is even higher for peripheral areas (Uttar Panchannagram and Panchasayar). Both of the Muslim dominated locations, share of OBC category are quite high (around 80%). In terms of linguistic distribution, the surveyed locations have three dominant language speaking groups. In the central locations, Jorabagan (21%) and Kalabagan (1.1%) have very low Bengali speaking population. In other locations Bengali-speaking population is the majority. The share of migrant population is highest for Uttar Panchannagram (64.6%) followed by Jorabagan (55.4%) and Panchasayar (48.9%). On the other hand, in two Muslim dominated neighbourhoods and in Dumdum share of migrants are very low. In terms of work participation rate (%) it is seen that the participation rate is higher for peripheral locations, Uttar Panchannagram (25.1%) and Panchasayar (22.8%).

In brief, the central locations are characterised by low education, non-Bengali speaking population, mainly lower social groups. On the other hand, the peripheral location is dominated by migrants, mainly Bengali-speaking, Hindu, SC and less-educated. Compared to these two zones, the workers in non-central older locations have lower migration rate, higher education.

Employment profile of the surveyed workers

The surveyed workers with fixed workplace are more in regular salaried employment (67.4%) compared to self-employment (29.6%) and casual wage employment (3.0%). This indicates that regular wage workers tend to be more

space-bound compared to self-employed and casual wage labourers. In terms of locational difference, in peripheral locations i.e. Uttar Panchannagram (73.6%) and Panchasayar (81.5%) workers are in regular salaried employment. On the other hand, the share of self-employer is highest in central locations i.e. Jorabagan (34.5%) and Kalabagan (35.2%).

The surveyed workers are mainly concentrated in three major industrial sector i.e. manufacturing (22.1%), trade, commerce and Hotel (32.7%) and household sector (24.9%). But this pattern is different for different locations. In case of Jorabagan majority of the workers are concentrated in trade, commerce and hotel (46.7%), manufacturing (18%) and household sector (17.2%). On the other hand, in Kalabagan, most of the workers are concentrated in manufacturing (43.6%) and trade, commerce and hotel (47.0%). In Dumdum, majority of the workers are concentrated manufacturing (26.6%), trade, commerce and hotel (25.9%), household sector (22.8%) and social, community services (13.49%). In Barabagan also the share of trade, commerce and hotel (30.9%), household sector (26.9%) are higher. In Uttar Panchannagram majority of the workers are concentrated in manufacturing, trade and commerce, household sector and services. In case of Shahid Smriti Colony, Panchasayar, majority of the workers are concentrated in household sector (52.6%) and services (23.7%).

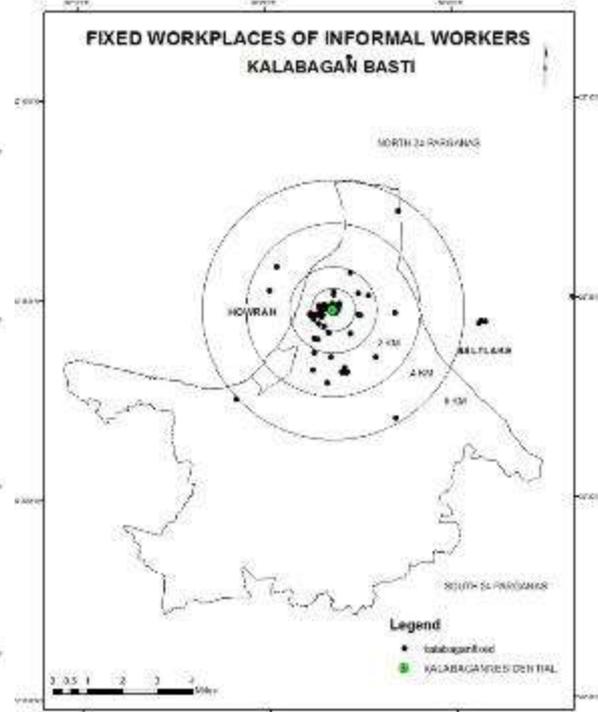

5. DELINEATION OF KOLKATA'S INTRA-URBAN 'EMPLOYMENT FIELDS'

Creation of spatial market smaller than a city-scale is the main indicator of spatial segmentation (Hanson & Pratt 1992). Hence, the first step of analysis is to understand the home-work linkages of workers engaged in different kinds of informal employment in Kolkata. The present section will try to map the employment fields of workers in different locations.

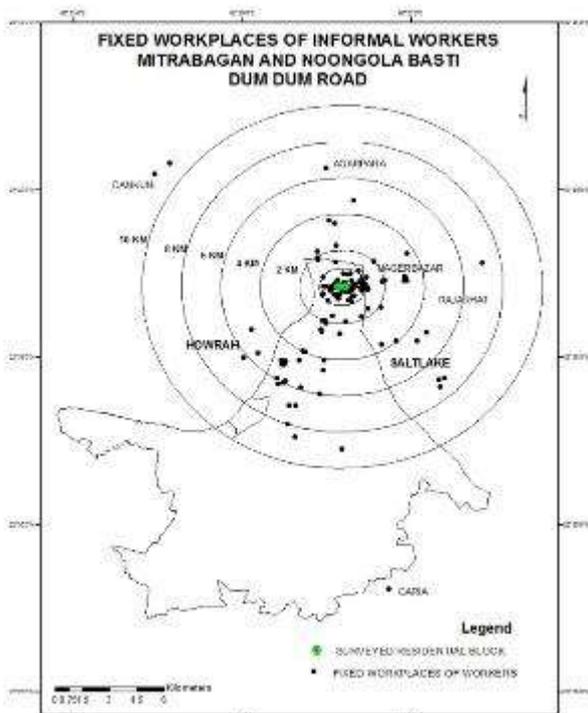

Map 2: 'Employment fields' of the informal workers in Kolkata Municipal Corporation

(d) Barabagan

e) Uttar Panchannagram

(f) Panchasayar

Source: Data collected from field-based survey, Jan-Dec, 2016

Workplaces of Informal Workers: The average home-workplace distance (all samples) is 1.46 km (see table 3). 81% of the workers surveyed tend to work within 2 km radius from their residential neighbourhood. Hence, it can be said that majority of the workers work close to their place of residence.

Table 18: Home-to-work commuting distance of informal workers in different surveyed locations, Kolkata Municipal Corporations

		Distance				Mean	Std. Deviation	N
		< 2 km	2 -4 km	4 -6 km	>6 km			
Central Core	Jorabagan	92.22	4.81	1.11	1.85	0.98	1.519	270
	Kalabagan	92.02	4.18	0.76	3.04	0.83	2.215	263
	Dumдум	73.09	10.55	7.64	8.73	1.8	3.29	275

Source: Collected from field survey, Jan-Dec, 2016

Central Locations:

The home-work distance is much shorter in central locations (for example Jorabagan and Kalabagan). It is seen that in Jorabagan, which is located in the central parts of Kolkata, has more compact ‘employment field’ around its locality. Average distance travelled by workers is around 1 km and over 92% of the workers work within 2 km radius from their neighbourhood (see table 3). In Jorabagan, majority of the workers were working in Barabazar and Posta region. As mentioned earlier, Barabazaar and Posta is a hub of wholesale trade. Hence, there are plenty of opportunities of working as shop keeper, accountant or freight handlers in this region.

The average distance travelled by workers in Kalabagan is shortest (0.8 km). In Kalabagan, majority of the workers work in Machua, in different occupations. Machua is a locality adjacent to Barabazaar, which is one of the largest wholesale fruit market in the eastern part of India. This market creates demand for a huge number of unskilled occupations such as sorting and freight handling. In other cases, the residents of Kalabagan work in surrounding localities like Jeliatoli, Phoolbagan in various small manufacturing units. Few workers work in distant locations like Park Circus, Zakaria Street, Rajabazar even in Khiddirpore. These are mainly Muslim dominated areas. This is indicating towards the fact that their economic space is segmented on communal lines.

Non-central Older Locations:

In Dumдум area, 73% of the workers work in the surrounding areas (within 2 km radius). The average commuting distance is 1.8 km which is much higher compared to central locations (Jorabagan and Kalabagan). The surrounding areas provide few economic opportunities like works in private households of the high end residential areas nearby. Few

workers work in various manufacturing units of the nearby localities. Many people commute to distant locations like Shyambazar and even to Barabazaar and other central locations.

In Barabagan, workers tend to work in surrounding areas and Tollygunj area. The average home-workplace distance is 1.5 km (see table 3). Some workers with fixed region of work tend to commute to Yadavapur and Garia. Many self-employed workers tend to work in the immediate surroundings of the locality.

Peripheral Locations: In the newer (peripheral) part of the city workers tend to travel more distances, and mostly they travel towards the central part of the city. In Uttar Panchannagram, the average home-workplace distance is highest (2.0 km) (see table 3). In Uttar Panchannagram, workers mainly go for work in manufacturing units of Topsisia and Martin Para (New extended part of Topsisia).

In Shahid Smriti Colony, Panchasayar the average commuting distance is 1.8 km (see table 3). In Shahid Smriti Colony, Panchasayar most of the workers travel up to Ruby More in the north, Bhagajatin and Yadavpur in the West. Many workers work in various localities of Yadavapur. The connection of the residents (especially older generation) with Yadavpur is very old and they have established networks there. Most of the women work in the surrounding localities as domestic helps.

6. LEAST SQUARE REGRESSION TO UNDERSTAND THE DETERMINING FACTORS

Many studies have used regression analysis to understand the commuting distance and the commuting time of the workers. Majority of the study have used various human capital related factors like age, education, gender, marital status, migration status, employment related variables (wage-non-wage, occupations, industries), locational factors (the dummy for locations).

The explaining power of the model is not very high (R^2 is 0.127). As the dynamics of city structure such as availability of jobs in the nearby areas, job densities, transport system, existing wage levels couldn't be introduced to the model, the explanatory power of the model is not very strong. But due to quantify the city structure variables and the unavailability of wage structure in the present dataset, these variables couldn't be included in the model.

From the regression analysis, it is seen that there is a commuting distance increase with increasing year of schooling. Scholars have discussed that the search boundary of the more educated workers are much wider compared to less educated workers. Again the wage level earned by the workers who are less educated tend to lower to support commuting longer distances (McLafferty & Preston 1992).

The effect of increasing age (proxy used for experience) has a positive impact on commuting distance, but the result is not statistically significant. There is a tendency of the young workers to work closer to their place of residence as their spatial information is much limited (Green et al. 2005).

As speaking of gender, it is seen women's spatially constrained workplaces. Women's shorter commuting trip have been discussed in the literature on commuting and labour market experience (Hanson & Pratt, 1991, 1992, 1995; Madden, 1981; Rapino & Cooke, 2011).

The married workers tend to commute longer distances compared to unmarried and widow/separated. Being married means more family responsibility which may lead worker to search and work at distant places. Though the effect of being married is different for women (Hanson & Pratt, 1995; Kwan, 1999; Madden, 1981; Rapino & Cooke, 2011) from men.

Source: Collected from field survey, Jan-Dec, 2016

Different employment types have different spatiality and hence require different commuting. It is seen that non-wage workers workplaces are more clustered closer to their place of residence compared to the wage workers. Again the workers in unskilled occupations tend to commute shorter than workers in skilled and semi-skilled occupations. The lower wages associated with unskilled occupations is thought to be a reason behind working closer to home. Various dummies are included to denote various industries. The effect of industries on commuting pattern was not statistically significant. The reason behind it is the spatial concentration of various industries at different places and the difference in residential locations of the workers. Hence the effect of various industries cannot be proven when all the locations are combined together.

Source: Collected from field survey, Jan-Dec, 2016

Note: *** significant at 1%; ** denotes significant at 5% and * denotes significant at 10%

Residential locations have major impact on workers commuting behaviour. The workers located in central locations (Jorabagan and Kalabagan) have the shortest commuting trips and the peripheral locations (Uttar Panchannagram and Shahid Smriti Colony, Panchsayar) have the longest commute. Even the non-central older locations have the longer commuting distance compared to the Joabagan (the base category).

The migrants tend to commute lesser distance compared to non-migrants, though the result is not statistically significant.

When the regression analysis is calculated for each locations separately, it is seen that the explanatory power of the models have increased. This is indicating that the location wise factors define the commuting pattern of the workers better than the city-wide scale. Few factors like gender, self-employment and skill level of occupation has significant effect on commuting for all the locations.

CONCLUSION

It is evident from the field survey that the labour market for informal labour is segmented spatially. From the quantitative part of the study, it is seen the average home-to-work travel distance is much shorter than the city-wide scale. Majority of the worker works closer to home creating a highly localised market. It creates a micro scale segmented market smaller than a metropolis. The commuting pattern is also location specific. The central-peripheral difference in commuting pattern is somewhat similar to the spatial mismatch theory. While the centrally located workers are more spatially confined, the peripheral workers are more spatially well distributed. But many workers from peripheral areas travel to central parts of the city. This region is a receiving region of workers from peripheral areas. Hence the average distance travelled by the workers in peripheral areas are more than the central part of the city.

From the regression analysis it is seen that some workers tend to commute even shorter distance. It is seen that the home-workplace distance is much shorter for women compared to men, self-employed workers compared to wage workers, unskilled workers compared to skilled and semi-skilled workers. Inter-industry differences in home-workplace distance are not found statistically significant. Even the impact of social characteristics in commuting is not noted.

ACKNOWLEDGEMENT

I am very thankful to Prof. Ravi Srivastava for his guidance and valuable insights.

1539 CITY ANATOMY – A PLANNING DECISION-SUPPORT DASHBOARD FOR SMART CITIES IN INDIA

Sarbeswar Praharaj

Faculty of Built Environment, University of New South Wales, Sydney, NSW 2054, Australia. Email – s.praharaj@unsw.edu.au

ABSTRACT

Amidst the sweeping trends of urbanisation and growing complexities of urban problems, public authorities, planners and researchers require novel methods to understand cities and identify appropriate solution pathways. This paper builds a dashboard—“City Anatomy”, by bringing together data on a range of urban indicators to recognize the state and trends in cities performance across 100 smart cities in India. The dashboard through a series of interactive applications, maps and charts illustrate a tangible, coherent and hard-to-grasp aspect of urban quality of life. City Anatomy dashboard harnesses the value offered by the advances in data science and urban informatics to support evidence-based planning decision-making in the aspiring smart cities. This article explains the approach, the data and the technology used to develop the City Anatomy dashboard and offers some vital lessons for building urban indicator data visualisation platforms at the national or regional scale.

Keywords: City Anatomy, dashboard, urban indicators, smart city, India

INTRODUCTION

Survey is essential to our understanding of cities, with data pertaining to the city as a prerequisite to effective planning and policy making. (Geddes, 1949)

Governments have long been generating data about cities, regions and the communities and infrastructure within their territories with an aim to deliver better services and guide public policies. Of late, the quantity and granularity of data productions have taken a massive leap with the introduction and deployment of the Information and Communication Technologies (ICT) drawing information from a range of networked devices, sensors and cameras embedded into the urban systems. Cities and governments that are applying the data-driven methodologies and practices in framing responses to urban challenges are branded as “smart cities” (Batty, 2013; Kitchin, 2014). As the production and analysis of data become increasingly vital for the management of cities, the field of urban informatics has opened up immense possibilities. In some senses, urban informatics is coincident with the smart cities movement—both looking to strategically use ICT, data and advanced analytics to understand the city and influence policy decision-making (Gray, O’Brien, & Hügél, 2016).

For many cities, the smart city has materialised into urban indicator projects that seek to compare urban performance within and across cities. Indicators are recurrent quantified measures that can be tracked over time to establish how well an area/city is performing with respect to its stated goals (Godin, 2003). As Kitchin (2015) mentions, indicator data provide a rational, neutral and comprehensive evidential basis for assessing the robustness of existing policies, to develop new interventions, and to decode and manage cities through measurement. Indicator-based assessments offer tangible evidence that brings a powerful sense of certainty, stability and control in public decision-making, and enhance the quality of urban policy debates. Cities that employ indicators have also cited gains in terms of educating and inspiring citizens, helping diverse stakeholders speak using a common terminology by breaking down “siloeed” mentality and coordinating actions in the same direction (Sulkowski, 2016). In other words, as Hezri & Dovers (2006) says, indicators act to provide a normative and rational bridge between knowledge and policy.

Although urban indicator and benchmarking projects have rapidly proliferated globally, most of them have remained relatively closed, with the underlying data, analytical approaches, and outputs locked inside organisations that undertake them. Such protectionist tendencies have faced sharp criticism (Kitchin et al., 2015a) as they fail to reveal the underlying assumptions, hidden agendas and falls short in shaping a dialogue around urban conditions. However, there has been a recent move by cities to open up the data, underpinning indicators and share them with citizens through “city dashboards”—focused on sharing information relevant to a city’s operation and performance via simple data visualisations, widgets and analytics (Batty, 2015). These dashboards provide dynamic graphics, maps and barometers in an easy to understand environment to engage widely with the policy-makers and citizenry. Experts believe that indicators and dashboards form crucial elements in the move towards data-driven smart cities as they employ a rigorous and transparent realist epistemology replacing protectionism and unaccountability, which have historically challenged rational decision-making and the management of cities (Kitchin, Lauriault, & McArdle, 2015b).

This paper reveals the making of “City Anatomy”—a dashboard built with open urban data and open source software for supporting smart city policy decision-making in India. The “anatomy of a city” is defined by Ascher (2005) as the art of separating the parts of urban systems in order to ascertain their position, relations, structure, and function. Our research uses the term “City Anatomy” to designate urban areas as organisms. We divide the cities functions into indicators and quantify them through data and visualisation to reveal the status and trends in urban performance and the health and metabolism of cities. The project assembles data on a range of indicators from across 100 cities in India selected for development under the recent “Smart Cities Mission”. By creating a national level digital platform, our research aids the theory of the post-democratic city in data-driven form (Barns, 2016) that enables “governance-beyond-the-state”. Our dashboard is conceived as an information output produced through the constructs of the smart city where the interplay

of data and urban informatics shape dynamic municipal conversations. We develop the dashboard as a planning support system (PSS) (Pettit, Bakelmun, et al., 2017) that can help policy planners navigate the growing complexities in making sense of data and urban conditions. By doing so, we fuel the debate around what Mackenzie (2006) terms “secondary agency” in the contemporary governance of the city—in which technologies and codes enable autonomous processing of data and evaluation of policies that do not necessarily require human intelligence.

SMART CITIES MISSION IN INDIA AND THE EXPERIENCES AROUND INDICATORS AND DASHBOARDS

The Smart Cities Mission (SCM) is a \$15 billion venture of the Government of India rolled out in 2015 with an aim to drive economic growth and improve the quality of life for people in selected cities. Each of the cities receives funding of \$150 million between 2015 and 2020 for developing modern infrastructure and regenerating designated precincts to enhance urban sustainability. Although the mission strongly advocates for performance-linked urban investments and merit-based project selection, the guidelines of the SCM (GoI, 2015) could not provide a practical framework to achieve such outcomes. Together with the smart cities initiative, the Indian government has also announced programmes for urban renewal, heritage development, improvements in sanitation etc.—all of which are devoid of any effective mechanisms for selection of projects or measuring their impacts on the baseline conditions over time. With an intensifying rate of urbanisation and an accompanying proliferation of urban development programmes, there is an increasing need for evidence-based planning decision support system that can help both in identifying the core challenges of cities and assess the outcomes of public infrastructure investments.

India’s experience around urban performance measurement through indicators is limited. The only major initiative came under the Indian Ministry of Urban Development (MoUD) in 2006, labelled as Service Level Benchmarking (SLB). The project (GoI, 2010) established key performance indicators (KPIs) covering water supply, wastewater, solid waste management, stormwater drainage and transport sectors. It encompassed: a) collation of performance data on selected indicators, b) implementation of improved information systems at the city and state level to support the provision of this data on an ongoing basis, and c) development of performance improvement plans based on the benchmarking data. In December 2009, MoUD released the SLB performance data of 28 pilot cities that highlighted the comparative advantage and disadvantages of cities. However, the outcome was merely published as a two-page Abstract report leaving little scope for digital engagement with the dataset. Neither the raw data was made available, nor it was visually mapped for broader sharing with the non-technical audience. The World Bank (2016) in an appraisal of this initiative denounced the diminutive reach of the benchmarking outcomes that lead to the failure of this initiative in generating significant debates, engaging the deep states and influencing policy discourse.

A more dynamic five-year action research project on urban indicator based measurement was initiated at CEPT University in Ahmedabad, operating under the franchise—Performance Assessment System (PAS). The project develops appropriate tools and methods to measure, monitor and improve delivery of water and sanitation services in urban India. PAS has adopted a set of KPIs for reforms by the states, as well as municipal corporations that are analysed to achieve city specific improvements in the sanitation sector. Currently, the PAS web portal (available at <http://www.pas.org.in>) hosts data repository contributed by 900 town and cities, from across 5 Indian states. The platform offers visualisations of the data at both state and city level and provides unrestricted access to each city’s database. Various tools developed by the PAS team enables interactive analysis of data for effective communication and dissemination of the assessment outcomes (Mehta & Mehta, 2013). PAS is indeed a successful venture for gathering, analysing and open publication of data on urban sanitation related services. But, the limited scope of the project on a specific sector meant that it could not be referred as a comprehensive model for planning decision-support.

In 2017, the Government of India has published a set of ‘Liveability Standards in Cities’ (GoI, 2016) to generate a Liveability Index of 116 selected cities under the SCM. The framework identifies a total of 79 Indicators (57 Core Indicators and 22 Supporting Indicators) grouped under 15 domains, such as governance, mobility, education, health, water supply, pollution etc. While the report outlining the methodology of the Liveability Index, spells out the process of data collection and definition of each of the indicators, it falls short in articulating whether the data will be openly accessible. There is apparently lack of intention to harness data from digital sources as the index is solely built around static data (Hickok, Lakshané, & Tiwari, 2016). More significantly, the initiative has translated into a backroom exercise with no interest shown towards the application of analytics for dynamic visualisation of data for generating democratic debates. Amidst these developments, experts are raising concern on the apathy of civil administration in India towards utilising digital technologies for visualising and opening up of public data (Patro, 2017), and there seem to be no lessons learnt from the experience of SLBs.

GLOBAL CASE STUDIES AROUND URBAN INDICATOR AND CITY DATA VISUALISATION

Since its emergence in the early 1990s, urban indicator projects have manifested at two different scales. First, a worldwide sustainability agenda has driven the shaping of indicators for city comparison at the global scale. A desire by cities and responsible organisations to conform to the UN Sustainable Development Goals (SDGs) and the Chapter 40 of Agenda 21 from the United Nations Conference on Environment and Development (UNCED) has translated into these projects. The Goal 11 of the SDG (United Nations, 2017) is to make “make cities and human settlements inclusive, safe, resilient and sustainable”, which along with the UNCED statement (1992) emphasises on the need for urban sustainable development indicators to provide solid bases for decision-making at all levels of governments. The best set of universal urban sustainability indicators is developed by the International Standards Organization (ISO) published in 2014 as the ISO 37120 - Indicators for city services and quality of life.

World Council on City Data (WCCD) hosts a consistent and comprehensive platform bringing together data on ISO 37120 indicators from across 82 cities. The WCCD portal (available at <http://open.dataforcities.org>) provides data, maps, and an interactive dashboard to visualise, explore and compare the cities performance over 100 indicators. The participating cities provide third-party verified data to the WCCD Global Cities Registry which is then uploaded to the datastore. Data are then visualised against indicators distributed across 18 themes, such as transportation, water and sanitation, and health. The portal provides three interfaces for data display—map view, graph view and trends view. The Map view (see Figure 1) scales down the data into proportionate circles displayed over the location of respective cities, translating into a dashboard. The graph view projects the data in a horizontal plane organising the cities based on their performance over an indicator in ascending order from left to right. The trends view provides annual historical data plotted over a line graph to indicate cities progress on a specific aspect over time. It is possible to explore the data of each city, or a few of specific interest, separately on the portal, in which the data on profile indicators are displayed on bar charts. Urban planners (Kitchin et al., 2015a; Pettit, Lieske, & Jamal, 2017) observe that the portal serves as a goldmine for policy decision-makers, businesses and interested citizens wishing to compare the performance between cities.

Figure 1: A snapshot of the map view under the WCCD web portal.

Source: <http://open.dataforcities.org/>.

The second group of indicator projects are undertaken at the national, sub-regional and even at the scale of municipalities. These are more bottom-up exercises driven by the rise of new managerialism and the demand for efficiency and transparency in public sector management. In these initiatives, indicators are used to diagnose local issues and assess the outcomes of public policies, programmes and investments (Holden, 2006). In doing so, the governments are moving beyond what Goldsmith and Crawford (2014) terms as ‘compliance model’—whereby public authorities view data reporting as a mere response to transparency agenda. Instead, they utilise data intelligence towards developing more active, problem- solving capabilities for the benefit of their constituencies.

The Centre for Cities in the UK has launched a national data tool at the beginning of 2015 with an aim to map out the patterns of economic growth and drivers of urban success. The portal is based on 18 indicators covering areas, such as demographics, housing, jobs and employment, environment and inequality, highlights the variation in performance across Britain’s 63 largest cities. The “Cities Data Tool” (available at www.centreforcities.org/data-tool) developed with the support of Future Cities Catapult gives users access to data on UK cities in a variety of formats. The datastore is designed with the capability of displaying data through maps, bar charts, time series analysis, scatter graph, bubble diagrams and through simple tables. The maps and bar charts allow visualisation of data on a specific indicator providing a comparative understanding of cities performance (see Figure 2). To measure trends over a specified period or simultaneously analyse multiple indicators, the users can select to display data through time series, scatter and bubble graphs. While performing the analysis over the portal, the national average on any indicator is shown along with the list of top 10 and bottom 10 performers. The site provides users with the option to download data, tables, maps and images, add their feedback on the data and share the outputs through popular social media channels.

CITY ANATOMY: A PORTAL FOR 100 SMART CITIES IN INDIA

After reviewing the state of play of global indicator dashboards and given there was no comprehensive, authoritative data visualisation portal for Indian cities, we decided to build “City Anatomy”. City Anatomy was developed to bring together data on a range of urban indicators and present complex datasets in an easy to use format for rapid screening and understanding. The project is also called the “100 Smart Cities Portal” as the analysis is undertaken with data from over 100 cities selected under the ongoing Smart Cities Mission in India. The organisation and layout of City Anatomy are significantly influenced by the WCCD portal. However, the challenges and complexity of building the City Anatomy were far more significant as we have mapped double the number of cities analysed over the WCCD platform. Also, our work had to deal with the requirement of simultaneously displaying data over 100 urban centres located in close proximities. In compare, the cities mapped by WCCD have more relaxed spacing as they spread across the world. This meant that we had to find a novel way to avoid clutter in the visualisation output. We have also made significant innovations in presenting data through charts whereby multiple indicators can be selected together for a superimposed view providing a richer understanding of comparative urban performance.

System Architecture and Technologies

City Anatomy is a web application consisting of a series of navigation controls for accessing content and visualising data. The interface is built using a Model-View-Controller (MVC) architectural pattern efficiently separating- (a) the backend data, logic and rules of the application, (b) controller which accepts input and converts it to commands for the model, and (c) the output view of the information. There are many third-party applications and online services, such as AWS QuickSight, Tableau, Qlikview and FusionCharts that can support visual analytics of data. These are very powerful tools and popularly used in a business context but lack support for highly customised interfaces. So, we decided to build a bespoke solution using best practice approaches, open source libraries and common standards to make the portal usable by almost everyone with a computer and internet access. The use of free, open source and interoperable technologies within the dashboard has enhanced the affordability and accessibility of the project. The design adheres to the classic web-information seeking mantra—general overview first followed by detailed information on demand.

The City Anatomy dashboard is built on an HTML5 language which provides openly licenced resources for use by all web developers. JavaScript libraries are used for the graphical user interface of the dashboard. Specifically, the Leaflet 1.2.0 JavaScript has been used to build the interactive maps and visual outputs that efficiently works across all major desktop and mobile platforms. The base map on which the analytics is presented has been adapted from the openly archived ‘Light Grey Canvas’—featuring an overall soft grey colour for land and darker grey for oceans, available at the ArcGIS Online collection. We have used Chart.js JavaScript to achieve a clear visual distinction between datasets through graphs

and animated charts. This technology supports redrawing of charts based on window size for perfect scale granularity of visual outputs. The jQuery (1.12.4) and Bootstrap (2.3.2) open source toolkit has been used in the front-end component library over CSS3 for developing a responsive grid system and smooth transitions. There is no server-side scripting of the portal. All assets are brought together in the presentation layer (web browser) and rendered into position using JavaScript. Data is manually ingested into the system from an Excel spreadsheet which is then passed on to the output side of the view through the logic system and content delivery network (CDN) where it is rendered on the web page and ultimately shown to the user. Figure 3 breaks down the process and technologies used in the project for a simplified understanding.

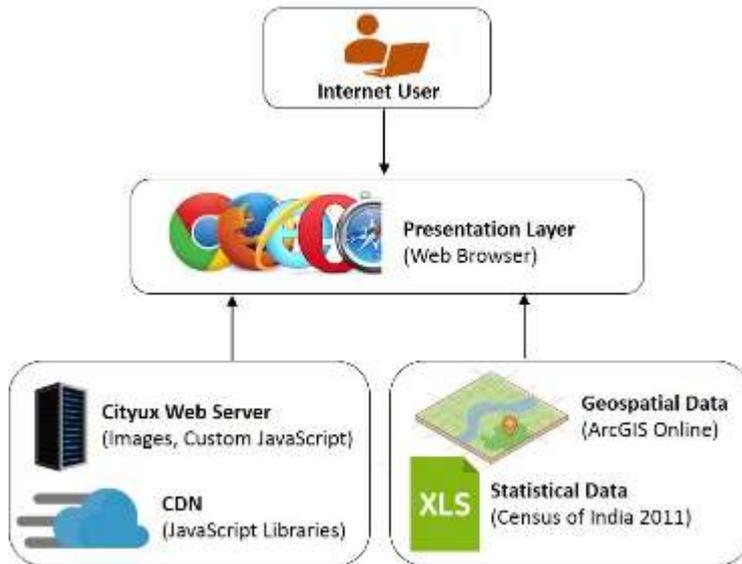

Figure 3: Technical Architecture of City Anatomy

Indicator Selection, Cities and Data

This paper focuses on 100 cities selected explicitly by the Government of India for development under the Smart Cities Mission. Each of these 100 cities receives funding of US\$150 million between 2015 and 2020 for developing smart infrastructure solutions in areas such as urban transport, water supply, solid waste management, command and control centres, environmental pollution management and health facilities. The current analysis thus can potentially facilitate the selection of policies and projects under the Indian Smart Cities Mission.

The research follows three basic principles for indicator selection: policy relevance, data availability, and geographical unit consistency. A thorough review of globally acclaimed city rankings and indexes was done to identify the most common thematic policy domains around which indicators will be formed. In terms of their focus, these indices span the interrelated areas of smart city ranking (Cohen, 2014; Giffinger et al., 2007; GoI, 2016; IESE, 2016), liveability (The Economist Intelligence Unit, 2017) and quality of life (ISO, 2014). We have taken specific care to select the most recognised publications that express opinions from a range of perspectives (i.e., government, academia and the private sector). We have also taken specific care to ensure that a lack of data availability does not influence the selection of proxy measures. Instead, the emphasis of this paper is to identify and use essential yet locally relevant indicators (Praharaj, Han, & Hawken, 2018) for which reliable data is available from public sources. Further, to avoid spatial scale mismatches in the data, known as ‘areal unit problems’ (Fotheringham & Wong, 1991), we have used data at the level of city municipal corporations on a consistent basis.

While the economy, mobility and physical infrastructure etc. have featured across the indicator systems consulted for this study, areas such as social cohesion often neglected as measures of smartness in cities. In this study, we have used a total of 60 indicators around nine thematic domains, as illustrated in Table 1. Social cohesion, behaviour and lifestyle have been included in this study as core predictors along with the commonly referred domains from literature. This inclusive approach in defining the broad indicator themes was necessary due to the high level of existing social and economic inequality in India’s cities (Kundu & Samanta, 2011) and an increasing trend of insecurity among disadvantaged communities with the emergence of smart city discourses (Datta, 2015). A total of seven variables were grouped under the demographic and social cohesion domain to uncover the patterns of social vulnerabilities in India’s aspiring smart cities. The second group of variables in Table 1 captures the economic potentials of cities and the supply of jobs amidst a rapid surge in young and working age population in India. A maximum of thirteen variables was selected under the domain of physical infrastructure and municipal service delivery. A set of five indicators are formed around skills and creative capacities. Six predictors define the domain of behaviour and lifestyle while seven are listed for measuring the shelter adequacy in cities. A total of 11 indicators are assigned over two themes overlooking local governance—urban development framework and resources and transparency and open administration.

The town amenities section of the district census handbook, published by the Office of the Registrar General and Census Commissioner at the Ministry of Home Affairs in India (Census of India, 2011), was referred to as the primary source of data. The latest available data on GDP was collected from the Open Government Data platform managed by the

Government of India's National Informatics Centre (<https://data.gov.in/>). Transport-related information was retrieved from a report issued by the National Transport Development Policy Committee set up under the Planning Commission, Government of India (NTDPC, 2013). The data on matters of governance and municipal capital expenditure were gathered from the individual local government websites.

Table 1: List of Indicators Used in the Analysis and Their Thematic Domains

Thematic domains	Indicators
Demography and social advancement	Population density in km/sq. km
	Decadal population growth rate in percentage
	Sex ratio
	Chile sex ratio
	Household size
	Female share of workers
	Literacy rate
Economic lead	Per capita GDP
	Work participation rate
	Working age population
	Dependent population
	Share of main workers
	Share of marginal workers
	Share of secondary and service sector workers
Access to public infrastructure	Percentage of households availing banking services
	Road density in km/sq. km
	Mode share of public transport (in percentage)
	Average trip length in km
	Percentage of households having access to treated tap water
	Percentage of households with access to drinking water within premises
	Percentage of households having electricity connection
	Percentage of households having access to latrine within premises
	Percentage of households having piped sewer connection with latrine
	Wastewater connected to closed drainage (percentage of households)
	Percentage of households with no waste water drainage connection
	Household level coverage of municipal solid waste (MSW)
	Efficiency of collection of MSW (in percentage)
Extent of MSW recycled and recovered (in percentage)	
Skills and creative resources	Gross enrolment ratio in higher education
	Number of colleges/lakh population
	Number of universities/lakh population
	Number of college graduates each year
	Creative and agile population (15-44 age group)
Behaviour and lifestyle	Percentage of households using solar energy
	Percentage of households using cleaner energy for cooking
	Percentage of households using fossil fuels for cooking
	Percentage of households having bicycle
	Percentage of households having enclosed bathroom
Digital services and communication	Percentage of households practising open defecation
	Percentage of households having fixed internet
	Percentage of households having computer/laptop
Housing and shelter	Percentage of households using mobile phones
	Percentage of households with condition of house as good
	Percentage of households having permanent house structures
	Percentage of households with condition of house as dilapidated
	Percentage of households with temporary/unclassifiable house structures
	Percentage of households residing in own houses
	Percentage of households residing in rented accommodation
Urban development framework and resources	Percentage of city population living in slums
	Status of city level Spatial development plans/Master plans/CDP
	Status of Ward level/Micro area Spatial development plans
	Functioning status of dedicated urban planning wing within ULB/DA
	Status of ULB empowerment to set and collect property tax
Transparency and open governance	Per Capita Capital Expenditure of the ULB
	Dedicated Local Government Website
	Status of online municipal budget sharing
	Initiation of e-procurement system (including vendor registration)
	Status of online availability of citizen Charters
	Status of online publication of Service level benchmarks
Availability of single-window civic service centres in the ULB	

Visualisation Outputs

The City Metric data visualisation platform has two core components: the map view and the chart view. The purpose of the map view module is to provide a single graphical representation of the current values for key indicators. The map view (see Figure 4) offers a navigation panel with nine icons placed at the left side of the screen, each representing a broad indicator domain. Once a user moves the cursor over one of those icons the individual indicators are shown in a separate panel running from top to downwards. Selection of an indicator will send a command to the system leading to animated visualisation of the data over respective cities. Figure 4 illustrates a visual output from the selection of “number of hospital beds/1000 population” within the domain of access to public infrastructure. By clicking on the circles, one can view the data and drill down to get more information from the data box displayed over the city. Such visual analytics support the identification of comparative advantage and disadvantage across cities on a particular indicator.

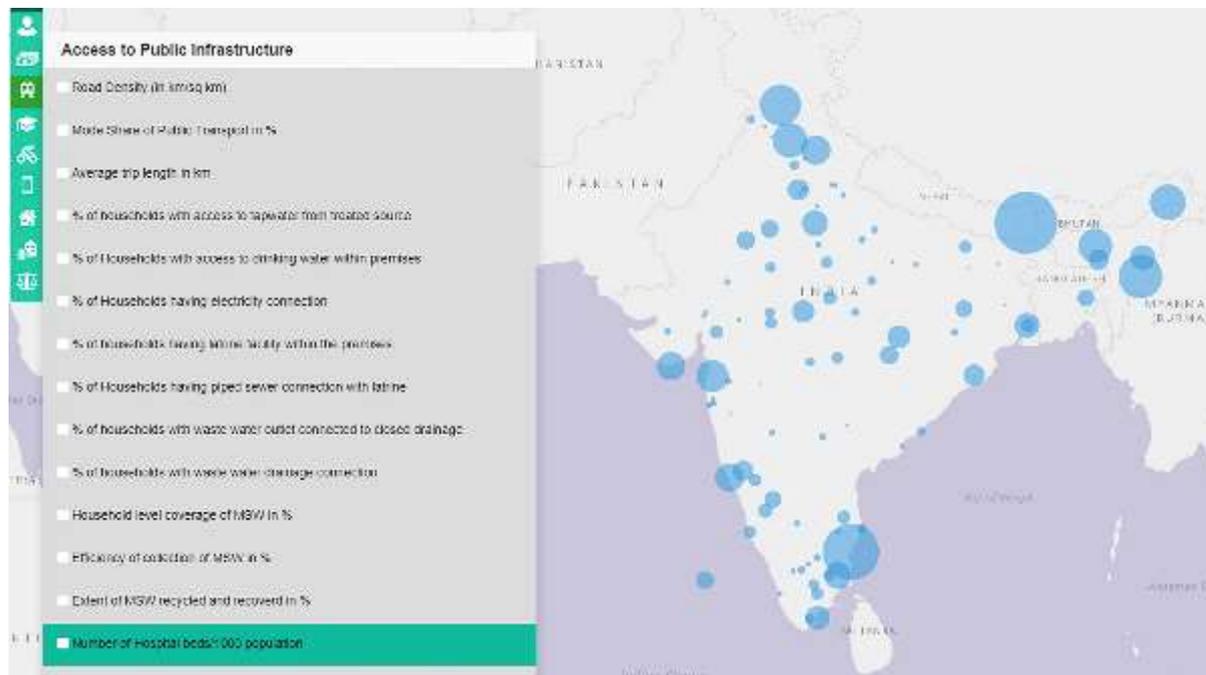

Figure 4: Map view in the City Anatomy Dashboard.

Source: <http://www.cityux.com.au/sarbeswar/map-view.html/>.

In contrast to the map view where one indicator can be selected at a time, the chart view provides the opportunity to choose two or more indicators for a detailed cross-cutting analysis and understanding of issues. Clicking on one of the icons in the left panel of the chart view module will automatically select all the indicators within the thematic domain, and a line graph will be generated as a superimposed view. The cities are represented on the X-axis, whereas, the Y-axis acts as a percentage scale of the data. The chart displayed in Figure 5 offer visualisation of a selection of 6 indicators within the behaviour and lifestyle domain. The indicators are presented in distinct colour with a legend provided at the top of the chart. It is possible to select or deselect by clicking on the respective indicators as required for the purpose of the user and the visual outputs will transform automatically based on the command. The interface is designed in a way that allows the operator to switch over from the chart view to the map view and vice-e-versa at any time for examining correlations in the analysis. The unique aspect of the chart view is that it advances understanding of the trends and consistencies in the performance of a city over a plethora of issues portrayed through the visual heartbeats.

time data is unavailable for Indian cities. However, with the smart cities projects taking shape and the urban environment getting intensely networked across the 100 cities, there will be possibilities of digital data generation. We will explore in future the opportunities of automated benchmarking of urban performance through finer grained real-time data feeds which we believe are essential for the success of the project. The goal is to continuously experiment with the digital tools for measuring and monitoring the advantage and disparities within and across the smart cities. Such projects help assert the role of government as a “platform provider” and facilitator of urban conversations for shaping healthy and democratic cities. Ultimately, the paper aids to reviving the art of town planning in the age of digital technologies and reinforces the view of Patrick Geddes (1949)—“survey is essential to our understanding of cities, with data pertaining to the city as a prerequisite to effective planning and policy making”.

1093A CRITICAL PERSPECTIVE OF SMART CITIES INITIATIVE IN INDIA: INVENTORY AND PROSPECTS

ABSTRACT

The Smart City paradigm aims to improve citizens’ physical quality of life in a scenario where the percentage of people living in urban India is getting higher and higher (World Urbanization Prospects, 2014). With the advent of “smartphones”, technology has helped mankind to solve some of its difficulties. On a similar note, “smart city” is a futuristic approach to alleviate obstacles triggered by ever-increasing population and fast urbanization which is going to benefit the governments as well as the masses. Modern day cities are deprived of vital elements like quality of life and socio-economic development which can be delivered by the smart cities. Smart cities are an endeavor to make cities more efficient, intelligent, sustainable and livable. This research paper explores various aspects and dimensions of a smart city. To bridge the gap in literature regarding the concept of smart and intelligent cities and its implementation, a framework has been developed to get better insights about the idea of smart and intelligent city. In this article, a new methodological approach is presented to evaluate to what extent the smart cities’ development pursues sustainable development goals in the fast growing cities of India. This methodology is called City Sustainable Indicators (CSI) approach. The CSI approach allows to estimate, with qualitative and quantitative indicators, how far smart cities are more intelligent and smart in environmental, economical and social perspectives. Moreover, this estimate can be performed before the technologies deployment. The methodology has been tested on the case study of metro cities of India like, Delhi, Mumbai, Kolkata and Bangalore etc. The implementation on the field, demonstrates that this methodology is able to give decision makers useful information on benefits generated by smart solutions deployment. This manuscript is relevant for the four major issues: Smart city initiative is used to enhance quality, performance and interactivity of urban services, to reduce costs and resource consumption and to improve contact between citizens and government; benefits are expressed with quantitative indicators; indicators are estimated before technologies or solutions implementation; smart city applications are developed to manage urban flows and allow for real-time responses; a smart city may therefore be more prepared to respond to challenges than one with a simple "transnational" relationship with its citizens. The paper highlighted how these factors can make the smart city initiative a successful initiative in India. The proposed methodological framework has been used to figure out various agendas for research and traces its practical implications.

1264 AND YET IT MOVES: PRICE BEHAVIOR IN URBAN PAKISTAN

James Herndon

The University of Alabama

ABSTRACT

This paper examines monthly prices from 2012 to 2017 for thirty-eight consumer goods across seventeen Pakistani cities. Prices converge both temporally and spatially. Goods that are not subject to price controls behave like those in other countries. A wage-adjusted Consumer Price Index shows that Pakistani cities are either “high” or “low” cost of living. Finally, a novel measure of cointegration ranks the most and least economically integrated cities. Pakistan’s urban markets are not perfectly integrated, but divergence typically does not occur along provincial, linguistic or ethnic boundaries.

JEL Codes: E30, N95, O12

1. INTRODUCTION

Do Pakistan’s cities work? Are they trapped in a nearly failed state unable to ensure the welfare of its people? Or has Pakistan created a space for urban firms and consumers to efficiently buy and sell goods? Plenty of evidence might suggest the former.

In 2011, President Obama called the disintegration of Pakistan “his biggest national security concern.” (Sanger, 2012, p. 112) How plausible is this nightmare scenario? Alesina, Easterly and Matuszeski (2011) constructed two measures of an “artificial state,” one for the straightness of borders and another for the number of ethnic groups straddling those borders. Pakistan was one of 13 countries in the worst third for both categories, alongside a since-dismembered Sudan. We don’t expect disintegrating states like South Sudan to provide their citizens with a surfeit of consumer goods.

But if failure was imminent, why did the World Bank’s 2016 Logistics Performance Index rank Pakistan 68th, well ahead of richer countries such as Lebanon, Iran, and Russia? According to a metric based on calorie consumption, The World Bank (2016) also found that poverty in Pakistan fell from 64 to 30 percent from 2001 to 2014. China’s government plans to invest over \$55 billion in Pakistan in coming years. They surely expect a return on those funds. (Sender and Stacey, 2017)

This paper will show what the World Bank and the Chinese already know: that Pakistan’s economy works, especially in cities. Firms can conduct arbitrage to ensure urban consumers have the basics of food, clothing and energy. Migration has largely eliminated significant differences in the urban cost of living in different provinces. That might not sound exciting, but it contradicts the dominant idea of Pakistan as a dysfunctional state unable to provide for its citizens.

This essay contributes to two strands of the economic literature. The first concerns price behavior. If the same good sells for two different prices it invites arbitrageurs to buy low and sell high until that discrepancy disappears, the “Law of One Price.” Thus price deviations convey information about market integration or lack thereof. Engel and Rogers (1996) found the international border between US and Canadian cities contributed more to their relative price volatility than thousands of miles of distance within each country. This occurred despite a free trade agreement, a common language and similar legal systems. Subsequent papers have focused more on prices within a single nation to eliminate confounding factors like borders and exchange rates. For the United States, Parley and Wei (1996) used a unit root test to show that prices converged nonlinearly; larger price differences provoked faster convergence. Morshed, Ahn and Lee (2006) found that price indices in India showed faster temporal convergence than those in the United States.

Much of the previous literature relied on unit-root tests, which may show a random walk when relative prices remain within the bounds set by theory. That explains the findings of nonlinear convergence also found by Fan and Wei (2006) in China. This paper tests for spatial and temporal convergence using econometric techniques that do not conflict with the underlying model. I will show that Pakistan’s price convergence compares favorably with that of India. This paper also reinforces previous literature on Pakistani prices. My results for specific consumer goods support those found in Alam and Bhatti (2014) while my attempt at quantifying changes in the cost of living in recent years updates Ahmad and Gulzar’s (2008) paper.

The second line of literature relates to urbanization in the developing world. Pakistan’s population disproportionately resides in the Indus river basin, one of 11 “mega-delta” regions in Asia and Africa. Seto (2011) noted these regions are at once magnets for migration, economically productive and threatened by rising sea levels. To explain the growth of cities in such poor countries, Glaeser (2014) constructed an open economy model where urbanization no longer relied on raising agricultural productivity or even a competent government. Glaeser found that optimal policies depended on both the quality of institutions and the size of the city. Most of the results in this paper will point to Pakistan’s policies being more effective than is commonly acknowledged, even by Pakistanis themselves.

Part 2 of this essay provides a brief overview of Pakistan’s history since 1947 with an emphasis on the erratic growth of cities. Part 3 describes the economic model and econometric techniques. Part 4 explains the data. Part 5 presents results supporting my conclusion that Pakistan’s urbanization has been more successful than is often recognized. Part 6 concludes.

2. PAKISTAN’S URBAN CONTEXT

When the British delineated Pakistan in 1947, they imposed that country on people which, outside of the Punjab, they themselves had been “unable to incorporate into their bureaucracy, running it instead as a military fiefdom.” (Kaplan, 2012). The new government maintained that hands-off approach; today the central government does not control sixty percent of its nominal territory (Rumi, 2012). Table 1, below, summarizes how that lack of effective governance means that quality of life still varies dramatically for cities in different provinces.

Table 1: Urban Pakistan by Province

Province	Population	Urbanization Rate	Gini	% Urban Children Fully Vaccinated	% Urban in Top Wealth Quintile
Punjab	110,012,442	0.37	0.30	74.4	49.6
Sindh	47,886,051	0.52	0.38	51.5	55.3
Khyber Pakhtunkhwa	30,523,371	0.19	0.31	58.0	17.7
Baluchistan	12,344,408	0.28	0.27	35.9	39.1

Source: Provisional Province Wise Population by Sex and Rural/Urban Census 2017, Pakistan Demographic and Health Survey 2012-13

The first major shock to Pakistan’s cities occurred in 1947 when millions of Urdu-speaking Muslims abandoned their ancestral homes in India for a new homeland. Over four and a half million Hindus and Sikhs left, while some six and a half million Muslims arrived (Mustafa and Sawas, 2013). Personified by Pakistan’s founding father (and Bombay lawyer) Muhamad Ali Jinnah, these “Muhajirs” gravitated towards cities like the capital in Karachi. (Inskeep, 2011). The 1951 census found that 48 percent of urban Pakistanis were recent immigrants from India. (Hasan, 2010).

After Independence, factors driving urbanization across much of the developing world arrived in Pakistan. Rising agricultural productivity in the 1960s pushed many villagers into the cities in search of work (Hasan, 2010). More often than not, they found it: gross domestic product per capita nearly tripled from 1950 to 1999 (Easterly, 2001).

Chaos in neighboring Afghanistan pushed over three million refugees into Pakistan in the years after 1978 (Memon, 2005). Laws preventing the cultivation of land funneled those Afghans into cities, a trend that continued after international aid declined in 1995 (Mustafa and Sawas, 2013). Not every disaster was manmade: widespread flooding in Punjab and Sindh in 2010 destroyed countless farms and hurled hundreds of thousands into makeshift camps on the edge of urban areas (Constable, 2011).

Today most internal migrants leave the poorer states of Khyber Pakhtunkhwa and Baluchistan and arrive at large cities in Sindh and Punjab (Memon, 2005 and Hasan, 2010). While no longer the capital, Karachi still grew from one million inhabitants in 1950 to over thirteen million in 2010 (Inskeep, 2011). Today native Sindhis are about ten percent of the population of Karachi, roughly half the size of the Pashtun population of that city (ICG, 2017).

Blank, Clary and Nichporuk (2014) found what while the residents of major cities in Pakistan enjoyed better access to education and healthcare, they increasingly saw their economic situation as worse than deprived rural areas. Blank, et al. argued that the center of gravity in Pakistan’s elections has shifted away from the rural areas to cities. The quality of life in urban Pakistan has real implications for the domestic and foreign policy of a nuclear power.

3. MODEL AND ECONOMETRIC TECHNIQUES

This paper assumes the same theoretical model as Engel and Rogers (1996), where a local monopolist maximizes profits selling each good. We model each good as the product of two intermediate inputs, one tradeable and one non-tradeable. Think of the non-tradable component as capturing transportation and marketing costs. In this model, the seller’s markup depends on the local elasticity of demand. Both the non-tradeable components and the markup prevent prices from fully converging. Still, if prices vary too much arbitrage can occur. What defines “too much?” Both transportation and opportunity costs increase with distance, so even with all other factors held constant we expect to see the relative price of some good in locations j and k fluctuating within a range proportional to the distance between j and k .

$$\frac{1}{d_{j,k}} \leq \frac{p_j}{p_k} \leq d_{j,k} \tag{1}$$

The range in (1) is the reason the literature began testing for non-linear convergence or discarding unit root tests entirely. If the relative price of a good in two places wanders within these bounds, prices might appear to behave like a unit root while simply remaining within the bounds set by our model. We should not expect to see perfect convergence across all locations or even between two cities in close proximity. However we can test whether or not the prices for a particular good in a particular city ever become truly untethered from the national market, or if convergence seems to occur spatially within each province to the exclusion of cities in other provinces. Either outcome would could indicate a market failure.

We need to identify items that could prove or disprove this hypothesis. If the government imposes price controls, we might misinterpret that similarity as evidence of an integrated market when it is instead the result of government intervention. This paper uses each item’s coefficient of variation as a baseline for inclusion. If the ratio of an item’s standard deviation to its mean averages less than 0.05, I assume that there is insufficient opportunity to cross the threshold in equation (1).

$$\frac{1}{T} \sum_{t=1}^{t=T} \frac{\sigma_t}{\mu_t} > 0.05 \tag{2}$$

I will examine price behavior at the level of individual consumer goods with two tests: one for each item temporally without city effects, another that measures an item’s convergence spatially between cities.

An autoregressive function of a price on its first lag tell conveys how quickly a price reverts to its mean. That is, how long does it take for a price shock to dissipate? Half-life offers the most intuitive measure of mean-reversion, telling us how it takes for a price shock to dissipate by half. A relatively short half-life could indicate a good that is seasonal, perishable or difficult to transport. Similarly, a beta coefficient approaching one might indicate a good that is not as susceptible to arbitrage.

$$price_t^* = \alpha + \beta price_{t-1}^* + \varepsilon_t \tag{3}$$

$$half - life \equiv \frac{\ln 1/2}{\ln \beta} \tag{4}$$

In order to remove individual city effects, I transformed prices using the forward orthogonal deviation described in Arellano and Bover (1995). Instead of losing an observation by taking a first difference, this subtracts the average of all future values.¹⁰²

$$price_{i,t}^* \equiv \sqrt{\frac{T-t}{T-t+1}} \left[price_{i,t} - \frac{1}{T-t} \sum_{s>t} price_{i,s} \right] \tag{5}$$

However, this still leaves us with correlation between our transformed error terms and the transformed lag. To avoid this complication, Arellano and Bover recommend using the second lag in levels as an instrumental variable¹⁰³. While every item undergoes the same transformations, the resulting half-lives should still be heterogeneous. While the incentives behind arbitrage are the same for different goods, we cannot assume every price behaves the same. For example, transportation costs will rise for easily damaged goods, while perishable items require either expensive storage or immediate resale.

While half-lives provide some sense of how quickly arbitrageurs take advantage of price discrepancies, they do not tell the entire story. Phillips and Sul (2007) devised a test for panel data with this dynamic in mind. Think of each individual city’s time series for any given commodity as having a time-varying idiosyncratic distance from the country’s overall trend, μ_t .

$$X_{i,t} = \delta_i \mu_t + \varepsilon_t \tag{6}$$

$$\delta_{it} = \delta_i + \sigma_i \xi_{it} L(t)^{-1} t^{-\alpha} \tag{7}$$

$L(t)$ is some increasing function that is divergent at infinity; I follow standard practice and use $\log(t)$. ξ_{it} is an error term. This semi-parametric form for $\delta_{i,t}$ under certain conditions allows me to test the null hypothesis $H_0: \delta_{i,t} \rightarrow \delta$ as $t \rightarrow \infty$ with a one-sided t-test. Phillips and Sul called this “log-t convergence.” This null hypothesis is the same as testing $H_0: \alpha \geq 0$,¹⁰⁴ a test that each city’s divergence from the common trend tends towards zero.

$$h_{i,t} \equiv \frac{\delta_{i,t}}{\frac{1}{N} \sum_{i=1}^N \delta_{i,t}} = \frac{X_{i,t}}{\frac{1}{N} \sum_{i=1}^N X_{i,t}} \rightarrow H_t \equiv \frac{1}{N} \sum_{i=1}^N (h_{i,t} - 1)^2 \tag{8}$$

$$\ln \left(\frac{H_1}{H_t} \right) - 2 \ln(L(t)) = \alpha + \beta \ln(t) + \varepsilon_t \tag{9}$$

In every period, the mean of h_t equals one, so H_t provides a scale-invariant measure of price dispersion during period t . If prices converge, H_t falls, which raises the left-hand side of the regression. Phillips and Sul found that discarding the first thirty percent of observations optimized their test for both size and power. While we might expect a positive beta coefficient, Phillips and Sul found that a $t_{\hat{\beta}} < -1.65$ represents the cut-off point for rejecting the null hypothesis of convergence at the 5 percent significance level.

In that initial paper, Phillips and Sul tested consumer price indices for 19 cities in the United States from 1960 to 2000. They decisively rejected convergence with $t_{\hat{\beta}} = -51.4$. But surely prices in each US city were not moving without any correlation to each other, so Phillips and Sul tested for “club convergence.” They ordered the indices by last observation, ran the log-t regression for the two most expensive cities, then kept adding more cities one at a time until the t-statistic fell below the -1.65 threshold. Whatever combination maximized the t-statistic they designated the “core group.” They then added cities to the core group one at a time, leaving cities in so long as the t-statistic exceeds zero, the threshold which Phillips and Sul found minimized the sum of Type I and Type II errors. Whatever combination of cities met this

¹⁰² Hayakawa (2009) showed that forward orthogonal deviation outperforms the first-difference method in both estimator bias and root mean squared error.

¹⁰³ I used the `xtabond2` command in STATA, per Roodman (2009).

¹⁰⁴ Phillips and Sul (2007) show that $\hat{\beta} = 2\hat{\alpha}$.

cut-off is now the first “club.” Then they repeated the process with the remaining cities. A city that does not fall into any club they labeled “divergent.”¹⁰⁵

The theoretical model at the start of this section prevents us from reading too much into a cities’ convergence into one club or another for any particular item. The final price captures local elasticity and a non-tradeable factor of production. Even holding that constant, the price of a good in any two cities could always wander within the boundaries in (1). The key signal in the noise is divergence, not convergence to any particular club.

In this paper I construct a monthly Consumer Price Index that controls for wages, a rough measure for each city’s cost of living. As described above, Pakistanis migrate freely within the country. If we subject those wage adjusted indices to the log-t test, we would not expect to see any divergent cities. Given free labor movement, a city with high cost of living would either need to provide amenities valued by its citizens or risk losing inhabitants to migration, whereas as a low cost of living city would attract them. “Clubs” inside of Pakistan should not be any more concerning than those found in America, assuming that they do not emerge along provincial or ethnic lines that might presage a genuine national cleavage à la Sudan.

If the Law of One Price held perfectly, then any differences we encounter should reflect either differences in mark-ups or transportation costs. For example, 95 percent of Pakistan’s international trade goes through the southern port city of Karachi (World Bank, 2016). So the price of an imported good in every other city could reflect the cost of the good in Karachi plus the local mark-up and transportation costs. If the cost in Karachi rises by 100 rupees, then the cost in other cities should rise by a predictable amount. If supply and demand adjust seamlessly to changes in price, then the relative price of a good in two cities will not vary over time. An unstable relative price indicates two cities are not integrated. This paper measures “relative volatility” of good *i* in cities *j* and *k* as the standard deviation of the normalized price difference.

$$rv_{j,k} \equiv sd \left[\frac{p_{j,t} - p_{k,t}}{\frac{p_{j,t} + p_{k,t}}{2}} \right] \tag{10}$$

If a good always costs twenty percent more in one city, $rv_{j,k}^i = 0$. Although their prices never converge we infer that they are perfectly cointegrated¹⁰⁶. The sum of relative volatilities provides an intuitive measure of different cities’ levels of integration for that item. The sum of all item’s $rv_{j,k}^i$ in one city tells us about the city’s economic integration overall. If one region had significantly higher scores across most or all of its cities, we may infer that something about that region is inhibiting arbitrage.

I chose this untraditional metric to take advantage of the available data. For any one good, we have seventeen cities’ worth of data. Multiple panel unit root tests can determine if two or more *I*(1) time series are in a long-run equilibrium, but the Pedroni (1999) and Westerlund (2005) tests can only test for seven covariates, while Kao (1995) assumes a constant integrating vector. In addition, all three assume that the covariates themselves are not cointegrated which is obviously not the case here¹⁰⁷.

4. DATA

Every Thursday, the Pakistani Bureau of Statistics visits multiple markets to record prices for 53 “essential commodities” in 17 cities across Pakistan: The capital, Islamabad, eight in Punjab (Rawalpindi, Gujranwala, Sialkot, Lahore, Faisalabad, Sargodha, Multan, Bahawalpur), four in Sindh (Karachi, Hyderabad, Sukkur, Larkana), two in Khyber Pakhtunkhwa (Peshawar, Bannu) and two in Baluchistan (Quetta, Khuzdar) (PBS, Methodology). Field offices contact shopkeepers directly in order to avoid nominal price controls. A weighted average of these prices forms the “Sensitive Price Indicator” (SPI). Prices for individual goods in different cities have been posted since January 2012. This paper makes use of 72 monthly observations for every item, from January of 2012 to December of 2017.¹⁰⁸

The PBS also collects prices for a broader Consumer Price Index (487 items) and a Wholesale Price Index (463 items). Prices for every good in the wider Consumer and Wholesale indices are not publically available. Table 2, below, summarizes the recent behavior for the indices. For the time period covered in this paper, we see an early surge in inflation followed by a gradual and irregular decline.

Table 2: Price Indices, 2007-2008=100

Period	CPI	WPI	SPI
2011-2012	162.6	181.3	178.7
2012-2013	174.5	194.6	189.6

¹⁰⁵ The log-t convergence results in this paper were obtained using the Stata module introduced by Du (2017), which filters the raw data in order to remove both trend and cyclical components prior to running the above tests.

¹⁰⁶ When $j = k, rv = 0$.

¹⁰⁷ For an accessible overview of these tests, see <https://www.stata.com/manuals/xtxtcointtest.pdf>

¹⁰⁸ The PBS posts the data in the .pdf file format; I extracted all prices using the Tabula program.

Almost every week, the Pakistani Bureau of Statistics posts daily wages in rupees for five occupations in the same cities as the Sensitive Price Indicator. Three trades have uninterrupted observations for every month: carpenter, electrician and mason. The wages used in this paper are the first available wage data for each month from January 2013 to December of 2017. The “wage” of a particular city refers to the mean of these three daily wage rates. Note that when we control for wages we lose the 2012 price data and have only 60 monthly observations.

5. RESULTS

Many items lack sufficient price variation to test convergence or divergence. I exclude fourteen goods with an average Coefficient of Variation less than .05 because I assume that their prices left insufficient opportunity for arbitrageurs to buy low and sell high. All were either utilities, processed foods or manufactured goods. See Table 3, column 2, below.

Utilities such as electricity charges and telephone calls are not subject to arbitrage, while certain manufactured name-brands such as "Lipton Yellow Label" tea are so standardized that even without price controls it still displays too little variation. Near-uniform prices do not imply integration or even a functioning market. For instance, sugar’s coefficient of variation was 0.032. Salman (2009) explained how price controls on sugar resulted in domestic shortages while millers predictably smuggled their sugar into India and Afghanistan to take advantage of higher prices. Before I tested the data, Salman mentioned in private correspondence that both ghee and cooking oil were under price control; both had a coefficient of variation less than .05 and were excluded. Of the 38 remaining goods, bananas had the highest Coefficient of Variation, at .30. That squares with our intuition that perishable, easily damaged goods are less subject to arbitrage. I exclude gas charges due to missing observations in Bannu and Khuzdar.

I measured the half-lives for 38 goods using the specifications in equations (3), (4) and (5). The closer the β coefficient on the first lag to 1, the more “sticky” the price. We would expect seasonal and perishable items to vary more month-to-month as the supply is irregular. That would leave them with lower coefficients and shorter half-lives. Non-perishable goods that are easy to transport and store should have more stable prices, coefficients closer to one and longer half-lives.

As detailed below in column 4 of Table 3, the overall median half-live across all items is 19.3 months. The median for perishable, and hence volatile, food was below that of non-food, at 16.3 and 24.6 months, respectively. How should we interpret these numbers? Parsley and Wei (1996) found that tradable goods in the United States from 1975 to 1992 tended to display a half-life of 16 to 20 months, exactly the range I find.

Alam and Bhatti (2014) also tested for the half-lives of Pakistani goods, although for a different specification: the half-live of the price relative to the price in Karachi or Lahore. While my numbers differ in magnitude, the relative sizes are similar for the same items. For example, Alam and Bhatti found that the half-life of prices in 10 cities relative to Lahore for onions and propane cylinders were 0.58 and 1.16 months, respectively. My specification produced 1.66 and 3.80.

When I examine items spatially by finding their Phillips and Sul log-t convergence clubs, I found similar results, as shown in Table 3, column 5. Out of 646 time series (17 cities by 38 items) only 43 were divergent from any club, about 6.6 percent. The two cities most likely to diverge were Peshawar and Bannu with 5 each, followed by Islamabad, Bahawalpur and Khuzdar at 4 each. While it is not heartening for the two cities in Khyber Pakhtunkhwa to diverge more often, the major Pashtun city of Quetta in Baluchistan only saw one item out of 38 diverge. The market for any given consumer good functions about as well in Pashtun areas as it does in the rest of the country.

The average item had 2 or 3 clubs. Kerosene, item number 44 in Table 3, broke down along provincial lines. Baluchistan and Khyber Pakhtunkhwa each saw their cities converge to each other and not cities in any other province. Even for kerosene, though, I still find that no city diverges, as specified by the model in (1). The only other paper I could find using the Phillips and Sul test on a wide range of goods, Dang, Yang and Chan (2017) looked at 85 tradable prices across 15 Asian cities from 1990-2008 and found that only 5 percent converged into a single club. While this study is not international and thus not directly comparable to theirs, it does highlight how difficult it is for prices to converge into a single club via the Phillips and Sul test, hence the emphasis on divergent cities and not the particular number of clubs.

To understand how this price behavior affects quality of life, we need a measure of price levels overall for each city. I was not able to locate an official CPI or SPI for different Pakistani cities, so I constructed one using the 38 items in this paper. As this index is composed entirely of items above the 0.05 coefficient of variation threshold, it is biased towards divergence and could serve as an upper-bound on price volatility. It excludes several basic items like cooking oil, electricity and diesel fuel. I weighted the remaining items by modifying the full Pakistani CPI weights found in the State Bank of Pakistan’s Inflation Monitor. Certain categories were not counted at all, such as health, transport, communication and education. The items in our 38 fell into categories that total .8, so I adjusted food and non-alcoholic beverages, for example, from 0.348 to 0.435 (i.e. 0.348/0.8). Items within each category received equal weight, so all 26 items in the food and non-alcoholic beverage category were weighted .0167 (.435/26).

For each city, I take the product of every price and its weight, then sum for the city CPI for that month. Then I divide by “wage” for the cost of living. Recall that I define “wages” as the mean daily wage for a carpenter, an electrician and a mason in that city-month. When I subjected the 17 cities’ cost of living time series to the Phillips and Sul test, I find that all cities converged into one of two groups: a “low” cost of living group of Islamabad, Rawalpindi, Sargodha and Bannu, while all other cities were in “high” cost of living group. See Figure 1, below. These clubs are in line with Phillips and Sul’s (2007) estimation that consumer price indices for 19 cities in the United States fell into three groups.

While urban Pakistan is not perfectly integrated, I do not see a single divergent city. That should not be surprising since Memon (2005) classified between 1.7 and 4.7 percent of Pakistan’s population as economic migrants. In spite of regional tensions, language differences and other obstacles, that freedom of movement ensures living standards remain somewhat even across the country.

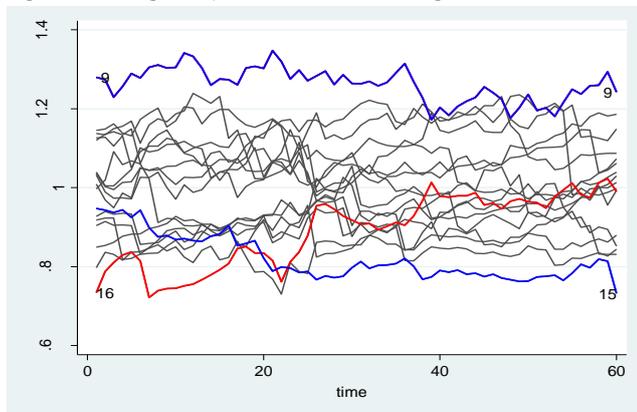

I found each city’s “relative volatility” by constructing a 38x17 matrix where each entry was the solution to equation (10) for one item and city. The last column of Table 4 represents the sum of all entries in each city’s matrix, normalized to a mean of 100. While the capital Islamabad is nominally the most expensive city over the time period, its high wages more than compensate for high prices. Islamabad is the most integrated city in Pakistan by equation (10). After Islamabad, the next six most integrated cities are all in Punjab, which matches our intuition since they are in close proximity both spatially and linguistically. Baluchistan’s cities are the least integrated by far. Until now, our results tended to support the notion of Pakistan as an integrated market, but some provinces appear more integrated than others.

Table 4: City Summary

City	Province	Population	Average CPI	Average Wage	Relative Volatility
1. Islamabad	Capital Territory	1,014,825	111.50	125.22	87.15
2. Rawalpindi	Punjab	2,875,516	107.40	123.85	88.95
3. Gujranwala	Punjab	2,948,936	99.97	99.50	94.50
4. Sialkot	Punjab	1,143,362	101.13	98.80	93.90
5. Lahore	Punjab	11,126,285	103.90	96.60	95.17
6. Faisalabad	Punjab	3,760,328	100.23	86.53	102.65
7. Sargodha	Punjab	1,091,045	96.29	90.42	99.55
8. Multan	Punjab	2,058,290	98.35	92.62	92.32
9. Bahawalpur	Punjab	1,171,258	99.70	77.13	94.33
10. Karachi	Sindh	14,910,352	96.71	104.20	102.93
11. Hyderabad	Sindh	1,832,755	93.76	100.50	97.82
12. Sukkur	Sindh	720,115	93.48	81.58	100.10
13. Larkana	Sindh	701,637	95.26	91.27	108.72
14. Peshawar	K-P	1,970,042	109.89	95.80	98.52
15. Bannu	K-P	49,965	93.49	112.49	98.22
16. Quetta	Baluchistan	1,001,205	103.84	115.03	115.60
17. Khuzdar	Baluchistan	277,136	95.07	108.45	129.59

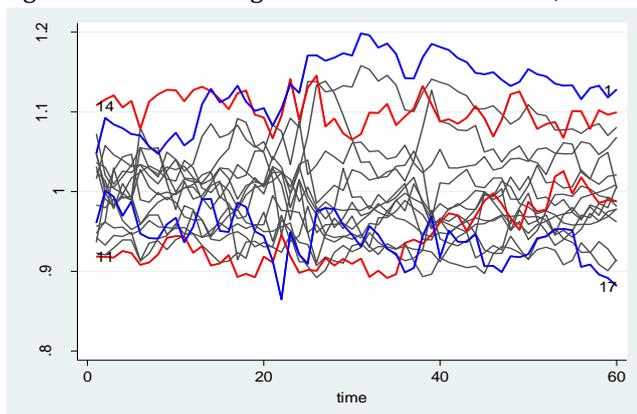

Note: Population from 2017 Census, Provisional Results. All values normalized to mean equals 100.

Figure 1: Wage-Adjusted Cost of Living Index for Pakistani Cities, 2013-2017

Note: Numbered time series in Figure 1 correspond to list in Table 4; 9 is Bahawalpur, etc.

Figure 2: Cost of Living Index for Pakistani Cities, 2013-2017

Note: Numbered time series in Figure 1 correspond to list in Table 4; 1 is Islamabad, etc.

To understand what drives relative volatility, I used the normalized value for all city pairs as a dependent variable in a cross-sectional ordinary least squares regression. Results are shown in Table 5, below. After controlling for individual city effects, a provincial border between two cities has the same effect as roughly 435 kilometers of distance. While they used a different specification for volatility, my findings are still an order of magnitude lower than Engel and Rogers' (1996) findings for the border between the United States and Canada.

Table 5: Relative Volatility

VARIABLES	(1) Model 1	(2) With City Controls
distance	0.000693** (0.000281)	0.000699*** (0.000222)
border	0.806***	0.305**

	(0.174)	(0.153)
Constant	-1.006***	2.008**
	(0.153)	(0.769)
Observations	136	136
R-squared	0.346	0.837

Robust standard errors in parentheses. *** p<0.01, ** p<0.05, * p<0.1

6. ROBUSTNESS CHECKS

The initial screening for a 0.05 coefficient of variation could have produced a “false positive.” If I include any of the discarded items and subject it to any of the same tests or place it in the Consumer Price Index, I would find a more integrated market with fewer opportunities for arbitrage. The results in this paper serve as an upper-bound on divergence and market failure for goods in the Sensitive Price Indicator.

While the half-lives generated by the forward orthogonal deviation are more reliable, I took the first difference of all prices and regressed it on the first lag and three lagged differences. This resulted in a median half-life of 33 months. I also ran a simple AR(1) regression using ordinary least squares; here the median half-life was 39 months. Those tests imply that arbitrage occurs much more slowly, but that is still well within the half-lives seen in the United States by Cechetti, Mark and Sonora (2002).

In the course of writing this paper, I repeatedly ran the Phillips and Sul test with new data as the Pakistani Bureau of Statistics updated its website. Because the club convergence algorithm starts with proximity in the last available time period, the individual cities in particular clubs did alter somewhat month to month. However, the average number of clubs and divergent series remained nearly constant.

When I just run the consumer price indices without controlling for wages, I obtain three groups and two divergent cities. However, it also has a much smaller vertical axis on Figure 2, below. That is to say, the cost of living after controlling for wages displays greater variation than the goods-based indices alone. This might be interpreted as evidence that goods are more mobile than labor.

The relative volatility scores could just be a proxy for city size. Imagine three cities all equidistant from each other. If some good costs less in one city and a firm wanted to buy low and sell high in one of the other cities, all else equal they would transport those goods to the larger market. I do find a negative correlation between cities’ population and relative volatility, but at roughly -0.1, there is certainly more driving this than market size. I regressed city volatility on population and total distance from the 16 other cities. The R-squared value was .4, which leaves a lot to explain beyond market size and opportunity cost.

7. CONCLUSION

I have passed over many of the problems facing Pakistan. Its shortcomings in education, healthcare and security remain severe. The roots of those problems lie in Pakistan’s history (Jaffrelot, 2015) and political economy (Ahmed, 2016). They are beyond the scope of this paper. Denial is a sure way to perpetuate failure, but too much focus on the negative means we could be blind to the rising living standards and economic opportunities that Pakistan’s cities offer for residents and migrants alike.

This paper used price behavior as a proxy for Pakistan’s economic integration. Certain frictions are evident, such as price controls that distort markets, incentivize smuggling and cause needless shortages. But when I consider basic consumer goods in a free market, I found that those prices behave much like our model predicts: a variety of local conditions might prevent perfect convergence, but across all goods I rarely see divergence either temporally or spatially. Furthermore, a measure of urban cost-of-living shows that every city falls into one of two groups. That lack of divergence might seem mundane, but it is worth noting that the government has very little influence across much of its own territory. When I measure how quickly relative prices adjust, the results indicate a highly integrated Punjab and a less integrated Baluchistan.

Why bother showing that Pakistan behaves much like any other country? Because it counters the dominant narrative of Pakistan: a flawed democracy rife with religious extremists, a nuclear-armed South Asian country unable to defeat insurgencies within its own borders. But that description could also apply to India. As Naseemullah (2013) noted “India tends to inspire more confidence than a more objective assessment of its condition would merit, and Pakistan inspires much less.” I hope that this essay can play some small role in changing that assessment for investors and policy makers.

1287 URBAN POOR AT THE MARGIN OF THE CAPITAL CITY OF NEW DELHI, INDIA: NEGOTIATING MARGINALITIES AND THE STRUGGLE FOR URBAN IDENTITIES

ABSTRACT

The concern of my research has been based on two sets of processes; the increasing urban affiliation of the working class leading to enormous migration and the continuing process of gentrification of the city leading to constant demolition of slums and squatter settlements to make a place for the 'exclusives'. With the presence of two such processes, I found this interesting to understand how the urban poor are making a sense of their place where increasing aestheticization of the city is continually pushing them out to the distant peripheries, denying their due share in the city-space and its benefits. With the sole objective to take out the real-life stories of hope and despair, the present work tries to inquire about the life in a city where I anticipate this attempt to provide a useful lens for evaluating the on-going urbanisation process and the nature inclusiveness of the poor into the city- space. The study is completely based on both quantitative and qualitative interviews across various working-class colonies in peri-urban Delhi where I expect the narratives to throw lights upon the way the people are trying to establish a stake in the city and accomplish an actual sense of the 'right to the city'. I believe, the way space is imagined by this majority can be a useful tool to explore how the process of place making is contemplating the global economic and political conditions of lived-spaces in an urban setting and how identity or citizenry is being shaped by the place and vice-versa.

1333 BRIDGING THE EAST-WEST DIVIDE? REFLECTIONS ON 'MULUND' AS A DIVIDED SUBURB OF MUMBAI

Sujayita Bhattacharjee

Department of Geography, University of Mumbai, India

ABSTRACT

Cities in India are surfacing as hubs of spatial inequality. The presence of disparities in Indian cities has been turning all efforts of urban development into a herculean task. Though various developmental strategies have been directed towards tackling this issue in India, spatial disparities have continued to grow in the country posing serious challenges to the policymakers. This is most evident in case of Mumbai, a city where the presence of skyscrapers and high-rises lay side by side with slums and squatter settlements. It is a city housing the multi-millionaires on one hand and the underprivileged on the other. The list perhaps can be endless when it comes to counting the spatial disparities confronting Mumbai. Lately, the Mumbai Suburban district has undergone tremendous growth that has brought it almost at par with the Mumbai City District. In fact, urban growth in the city district has been stagnant in the recent years, with most of the growth taking place in the suburban district region. However, the nature of growth has been uneven, leading to further intensification of spatial disparities. Empirical realities reveal that each suburb of Mumbai is endowed with its own unique urban-social character. Therefore, to comprehend the nature of spatial inequalities in suburban Mumbai in a holistic way a deeper inquiry focusing on individual suburbs is required. Taking this into consideration, the present study is focused on Mulund, the easternmost suburb of Mumbai. Mulund is the first planned suburb of Mumbai. It is also popularly known as the prince of suburbs. But as a matter of fact, in recent times Mulund has undergone the emergence of tremendous spatial disparities. These disparities have rendered the suburb a dualistic character, where on an average the western part of the suburb is flourishing and the eastern part is decaying. This divided nature of the suburb stands as an obstacle to its balanced socioeconomic development. Hence, keeping this in mind, in this study, an attempt has been made to analyze the east-west divide of Mulund comprehensively. It is anticipated that by means of attaining a deeper understanding of the issue, necessary insights can be drawn from it for bridging this unwanted divide.

Keywords: City, Suburb, Spatial inequality, Spatial Disparity, Growth, Development

INTRODUCTION

In present times, cities across the world are emerging as complex entities. Amin and Thrift, (2009) describes the changing characteristics of cities, in the following words,

'Cities have become extraordinarily intricate, and for this, difficult to generalize. We can no longer even agree on what counts as a city ... Most cities now sprawl across many miles incorporating settlements of varying composition, derelict areas, parks and gardens, factories, shopping centers, parking areas, warehouses, dumps.'

This holds true for Indian cities too, including Mumbai. The fast pace of growth in Mumbai has already pushed its core or the Mumbai City District into a saturated state, with most of the present growth taking place in the Mumbai Suburban District. Thus, suburban growth has become a major characteristic feature of Mumbai. However, the nature of growth has not been even, leading to the emergence and intensification of spatial disparities. Since, each suburb of Mumbai is unique and is endowed with its own urban-social character, for comprehending the nature of spatial disparities in suburban Mumbai in a proper way it is necessary to undertake an in-depth inquiry focusing on individual suburbs. Taking this into consideration, the present study is focused on Mulund, the easternmost suburb of Mumbai. This suburb has not only been witnessing tremendous growth but also has been struggling to cope with the emerging spatial disparities. These disparities have rendered it a divided character that stands as an obstacle to its balanced socio-economic development. With a focus on the issue, the present study attempts to analyze this east-west divide of Mulund comprehensively.

It is worth mentioning that the east-west divide is not an exception to Mulund. It is in fact, a common feature throughout Mumbai. Therefore, by means of this study, it is hoped to gain a deeper understanding of the issue, with necessary insights drawn that can help in bridging this divide for Mulund in particular and Mumbai in general.

Study Area

The study area, Mulund is a prominent suburb of Mumbai. It lies in the T ward of Mumbai Suburban District (Fig 1) and forms a part of the Kurla *Taluka*. Though the T-ward also includes some portion of the Sanjay Gandhi National Park adjacent to the suburb of Mulund, for this study the focus is on the suburb area.

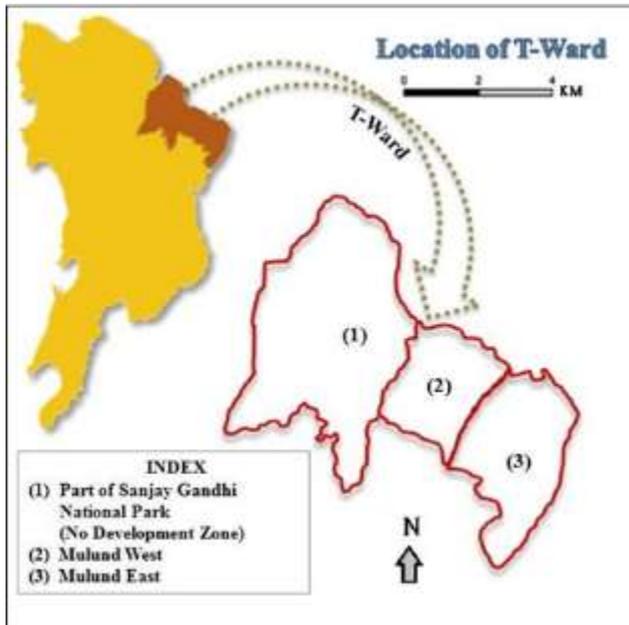

Fig 1 – Location of T-ward in Mumbai

It is surrounded by the city of Thane in the north, the Sanjay Gandhi National Park in the west, the Thane creek in the east, Bhandup in the southwest, and Kanjurmarg in the south. It geographically extends from 19°13'N to 19°17'N latitudes and 72°94'E to 72°96'E longitudes.

Mulund is one of the most densely populated suburbs of Mumbai. As per the 2011 census, its total population is 3,41,463 persons. The total male population of Mulund is 1,76,156 and the female population is 1,65,307 (District Census Handbook: Mumbai Suburban District (2011) Village and Town Wise Primary Census Abstract (PCA), 2011). The suburb is spread over 35.88 acres. It is divided into two parts – Mulund East and Mulund West – by the suburban railway line passing through it. Mulund East stands as a predominantly residential area, whereas, Mulund West is dominated by residential complexes, several business centers, and plush shopping malls.

OBJECTIVES

The main objectives pertaining to the study are –

1. To examine the nature of east-west divide in Mulund,
2. To identify and elucidate the problems associated with the east-west divide in the suburb.
3. To reflect on the necessity and possibilities of bridging this divide.
4. To formulate viable measures for confronting the issue.

METHODOLOGY

The study is based on both primary and secondary data. Primary data are mainly collected by means of personally visiting the study area and interviewing the residents using semi structured questionnaires. A total of 100 residents' selected using simple random sampling, were interviewed. Besides, various secondary sources of data published in the form of reports, books, and journals are also consulted. The data thus collected are synthesized to prepare the research paper.

ANALYSIS AND DISCUSSION

Mulund is said to be the earliest planned suburb of Mumbai. It is one of the most popular eastern suburbs of Mumbai. Mulund's infrastructural development has even earned it the title of 'prince of suburbs'. However, the emergence of spatial inequalities has rendered the suburb a divided nature in the form of its emerging east-west divide that has overcast its picture perfect status.

THE EAST-WEST DIVIDE

Characteristically, Mulund East stands as a predominantly residential area, whereas, Mulund West is dominated by residential complexes, several business centers, and plush shopping malls. The dramatic change of Mulund, especially its western part began during the late nineties when old factories and mills came to be replaced by new malls, multiplexes, and skyscrapers. This eventually paved way for the growth of service sector in Mulund. The LBS Road passing through the western part of the suburb has emerged as the hub of real-estate development in Mulund. Two prominent malls, namely, the R-Mall and the Nirmal Lifestyle emerged along the LBS Road to mark the beginning of mall culture in Mulund. At present, the R-Mall is fully functional; however, the Nirmal Lifestyle has been shut down and is developed into a residential project. The evolving landscape along the R-Mall and the Nirmal Lifestyle is evident from a comparison of the past and present satellite imageries of the area.

The magnificent growth of real-estate along the LBS Road and ACC Road has brought about dramatic changes to the landscape of Mulund west (Fig 2 & Fig 3). Many defunct factories, and *Chawls* housing the factory workers, have been

replaced by residential and commercial high rises. The occurrence of ‘rent gap’ or the difference between actual rent and potential rent has benefited the developers, contributing to the occurrence of redevelopment and gentrification in the area.

Fig 3: Changing Landscape along the LBS Road. [Source: Google Earth Pro, 2018] (1) Imagery Dated 20/10/2000, (2) Imagery Dated 12/10/2009, and (3) Imagery Dated 25/01/2018.

Knox and Pinch (2006) points out that,

By means of buying run-down properties at a cheaper rate, the developers are easily able to pay builders’ costs along with the interest incurred on mortgage and construction loans, and thereafter sell the redeveloped property at high-profit margin.

Thus, the once working-class neighborhood of Mulund west witnessed gentrification – ‘the process by which working class residential neighborhoods are rehabilitated by middle-class homebuyers, landlords and professional developers’ (Smith, 1982). Consequently, real-estate prices in Mulund shot up sky high, especially along the LBS road. According to Patel, one of the residents of a posh housing society along the LBS road:

Growth in real estate sector of Mulund has been tremendous. I remember, in the year 1984, Independent villas were sold at the rate of Rs.300 to Rs.500 per sq.ft, but today their prices have gone as high as Rs.15,000 to Rs.25,000 per sq.ft.

The impact of this growth has also percolated to the nearby areas. The western part of the suburb today not only stands as a retail and realty hub but is also emerging as an important Secondary Business District (SBD) of Mumbai. Due to the growth of commercial realty, comparatively lesser prices to the existent business hubs of Mumbai (Fig 4), and availability of larger floor space, etc various organizations like ‘BFSI-India’ and ‘ValueAdd’ have relocated their offices from other areas to Mulund West.

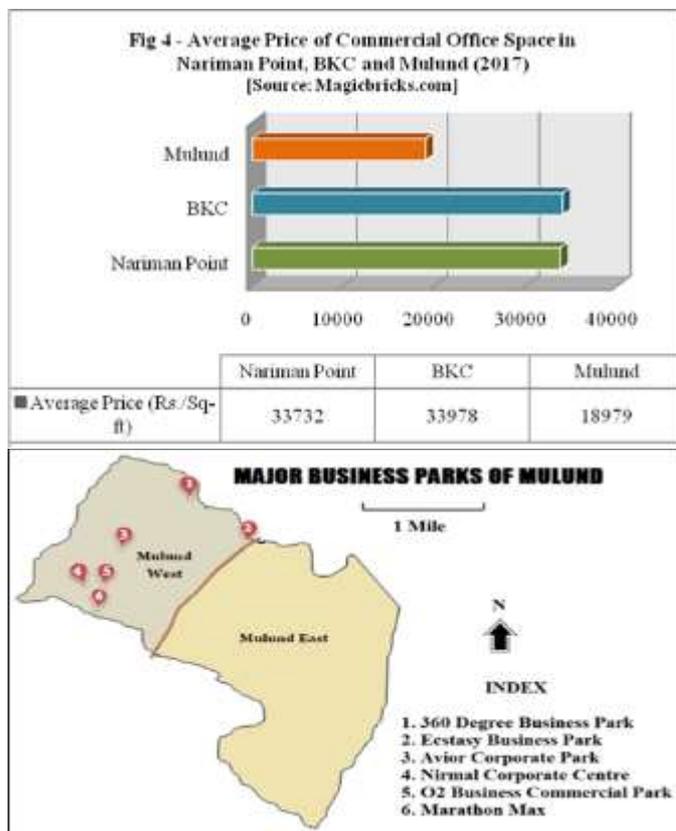

Fig 5 – Major Bussiness Parks of Mulund

Considering the advantages that the area offers as a business hub it has also become a preferred location for many business startups too. The coming up of a number of business parks like the 306 Degree Business Park, O2 Business Commercial Park, and Ecstasy Business Park have accommodated the emerging office spaces in the area (Fig 5).

Considering the tremendous growth of the commercial market in Mulund West, and the higher returns offered by the commercial spaces here, the area has turned into an investment hub. However, on the flip side, Mulund East is not able to keep up with the fast-paced development of Mulund West. An article published in the Indian Express states,

‘Mulund East has a sizable number of the working class, government servants, several pensioners and a large Marathi population. But much of the real estate activity is in the more prosperous Mulund West. (Alok, 2017)’

The process of gentrification post de-industrialization and consequent displacement of the working class and pouring in of the more affluent population changed the basic economic structure of Mulund West. An analysis of the real-estate prices in Mulund during the last five years reveals the growing edge of Mulund West over Mulund East in terms of real-estate business (Fig 6).

The provisions of civic amenities in Mulund too, reveal an imbalanced pattern adding to the grievance of the residents of the east.

According to Waghmarhe, a resident of Mulund East,

The western part of Mulund is emerging as a self-sufficient area with ever-growing amenities and facilities. From the street food to top quality restaurants, and from street markets to branded lifestyle shopping facilities, Mulund West has it all. Boutiques, spas, and salons have come up in the area to cater to the high-end fashion and beauty needs. People residing in the east are often required to depend on the western part for availing these facilities. The western part is also safer compared to the east. If required, women can safely move around in the west even at 2 AM, but the same cannot be said for the east.

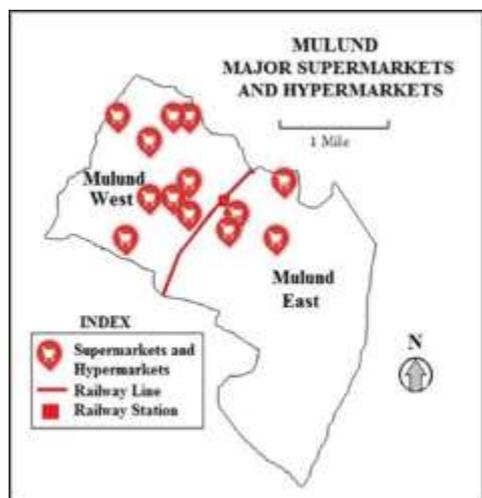

Fig 7 – Map of showing the spread of major supermarkets and hypermarkets in Mulund

Another resident of Mulund East, Shinde points out,

All petrol pumps and gas stations of Mulund are located in the west. People residing in the east are compelled to go to the west for getting their vehicles fueled. This adds to the problem of traffic congestion in the west. Even the number of public toilets in the east is negligible. Comparatively, there are many public toilets in the west. The eastern part also suffers because of the existence of a huge landfill overloaded with waste.

Mulund houses a prominent dumping ground of Mumbai. This 44-year old dumping ground is spread across 25 hectares in the eastern part of the suburb. According to an article published in The Asian Age,

‘Every day about 60,000 metric tonnes of garbage is dumped at Mulund dumping ground. Currently, there is around 70 lakh metric tonnes of garbage, with its height as high as 36 metres, at the dump. (Parab, 2017)’

Fig 8: Increasing area under dump at Mulund dumping ground. Source: [Google Earth Pro, 2018] – (1) Imagery Dated 03/12/2000, (2) Imagery dated 15/12/2009, and (3) Imagery dated 25/01/2018.

It is worth mentioning that the dumping yard is second largest in the city and it has long exceeded its capacity. The people residing in its vicinity are living amidst foul smell and threat of vector-borne diseases. Another article published in the Times of India states,

'The Mulund dumping ground has left citizens gasping for breath, not just because of the horrid stench, but also because of frequent fires which envelop large swathes in thick smoke. The dumping ground has become a health hazard for 3,000 flats of Hariom Nagar, barely 100 meters away. (Sen, 2017)'

These spatial inequalities within Mulund, existent in the form its east-west divide, stands as an obstacle to the balanced development of the suburb. With the intensification of these disparities, both halves of Mulund are attaining dissimilar characteristics. It is a cause of discomfort and distress to the residents, especially of the eastern part as Mulund.

BRIDGING THE DIVIDE

In order to ensure balanced socio-economic development of Mulund, it is necessary to bridge the existing east-west divide immediately. Although various policies have been implemented by the government to tackle the issues of uneven urban growth in Mumbai, specific policies targeting the east-west divide of Mumbai in general and Mulund, in particular, are absent. In fact, many of the issues such as, lack of public toilets and absence of petrol pumps in the east are the result of policy drawbacks. It is most likely that the presence of east-west divide went unnoticed during the allotment of these facilities to the suburb. Thus, the foremost task towards bridging the east-west divide is to address it through proper policy interventions of the government.

Infrastructural drawbacks, lack of civic amenities, and incidences of crime etc. in Mulund East require a close attention of the concerned authorities. In this regard, BMC's (BrihanMumbai Municipal Corporation) plan to start a 'waste to energy' project at the Mulund dumping ground is commendable. Though the plan is still at an infancy stage, it definitely reflects on the concern of the policymakers to resolve the issue. Another important milestone towards waste management is the new mandate issued by BMC 'for all new buildings to have a permanent arrangement for segregation of waste before they are granted a no-objection certificate from the BMC' (Vaidya, 2018). As per the Development Plan for Greater Mumbai 2014 – 34, the Mulund Dumping Ground is going to be shut down, but for various reasons the October 2017, deadline for the same has already been missed. The same plan laid down various provisions for development across Mumbai including Mulund. For instance, the proposed Goregaon-Mulund Link Road project, and the Tansa pipeline cycle track project. However, majority of these policies are framed with the perspectives on overall development, rather than any specific take on bridging the east-west divide. This necessitates the need for formulating proper policies to bridge this divide and thus, combat the existent spatial inequalities.

SUMMARY AND CONCLUSION

The key findings of the study reveal a fourfold scenario, comprising – strengths, problems, prospects, and threats, summarized as follows

Strengths:

- There is a growth of real estate, business, and service sector activities in Mulund West.
- Mulund West is emerging as a business district.
- Mulund West is a preferred location for many business startups.

Problems:

- The growth of spatial disparities has led to the formation of an east-west divide in Mulund.
- Mulund East is not able to keep up with the fast-paced development of the west.
- There is a dearth of petrol pumps and gas stations in the east.
- Mulund East is comparatively less safe than the west.
- There are a negligible number of public toilets in the east.
- Dumping ground in the east, has long exceeded its capacity, and is causing several problems

Prospects:

- Policy interventions of the government targeting the east-west divide can control the problem.
- BMC's plan to start a 'waste to energy' project at the Mulund dumping ground is a positive aspect.
- BMC's rule for new buildings to have a permanent arrangement for waste segregation at the source for receiving NOC is another positive aspect.
- Plan for the closure of Mulund dumping ground as per the Development Plan for Greater Mumbai 2014 – 34 can be of great help.

Threats:

- The east-west divide poses an obstacle to balanced development of Mulund.
- Both the halves of Mulund are attaining dissimilar characteristics.
- Infrastructural drawbacks, lack of civic amenities, and incidences of crime are growing in Mulund East.
- A threat to health from contamination and vector-borne diseases is faced by the residents of the east.

Thus, in conclusion, it can be said that for ensuring a balanced development of Mulund, it is of utmost necessity to bridge the existing east-west divide. The adoption and implementation of the following measures can serve towards bridging the divide:

1. Specific policies targeting the issue of east-west divide must be framed by the government. For example, plans for setting up petrol pumps and public toilets in Mulund east must be framed;
2. Efforts must be made to promote the growth of business and service sector uniformly across the suburb;
3. Strict actions must be taken to control the issues related to crime in the suburb. The necessary measure must be made to make the eastern part of Mulund safe like the western part.
4. A master plan is to be made by BMC to create alternative spots for garbage dumping. Also, people should be educated to sort waste into biodegradable, recyclable, inert, composite and hazardous or toxic at the source before disposal.
5. The plans that have been formulated (like the closure of Mulund Dumping Ground) must be implemented within the stipulated time.
6. Residents must be encouraged to get actively involved in the development activities of the suburb.

RS02.1. Cooperation and Development

1474 DEVELOPMENT WITHOUT, DEVELOPMENT WITHIN: REGIONALISM AS THE KEY TO SUSTAINABILITY AND INCLUSIVENESS IN SOUTH ASIA

Sampurna Goswami

Department of International Relations, Jadavpur University, Kolkata.

ABSTRACT

The post 1990s world order has witnessed a swell in the waves of Regionalism and Regional Cooperation. The perceptible dilution of borders, demarcation of the world in terms of geographical regions determined by common characteristics, shared interests and patterned interactions primarily governed by Regional Associations formed to address regional security, political and economic issues are concentrating majorly on developmental aspects more than ever before. South Asia being one such emerging region, where, apart from the two major Regional Associations namely SAARC and ASEAN, various sub-regional groupings like BCIM Economic Corridor, BIMSTEC, BBIN etc., are concerted interstate initiatives at infrastructural development within the region in order to facilitate free flow of goods and services and enhance people to people contact. However, the borders, much of which is undefined, the presence of a huge number of different and often warring ethnic groups and the political instability of the member states often posed constraints in realizing the objectives of planning chalked out by the policy makers of the supranational regional bodies for regional development. The complex milieu depicts a picture of violence and instability at the domestic spheres of states that, again, is seen to bar regional progress. However, it is important to note that regionalism can actually be viewed as a prime mover for addressing pressing domestic issues and securing development that is inclusive and ensuring wellbeing that is sustainable in this region of very rich biodiversity. For instance, the Kaladan Multimodal Project, which is a bilateral project of India and Myanmar passes through the Rakhine state of Myanmar, inhabited by the Rohingyas. What is important is to understand that Rohingyas and the related issues of violence have already hampered the potentials of the project. On the contrary it can be assumed that Kaladan Multimodal Project in the long term can actually help in eradicating the problem as it may have a positive impact on Myanmar's most underdeveloped state, the Rakhine. These cases in point are delved into this submission, based upon a combination of research methods, making use of secondary data sources on the main, in an attempt to underline the contention that institutionalized regionalism per se could actually help constituent member states in successfully addressing excruciating domestic issues by ushering in development that is inclusive and sustainable. This paper hopes to tease out posers in context of participation, empowerment, consensus, equity and governance that may be taken up for future research.

Key Words: Regionalism, Development, Sustainability, Inclusiveness, South Asia.

INTRODUCTION

The connotation of the word "Development" still blows the center stage of debates especially when the term is used in the context of Political-Economic sphere. The basic questions that eventually emanates from such debates includes, for instance, what is development? What is the thin line of difference between 'growth' and 'development'? What are the basic parameters of measuring the extent of development? so on and so forth, still remains ambiguous and therefore have often given rise to tumultuous discussions amongst the academic circles. In spite of the ambivalent nature of the term, a certainly weak but unanimous agreed definition of the term can be used as an introduction to this paper. The term Development can be defined as a process of improving the quality of human life through multi-dimensional processes that ensures improving living conditions and quality of life, that ensures in enhancing a feeling of self-esteem amongst the individual through the establishment of social, economic and political institutions and finally providing individuals, freedom of choice by creating a plethora of alternatives at their disposal. Through the introspection of the aforementioned definition of Development, it is clear that the process of development is convoluted in the sense that it requires the engagement of an array of socio-political and essentially economic institutions to go deep into the predicaments of society and address through a more transnational approach rather than staying confined within the territorial boundaries of the 'Nation-states'.

In this context, the role of Globalizations calls for greater analysis, as the concept of Transnational Development for the first time was brought into limelight by adopting the process of Regionalism and Regionalization which shall be discussed in greater details in the later part of this paper. Apparently the process of regionalism has brought about considerable success in the developed region of the world namely the Europe, the North America and significantly Asia Pacific but the same process has spurred conflicts and confrontations in the underdeveloped Global South to a considerable extent. What also requires analysis is the eventual fragmentation and breaking down of European Union in the wake of the recent refugee influx and the challenges it has posed on the celebrated concept of Regional Integration. Following the process of Globalization and under the compulsions of Structural Adjustment Programs, most under developed and developing nations did adhere to the policies of World Trade Organization. In order to challenge the discriminating standards laid down by the hegemonic west, the Third World nations also began to organize themselves into regional and sub-regional groupings but the inherent political instability and severe underdevelopment had backfired the process of regionalization in such areas and one such region is the South Asia.

The complex milieu of the South Asian Politics have often challenged the regional settings that was perceived by the policy makers of the organizing states. The presence of China as a powerful and essentially *realpolitik* nation have remained another impediment towards the achievement of a successful regional setting. However, India with the objectives of 'developing' the region through the process of integration and cooperation has occasionally failed in the face

of ethnic conflicts, political confrontations, illegal immigration and problems of insurgency as a culmination of uneven growth and development. Irrespective of such dilemmas, India have frequently engaged in Regional Associations like SAARC and Sub-Regional Groupings like Bangladesh-China-India-Myanmar Economic Corridor (BCIM EC) or BIMSTEC¹⁰⁹ Cooperation. At bilateral levels India have constantly tried to maintain amicable relations with its neighboring states through her non-interventionist Foreign Policy. However, the Indira Doctrine and the subsequent incorporation of the doctrine into Indian Foreign Policy objectives strained her relations with Sri Lanka and other potential neighbors. India's estrangement with Pakistan and the Sino-Pakistan all weather friendship has lured India to turn towards her South East Asian Neighbors in general and ASEAN in particular.

India's engagement with Myanmar blatantly proves that India is now more interested in carrying out its diplomacy with South East Asia. India's Look East Policy followed by the terminologically transformed Act East Policy have accentuated the Indo-Myanmar Relations by considering India's North East a launching pad. However, question arises as to whether such arrangements on the part of South Block will actually have any positive implication? The underdevelopment of North East as a region until now have proved to be a major inhibition in the smooth harnessing of regional integration and in this context, sustainability plays an imperative role. Yes, it is true that regionalism does play a pivotal role in ensuring development that is inclusive in nature but in case the region is inundated with insurgency, warring ethnic communities and social economic blemishes, then the question of sustainable development comes into the play. Sustainability and inclusiveness in South Asian context is yet challenging, taking into account the motley socio-economic and political scenario. Regionalism is expendable if the policy makers only consider transnational development, as regional development sounds ludicrous when the states themselves are underdeveloped.

Thus, the present attempt shall focus on analyzing the challenges of creating sub-regional arrangement within South Asia with special emphasis on India's engagement with Myanmar. On the basis of a methodology mostly based on secondary data and a sophisticated extent of non-participant observation, the paper shall tease out the issues and causes of impediments that the policy makers in the region are facing regarding development. The paper shall attempt to analyze the question of sustainability and inclusiveness of a geographical area that is marked by rich biodiversity and at the same time an area that is considered potential in terms of a launching pad for diplomacy and consequent regional development. The paper shall focus primarily on the Indo-Myanmar border regions with consideration to Kaladan multi-modal project and shall also upheld the issue of the ongoing crisis in the Rakhine state of Myanmar which is a party in the Kaladan Project. In the process, the paper shall try to broach the Rohingya issue as a major impediment towards the successful regional integration and will try to understand how, Sustainability and regionalization can ensure inclusiveness in South Asia.

REGIONALISM AND DEVELOPMENT: CAN BOTH BE ABUTTED? A THEORETICAL MANIFESTATION

Regionalism in the discourse of International Relations is defined as a contiguous geographical landmass, which may include water bodies and archipelagos as well, and the nation states fitted within this area has shared characteristics, common interests and patterned interactions. This definition clearly states that that a 'region' essentially consists of nations that shares their territorial boundaries and at the diplomatic level they have certain interests that are common in the sense that, within the region they are trying to promote policies that are beneficial for all the member states. Following this definition, therefore it can be extrapolated that European Union is a Region, similarly Asia Pacific is a region but BRICS¹¹⁰ or IBSA¹¹¹ is not a region rather multilateral forums. Rajiv Sikri, advocates that Regionalism is posthumous phenomenon, that culminated first, from the advent of globalization, that in itself became a dilemma because of the limited role of state and the restrictions that were imposed on border trade and people to people contact. Secondly, as the end of cold war, that has given opportunities to the states to establish relationships and reopen the borders to resuscitate economic and political cooperation and finally, the colonial borders that had apparently lost its relevance in the second half of the 20th Century (Sikri, 2009). The increasing scope, fluidity and non-conformity of the new region was often known as the wave of "New Regionalism". Schulz essentially argued that regionalism is a heterogeneous, pluralistic and multi-dimensional but nevertheless global (Michael Schulz, 2001). Schulz also argued that the world order, today is a tri-polar one that centres around EU, NAFTA and Asia Pacific. In this context, regionalism therefore became a fledging opportunity for the nation states in the world to create a new apotheosis of development, cooperation and growth. Regionalism is often viewed as a counterintuitive process of Globalization amongst the third world nations. Regionalization has enabled the third world to create a labyrinth of developmental ventures that will promote an all-round development of region and at the same time allow the states to recover the afflictions imposed by the colonial boundaries through enhanced border trade and people to people contact. SAARC¹¹² and ASEAN¹¹³ are two such regional groupings that are working to meet the challenges of the discriminatory world order that still amplifies the dichotomy of the Global North and the Global South.

Analysis of the aforementioned explanation of Regionalism portrays that, it is now a tool used by the nations to promote development through transnational cooperation and engagement. India being the most powerful in terms of economy and politics amongst its neighborhood is also extracting regionalism as a process in order to achieve its foreign policy

goals. India's advocacy with Myanmar is considered one of the most delicate areas of Indian diplomacy as it focuses on enhancing India's long term foreign policy goal of engaging with the ASEAN nations and in the course achieve an all pervasive development for India's North East that remains India's most neglected area in terms of growth and progress. But the most germane question that arises is, can India actually achieve an all pervasive development through regionalism? The answer is complicated, it is convoluted because on one hand, Regionalism is obviously a sustainable approach but at the same time, 'development without' achieving 'development within' becomes superfluous. In order to understand this complex milieu, it is important to analyze Walt Rostow's Developmental Theory. The five stages of development as enumerated by Walt Rostow is an extraordinary contribution to field. Rostow's economic theory is essentially based on five stages of development, which he argued to be incontrovertible for all the developing nations. The First Stage is traditional stage, where it is difficult to expand production beyond a limited ceiling, because the nation's pre-Newtonian science and technology, rigid agriculture and hierarchical social structure. The Second Stage, pre-condition for take-off, is marked by some external source or impulse, that manifests a change in whole range of institution, which may include policies. The Third, Stage is where take off is attained, the industrial output increases appreciably, the economic and political institutions are shaped in order to permit growth. The Fourth Stage is the 'Drive to Maturity', a period of consolidation. A period where modern science, technology is extended to most of the branches and finally the Fifth Stage, where development process is reached resulting in an era of mass consumption which further involves consolidation and advancement (Rostow, 1959).

According to Rostow's stages of Development, Regionalism or diplomatic policies of Bilateral Engagement and Regional Integration can be considered as the second stage in the developmental process. The Neo-functional theorists who proposes development through Regional integration like Lindberg tried to argue that political socialization, interest articulation and aggregation, political communication and decision output are some of the chief categories of political integration(Lindberg, 1970). Therefore, it is clear that in order to achieve development through regionalism, a change in the range of political institution becomes necessary and this very dogma of the Neo-functional paradigm coincides with Rostow's second stage of the developmental theory. This entire theoretical enigma therefore raises the question that can regional development be a success story? What is important is to understand that Neo-functionalism as a school of thought emerged with the success of European Union in the post-World War II scenario as a result it calls one attention to the issues and opportunities that emanate from the growth of regions amongst the third world nation who are still in the transitional phase of development following Rostow's model. In this context, the paper shall try to nurture and introspect the ground realities of regional integration in South Asia with special emphasis on India-Myanmar Bilateral Engagements and projects.

INDIA-MYANMAR ENTENTE: A 'REGION' WITHIN A 'REGION'

India's Look East Policy adopted in 1991 by P.V Narshima Rao was an initiative to enhance India's bilateral ties with the ASEAN Nations, yet India considered Myanmar to be diplomatically the most important and pivotal to India's foreign Policy objectives. Professor Baladas Ghoshal points out that the drivers of India's recent Myanmar policy is first, the fact that Myanmar is the gateway of the South East Asia, it is the only country that shares land and maritime boundaries with ASEAN nations which can be lucrative for Trade and Commerce especially for the North Eastern states of India. Secondly, the problem of insurgency and the vulnerability of the Indo-Myanmar border to illegal arms trade, drugs trade and infiltration compelled India to engage with Myanmar on a more amiable terms in order to occlude the problems at the buffer zone. Finally, India's policy to counter China as the regional hegemony was another determinant in India's derivatives to engage with Myanmar. Myanmar's all-weather friendly relation with China and the China-Pakistani entente left no other option at India's disposition but to actually shake hands with Myanmar's Military Junta as a strategy to counter Chinese influence in the sub-continent (Ghosal, August 2014). In the course of time, India's bilateral relations with Myanmar which was essentially directed towards ushering in development and security for India's most underdeveloped North East compelled India to enter into certain sub-regional groupings that were mostly based on infrastructural development and connectivity, for instance the BCIM Economic Corridor¹¹⁴ a multilateral arrangement and the Kaldan Multimodal Transport Project, a bilateral arrangement.

BCIM EC

The Bangladesh China India Myanmar Economic Corridor (BCIM EC) is a connectivity and infrastructural development project that aims to connect Kolkata in India and Kunming in China through a roadway that will enhance connectivity and trade amongst the four host countries. What is important is to note that Bangladesh and Myanmar are two most underdeveloped nations in the region while China and India are the two most developed ones, but the fact that this particular initiative will bring about development in India's North east and China's South West, the nations 'most underdeveloped sections draws the attention. The BCIM EC as a part of India's Act East Policy and China's Belt and Road Initiative is now considered to be a 'Bridgehead Strategy' by the Chinese government in order to develop its relations with Russia and other Asian Neighbours¹¹⁵. BCIM is obviously promising as a regional integration process but certain issues call for a more sustainable approach especially when it comes to the question of developing India's North East.

The Regional ethno-political conflicts have spurred insurgency activities along the North Eastern and North and South Western part of Myanmar. The plethora of tribes marked by their lingo-religion and ethnic diversity along with the

¹¹⁴Bangladesh, China, India, Myanmar Economic Corridor.

¹¹⁵Reinhardt, Dieter and AnjaSenz. 2014. "Closer Cooperation in the BCIM Region-A New Success story of Asian Regionalism?". *Connecting India, China and South East Asia*. <http://econpapers.repee.org/scripts/redir.pdf> (accessed on February 14, 2017).

problem of impecuniousness of the population that compels them to engage in illicit activities, precipitated by the region's nexus with countries like Bangladesh, Bhutan, Myanmar and necessarily China have inundated the region with insurgency activities sponsored mostly by China, some of which are gross and dangerous for instance NSCN (K) and ULFA (Chatterjee, 2015). The fact that this region have remained untouched in terms of growth and development is now proving to be gouging for India.

These groups are mainly recruited by ethnic minorities and they demand for greater autonomy or an independent state¹¹⁶. The primary reason for such secessionism is the uneven development. The destitution and poverty and the still undergoing process of civilization of the tribes have been a major factor. Resource conflicts regarding usage of river water and the allocation of the imperative metals amongst the bordering states adds up to the conflict. Land use rights and environmental issues again calls for a sustainable approach on the part of the policy makers. What is important is to understand that the region is rich in bio-diversity and has bounteous reservoirs of metals and other resources often inhibits government's actions to take up developmental projects as most tribes especially those of Nagaland and Mizoram protests against such development projects through violent means¹¹⁷.

The Asian Highway 1 of which, BCIM EC is just an attached string starts from Kolkata and reaches up to Moreh, the bordering town in Manipur and enters Myanmar through Tamu. What astonishes, is the condition of the so called international roadway on the Indian side, the lose security, cases of frauds where the military personnel are involved and the open selling of arms at Moreh. It is true that Manipur in itself is critical in the eyes of Indian policy makers due to presence of a large number of insurgents but at the same time, the negligence on the part of government stakeholders in the borders is noteworthy. On the contrary, the road after entering Tamu in Myanmar takes an antithetical course, where security is comparatively tightened, the condition of the road is spellbinding and the town with all facilities of proper boarding and lodging is suitable enough for porters to carry out trade and transaction¹¹⁸. The Chinese investment in maintaining the section of the roadway that passes through Myanmar depicts the degree of seriousness of China on entering into regional cooperation with India. Such a seriousness is somewhat missing on the Indian side, the Rhi-Zhowkhatar border illustrates this sufficiently as the Rhi-Tidim road is supposed to be built by India on behalf of Myanmar, but the progress is tremendously slow. India's adoption of regionalism and the subsequent decisions of investing in Myanmar at times sounds gibberish due to India's negligence and corrupted local governments. This is what is needed to be transformed and renovated to reach the desired regional goals.

The Kaladan Multimodal Transport Project

The Kaladan Multimodal Transit transport Project is another watershed in the India-Myanmar relations. The transport project aims at connecting the land and the Maritime Bordering Areas through a multimodal transportation project under the Nodal agencies of Ministry of External Affairs on the Indian Side and Ministry of Foreign Affairs at the Myanmar side. The project perceives to connect Sitwe port in the Rakhine state of Myanmar to the Kolkata Port, via inland water transport from Sitwe to Paletwa, from Paletwa to the Indo-Myanmar Border and then entering Mizoram through Lawngtlai and joining the National Highway 35¹¹⁹. What calls for greater attention is the fact that the project is supposed to connect two most underdeveloped divisions of India and Myanmar. Mizoram on the Indian side is untouched in terms of development and growth. It is mostly inhabited by numerous tribes with Christian missionary as the principal civil society. The Rhi-Zhowkhatar border trade post is fledging in terms of trade where a paltry number of items are traded legally while substantial amount is exchanged through the Indo-Myanmar friendship bridge illegally.

The area surrounding the friendship bridge is inhabited by small tribal population, a population that is insolvent and this destitution compels them to engage in phony arms and drugs trade that brings in huge sinecures. Such an illegal arms and drugs trade is mostly controlled by the mafias¹²⁰. Face to face interaction with the police commissioner and the district magistrate of Champai, revealed that the arms are mostly manufactured in Cambodia and is carried by the local stakeholders and traded to India illegally while synthetic drugs are manufactured in Myanmar itself as Myanmar is part of the 'Golden Crescent'. The officials as well as the solvent middle class population of the Zhowkhatar village also advocated that children and women are mostly engaged in the illicit trade and they are paid substantially. What is also very important is to note that the governments of Myanmar as well as India have received adequate amount of funds for constructing the Rhi-Tidim Road from the Asian Development Bank, but astonishing enough is the fact that some private enterprise have infiltrated into the project enervating the degree of progress (Singh, 2015).

The Lawngtai border outpost is at its neophyte stage, where it can be assumed that the scenario could not be better, if not worse. Guwahati based Journalist Rajeev Bhattacharya in his article in First post proposes that although Lawngtai is pristine in regards to militancy and local tribal agitation, the rugged topography and the inaccessible terrain inhibits the

¹¹⁷Op. Cit., 6.

¹¹⁸ The section is mostly based on the author's observation of the border trade scenario during the field visit to Moreh-Tamu Border in Manipur as a part of delegation for a MAKAIAS sponsored project titled "*Peace, Development and Community: The Look East imagination with special reference to the North East India*" from January 9-14, 2015.

¹¹⁹Report of the Ministry of External Affairs, Government of India published on April, 2014, <http://www.mdoner.gov.in/content/introduction> (Accessed on April 26, 2018)

¹²⁰The section is mostly based on the author's observation of the border trade scenario during the field visit to Rhi-Zhowkhatar Border in Mizoram as a part of Delegation for a MAKAIAS sponsored project titled "*Peace, Development and Community: The Look East imagination with special reference to the North East India*" from march 20-25, 2015.

smooth completion of the project. He furthermore claims that the worker's condition is heinous and the dearth of medical facilities and technology and hostile living conditions along the stretch is prohibiting the project's success.¹²¹ What has also become a major impediment is the local landowner's agitation against the government to disburse compensation for a slice of land acquired for the project¹²². However, the ushering in of the new regime under Prime Minister Narendra Modi and his inquisitiveness to develop North East, brings about some hope that the Kaladan Multimodal Project along with the two functioning Border Trade Zone along the Indo-Myanmar Border stretch, the Rhi-Zhowkhatar in Mizoram and the much celebrated Moreh-Tamu in Manipur will endure a resuscitation in terms of development and growth.

On the other side, the Rakhine state of Myanmar is the most underdeveloped area within the country. Sitwe port being situated in the Rakhine state and the subsequent involvement of the Sitwe port in the Kaladan Project is supposed to have positive implications on the Rakhine state but the major challenge that is chugging the process of completion of the Project on the Myanmar side is essentially the ongoing ethnic conflict surrounding the 'Rohingyas'. The issue of Rohingyas although is no longer confined within the boundaries of Myanmar, it has been played as a political game by both Myanmar and India, where India's stand until now has been ambiguous. India's objective of countering the Chinese influence on her eastern neighbour has compelled India to remain silent on the Rohingyas. The fact that Rohingyas are increasingly infiltrating in India through the Bangladesh Border is also making India skittish. India is oscillating between humanitarianism and power politics and in this case India's position is quite clear. But can power alone help India to achieve its desired goals is now a major question.

Narendra Modi's recent visit to Myanmar, after the violent conflict that broke out in the Rakhine state between the Military forces and the Arakan Rohingya Salvation Army (ARSA) was a skilful attempt to sidestep the violence. Modi, signed 11 economic deals and also encountered Aung San Syu Ki regarding the delayed Kaladan Multimodal Transport Project which is supposed to encompass a substantial area of the conflict stricken state of Rakhine¹²³. Modi, adeptly avoided to use the term Rohingyas and in the firm belief that the Myanmar Government is dominated by the Buddhist majorities, Modi, found the time suitable to strike a number of deals and maintain a good relation with Myanmar in order to achieve its Act East Policy goals. But can only policies bring about the desired level of development?

Going back to the theoretical manifestations used to explain the relationship between development and regionalism, it is now quite clear that regionalism as a policy can be one of the best ways to ensure development. Taking into account the fact that Regionalism can be designated under the second stage in Rostow's model, it is important that the nations strengthen and transforms adequately the base, that is the first stage in itself. In case of India and Myanmar in particular and the South Asia in general, the nations have successfully adopted the policies of Regionalism and Regional Integration without achieving the desired level of development within the limits of their territorial boundaries. In case of North East, a sector that is already underdeveloped, still following a rigid agricultural economic model and where the population is known to have been engaged in illicit activities of arms and drugs trade for a long period of time, in order to appropriate monetary benefits for themselves, infrastructural development, for instance, transnational roadways and cross border people to people contact is somehow acting as a boon in earning greater sums through such apocryphal means, where the loose security mechanisms at the borders as well as cases of frauds that are quite common is just another blast in the already ignited fire of violence.

In order to reach the Third Stage of Rostow's model, the very basic attributions of development at the grass root level is needed to be attained. In case of South Asia, there is a huge gap in between the first and the second stages let alone the question of reaching the third stage. Nations have adopted policies, there have been huge institutional transformations, but where is the implementation? It is highly important that India tries to develop North East as a whole, at least to a desired level where substantial population is employed, the problems with land acquisition is settled with the local stake holders, the problem of inaccessibility is resolved and the government is well accepted by the localities. Regionalism is the key to ensure development but a considerable development is also needed to adopt regionalism and regional integration as a process. This conundrum is now becoming increasingly critical. The recent Rohingya influx in India and crisis surrounding the Buddhist refugees in Mizoram is what needs exigent policy making for activating Kaladan's successful completion.

CONCLUSION

Institutional regionalism, is obviously the most potential and effective tool to ensure inclusiveness and sustainability in South Asia. It is now quite clear that the North Eastern borders of India is critical, in the sense that the presence of warring ethnic groups and the pernicious insurgencies spurred by the area's inaccessible topography have not only impeded the government's repeated attempts to open up the sector to external forces of International transactions and creating a regional market but at times have used such initiatives to activate their illicit activities of arms and drugs trade sponsored mainly by China which is now divulging.

On, the contrary, the nations within a region should have a desired level of development and political consolidation to engage in regional integration. In fact the refugee crisis of Europe have considerably challenged the very idea of regional

integration and the estrangement of Britain from the Union have called for greater attention and discussion on the part of the academicians and policy makers. The conundrum in case of the South Asia lies in the fact that the nations are mostly underdeveloped, political instability and corruption is another major factor that is adding to this enigma and finally the presence of China, and its *realpolitik* foreign policy is highly intervening the regionalization process involving India. It is important to note that, if India really needs to succeed as a regional power, it first needs to ensure its own socio-economic and political development. India precarious borders and its fragmented politics is increasingly being used by China to nurture insurgency activities by providing arms and ammunitions as well as by infiltrating huge sums of money. It is also important to realize that to lure India's neighbours, India should essentially invest exorbitantly on the neighbouring states' infrastructural development and this particular area is substantially captured by China as China is confident about its own economic power.

India's ambivalence regarding the Rohingyas and her ignorance towards the crisis may have negative implications for the Kaladan Multimodal Transit Transport Project. It is also important that India secures its borders adequately in order to open up for cross border trade and people to people contact, this is where sustainability comes into the picture. What is creating the fuss is the fact that such transnational infrastructural projects are actually opening up greater possibilities of illegal arms and drugs trade. India needs to realize the fact that her borders are already susceptible to baneful infiltrations and this calls for a tightened up security at the domestic level itself. Development that is sustainable and inclusive in South Asia is possible through regionalism only when the member states' domestic development has attained considerable development within itself. The policy makers need to be more circumspect while adopting policies of regional integration, especially when the spatial development is at an exigent stage. The present scenario of the Indo-Myanmar integration can have two possible outcomes, one, where the present pace of regional integration actually resolves the crises and successfully achieves the desired result of development, as perceived by the policy makers or the regionalization process as a whole fails and shatters into pieces in the face of violent conflicts, refugee influxes, phony trades, geographical inaccessibility and last but not the least corruption on the part of local government stakeholders. This paradox of regional integration in South Asia calls for future research and introspection through participatory observations and critical anthropological surveys.

1562 COMPARISON OF THE POTENTIAL COMPETITIVENESS OF ASIAN COUNTRIES

Nariyasu YAMASAWA

Manager of Statistics Committee Office in Ministry of Internal Affairs and Communications. Email: yamasawa@atomi.ac.jp

ABSTRACT

Country's competitiveness is very important notion for companies and even government. Business people and government pay attention to the ranking of their country. But definition of competitiveness is unclear. We define the competitiveness from an economic point of view.

We have developed a ranking of potential competitiveness for South India, ASEAN countries, China, Hong Kong, Korea and Japan. The word "competitiveness" is popular and several institutes such as Institute for Management Development (IMD) and World Economic Forum (WEF) publish rankings every year. But result is different, because competitiveness may be defined in many ways. We define competitiveness as increase per capita gross domestic product (GDP). Growth rate tend to be high for developing countries because the starting point is low. If national income is high, high growth rate is not necessary. So, we conclude increase of GDP per capita is appropriate index of country's competitiveness. And we define potential competitiveness is its forecast about 10 years forward or so. It shows how much every nation and region will have competitiveness in the future. Potential competitiveness and realized competitiveness do not correspond completely because potential competitiveness indicators are based on data provided at the initial point in time of the period under measurement and we need to acknowledge the possibility of unforeseen events occurring over the next ten years.

We made the ranking of increase in GDP per capita among 50 countries. It indicate realized competitiveness. In 80's, Japan is in the 1st place, Norway is in the 1st place in 90's and Singapore is in the 1st place in 2000's. In 2010's, Ireland is in the 1st place, but it is result of exceptionally high growth in 2015 because of the transfers of the headquarters to Ireland. In Asian countries and economies, 2010's best 3 are Singapore, Hong Kong, and Korea.

In case of compiling potential competitiveness index, we use various economic and social indicators such as (1) education expenditure (% of GNI), (2) mobile cellular subscriptions (per 100 people), (3) life expectancy at birth, total (years), and (4) urban population (% of total). Selection of indicators for an item such as education or science and technology varies depending upon the characteristics of the item, but is based upon the endogenous growth theory. Each indicators show the factors of country's competitiveness. For developing countries, it is a clue for higher growth.

We developed the potential competitiveness on the basis of results from data in 2015. The ranking is based on data collected in the 2015 survey. Hong Kong is in 1st place. Singapore is in 2nd place.

JEL Classification O47

Keywords: competitiveness, Asian economy, economic growth, aggregate productivity

INTRODUCTION

Country's competitiveness is very important notion for companies and even government. Japanese government set up industrial competitiveness council from 2013 to 2016. Future investment council succeed it. Business people and government pay attention to the ranking of their country. But definition of competitiveness is unclear. We define the competitiveness from an economic point of view.

Competitiveness can be measured in different ways. This paper discusses "potential competitiveness", which is defined not as an outcome of economic growth, but as an ability to be competitive in future.

The measure primarily seeks to determine if a country is equipped with the necessary groundwork for future improvement in competitiveness. For example, High-level education and good infrastructure mean strong potential competitiveness.

Competitiveness ranking is published by Institute for Management Development (IMD) and World Economic Forum every year. But result is not equal. In 2017, Hong Kong is in 1st place in IMD, while Hong Kong is 6th place in WEF.

Table1 Competitiveness Rankings

	IMD	WEF	ΔGDPper capita
1	Hong Kong	Switzerland	Ireland
2	Switzerland	USA	Singapore
3	Singapore	Singapore	Sweden
4	USA	Netherland	Hong Kong
5	Netherland	Germany	United States
6	Ireland	Hong Kong	Australia
7	Denmark	Sweden	Germany
8	Luxembourg	United Kingdom	Turkey
9	Sweden	Japan	Korea, Rep.
10	UAE	Finland	New Zealand
	China(18) Japan(26)	China(27)	Japan(12) China(16)

IMD: International Institute for Management Development (2017)
 WEF: World Economic Forum (2017)
 ΔGDP per capita: Increase from 2010 to 2016 of GDP per capita(constant US\$)

1. EXISTING COMPETITIVENESS RANKINGS

IMD: World Competitiveness Yearbook

One of the existing, representative competitiveness indicators is provided by The World Competitiveness Yearbook, published by the IMD in Switzerland. The IMD develops rankings of competitiveness using a variety of different indicators. They use not only hard data such as GDP but also soft data such as questionnaire surveys. But they do not give reasons for its selection of such indicators.

IMD has published yearbook since 1990. In 1990, Japan is 1st place, but USA become first place after 1995 and Singapore and Hong Kong become in 1st place in 2010's.

Japan experienced very fast decline of the competitiveness. The rank fell to 30th place in 2002. Though rank of Japan rise in 2003, after that, it seems gradual decline continues.

Table2 Best 3 of IMD Ranking

	1st	2nd	3rd
1990	Japan	Switzerland	USA
1995	USA	Singapore	Hong Kong
2000	USA	Singapore	Finland
2005	USA	Hong Kong	Singapore
2010	Singapore	Hong Kong	USA
2011	Hong Kong	USA	Singapore
2012	Hong Kong	Singapore	Switzerland
2013	USA	Switzerland	Hong Kong
2014	USA	Switzerland	Singapore
2015	USA	Hong Kong	Singapore
2016	Hong Kong	Switzerland	USA
2017	Hong Kong	Switzerland	Singapore

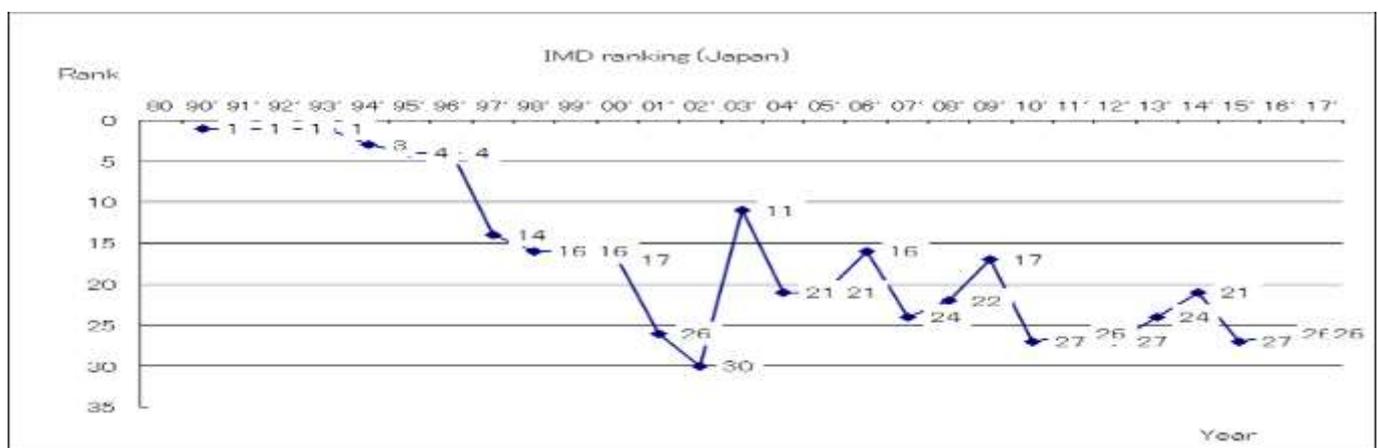

Figure1 IMD Ranking of Japan

WEF: The Global Competitiveness Report

Another famous competitiveness ranking is The Global Competitiveness Report by the World Economic Forum. The Global Competitiveness Report 2016-2017 assesses the competitiveness status of 138 economies. They define competitiveness as the set of institutions, policies, and factors that determine the level of productivity of an economy, which in turn sets the level of prosperity that the country can achieve. the Global Competitiveness Index (GCI) combines 114 indicators that capture concepts that matter for productivity and long-term prosperity

Compare to IMD, rank of Japan is relatively high. Japan is in 9th place in 2017, while IMD rank is 26th place.

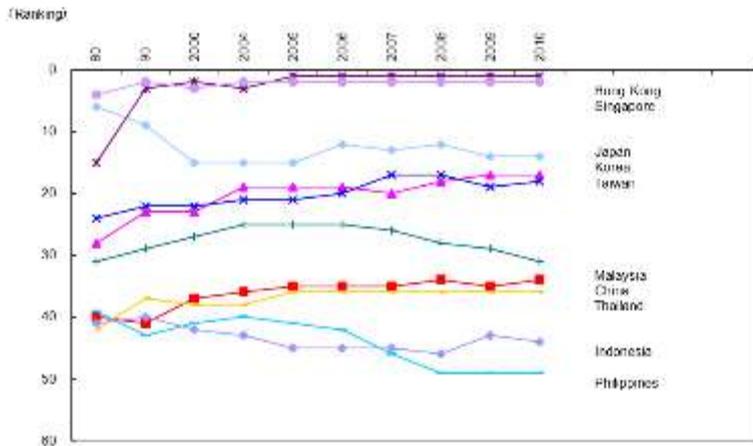

Table3 Ranking of Asian Countries and Economies (WEF)

	2009		2017	
1	Singapore	5.55	Singapore	5.71
2	Japan	5.37	Hong Kong	5.53
3	Hong Kong	5.22	Japan	5.49
4	Taiwan	5.20	Taiwan	5.33
5	Korea	5.00	Malaysia	5.17
6	Malaysia	4.87	Korea	5.07
7	China	4.74	China	5.00
8	Thailand	4.56	Thailand	4.72
9	Inodonesia	4.26	Inodonesia	4.68

JCER: Potential Competitiveness Report

Japan Center for Economic Research (JCER) published “Potential Competitiveness Report” from 2004 to 2010. We followed this methodology. While the IMD uses questionnaire surveys, JCER features quantitative analyses based on available socio-economic data.

Figure2 Ranking of Asian countries and economies (JCER)

2. THOUGHTS ON COMPETITIVENESS

What is competitiveness ?

Competitiveness may be defined in many ways. When an indicator is assumed to express competitiveness, it is important to determine if it represents the “cause” or the “effect” of competitiveness. For example, high-level education or labor productivity is a cause of a nation’s strong competitiveness, while an increase in income is an indicator that represents the effect of such competitiveness.

In this paper, we have used per-capita GDP as an overall competitiveness indicator. The greater the per-capita capital and the higher the productivity for a given period, the greater the growth of per-capita income. A competitive country is one that can provide products or services to domestic or foreign markets efficiently. An appropriate comprehensive indicator that measures such competitiveness should be based on per-capita output.

GDP growth rate

Needless to say, growth rate of GDP is very important. But, they tend to be high for developing countries. In 2016, Lao PDR recoded the highest growth rate, 7.0% among 13 countries and economies listed on the table. And 6% base growth

is shown in Cambodia, Philippines, China, Myanmar, and Vietnam. Growth rates of developed countries and economy are lower than developing countries.

Table4 Growth Rate of Asian Countries and Economies

Country Name	2010	2011	2012	2013	2014	2015	2016
Bangladesh	5.6	6.5	6.5	6.0	6.1	6.6	7.1
India	10.3	6.6	5.5	6.4	7.5	8.0	7.1

GNI per capita

GNI per capita is used for analytical classification by IMF. They define that countries which GNI per capita is over 12235 US dollars are high income country and countries which GNI per capita is below 1005 US dollars are low income countries. It is useful for seeing the present conditions of the countries, but it does not tell us future conditions. It is a static indicator.

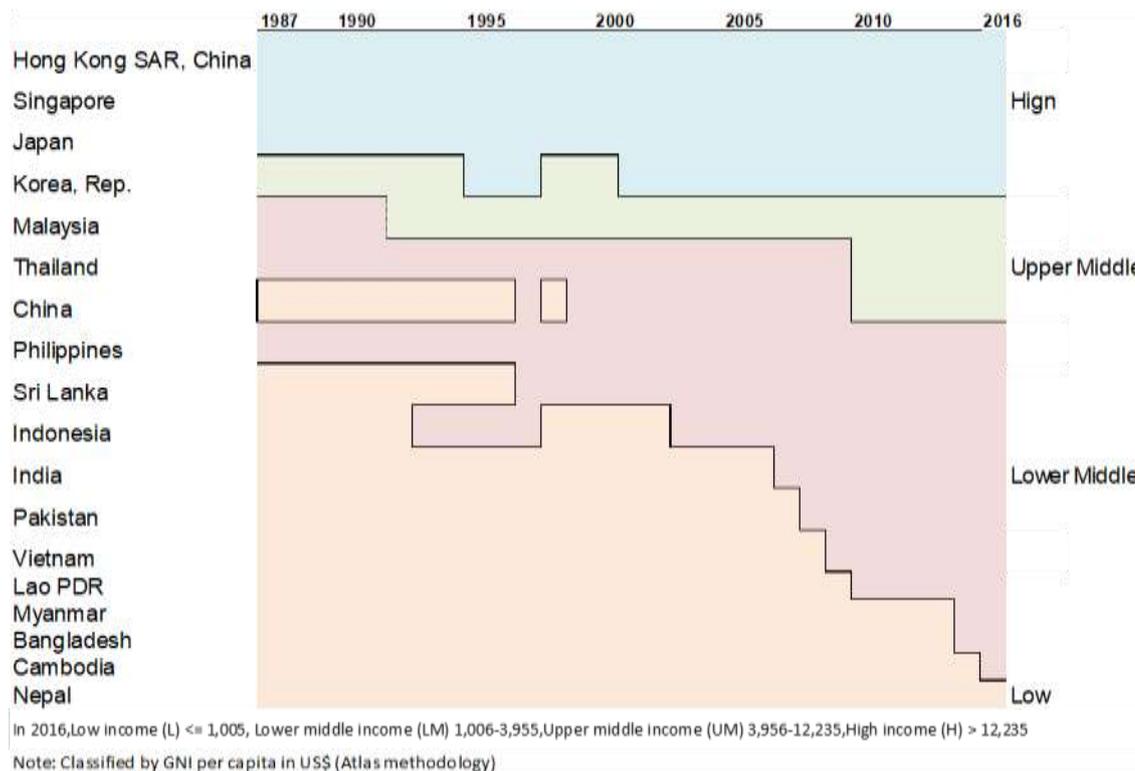

Figure3 World Bank Analytical Classifications

Increase in GDP per capita

The level of per capita GDP may be regarded as an indicator of the competitiveness of a country, but what is important is the per capita increase of GDP. For measurement of growth, the rate of change may be regarded as an indicator of competitiveness, in which case, generally, the lower the level of GDP, the higher the rate of growth. A currently highly competitive country should naturally be considered more competitive than a country without any existing competitiveness. So it is not appropriate to use the rate of change in the calculation of competitiveness. We have therefore

adopted the amount of change in per capita GDP as a competitiveness indicator that adds the level of GDP to the rate of change as follows:

Level × rate of change = amount of change

Potential competitiveness and per capita GDP increase

Potential competitiveness computed using various indicators shows the potential capabilities of a country at a given moment to compete over the next ten years. For instance, the potential competitiveness indicator as of 1980 indicates a country’s ability to increase per-capita GDP during the 1980s.

Potential competitiveness as of '80 → influential on competitiveness in the 1980s
 Potential competitiveness as of '90 → influential on competitiveness in the 1990s
 Potential competitiveness as of the latest period
 → will be influential on competitiveness over the next 10 years

Potential competitiveness and realized competitiveness do not correspond completely because potential competitiveness indicators are based on data provided at the initial point in time of the period under measurement and the possibility of unforeseen events occurring over the next ten years needs to be acknowledged.

3. EMPIRICAL RESULTS

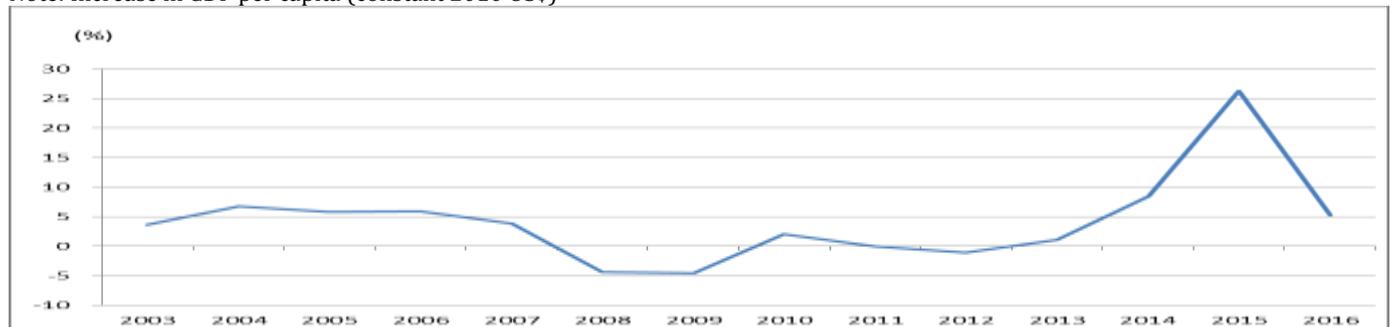

GDP per capita Ranking

Table is the ranking of increase in GDP per capita among 50 countries. In 80’s, Japan is in 1st place, Norway is in 1st place in 90’s and Singapore is in 1st place in 2000’s. In 2010’s, Ireland is in 1st place, but it is result of exceptionally high growth in 2015 because of the transfers of the headquarters to Ireland. In Asian countries and economies, 2010’s best 3 rankings are Singapore, Hong Kong, and Korea.

Table5 GDP per capita ranking

	1980-1990	1990-2000	2000-2010	2010-2016
1	Japan 12417	Norway 21447	Singapore 13180	Ireland 18249
2	Norway 11734	Ireland 19876	Hong Kong SAR, China 9534	Singapore 6031
3	Switzerland 9384	Denmark 11282	Australia 7650	Sweden 4243
4	Singapore 8869	Singapore 11212	Sweden 7383	Hong Kong SAR, China 4176
5	Denmark 8191	Netherlands 10650	Switzerland 6991	United States 3821
6	Finland 7854	United States 8743	Korea, Rep. 6982	Australia 3797
7	United States 7578	Australia 8396	Norway 5914	Germany 3766

Figure4 Real GDP growth of Ireland

Potential competitiveness

Adopt the per-capita increase of GDP as a judgment criterion for international competitiveness, and then look for factors that increase this increase for each item.

We call the variables which influence over the next 10 years as potential competitiveness factor. If we find the variables, we forecast over the next 10 years competitiveness by using latest data.

Estimate potential competitive index
 ↓
 Determine potential competitiveness ranking

4. ESTIMATION

Variable selection

We intend to make rankings for not only ASEAN4 but LMCV (Lao PDR, Myanmar, Cambodia and Vietnam) and south Asia. In case of estimating competitiveness, there is constraint of data availability. JCER use 30 indicators to compile potential competitiveness but it is impossible to gather such numbers of indicators unless creating new data.

So we select variables in view of both correlation and availability. We use world development indicators which contain 1574 series. We start to check the correlation between variables in 1980, 1990 and 2000 and ΔGDP per capita in 1980-1990, 1990-2000, 2000-2010 respectively. And we calculate data availability rate. Which is the ratio number of available data to number of all possible data. Because we check three period, that is, 1980,1990,2000, if all data is available, it will be 651(=271 × 3) data.271 is the number of all the countries and 3 is the number of period.

We made index by correlations multiply availability rate. And we sort by the index.

We choose 14 series, but there are few data of Machinery and transport equipment, we basically use 13 series.

Table6 Variable selection

Series Name	Correlation Coefficient				No. of samples	Available Sample Rate	Index
	1980	1990	2000	average			
			①				
1 Population density (people per sq. km of land area)	0.2	0.6	0.5	0.4	616	0.95	0.49
2 Population ages 40-44, female (% of female population)	0.4	0.4	0.5	0.4	580	0.89	0.44
3 Concessional debt (% of total external debt)	0.1	0.0	-0.6	0.2	376	0.58	0.35
4 Fixed telephone subscriptions (per 100 people)	0.4	0.2	0.4	0.3	567	0.87	0.34
5 Mobile cellular subscriptions (per 100 people)	0.1	0.2	0.3	0.2	611	0.94	0.32
6 Rural population growth (annual %)	-0.5	-0.4	-0.3	0.4	627	0.96	0.29
7 Life expectancy at birth, total (years)	0.3	0.5	0.3	0.3	589	0.90	0.28
8 Age dependency ratio (% of working-age population)	-0.2	-0.1	-0.3	0.2	502	0.77	0.26
9 Survival to age 65, male (% of cohort)	0.2	0.5	0.3	0.3	582	0.89	0.25
10 Physicians (per 1,000 people)	0.2	0.2	0.5	0.3	338	0.52	0.25
11 Machinery and transport equipment (% of value added in manufacturing)	0.7	0.1	0.4	0.4	366	0.56	0.24
12 Gross fixed capital formation, private sector (% of GDP)	0.2	0.2	0.5	0.3	291	0.45	0.24
13 School enrollment, secondary (% gross)	0.3	0.2	0.4	0.3	374	0.57	0.22
14 Mortality rate, infant (per 1,000 live births)	-0.3	-0.5	-0.3	0.3	557	0.86	0.22

Note:"Correlation coefficient 1980" means correlation between series in 1980 and ΔGDP per capita 1980-1990.651means all country number 271 multiply 3 terms.

Table7 Potential competitiveness factors by category

Demography		Telecommunication	
	Population ages 40-44, female		Fixed telephone subscriptions
(-)	Age dependency ratio		Mobile cellular subscriptions
Lifespan		Agglomeration	
	Survival to age 65, male		Population density
	Life expectancy at birth, total	(-)	Rural population growth
(-)	Mortality rate, infant	Science and Education	
Debt			Physicians
(-)	Concessional debt		School enrollment, secondary
Investment			
	Gross fixed capital formation, private sector(% of GDP)		

Classification

For the analysis of the result, we classify 13 series to 7 categories. For the demography, there are population ages 40-44 of female and age dependency ratio. For the lifespan, there are survival to 65 of male, life expectancy at birth and mortality rate of infant. For debt, there is concessional debt. Concessional debt is defined as loans with an original grant element of 25 percent or more. For the telecommunication, there are fixed telephone and mobile cellular subscriptions, For the agglomeration, there is population density and rural population growth. For the science and education, number of physicians and school enrollment of secondary school.

Some people think lifespan is not cause but result of GDP growth. But we check the correlation variables at initial point and future growth. Lifespan should be regarded as proxy of goodness of social insurance system.

Model

To make sure the variables are appropriately selected, we tested coefficients of the following formula. GDP_{it} is gross domestic product, POP_{it} is population, α and β is parameters, x_{it} is 1st principal component of potential competitiveness factors.

$$\Delta \left(\frac{GDP_{it}}{POP_{it}} \right) = \alpha + \beta x_{it-1} + \varepsilon_{it}$$

We use panel data. Cross section data is consist of ASEAN countries, South Asia countries, China, Hong Kong, Korea and Japan. Time series data is of 1980, 1990, 2000. We estimate with both fixed effect model and random effect model.

The formula is appropriate for the idea of potential competitiveness. x_{it} is in the initial point of increase in GDP over 10 years. Series x_{it} in 1980 will influence increase in per capita GDP from 1980 to 1990. Potential competitiveness in the latest period will be influential on competitiveness over the next 10 years.

Competitiveness related variables may correlate each other, there may be a multicollinearity problem. So we put 13 variables together by prime component analysis.

Estimation Result

Estimation Result is on the table. According to the table, Housman test does not reject the hypothesis that random effect is correct. So we use random effect's result.

Table8 Estimation Result (2)

Dependent Variable: Δ GDP per capita
Total pool (unbalanced) observations: 47

Variable	Fixed	Random

Adjusted R-squared	0.795	0.541
Houseman Test(P-Value) (random effect is correct)	0.7755	

Note: Δ GDP1:increase in GDP per capita(constant 2010US\$), C:constant coefficient, PCA: 1st principal component of 13 valuables.

Potential Competitiveness Ranking

We made potential competitiveness ranking. Potential ranking is estimation or forecast of increase in GDP per capita used by 1st component of 14 series.

Latest ranking means that the high ranking counties and economies will have more competitiveness in the future. Because present data affect the future GDP per capita. Hong Kong is 1st place and Singapore is 2nd place. CLMV countries show low competitiveness. Even the growth rate is high, it takes time to increase GDP per capita.

Table9 Potential Competitiveness Ranking

Country	1980	Country	1990	Country	2000	Country	2010	Country	2016
Vietnam	1053	Singapore	9745	Singapore	9820	Singapore	8919	Singapore	8746
Thailand	1180	Hong Kong	7864	Hong Kong	7312	Hong Kong	6921	Hong Kong	6837

Japan	7033	India	419	India	292	India	418	Bangladesh	728
Indonesia	677	Vietnam	278	Bangladesh	231	Bangladesh	314	India	421
India	486	Pakistan	195	Philippines	189	Philippines	15	Lao PDR	403
Hong Kong	6376	Cambodia	-9	Myanmar	130	Cambodia	-75	Cambodia	164
China	2207	Myanmar	-74	Pakistan	-495	Lao PDR	-124	Myanmar	24
Cambodia	95	Bangladesh	-181	Lao PDR	-610	Myanmar	-467	Philippines	-299
Bangladesh	107	Lao PDR	-266	Cambodia	-937	Pakistan	-1021	Pakistan	-1358

Analysis of regional effect

We investigate the effect of spatial effect. First, we estimate by spatial model. We use weight matrix. It is designed that the country which have common border economically affect neighbor countries.

$$y_{it} = \rho \sum_{j=1}^n w_{ij} y_{jt} + \beta x_{it} + \varepsilon_{it}$$

IF ρ is significant spatial effect exist, But estimation result shows that special effect does not exist.

Table10 Estimation result

Dependent Variable: Δ GDP per capita
 Total pool (unbalanced) observations: 47

Variable	Random
	Coefficient
C	2157.22 ***
PCA	1001.56 ***
W Δ GDP per capita	0.12

Adjusted R-squared 0.518

Houseman Test(P-Value) 0.4772
 (random effect is correct)

In the second analysis, we use dummy variables. If coefficient is significant, reginal specific effect exist in terms of potential competitiveness factor to increase in GDP per capita.

$$\left(\frac{GDP_{it}}{POP_{it}}\right) - \left(\frac{GDP_{it-1}}{POP_{it-1}}\right) = \alpha + \beta x_{it-1} + \gamma D_i x_{it-1} + \varepsilon_{it}$$

Table11 Estimation result

Dependent Variable: Δ GDP per capita
 Total pool (unbalanced) observations: 47

Variable	Random	Random
	Coefficient	Coefficient
C	2166.21 ***	2174.15 **
PCA	1029.34 ***	1187.41 ***
PCA*ASEAN	55.77	
PCA*ASEAN4		-688.56
PCA*CLMV		-1126.15 ***
PCA*SOUTH	-279.77	-1024.90 ***
PCA*SGP		896.11 ***
Adjusted R-squared	0.518	0.841
Houseman Test(P-Value) (random effect is correct)	0.7803	0.8407

The first estimation we use dummy variables of ASEAN and South East. Base line is East Asia. It is not significant that the country group effect.

But if we divide ASEAN into ASEAN4 (Thailand, Malaysia, Philippine, Indonesia), CLMV (Cambodia, Lao, Myanmar, Vietnam) and Singapore, group effects of South East, CLMV and Singapore is significant. There are some evidence of country group effect.

Group effect of CLMV is significantly negative and group effect of South Asia is also significantly negative, while Singapore is significantly positive.

CONCLUSION

We defined competitiveness as increase in GDP per capita, and estimate the potential competitiveness. We select variables which relate to increase in GDP per capita over the next 10 years. We also take availability into consideration. We select 13 series and make categories such as demography, lifespan, and so on.

We estimate potential competitiveness indicators. This indicator show the competitiveness in the future.

According to the latest data, Singapore is the 1st place, Hong Kong is the second place, Korea is the 3rd place in the potential competitiveness ranking.

APPENDIX2 VARIATION OF GDP STATISTICS

There are many kinds of GDP related statistics. GDP is domestic product and GNI is national income. For the discussion of middle income trap, some people use GDP and other people use GNI (Yamasawa 2013). If we focus on multinational companies, GNI is appropriate, but it will be difficult to distinguish between competitiveness of countries and competitiveness of companies. GDP is appropriate measure of competitiveness of countries.

There are nominal or current price GDP and real or constant price GDP. Because nominal value is fluctuated by the domestic price, constant price GDP is appropriate. Current US dollar basis GDP is influenced by not only domestic price but exchange rate. PPP basis GDP is influenced by domestic/foreign price difference in addition.

International comparison requires a unified unit, which may be dollar-based or purchasing power parity (PPP)-based. We have adopted the dollar as a measure that is exchangeable via trade. A PPP-based measurement indicates the strength of a country's domestic purchasing power, but for international comparison a measurement that is based on the internationally arbitrated dollar value is more appropriate.

Note that for the constant price basis, the growth rate are the same among PPP basis, US dollar basis and local currency basis.

We conclude that increase in GDP per capita measured by constant US dollar is the best for the ranking of competitiveness.

1750 WASTE OF WOODEN FURNISHING INDUSTRY: STRATEGIES TO IMPLEMENT SUSTAINABILITY AND SOCIAL RESPONSIBILITY – THE CASE STUDY OF THE JOINERIES IN UBERLÂNDIA, BRAZIL

Fernando Moreira da Silva, Juliana Cardoso Braga

CIAUD, Lisbon School of Architecture, Universidade de Lisboa

ABSTRACT

In Brazil, the wooden furnishings industry is comprised of approximately 16,000 companies of various sizes. It is estimated that most furniture companies (84%), consist of MSEs - Micro and Small Enterprises, are cabinetmakers performing customized work. Currently, these companies use MDF - Medium-Density Fibreboard as their main raw material. Brazil is the world's seventh largest producer of reconstituted wood panels in the world; in 2016, the production was 7.98 million cubic meters. A large part of this production (95%) goes to the domestic market. This paper presents partial results of a research project, from the diagnosis phase performed in joineries, small furniture companies in the city of Uberlândia, Minas Gerais State, Brazil. The production process of these joineries is not sustainable and results in a large volume of discarded waste on the outskirts of the city. In July 2016, there were 99 points of irregular disposal of waste of various types. This practice occurs, mainly, due to the low social and environmental awareness of cabinetmakers, and due to the lack of proper management of industrial waste by the municipality. The insertion of a set of ecodesign strategies in the MSEs can promote greater competitiveness for companies generating new business opportunities, creating more favourable conditions of competition among companies of the sector, improving their income while simultaneously promoting commitment and the sharing of responsibility (social, environmental, cultural) by all stakeholders. In this case, it is noted that the progress of these furniture MSEs depends fundamentally on minimising the generated waste of materials and this can only be achieved by the implementation of new practices and cultural/mentality changes; also by greater cooperation among small companies and designers, aiming a sustainable development, innovation and entrepreneurship; to focus on the human beings to establish regional and urban policies. To obtain more efficient results, we have to face the problem of the waste generated by these small familiar joineries focusing on people, integrating them in the system and not only by producing laws and guidelines. The project we have been developing with some of these joineries and the local furniture unions shows that with some specific changes and the use of a language that the cabinetmakers understand, we can achieve our goals for a more sustainable regional development and social integration.

Keywords: Cooperation and Development, Environmental Issues, Innovation and Entrepreneurship, Social integration, regional development, sustainability.

1- INTRODUCTION

Source: Adapted from IBGE (2008)

Fig. 1 - Mesoregion of the Triângulo Mineiro and Alto Paranaíba located in the western region of Minas Gerais - Brazil.

In the Triângulo Mineiro region, located in the west of Minas Gerais, Brazil, there are about eight hundred Micro and Small Enterprises – MSEs of furniture whose production is essentially tailor-made, guided by personalized projects. However, professional practices, as well as manufacturing processes, are not driven by sustainable production, a situation that has generated a large volume of waste discarded irregularly on the outskirts of cities.

The waste from the furniture sector in the region consists mainly of remnants of reconstituted wood (sawdust and flakes from particle boards and Medium Density Fiberboard - MDF) and generates approximately 20,000 m³ of waste annually (Nunes, 2013). The large number of furniture MSEs, sprayed over a vast territory and the small size of these productive structures, make it difficult to raise awareness. However, the problems caused by this circumstance are not limited to the large volume of waste; one should also consider the health risks of woodworking workers due to inhalation of small particles of wood containing a toxic and carcinogenic substance called formaldehyde which is used in the production of reconstituted wood plaques. In addition, the accumulation of residual dust, if neglected, can create fire hazards due to its flammable characteristic. Studies show that, in order to solve this problem, only environmentally adequate waste generated by the industries is not enough. In this sense, "it is fundamental to reduce the source of the consumption of resources, fundamentally aiming at reducing waste and, consequently, reducing the impact on the environment." (Pereira, Carvalho & Pinto, 2010: np)

The inclusion of design as a strategy for sustainability is considered by several authors as fundamental for minimizing environmental impacts at all stages of the product life cycle. The bottleneck of the issue is that most of the existing tools are directed to the design and production of large-scale products. In addition, given the geographic, economic, social and cultural differences of each region, it is understood that the insertion of sustainable design in local contexts and/or non-industrial production scales is indispensable to enhance the specificities of the region's carpenters, minimizing solid waste, waste of materials and environmental damage caused by the lack of management of waste generated by the furniture industry.

In view of the above, this research intends to develop a sustainable strategic design model for furniture MSEs in the Triângulo Mineiro region. The model will involve a set of interdependent variables with the objective of aligning different aspects of design that will have sustainability as main pillar. We hope the model will be developed in a participatory way, involving the various interested stakeholders (carpenters, manufacturers, designers, unions, universities, and local public authorities). It is therefore important that trade unions and trade associations, manufacturers, carpenters and designers contribute with important information for this research and the generation of ideas for the management of design solutions. The involvement of the communities most affected by the irregular disposal of waste and the support of local public authorities will also be of great importance. In this way, it is intended to integrate the theoretical knowledge to the practices of sustainability favoring the exchange of knowledge and the transfer of innovation to the personalized (or customized) furniture sector.

The important consumer market for residential furniture on demand in the Triângulo Mineiro region has subsidized a significant number of furniture manufacturers, around eight hundred companies, formal or informal. According to the diagnosis made by Senai (2006), the segment of residential furniture by order accounts for 84% of the turnover of the sector of the region. However, most of these micro-enterprises have no knowledge on how to use sustainability practices in their business. An example of this is that the MSEs in the region have not only generated great quantities of waste per year, but also have been disposing it in the outlying areas of the cities of the state of Minas Gerais (Nunes, 2013). This situation has contributed to aggravate the living conditions of the populations that live in the cities peripheries of the State.

Residues from the furniture sector in the region are mainly composed of remnants of reconstituted wood (sawdust and flakes from particle board and MDF). However, the problems caused by the abandonment of debris without any treatment and outside the places previously prepared to receive them are not limited to their volume: it is a public health problem. This is because it should be considered that the practice of irregular dumping of these wastes in the periphery of cities and the burning of fire as a way to clean the land emits toxic substances in the atmosphere and increases the risk of uncontrolled fire due to high flammability of sawdust. This makes this factor very significant for the worsening of the living conditions of populations that subsist on the poverty line or below that threshold, both from the symbolic point of view (treating them as garbage) and from the social point of view (encouraging degradation of public space, cause and effect of risky or socially deviant behavior).

2- FURNITURE INDUSTRY: INTERNATIONAL AND NATIONAL SCENARIO

The world furniture industry is characterized as a sector composed mostly of small and medium-sized enterprises, with a high degree of specialization and that demand intense labor and can therefore have a positive or negative impact on the employment rate of an economy (Crocco & Horácio, 2001). The sector is formed by large productive chains, which are able to offer important gains of scale and agility in the stages of the productive process. Generally, smaller firms manufacture and supply components and accessories for larger companies, allowing greater efficiency and flexibility of production with the horizontality and agility of the productive processes.

The introduction of new automated equipment, business management techniques and increased horizontal production contributed to productivity in the furniture industry, made processes more flexible with the production of several types of products on the same production line, and reduced industrial costs. All these transformations, combined with the introduction of a wide variety of raw materials and finishes made possible by the introduction of MDF, MDP and other materials, contributed to the mass consumption of furniture, especially the standardized rectilinear furniture that compete in a market determined by the lowest price. These furniture pieces are designed so that the assembly could be carried out by the user, eliminating the figure of the assembler. At the other end are the furniture pieces that seek to distinguish themselves through design, pursuing the strategy of differentiation and exclusivity, as in the case of Italian companies. Therefore, the competitiveness of furniture companies is due to the high degree of specialization and employed technology, the application of new materials, the development of commercial and distribution strategies and, above all, the introduction of design (Gorini, 1998).

At National level, despite the diversification, the production chain of the furniture industry has a historical specialization in the production of articles made from wood, due to the abundance of inputs of forest origin in the country (Galinari et al, 2013). However, due to environmental and legal restrictions for obtaining solid wood, the manufacture of wood panels (agglomerate, MDF, MDP, etc.) produced from reforested pine and eucalyptus has been expanded in Brazil. According to information from the Brazilian Tree Industry - IBÁ, the production of reconstituted wood panels (MDF, MDP, etc.) in Brazil in 2015 was 7.98 million m³, of which 95% was destined to the domestic market. Brazil is the seventh largest producer of reconstituted wood panels in the world (IBÁ, 2015).

The follow-up of wooden furniture in Brazil consists of approximately 16 thousand companies of various sizes (Movergs, 2014) that produced 476.2 million pieces in 2013 (IEMI apud Capistrano, 2014) and are sprayed all over the national

territory (Galinari et al, 2013; Leão, 2009). However, most of these companies are concentrated mainly in the South and Southeast regions. In these regions are also located the main furniture poles that produced a total of 282 million pieces in 2013: Bento Gonçalves -RS (17.7%), São Paulo metropolitan region (9.1%), Araçuaia-PR (8, (5.8%), Greater São Paulo - SP (6.6%), Ubá - MG (5.9%), Curitiba - PR (3.8%), São Bento do Sul - SC -ES (2.4%), Belo Horizonte - MG (1.5%), Lagoa Vermelha - RS (0.8%), Rio de Janeiro - RJ (0.2%). These data refer to the percentage of pieces produced on the total of the poles (IEMI apud Capistrano, 2014).

It is estimated that around 13,500 furniture companies are predominantly made up of formal micro and small enterprises with vertical and unskilled production processes. (FIEMG, 2002; Garcia, 2005)

The number of large establishments with more than 500 employees would be almost irrelevant. These companies have carried out the gradual introduction of high technology, but most of them still use outdated equipment and production systems (FIEMG, 2002). Even large companies are basically servicing the domestic market, due in part to the high prices of wood panels in the domestic market (Leão, 2009); the low technology employed; and the lack of product differentiation due to the lack of investment in design, with the predominance of imitation products (Castro & Cardoso, 2010; Crocco & Horácio, 2010; Galinari et al, 2013; IEL, 2002). One of the main obstacles to the development of Brazilian companies concerns the lack of insertion of the design to support the conquest of new markets and the creation of a Brazilian design.

Between 2009 and 2013, there was a 23.3% increase in the number of companies involved in the follow-up of wood furniture in operation in the country and production growth was 28.7%. In 2013, the furniture sector showed a 3.4% increase in the number of pieces produced compared to 2012. Between 2009 and 2013, the average production growth was 6.5% per year (IEMI apud Capistrano, 2014). The product lines that presented the greatest growth of production in the period were furniture for living room with 40.5%, furniture for kitchen and others with 35.3% (MOVERGS, 2014). This growth can be explained by the stabilization of the Brazilian economy in the period and by the expressive migration of consumers from class D to C. Residential furniture accounts for approximately 73% of the total production of the sector, with the remainder composed of office furniture (18 %) and institutional furniture, for swimming pools, terraces, gardens, etc. (9%). According to Galinari et al (2013), the expressive participation of the national furniture industry in the employment levels and the dissemination of the furniture production chain throughout the country demonstrate the importance of the sector to the Brazilian economy.

IEMI estimates that approximately 76% of furniture companies in Brazil in 2011 manufactured standardized products (produced in series and without the possibility of personalization by customers). However, since then there have been changes in the Brazilian real estate market with the reduction of useful areas of the real estate, valuing the solutions offered by the furniture made to measure that maximize the use of space (GALINARI et al, 2013). Due to the spraying of these companies across the national territory and the large number of microenterprises that work in informality, it is believed that the manufacture of furniture under measure is much more expressive.

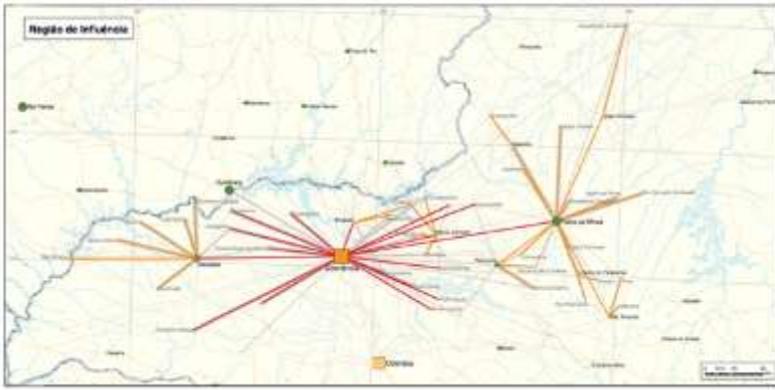

The growth of the furniture sector in recent years, between 2009 and 2013, was driven by the increase in the income of Brazilians; the temporary reduction of the IPI - Tax on industrialized products; the growth of civil construction - especially with the contribution of the *My Home My Life* program of the Federal Government, leveraging the real estate market and the consumption of durable goods. With the adverse political and economic scenario faced by Brazilians since the beginning of 2015, there is a slowdown in the national furniture production.

3- THE SCENARIO OF THE TRIÂNGULO MINEIRO AND ALTO PARANAÍBA

3.1 Characterization of the region

An expressive amount of furniture MSEs is located in Minas Gerais, in the region of Triângulo Mineiro and Alto Paranaíba - TMAP. The Triângulo Mineiro region is located in the western region and the Alto Paranaíba in the eastern region. The mesoregion is made up of sixty-six municipalities, seven of which are considered microregions, due to their different production, distribution, exchange and consumption structures, namely: Uberlândia (662,362 inhabitants), Uberaba (332,126 inhabitants), Araguari (116,267 inhabitants) , Patos de Minas (148,762 inhabitants), Araxá (102,238 inhabitants), Ituiutaba (103,333 inhabitants), and Patrocínio (88,648 inhabitants). The region of the Triângulo Mineiro and Alto Paranaíba, with its 66 municipalities, totals an estimated population of two million inhabitants, and has an area equivalent to 53,719 km² (IBGE, 2015).

According to IBGE (2008), Uberlândia is the second largest municipality in the state of Minas Gerais, with the third highest HDI (0.789) in the state and is the most influential city in the Triângulo Mineiro and Alto Paranaíba region. The city is considered a regional capital due to the intensity of flows of consumers who are going to the city in search of goods and services. The municipality is referred by a large number of neighboring cities as being the main destination for the realization of a diverse set of activities in the areas of health, education, commerce, services, entertainment, among others. Therefore, Uberlândia became an attractive pole of migration of populations of increasingly diverse regions (IBGE, 2008; SMPU, 2013), housing a contingent of people mainly from other regions like Minas Gerais, São Paulo, Goiás and Bahia (Guimarães, 2013).

Source: Adapted from IBGE (2008).

Fig. 2 - Region of influence of the city of Uberlândia-MG in the Triângulo Mineiro region.

Uberlândia consolidated its regional centrality, mainly due to its strategic geographical position in the regional and national context, as the city is served by a road and rail network and an Intermodal Cargo Terminal that links the city to the main markets of the country and the world (SMPU, 2013). Its position as a junction of several highways easily interconnects the city to the three main Brazilian urban centers - Belo Horizonte, São Paulo and Rio de Janeiro.

The region of the Triângulo Mineiro and Alto Paranaíba presents a relevant economic and social performance in the national, state and regional scenario. In 2010, thirty-seven cities in the region had per capita values above the national average. Its diversified activities make the municipality capable of attracting great migration and investments. Its economy is mainly driven by a network of commerce, services, industries (agroindustrial, food, sugar, alcohol and tobacco), telecommunications, education, health and the modernization of commercial agriculture. An excellent communication infrastructure (radio, television and press) and event reception (congresses, festivals, sports games) also help in its capacity to influence, disseminate products, ideas and events. This diversity of economic activities act as centripetal and centrifugal forces in their region of influence that attract investment and trade flows (Guimarães, 2013).

3.2 Furniture MSEs (Medium and Small Enterprises) in the region

The region of the Triângulo Mineiro and Alto Paranaíba groups an expressive amount of furniture EPEs. The SINDMOB - Furniture Industry Union of the Triângulo Mineiro and Alto Paranaíba has about eighty associated companies and seeks to promote, mainly, lectures, exhibitions and trips for companies in the sector. In 2006 SINDMOB in partnership with SENAI and SEBRAE carried out a diagnosis of the furniture industries of the region. Estimates made by SINDMOB indicate the existence of approximately 200 formal furniture MPEs. However, as presented by the national furniture scenario, it is estimated that the number of furniture companies is much larger, around eight hundred MEPS, due to the informality of most of the industries in the sector (verbal information). The sector is characterized by the predominance of micro and small enterprises, 96% are micro enterprises (up to 19 employees) and 4% are small (from 20 to 99 employees), and by the small number of employees - an average of 6.2 employees per (SENAI, 2006).

The production of MSEs is essentially made-to-order and custom-made furniture. The diagnosis carried out by SENAI (2006) confirms the predominance, in the region, of companies that produce custom furniture and on order 94%. Of the other companies, 3% produce in series on demand and another 3% produce furniture in series with its own product line.

Tailor-made furniture producers consist mainly of small and micro-sized family-owned enterprises with a very small number of employees, with a low degree of specialization and low-tech production, a high level of technical qualification, and the flexibility to meet the specific needs of each client (Dal Piva, 2006; SENAI 2006). Its structure is also essentially characterized by verticality and low technological level. The process of production of the joinery is practically semi-handmade, resulting in a customized final product that fits the defined functions and spaces. They usually result in quality furniture and therefore high cost but still compete with the high-tech companies that produce modular furniture (Dal Piva, 2006).

It is important to consider that production systems have a low degree of specialization, production of low technological level and occur vertically, that is, different production processes are carried out by the same company. This process requires a series of steps that begins: with the analysis of the project, which is prepared by a professional (usually a designer or architect) or by the carpenter himself; then cost calculations are performed; the individual negotiation of each piece of furniture; visit at the customer's house for measurements; calculation and purchase of raw material; accompaniment of all the production until the transport and the assembly - that often is finalized in the residence of the own client. Generally, all this process is carried out by the owner of the joinery that participates in the entire production chain.

Dal Piva (2006, p. 17), points out some advantages of the custom-made manufacturing process:

- The customer finances the manufacturing making part of the advance payment;
- The furniture is personalized (customized);
- The furniture occupies better the space of the residence;
- There is greater profitability per unit of manufactured product;
- The administrative structure of the company is lean;

- There is polyvalence of the joiner.

However, the exclusivity of the products and the low use of technology do not allow for the standardization (reduction of the variety of parts economically) and the interchangeability (ability to use parts for use in the same product or in different products) economical way. The advantages of standardization are that it allows loss reduction, rationalization of production, reduction of costs and quantity of items in production. On the other hand, standardization does not allow the fulfillment of all customers' wishes, limiting the diversification that is a major trend in the current market.

Tailor-made manufacturing requires a large number of operations and specialized labor, which increases the cost of the product and makes small carpenters unable to compete with large manufacturers. In this sense, the main disadvantages of the custom-made furniture manufacturing process are highlighted (Dal Piva, 2006, p. 18):

- There is an excess of manual operations;
- Lack of productive machinery;
- The acquisition of raw material and inputs is done by means of small quantities acquired from intermediaries, whose price is always higher;
- Specialized workforce is rare;
- There is low productivity;
- The product has an excess of raw material, making it inaccessible to most people;
- There is a need for professionals to design special projects.

The main raw material used by carpenters is the panels of reconstituted wood, mainly the MDF due to characteristics such as: ease of machining, which allows the manufacture of pieces with profiled edges or cushioned doors; dimensional stability; versatility of colors, diversity of finishes and textures; ease of finishing as painting, among other advantages (Dal Piva, 2006; SENAI, 2006; SENAI, FIEMG & Masisa, 1997). The MDF is mainly used for the manufacture of cabinet doors or furniture in general, drawer fronts, and tops that need machining of the profiles. Despite the existence of a plate factory in the city of Uberaba, most companies, around 80%, acquire panels of local reseller companies due to the small volume of purchases made to each customer (Oliveira et al, 2012).

Most carpenters in the region (86%) produce residential furniture (furniture for dormitories, kitchen and residential furniture in general), 2% manufacture office furniture, 1% work on furniture remodeling, and 11% produce other product types (pool table, lay boxes, among others). These products are mainly destined for the local market, in a fierce competition based on prices - 66% of sales are made in the city where the company operates, 26% in other cities in Minas Gerais, and 8% of sales are for other states (SENAI, 2006).

The sector also depends on a support structure for the production process involving: machinery and equipment; third party services such as equipment maintenance, transportation, graphics, accounting, computer and design; raw materials and accessories such as varnish, paints and various wood panels. Among these services, industries mainly consume accounting (73%), maintenance of machinery and equipment (32%), transportation of goods (30%), and design (23%) (Oliveira et al, 2012).

Regarding design, 72% of the furniture companies in the region claimed to make use of furniture development, however, design is still not perceived as a key factor for the success of the activity (SENAI, 2006). However, it was not clear from the research that these firms employ design, and therefore this requires further investigation. What is observed as the most common practice in the region is: (i) the development of custom designs by the designers and subsequent indication of the services of the carpenters; (ii) carpenters who outsource the design projects to assist customers who directly seek the joinery; (iii) carpenters who develop their own projects, through trainees with training in design; (iv) carpenters who develop their own projects, through a designer without design training.

Therefore, the furniture sector of the Triângulo Mineiro and Alto Paranaíba region is characterized by the predominance of micro and small companies that produce furniture under measure, production of low technological level, and lack of investment in design. All these facts reduce the productivity and competitiveness of these companies and make most of the production go to the market of the region itself, in a fierce competition based on prices.

4- FURNITURE WASTE

If on one hand the furniture sector generates a large number of jobs, on the other, it is also considered a major consumer of raw materials and waste generator. The industry makes integrated use of materials that, due to their distinct nature and lack of an adequate management plan, end up hampering reuse, recycling and other forms of appropriate final disposal. The most commonly used materials are wood derivatives (solid wood, wood veneers, plywood or particle board, reconstituted wood panels such as MDF and veneers); metals used in handles, hinges and slides; chemicals (paints and varnishes, glues and resins); plastics (edge ribbons, laminates, handles, etc.) and textile fabrics and leathers (natural and synthetic). (Nahuz, Figueroa & Lelo, 2002; Kozak et al, 2008)

In addition to the diversity of materials, the production of customized furniture requires a number of productive processes such as machining (cutting, drilling, milling,); sanding; assembly (fixing and gluing); transport; and cleaning. These processes generate a large volume of waste of various types (sawdust, dust, panel patches, edge ribbons, packaging debris, bolts, glues and taws).

The estimated annual volume of waste from the furniture sector of Uberlândia and region corresponds to approximately 22,000 m³, of which a significant part is composed of residues of wood (dust, sawdust and MDF flaps). The presence of

urea-formaldehyde or phenol-formaldehyde used in the composition of reconstituted wood panels, requires special attention due to the fact that this resin is part of the International Agency for Research on Cancer (IARC) list of carcinogenic products.

For all this, the joineries of the Triângulo Mineiro and Alto Paranaíba have an expressive environmental liability, mainly due to the irregular disposal of residues on periphery lands of the cities of the region. This practice stems from factors such as: municipal policy, not sensitive to environmental issues; the lack of municipal management aimed at the adequate disposal of this type of waste; the resignation of the most needy people who live in the neighborhood of these ditches; the reduced or no interest in assuming the share of environmental responsibility on the part of the entrepreneurs of MSEs in the region and the weak social and environmental awareness of designers about the environmental impacts of their projects.

Source: The author

Fig. 3 - Locations in the outskirts of the city of Uberlândia, used for irregular waste disposal.

According to the diagnosis made by SENAI (2006), 90.8% of the furniture manufacturers in the region rest industrial waste, 3.7% sell them and only 5.5% recycle. In July 2015 the municipality had ninety-nine critical points of irregular dumping of indistinct waste, distributed mainly in public areas of the city. It is understood that these facts do not exhaust a very complex conjuncture, difficult to transform. Targeting the generated waste in an environmentally sound way is not enough to solve the problems dealt with: "reducing the source of resource consumption is fundamental, aiming, fundamentally, to reduce waste and, consequently, reduce the environmental impact". (Pereira, Carvalho & Pinto, 2010)

However, in the specific case of the Triângulo Mineiro region, few actions have been taken to combat the advance of environmental degradation. In addition, there is a lack of tools to train, educate, guide and foster a new local culture that favors responsible positions on the part of professionals and micro and small industries, regardless of the sectors of activity.

4.1 Consequences of poor management of woodworking waste: social, environmental and economic impacts

However, the problems caused by the abandonment of debris without any treatment and out of places previously prepared to receive them are not limited to their volume. The consequences of the poor management of woodworking waste also cause social, environmental and economic impacts as described above. With regard to social impacts, it is also important to consider public health risks from the toxicity of substances used in the production of reconstituted wood plaques. Formaldehyde, for example, is a carcinogenic solution used as an adhesive resin in the production process of this type of material (Pereira, 2013). Due to the use of formaldehyde-containing resins, the formaldehyde emission occurs both through the manufacturing environment and through the plates produced with these resins. (Maloney, 1993)

Special control and concern should also be devoted to the health of joineries' workers due to the risk of inhalation of small particles of reconstituted wood containing formaldehyde. In addition, the accumulation of residual dust generates fire hazards, if neglected, due to its flammable characteristic. Santos and Dias (2012, p.8) affirm that "the existence of a significant contingent of people who extract from their residues their main source of survival, adds to the problem of waste a socio-cultural and anthropological dimension, which, together with environmental and sanitary impacts, requires strict consideration".

Joineries also suffer financial losses due to the lack of adequate management of their waste and, mainly, the waste of raw material caused by the lack of optimization of the wood panel cuts, inadequate separation and storage of the parts that can be reused.

Environmental, economic and social issues must be considered when analyzing the consequences of the practice of irregular waste disposal by the woodworkers on the outskirts of cities aggravated by the common practice in the region of firing with the intention of carrying out land cleaning. The problem of the conjugation of these practices consists in the emission of particulates and GHGs in the atmosphere that increases the risks of uncontrolled fire due to the high flammability of the waste in the form of sawdust. This makes this factor very significant for the worsening of the populations' living conditions that subsist on the poverty line or below that threshold.

5- STRATEGIC THINKING

The term strategy has been used differently over the years, and in different fields (administration, marketing, military, design) but there is no universally accepted definition. In recent works, Mintzberg, Ahlstrand and Lampel (2008) and Mintzberg et al (2002) investigated the origins of the strategy and the views of different currents of thinking from five definitions: strategy as a plan, as a pretext, a standard, a position or a perspective. The first and most traditionally used definition is strategy as a plan, understood as an intention, a guideline, or a set of guidelines designed to deal with a specific situation. Strategies are formulated consciously, before the actions to which they will be applied. Therefore, they are also considered as future plans of the organizations, ie, intended strategies (Mintzberg et al, 2002). The definition presented by Glueck (1980), from the administration point of view, reinforces this vision. For the author, strategy is a unified, broad and integrated plan that can determine, through a normative model, which actions and / or human and material resources are needed to ensure that the company's goals are achieved. This vision is also strengthened in the field of design. For Best (2010), the strategy is a plan that describes how the company intends to fulfill its mission and vision vis-à-vis different parts of the organization. Bruce and Langdon also understand the strategy from a plan:

A strategy is a declaration of intent, defining where you want to be in the long-term. (...) Without a strategy, decisions made today could have a negative impact on future results. (...) Strategy concerns itself with what is ahead, looking at where you are going, and how to get there. (Bruce & Langdon, 2000, pp. 6-7)

However, Mintzberg, Ahlstrand and Lampel (2008) and Mintzberg et al (2002) criticize this point of view because they consider that the desired strategies are not always realized. In this sense, they believe that, in practice, strategies are composed of a combination of "deliberate strategies" (characterized by fully implemented guidelines), "unrealized strategies" (characterized by unfulfilled directives) and "emerging strategies" (irrespective of the guidelines, and it was not provided for in the guidelines). Most of the implemented strategies involve both deliberate and emerging issues. Zurlo (2012) shares this position by stating that in practice there is often a gap between a strategic decision and its achievement.

The progressive formulation of the strategy is more useful for the incorporation of design in the company in the long term, because the emerging strategies allow the insertion of design ideas in a collective process of consensus building among stakeholders. For Mozota (2003), strategic design is a factor of competitiveness and differentiation for companies, it means contributing to the organizational culture of companies, seeking opportunities for innovation and identity, offering a unique combination of value. According to Zurlo (2012), strategies are interpreted in different ways and can be associated with a plan or set of followed actions and precise results; as a model, where entrepreneurs seek a reference in other organizations that represent the best in certain areas; and as positioning, where companies must find a place in the market and differentiate themselves from competitors, in line with Porter's (2008) competitiveness vision. However, when the strategy is associated with a plan, it reiterates the necessity of adapting the guidelines, since the conception of strategies does not always coincide with reality, and in this case, it is necessary to change direction.

Strategic design is seen as an interdisciplinary field that can interact on various business activities with the purpose of generating value, allowing companies to enter a new market or increasing their participation in it and, for this reason, plays an important role in the transition process towards sustainability (Mozota, 2003). According to Best (2010), design acts in an integrated way with other disciplines and professions and provides an integrative and holistic approach on the cultural, environmental, political and social impact of the organizations. In addition, strategic design can generate eco-projects that are technically and economically viable, reorienting production and consumption systems to the formation of a more sustainable mindset. (Manzini & Vezzoli, 2008)

Based on studies of European design-oriented MSEs, Mozota (2006) presents a Design value model as differentiator, integrator and transformer, called the four powers of design: 1. Design as differentiator - design as a source of competitive advantage in market by creating value for the brand, higher price, loyalty or customer orientation; 2. Design as an integrator - design as a resource to improve product / process development, developed to favor modular design, to develop user-driven innovation models and project management; 3. Design as transformer - design as a resource to create new business opportunities, to improve the company's ability to face changes, or as expertise to better interpret business and the market; 4. Design as good business - design as a source of sales increasing, better profit margins, greater value for the brand, greater market share, better investment return; design as a resource for society (inclusive design, sustainable design).

6 CHALLENGES AND OPPORTUNITIES IN THE INSERTION OF THE STRATEGIC DESIGN IN THE FURNITURE MSEs

In Brazil there is a very complex and difficult situation to transform and overcome for the implementation of strategic design in the business sector. This is due to facts such as lack of interest and commitment from relevant partners (local public leaders, associations, NGOs). In addition, in the specific case of the furniture sector of the city of Uberlândia and region, it was possible to identify some of the main obstacles presented by the MSEs themselves: 1. Lack of interest of the stakeholders to dedicate a coordinated effort to solve common problems together; 2. Lack of motivation induced by poor understanding of sustainability aspects or lack of recognition of the importance of design for their business; 3. Difficulty in continually taking on the proposed practices, modifying internal policies and assuming co-responsibility with others; 4. Low confidence, transparency and belief in mutual efforts to achieve group goals; 5. Cultural and behavioral resistance to organize and carry out changes in productive processes; 6. Lack of understanding about the value or need to invest time and financial resources in the design process.

However, it is important to consider that these companies, mainly composed of MSEs of family origin, with low degree of specialization and production of low technological level, most of them face many difficulties to remain in the market. There is still a dichotomy between the perspectives of design application in the business sector and its implementation, and a general lack of conviction about the application of design as a tool for business management and as a factor of innovation. The fact is that the importance of design for organizations is still little recognized by corporate managers (Mozota, 2006). One of the biggest problems hindering the insertion of the design in the companies "resides in the lack of knowledge on the part of the entrepreneurs, of the design meaning and what can be changed in the company, besides some prejudices, as, for example, that the design is expensive" (Santos & Menezes, 2009, p.97).

6.1 Strategies for the development of sustainable products

The insertion of sustainable design strategies in local contexts and non-industrial production scales is very relevant for companies and indispensable for reducing the generation of solid waste, material waste, pollution and environmental damage caused by production of customized furniture. According to Fiksel (2009), sustainable design practices not only represent ethical behavior and good citizenship but, above all, a business value strategy. This principle of generating value and economic benefits for companies is known as eco-efficiency - doing more with less. It is part of this perspective to reduce the consumption of resources (energy, materials); to reduce environmental impact (reduce emissions, waste and use of renewable resources); and to create value (providing better products, additional services, offering benefits to customers). Several corporations around the world already recognize sustainability as a way of developing, growing and surviving businesses and their ability to stimulate new business opportunities, improve competitiveness, increase customer confidence, and motivate employees, local communities, partners, etc.

Organizational changes for the implementation of eco-efficient design strategies also favor innovation and can offer a greater capacity to attract customers, as it improves the image of the organization and allows them greater profitability through the reduction of environmental impacts, among other issues. All these benefits obtained by adopting the principles of design and sustainability need to be integrated at a strategic level so that they can act more effectively. (Bhamra, 2007)

Ecodesign strategies aimed at a systemic approach involving all stages of product life should be considered during product design. In this sense, whenever possible, designers should apply a set of ecodesign strategies involving the entire product life cycle, i.e., considering the stages of pre-production, production, distribution, use and disposal.

According to strategies presented by several authors (Barbero & Cozzo, 2009; Behrendt et al, 1997; Bhamra, 2007; Brezet & Hemel, 1998; Fiksel, 2009; Gilsbert & Garcia, 2004; Manzini & Vezzoli, 2008), it was possible to identify seven key strategies and their tactics for the development of sustainable products: 1- the choice of low impact materials; 2- reduction in the consumption of materials (raw materials and energy); 3- optimization of production; 4- optimization of the distribution; 5- optimization during use; 6- extension of product life; 7- product end-of-life optimization.

Despite the potential benefits of sustainable design strategies, Braungart and McDonough (2002) strongly criticize these practices that aim to make products or systems less destructive. According to the authors, these strategies are fatally limited and advocate the cradle to cradle approach - from cradle to cradle, where materials and products must be developed as biological nutrients (which can be consumed by micro-organisms or other animals) or as nutrients (free of toxic materials that can return to the industrial cycle from which it comes unlimited). In this approach, the materials can be reused, no residue is produced or they can be fully recycled, so there would be no negative impacts due to the closed cycle of the materials.

However, we need to consider that the cradle to cradle approach will certainly have a long way to go and in the meantime we need to deal with a large amount of existing materials and products that cannot return to biological systems because of their toxicity. Therefore, it is necessary to minimize the environmental impacts, mainly from this type of product and therefore, according to Manzini and Vezzoli (2008), recycling is seen as an unavoidable operation, where both the producer and consumers are expected to pay not only for the product but also by its final disposal.

With regard to recycling, technological solutions are being improved with the objective of increasing environmental gains, as in the case of transforming urban waste into electricity. The first plant of this type installed in Brazil, which does the waste treatment, has entirely national technology, developed by the company *Usinaverde*, headquartered in the city of Rio de Janeiro. The pilot project has the capacity to process 30 tons of non-recyclable municipal waste per day, with enough power generation to serve 20,000 inhabitants. It is important to add that the gases extracted from the boiler are neutralized by a filtering process before they are released into the atmosphere. The remaining solid residue is transported to a decanter and can be reused by the construction industry, ensuring control of the emission of pollutants (Varanda, 2008). On the other hand, the development and improvement of new technologies for the incineration of waste as a way of generating energy is already a resource provided for in Law 12,305 of August 2, 2010, which establishes the National Solid Waste Policy - PRNS (BRASIL, 2012).

The establishment of efficient systems for collection of materials, separation at source and final disposal environmentally appropriate should encompass shared responsibilities throughout the product life cycle. These initiatives require collective participation involving all generators - community, manufacturers, importers, distributors, traders and public authorities - and the latter should stimulate others, both through fiscal incentives, the valorization of recycled raw materials, education campaigns, but also through stricter legislation, oversight, or even penalties. In this regard, it should be remembered that according to Article 9 of Law 12305/2010, "in the management and management of solid waste, the

following order of priority must be observed: non-generation, reduction, reuse, recycling, waste treatment and environmentally sound final disposal of tailings ". According to Brown (1991) this would alleviate the problems of waste disposal as storage areas are becoming increasingly scarce. A serious problem already faced, mainly, by the big urban centers.

Therefore, according to the order of priorities established by the National Solid Waste Policy (PNRS) recycling should not be seen as the ideal solution for the final destination of the products, as it is also a polluting process, as it requires trucks to collect and transport to the processing industry, a process that also consumes energy and causes waste emissions. Hence, the correct final destination should be used as one of the last resources for the objects.

Above all, we should avoid discarding objects, producing smarter goods that minimize the resources necessary for their production, that are durable, lightweight, foldable, stackable, and use materials from renewable sources, can be reconfigurable, adaptable, can be standardized, dismountable, upgradable, reformed, repaired, reused, more energy-efficient, water-efficient and have more compact, reusable or biodegradable packaging. Of course, in most cases, it is not possible to adopt all these strategies for the same product, because these characteristics will be determined according to the function for which the object is intended. The fact is that only with a deeper awareness of the impacts linked to the product life cycle, and with the interference of political forces aimed at the global management of resources, society will be able to reduce its impacts considerably. To do so, it must act preventively, in a systemic and strategic way, even before the first stage of a product's life cycle, encompassing the principles of ecodesign even during project activity. These principles should also consider the geographic, economic, social and cultural differences of each locality, implementing in the companies requirements of sustainability from the environmental, social and economic as well as the cultural point of view, respecting the specificities and characteristics of each region.

7 IMPLEMENTATION OF THE CACO PROJECT

The production process of the joinery is not sustainable and results in a large volume of discarded waste on the outskirts of the city. In July 2015, there were ninety-nine points of irregular disposal of waste of various types (verbal information). This practice occurs, mainly, due to the low social and environmental awareness of cabinetmakers, and due to the lack of proper management of industrial waste by the municipality. To obtain more efficient results, we have to face the problem of the waste generated by these small familiar joineries focusing on people, integrating them in the system and not only by producing laws and guidelines.

This paper presents partial results of CACO research project, from the diagnosis phase developed in 15 customized furniture companies in the city of Uberlândia, Minas Gerais State, Brazil.

The word "CACO" (shard) was proposed due to its meaning: a piece, small fraction, part or remainder of something. The use of this term is meant to represent, symbolically, the need to connect the different areas necessary for the development of the proposed project and integrate "fragmented" knowledge in favour of more sustainable actions for the furniture sector.

It is believed that the insertion of a set of ecodesign strategies in MSEs can generate greater competitiveness for companies generating new business opportunities, creating more favourable conditions of competition among companies of the sector in the region, improving their income while simultaneously promoting commitment and the sharing of responsibility (social, environmental, cultural) by all stakeholders. In this case, it is noted that the progress of furniture MSEs depends fundamentally on minimising the waste generated and the wastage of materials.

The project we have been developing with the joineries and the local furniture unions shows that with some specific changes and the use of a language that the cabinetmakers understand, we can achieve our goals for a more sustainable regional development and social integration.

The CACO research project involves the development of a sustainable strategic design model aiming to minimise the waste produced by furniture manufacturers in the city of Uberlândia.

Strategic design proposals should generate direct and indirect benefits for companies. With the reduction of waste, it is expected that there will be an increase in the firm's profitability. Therefore, environmental and economic progress, if achieved, can also generate social and cultural benefits through the maintenance of jobs, the preservation of this millenarian craft (know-how), and the permanence of some cabinetmakers in the market.

The model will be comprised of a set of ecodesign strategies that will be implemented systemically in all phases of the product's life cycle (pre-production, distribution, use and disposal). The strategies are being defined from the conclusion of the diagnosis phase.

The model intends to supply, firstly, the needs and collective problems – already diagnosed as being common issues among the companies in the sector. However, according to Freitas e Merino (2011), it must also be considered that each company has individual needs and, therefore, the implementation process must meet the geographic, economic, social and cultural characteristics of each one of them.

The project diagnosis phase was implemented in fifteen MSEs (with a minimum number of 06 and a maximum of 20 employees) who produce customised furniture and use MDF as the main raw material. The data was collected through: (i) semi-structured interviews; (ii) direct observation with mechanical support; (iii) documentary research; and (iv) data collection (toolkit) on the volume of waste generated during the production process.

According to Rampersad and Hubert (2007), waste is usually hidden by the workers because it is considered as a normal symptom in the workplace. Therefore, the diagnosis was made to detect the main causes of waste generation in the joineries by analysing all phases of the customised furniture life cycle. In order to evaluate the generation of residues during the production of furniture, a toolkit was created with the objective of detecting the amount of used material (material input). In this sense, the employees were guided and monitored during the use of the toolkit, which aimed to register: (i) the form used for the planning of the cut; (ii) and the consumption of material (new and reused MDF sheets). In addition, during the furniture production process, the generated waste was separated, identified, weighed and measured in order to identify the percentage of material loss during the production process waste.

The joineries' owners declared that in general each of them uses an average of 110 MDF sheets monthly (white and coloured), which are purchased from resellers. According to the carpenters, the MDF is responsible for approximately 42% of the furniture manufacturing costs. This data demonstrates the importance of MDF in economic spending and reinforce the need for optimisation and better use of MDF sheets even for the financial health of the companies.

The diagnosis phase allowed us to already identify several common causes for MDF waste:

a) Pre-production: All the companies work with approximately five different MDF brands. The wide colours and brands variety has increased losses, reduced the possibilities of reuse, and contributed to the generation of a large volume of waste.

b) Production: lack of concentration of employees due to the use of the cell phone while working; lack of employees' commitment; absence of verification protocols (of material, tools and procedures) for assembling the product. It was also verified that all the owners of the studied companies accumulate a significant amount of activities (elaboration of the budget, negotiation with clients, surveying of measures, the realisation of production order, production of furniture and, when necessary, administrative activities). The accumulation of functions also contributes in part to reworking caused by measurement error and communication problems between management and production. 80% of the furniture companies have a production process per project, being each joiner responsible for the complete execution of the furniture. The practice of production by the project is causing a lot of waste due to the lack of planning, especially during the cutting stage of the sheets. In 100% of cases, MSEs cut the material without performing at least surface calculations or analyse the best way to make good use of the sheet. Only one of the companies uses software for sheet optimisation. Although employees are systematically advised to reuse MDF scraps to produce smaller items (drawers, shoe racks, slats, etc.), MDF leftovers accumulate very quickly. Due to overlapping MDF scraps, disorganisation, dust accumulation, and lack of inventory control, the workers prefer to use new sheets, even to make smaller objects. In all studied companies there are no spaces or shelves organised to receive leftovers. The most common practice consists of stacking pieces that are pressed against the walls of carpentry (taller pieces are placed on the bottom and lower ones on the front). However, the arrangement of pieces without any classification by size, thickness, or colour makes it difficult and doesn't encourage reuse, since it prevents the quick identification of the desired piece. Added to this the leftovers accumulate a large amount of dust.

c) Distribution: The transportation of goods, in 80% of cases, is carried out by own truck. The finished products are packed with blankets, cardboard and/or bubble wrap. With the exception of the blankets, the other packaging materials are usually used once or twice and then are sent to the municipal landfill. These packages do not always protect furniture sufficiently during transport, causing havoc and rework. In addition, recyclable packaging is usually mixed with other non-recyclable ones (such as MDF), making it impossible to dispose correctly the final product.

d) Use: The companies do not offer guidance to the users on the correct ways of maintenance and cleaning of the furniture. This is done verbally, and only when asked by users. In addition, the studied companies do not offer maintenance or repair services for furniture. This type of service is only provided, in special cases, to established clients. It is concluded that the lack of information on the correct maintenance of furniture and the lack of repair services can lead to a reduced shelf life.

e) Disposal and/or recycling: Among the fifteen studied companies, four joineries carry out the final destination of the waste in the municipal landfill. The other companies dispose their waste irregularly. These practices cause public health risks arising from the toxicity of urea-formaldehyde or phenol-formaldehyde additives used in the production of reconstituted wooden boards, these substances are on the list of carcinogens issued by the International Agency for Research on Cancer (IARC). The companies don't carry out the separation of residues (MDF, plastic, cardboard, screws, etc.). There is also no suitable place to receive recyclable materials in the municipal landfill for recycling. Therefore, in general, companies have been using this fact to justify the lack of separation of furniture residues.

8 CONCLUSIONS

After the diagnosis phase of the CACO project, and to encourage the non-generation, reduction and reuse of waste, some preliminary strategies have already been proposed to the joineries' owners, a set of measures of sustainable strategic design in the furniture MSEs of the region, encouraging the change of culture with the objective of reducing the consumption of resources and to minimise the waste: i) in partnership with designers from the region, to develop annual catalogues of colour trends and MDF standards, with the objective to reduce significantly the number of colours recommended by the woodworking shops to users and, consequently, increasing the possibilities of reuse of raw materials; ii) to improve the layout of the company and the organisation of workbenches in order to reduce production time, increase worker concentration, and reduce material losses caused by errors; iii) to create a checklist for measures

surveying in order to minimise errors that occur during the measurement conference; *iv*) to designate a single employee to perform the sheet cutting, facilitating the flow optimisation and control of new and/or reusable raw materials; *v*) to provide training on cutting planning to optimise the use of MDF panels, or even using software to reduce losses and waste; *vi*) to encourage the use of software which enables wood panel planning and optimisation of cut-outs, reducing waste and the cost of purchase of equipment and material; *vii*) to carry out the planning of cutting of the furniture from a modular approach (when possible) aiming a greater use of the sheet; *viii*) to create a suitable shelf for facilitating reuses with stock organisation and classification of the MDF pieces according to the dimensions and colour of the pieces of panels; *ix*) to replace disposable packaging, used during transport, with reusable packaging; *x*) to create a checklist of delivery and assembly of the furniture in order to avoid errors and rework, reducing unnecessary travel, fuel consumption, CO₂ emission and delays in delivery; *xi*) to create an instruction manual with the purpose of informing users about the correct maintenance of the furniture (optimising life span); *xii*) to indicate the collection system (environmentally correct final disposal), reuse and/or recycling (donation and/or renovation) of the furniture after use; *xiii*) to guide companies on disposal methods for environmentally sound waste; *xiv*) to provide repair services; *xv*) to promote the recycling of materials such as plastic, cardboard, aluminium and others; *xvi*) to create a communication platform for buying, selling and exchanging material between manufacturers.

The platform will be developed and made available to MSEs in order to sell debris material with potential for reuse, for example, medium or large indentations reconstituted wood plates. This communication channel intends to confirm the reduction of waste, encouraging the separation and proper storage of materials, while demonstrating the value of products that are commonly disposed of by such factors as reduced demand for very specific colour panels, and improper storage. The entrepreneurs are motivated to implement the strategies proposed by CACO Project in the joineries because we could prove them that they are losing a lot of money (at least 1/3 of the profit) without the implementation of basic measures. The insertion of a set of ecodesign strategies in the MSEs can promote greater competitiveness for companies generating new business opportunities, creating more favourable conditions of competition among companies of the sector, improving their income while simultaneously promoting commitment and the sharing of responsibility (social, environmental, cultural) by all stakeholders.

There is still a long way to accomplish the objectives of this research project, but we already see some benefits in the process used by the joineries in Uberlândia, due to the direct involvement of all the stakeholders in the project, mainly joineries' owners and workers and the unions, the incorporation of our guidelines and the awareness that we can only achieve sustainable processes using a "simple language" that all can understand.

1245 PORTRAYAL OF CLIMATE CHANGE NEWS IN THE NEWSPAPERS OF BANGLADESH

ABSTRACT

Climate change has emerged as a new threat to the existence of the mankind and Bangladesh is recognized worldwide as one of the most vulnerable countries to the impacts of global warming and climate change due to its' unique geographical location, dominance of floodplains, low elevation from the sea, high population density, high levels of poverty, and overwhelming dependency on nature, its' resources and services. Bangladesh is already recognized as one of the most vulnerable and disaster-prone countries of the world due to climate change. Floods, droughts and tropical cyclones are common phenomenon. Temperature rise due to climate change hampers the production of food grains, and also exacerbates saline intrusion, which in turn will threaten human health by increasing the risk of vector-borne infection. Where communities are often threatened by different problems, it is necessary to take some steps to limit the adverse impact of climate change. Along with steps taken by government and non-government organizations, mass media as agenda setter can play a prominent role in building awareness about all types of hazards, disasters and risks caused by climate change. While a number of initiatives have been taken by the government and non-government organizations, ways to fight against the hazards of nature and disasters caused by climate change should also be addressed. Mass media can be used to disseminate appropriate messages to the target groups in this regard since they are perceived as gatekeepers of information and their prominent role in building awareness about different issues including environment, health, climate change etc. is well established. Considering the influence that mass media can exert in building awareness on climate change, the present study is an attempt to explore the portrayal of climate change news in the newspapers of Bangladesh. Alongside, the study seeks to answer how and in what capacity newspapers cover climate change news, how much importance climate change news get, the treatment of news, their sources and styles, as well as the issues covered. Content analysis in the form of both qualitative and quantitative has been used in the present study to examine the portrayal of climate change news in the mainstream newspapers of Bangladesh. The findings of the study reveal that although newspapers are paying attention to cover different aspects of climate change, however, most of the news still do not get appropriate treatment. Most of the published news are straight jacket in nature without having details elaboration of the facts. Although a few interpretative reports are published in the newspapers of Bangladesh but the number is scanty. The study therefore, suggests to publish more interpretative and investigative news so that people become aware of the issue and can take appropriate actions to limit the damage caused by climate change.

1272 SOCIAL WORKERS' ROLES IN CLIMATE CHANGE ADAPTATION - A CASE STUDY OF ADAPTATION TO "EXTREME HEAVY SNOWFALL" IN JAPANESE SOCIETY

Satoru Ono¹, Hiroari Shimizu¹, Michinori Kimura²

1 Ritsumeikan Univ. (contact us: sono.psrits@gmail.com)

2Lake Biwa Environmental Research Institute

ABSTRACT

This study contributes to build sustainable society adapting to global climate change. Japanese society is exposed to various kinds of disaster risk caused by extreme climate, landslide, earthquake, volcano activity, and so on. In addition, it is said that disaster risk of "extreme heavy snowfall" will be remaining even if the amount of snowfall in the year decrease by global warming. Japanese society, especially in heavy snowfall area, had adapted to snowfall to maintain their social and economic activities, and to sustain their own well-being. However, Japanese society also confront the problems which derive from aging society and population declining. Adaptation system to heavy snowfall should also be established strategically to correspond to aging society.

This work focuses on social workers' role in adaptation to heavy snowfall in Japanese society. The existing researches are saying that there are three discussion focuses for snowfall adaptation- planning of snow shoveling, keeping social work, and human resource development. About the viewpoint of social work, health condition check for the high medical independents is essential mission even if it is in heavy snowfall, but snow cover is preventing social workers from conducting it. This implies the importance of collaboration system among social workers, community leaders, and the local government in extreme snowfall condition.

The authors conducted interview surveys and questionnaire surveys in Takashima city, one of the extreme snowfall area in Japan, to clarify the collaboration system especially network for social work operation. The interview surveys were conducted to the public health nurses in the local government and some welfare commissioners in the local communities authorized by the local government. Next, the questionnaire survey was held to all welfare commissioners in Takashima city to ask their reaction to extreme heavy snowfall in January 2017, collaboration among the stakeholders in previous snowfall, and their problem consciousness to social workers system in snowfall condition.

From the interview surveys, the public health nurses have the problem consciousness of health check process. They have the enormous data about the health, mental, and social condition of high medical dependents, and they make the decision of health check process in heavy snow condition. They make "triage" about emergency degree and decide whether a certain citizen is needed to patrol or it is sufficient to call telephone only. However, if a high medical dependent cannot be assisted by his/her family, social worker should patrol for him/her even if the emergency degree of health check is not high. They pointed the importance family level or community level collaboration about social work.

Through the interviews and questionnaires, the lack of community collaboration has been pointed but the authors also found the limitation of community collaboration in social worker in the current system.

Keywords: Climate Change, Adaptation, Social Worker, Snowfall, Community Welfare Commissioner

INTRODUCTION: ADAPTATION TO CLIMATE CHANGE IN JAPANESE SNOWFALL DISTRICT'S CONTEXT

Climate change adaptation has been essential problem not only in national decision-making level but also community level. Rain, droughts, and heat are especially well-known disaster caused by climate change and the governments have been investing to safety against these threats. However, the problem caused by snowfall disaster is remaining and haven't been regarded as the essential disaster sufficiently. Kawase et al. (2016) is pointing that the amount of snowfall will decrease in these decades, but the risk of heavy snowfall will be remaining.

On the other hand, a major part of Japanese snowfall district is encountering the needs to adapt to future population declining and aging society problem. It means adaptation to snowfall disaster should be planned as the comprehensive program based on the future prediction of population, human resource, and collaboration system. There are the existing researches about snowfall as the risk factor of social/economical activities (for example Kamimura, 2003; Numano, 2013) and about decision making method for climate change adaptation in municipal/community level (for example Baba et al., 2011; Ichihashi et al., 2015), however the existing research of snowfall adaptation seem to be insufficient.

The authors' research group have conducted the fieldwork in Japanese mountainous area in Takashima city and described stakeholders network for snowfall adaptation (Ono et al., 2017). In the previous research, the social workers' activities were observed especially in health issues in snowfall situation. Considering the future prediction that aging society is proceeding in alarming rate and social workers will decrease due to population declining, the collaboration system for health issue in snowfall situation should be reconsidered based on current situation understanding.

This research especially focuses on the Community Welfare Commissioners (CWC), who are elected from the community members recommended by the mayor based on the law, and who work for the citizens' health and welfare especially handicapped people and elderly. CWC system have 70 years history in Japan, but there are some problems pointed out, therefore the discussion of the CWCs' role is important to develop the collaboration system for climate change adaptation.

This research includes mainly three sections. The first is structuralization of snowfall problem in Japanese mountainous area and the questionnaire survey will be designed building the research questions (Chapter 1). Next, the result of the survey will be summarized focusing on information gathering activity (Chapter 2). After that, the trend of the relationship between attribution and information gathering activities through logit model regression analysis (Chapter 3).

1 PROBLEM STRUCTURALIZATION OF SNOWFALL AND CWC'S ROLES IN DISASTER

1.1 Problem Formulation from the Existing Research

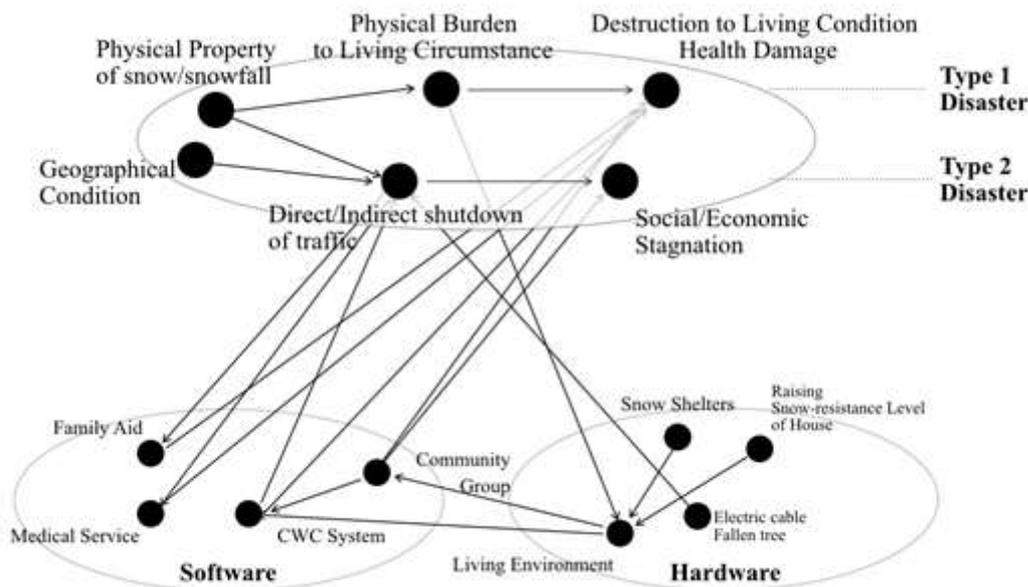

Fig. 1 Hypothetical Problem Structure of Snowfall Disasters

A lot of literatures have attempted quantitative research of snowfall risks, but there is few research to formulate snowfall problem in rural area. Kuriyama (1982) attempted description the overall picture of snowfall disaster's problem structure. Kuriyama's work classified snowfall disaster into two types from the physical property of snow/snowfall. The first is destruction to living condition and human health damage which derive from snow's high weight and low temperature. High weight of snow often causes not only house collapse but also stagnation of snow removal, that avoid the elderly persons daily activity and communication. The second is social/economic stagnation which derive traffic risk, stagnation and accident. Traffic stagnation avoids resource distribution and human traffic which causes restraint of daily activity, commutation, and medical care. In addition, Kuriyama's work seemed not to be careful to it, snowfall disaster's impact in local community include less deviation because snow falls equally in local area and stagnate in a long/short time on the landing place. It can cause community collaboration difficulty that the community members, even if they are sufficiently young and healthy, should spare their time for keeping safety around their/their families' living place and the time for mutual aid in snowfall situation will be limited. Snow's physical property directly/indirectly affects to human and social activities.

On the other hand, snow disaster's risk factor is living not only physical property of snow/snowfall but also geographical condition, hardware and software. It means it should seriously affect to human health and safety from snowfall; whether there are efficient system to collaborate for snow removal, health care watching, and snow discharging or not; whether there is sufficient snow shelter, highly snow-resistant house, and melting system or not, and whether there is efficient management system of voluntary human resource. (The detailed discussion of snowfall disaster formulation will be held in Ono, et al. (2018).)

1.2 Hypothesis and Research Questions of CWCs' Activities

Fig. 1 shows the hypothetical model of causal relationship among snowfall disasters' risk factors and CWC's activities according to the existing researches and preliminary investigations. CWCs are responsible to keep the community members health and safety, therefore they communicate thickly with the elderly, the highly medical dependents, and the handicapped people in their communities (called "Jichi-kai", "Chonai-kai", or "Ku"). Through the daily communication to them, and sometimes to the government officers, the other social workers, they accumulate the information to their usable media (brain, memorandum, or offline PC). In the emergent case, for example snowfall situation, they should conduct additional information gathering about the situation-specific issues about families' support, medical condition, and so on. However, the existing research described that there are difficulties for information gathering which derive from "relationship of mutual trust" and "privacy". Matsuzaki (2014) observed the CWCs activities in a city and explained of the activity difficulty that some community members deny to give information even if CWCs are living in the community for a long time because of their pride, anxiety, privacy. Clarification of information gathering difficulty should be essential survey theme to gain the knowledge to develop the adaptation system in Japanese rural communities. It indicates the CWC's experience and contribution in the community affect to the degree of information gathering.

Table 1 The Contents of Questionnaire Survey

Question	Format

History as a CWC (n = 151)	
1st period	75
2nd period	44
3rd period	17
4+th period	15

According to Fig. 1, this study classified the information gathered by CWCs into four types: 1) Health condition, this is about whether there are any negative health impact of the elderly and so on caused by snow's physical properties; 2) Living Condition, this is about whether there are any destruction or anxieties in the living environment; 3) Medical Condition, this is about whether there is sufficient medical service or medical advisory opportunities especially about dialysis; and 4) Families' assistance, it is about whether there is sufficient aids by families to keep health and safety. In this paper, the result of case study based on questionnaire survey about current situation of information gathering by CWCs in snowfall situation will be expressed, and the difficulty structure of CWCs activities will be discussed based on the explanatory analysis of causal relationship between the attribution (community experience and contribution) and information gathering (necessity and achievement).

1.3 Research Method: Questionnaire Survey in Takashima city, Shiga, Japan

Table 1 is displaying the questionnaire contents distributed to the all CWCs in Takashima city. In Chapter 3, this paper attempts regression analysis between attribution and information gathering. Then, because the respondents answered the necessity and achievement of information gathering by 0-1 pre-coded numbers, logit model will be applied in regression analysis.

The questionnaire sheets were distributed through the all-members conference (2017/12/7~12/28) and n = 153 sheets/163 have been received (efficiency rate: 93.9%). Takashima city experienced extremely heavy snowfall January 2017, and all respondents encountered this snowfall as the CWCs.

2. RESULT OF SURVEY: CURRENT SITUATION OF CWCS AND INFORMATION GATHERING

2.1 Attribution

Table 2 summarize the result of survey about the respondents' attribution. According to it, the 60+% of respondents are male people and this ratio have statistically significant difference with population ratio in Takashima city (by chi-squared test, $p < .05$). Next, the obvious tendency can be observed in "Age". The arithmetic mean is 66.9 years old and standard deviation is 4.94. There are 6 main districts in Takashima city, and significant bias of the number of respondents have not be observed. The question about occupation is asked with the respect to the job location, and the approximately same number of respondents answered, "work for something" or "unemployed". As the job location, 80% of employee or employer respondents answered Takashima city. After that, about history as a CWC, the half number of respondents answered that they were 1st period as CWCs. It means 50% of respondents encountered heavy snowfall situation in January 2017 after only a month preparation.

2.2 Information Gathering

In addition, the result about information gathering activities in snowfall situation in 2017 January have been described in Table 3. This displays that the 60-70% of respondents recognized the needs of the four types of information in the past snowfall situation. On the other hand, about 70-80% of them are not considering the information gathering activities as high standard. Especially, 80+% respondents are considering that they couldn't gather the medial condition information of the elderly and highly medical dependents. It means the greater number of CWCs encountered difficulty to access the kinds of information in snowfall situation.

Table 3 Survey Result (Information Gathering)

Question	Frequency of Yes
Recognition of Information Needs	
Health Condition ($n = 145$)	105
Living Condition ($n = 144$)	96
Medical Condition ($n = 143$)	87
Families' Assistance ($n = 142$)	89
Achievement Evaluation of Information Gathering	
Health Condition ($n = 105$)	37
Living Condition ($n = 96$)	29
Medical Condition ($n = 87$)	16
Families' Assistance ($n = 89$)	23

3. LOGIT MODEL REGRESSION: RELATIONSHIP BETWEEN INFORMATION GATHERING AND ATTRIBUTE ITEMS

3.1 Method

As explained in Chapter 1, logit model is applied to analyze the relationship among attribute items and information gathering. The variables were coded as below:

- 1) Response variables (necessity and achievement of information gathering) were defined 0 (No) and 1 (Yes).
- 2) Explanatory variables (all attribute items) were set 0 (Not applicable) and 1 (Applicable) converting into category variables.

Regression analysis was conducted by R, statistical analysis application, and the explanatory variables were selected to optimize (minimize) AIC, Akaike's Information Criteria.

3.2 Result and Discussion

The result of regression analysis has been described in Table 4. There are two major trends in needs recognition of information. The first is the difference of information needs between the generations. The regression result says that respondents between 70 and 75 tend to recognize more needs of living information than the other generations, but the generation are less interested in the medical information than 50-60 and 75-80. It indicates the generation gap of problem understanding of snowfall as CWCs.

The second trend of information needs recognition is the difference caused by participation to the community. According to Table 4, the information needs about living, medical, and family assistance condition is negatively affected by "House husband/wife", and "NPO activity". On the other hand, they are also positively affected by "Community Salon". It would mean that the respondents who continuously participate the social activity can gather the information the living information and medical information through their activities. However, community salon activity managers tend to answer weakly positive recognition to health and family assistance condition. It will indicate that the daily activity in the

community give the information to CWCs. In addition, the CWCs who participate community salon activities are motivated by the activity to gather the information to health and family assistance condition.

Table 4 also shows the result of regression analysis of achievement evaluation and two major trends can be observed about this topic. The first trend is, it is also observed in information needs, about the generation gap. As explained in the previous chapter, the trend of achievement evaluation is totally negative. However, the result indicates the younger generation tend to recognize higher evaluation of living and family assistance information. It means that the patrol activity in snowfall situation would take the great part of information gathering. The patrol activity need the great energy because there is uncertainty whether they can use the automobile, and if not, whether they can walk safely to the destination.

The second is the district gaps of information sharing system. The districts A, B, and C are not designated as “Heavy Snow District” by the law, and they are regarded as the area where there is not heavy snow. Then, the statistically significant negative coefficients have been detected about family assistance information. It means there is the information sharing system gap between the snowfall area(DEF) and ABC.

Table 4 Result of Logit Model Regression

CONCLUSION AND FUTURE RESEARCH

Through the summary of the survey and logit model regression, the trend of information gathering has been extracted. This is the exploratory analysis about the relationship between attribution of CWCs and information gathering behavior. For the future research, the understanding of causal relationship among the information gathering behavior and the explanatory factors including attribution is essential. Especially, from this research, identification of the CWCs’ information source to decide their behavior is the interesting future research question.

ACKNOWLEDGEMENTS

We couldn’t proceed this research without the all CWCs in Takashima city and the government officers who are responsible to CWC system management. We are grateful to their all cooperation. This work was supported by JSPS KAKENHI Grant Number 17K00707.

1293 MAHATMA GANDHI'S RELEVANCE IN CONTEMPORARY ENVIRONMENTAL ISSUES

Susmita Mukherjee

Department of History, Syamaprasad College, Kolkata. susmitamuk@gmail.com

The concept of environmentalism emerged after industrialisation. Before industrialisation there existed elements on environmental sensibility. While some tribes pursued a species to extinction other tribe prudently preserved it. There were peasants who haphazardly tilled the lands and others who carefully designed new systems of water and soil management. Classical literature of both the East and the West reflect a love for nature. These may constitute pre-history of environmentalism but not environmentalism. The peasant or the poet never crossed the threshold of their locality or offered an alternative view of reorganising nature. "That needed the Industrial Revolution, widespread industrial degradation and the response we term "environmentalism".¹²⁴ The first historian to speak about this connection was the Cambridge scholar G.M. Trevelyan in a lecture in 1931.

Industrial Revolution never took place in India as it did in the West. However, the British government in order to maintain its superiority over the colonized nation introduced certain economical and technological advancement. Industrialization, pursued in India, however limited, by the British was not palatable to Mahatma Gandhi. Gandhi was not an environmentalist in the modern sense yet he is often described as the 'apostle of applied human ecology.'¹²⁵ Environmental concerns were minimal in his time yet Gandhi evolved his own views of environmentalism.

GANDHI CRITIQUING MODERN CIVILIZATION WITHIN THE DISCOURSE OF NATIONALISM

On his return from South America where he spent 21 years as a lawyer and political campaigner, Gandhi began to acquaint himself with the economic and social condition of rural India. He travelled extensively in the Indian countryside and also during organising the peasant movements in Champaran and Kheda in the second decade of twentieth century he felt the pulse of the country. He realised that colonialism represented a system of economic and political exploitation. In order to combat that, he realised that the method of Satyagraha and non violence that he had evolved and adopted in South Africa was India's best hope. From the deeper understanding of colonialism Gandhi had the realization that it was not possible for India to imitate western patterns of industrial development. Perhaps he also felt that by talking about development of rural India he could foster unity among the Indians and prepare them to fight British colonialism. Gandhi himself renounced western dress and western mode of living and began to dress and live like an ordinary Indian villager. He identified himself with the poor Indian. Systematic denouncement of western civilization was also a technique to criticise the British imperialism. Gandhi writes in Young India, "God forbid that India should take to industrialization after the manner of the West. The economic imperialism of a single tiny island kingdom (England) is today keeping the world in chains. If an entire nation of 300 millions took to similar economic exploitation, it would strip the world bare like locusts."¹²⁶ India would never follow such a sinful path.

Food and clothing are the bare necessities of human existence. Under the British colonial rule the impoverished villagers were in need of these two things. Gandhi intelligently picks up these issues. In an interview with Charlie Chaplin in London, Gandhi said that every nation should be self contained. India was once self contained and he wanted that to happen again. He said England with her large scale production had to look for a market elsewhere. England was exploiting India. According to Gandhi, "An exploiting England is a danger to the world, but if that is so, how much more so would be an exploiting India, if she took to machinery and produced cloth many times in excess of its requirements."¹²⁷ He categorically stated that for food and clothing he would be dead against industrialisation.¹²⁸ In an interview in London Gandhi said, "These nations (Europe and America) are able to exploit the so called weaker or unorganised races of the world. Once these races get elementary knowledge and decide they are not going to be exploited they will simply be satisfied with what they can provide themselves. Mass production then at least, where the vital necessities are concerned will disappear"¹²⁹ Gandhi felt that if production became localised then the temptation to speed up production indefinitely and at any price disappeared.¹³⁰

Gandhi's writings are replete with this kind of attack on western nation specially England. In the same interview with Charlie Chaplin in London Gandhi emphasised the fact that machinery in the past had made the Indians dependent on England and the only way we could rid ourselves of the dependence was to boycott all goods made by machinery. "That is why we made it the patriotic duty of every Indian to spin our own cloth. This is our form of attacking a very powerful nation like England...."¹³¹

It is a well known concept that Gandhi was a harsh critique of modern civilization and gave an alternative solution to it i.e., rural development. I would argue that Gandhi's concept of environmentalism was an offshoot of his attack on British

colonialism or imperialism in general within the broader framework of Indian nationalism. His criticisms of the selfishness and competitiveness of the modern society had ecological undertones. Gandhi was not perhaps consciously propagating environmental protection though we cannot deny that Gandhian philosophy had deep interrelation between man, nature and environment.

Gandhi realised that in order to fight colonial imperialism it was important to revitalise Indian villages as self reliant units. He himself began to dress and live like an ordinary villager. Being a prolific writer he began to portray idealised and romanticised Indian village where the poor villagers would not be exploited and would have a supplementary industry along with agriculture. Spinning wheel and handloom were his answer. He wanted concentration of wealth not in the hands of few but in the hands of all. "I hate privilege and monopoly. Whatever cannot be shared with masses is taboo to me."¹³²

PATRONISING RURAL DEVELOPEMNT

In *Hind Swaraj* Gandhi perceived modern civilization as a curse that destabilised man's oneness with nature and environment and also undermined stable and long established communities. This modern civilization, according to Gandhi, was fundamentally flawed and it was aggressive, violent, exploitative, imperialist, brutal, unhappy, restless and devoid of sense of direction and purpose Gandhi believed that for this simple reason our ancestors dissuaded us from luxuries and pleasures. India had had its thousand year old plough, mud cottages and indigenous education bereft of any life corroding competition. It was not that Indians did not know how to invent machineries but our forefathers realised that they concentrated on that then they would slaves and lose their moral fibre. To our forefathers cities were a snare and a useless encumbrance where people were never happy because there would be gangs of thieves and robbers and prostitution.¹³³ He was perhaps trying to uphold the fact that village was the real place for the Indians from where they could fight an uneven battle with British imperialism. In this fight self discipline and moral regulation of desire that formed the very essence of human dignity was extremely important¹³⁴ which modern civilisation denied. Modern civilization gave utmost importance to consumption and accumulation of wealth in the possession of a handful of capitalists. This minuscule group propagated nothing but a craving for wealth and a hunger for worldly pursuits.¹³⁵

Gandhi took up village reconstruction programme as a "concrete expression" of truth and non-violence.¹³⁶ What was his concept of village? In 1937 when he moved to Wardha to devote himself to rural reconstruction he defined his ideal village, "It will have cottages with sufficient light and ventilation, built of a material obtainable within a radius of five miles of it. The cottages will have courtyards enabling householders to plant vegetables for domestic use and use of their cattle. The village lanes and streets will be free of all avoidable dust. It will have wells according to its needs and accessible to all. It will have houses of worship for all, also a common meeting place, a village common for grazing its cattle, a co operative diary, primary and secondary schools in which industrial [i.e., vocational] education will be the centre fact, and that it will have panchayat for settling disputes. It will produce its own grains vegetables and fruit, and its own khadi. This is roughly my idea of a model village"¹³⁷

In this self reliant villages as envisaged by him, Gandhi wanted the villagers to stand erect and not be tempted by the allurements of machine age; rather he wanted them to make their body machines perfect and efficient of work and to get the best out of it. He wanted dues for every Indian villager so that they could sustain themselves. The development of village industries was intended to help the poor in the villages, guarantee them gainful work and arrest migration to the cities. In this context spinning wheel becomes very important for Gandhi. Gandhi was almost obsessed with spinning wheel. Spinning Khadi was seen as a supplementary means of income for the villagers in addition to cultivation. He did not want the villagers to be idle and go hungry when there was no agricultural season. Very consciously, I would argue, he wanted to bridge the gap between the urban and rural life.

Gandhi was not against modern technology as propagated by many. He wanted decentralization of political and economic so that villagers could have control over their own affairs. He said that if the country could have electricity in every village home, he would not mind plying their implements and tools with the help of electricity. In that case he suggested that village communities or state would have own power houses just as they have grazing pastures.¹³⁸ Machinery could only be used for philanthropic needs. He says that if America would share the technology of bridge building and built bridges in India free of cost he would willingly accept. But he knew that when machinery would be used for mass production then distribution would be localised in urban areas denying the villagers a right to it.

To Gandhi law of human being was not killing competition but life giving cooperation. To put up a resistance to British colonialism it was not the good of the few, not even the good of the many but the good of all was required. Without including the rural population the national movement against the British would fall flat

RELEVANCE OF GANDHI IN THE LATER NON VIOLENT MOVEMENTS IN NDIA: CHIPKOO MOVEMENT.

Mahatma had considerable influence on the contemporary environmental movements in India. From Chipkoo to Save the Narmada of the present time, environmental activists have heavily relied upon the Gandhian values of ecological

138 Ibid

prudence and frugality and followed the Gandhian model of decentralized democracy and village *Swaraj*. Some of the important figures of these movements like Sunderlal Bahuguna or Baba Amte or Medha Patkar have repetitively underlined their own debt to Gandhi.

The Chipkoo movement was started by the local villagers for safeguarding their own local ethnic and marginal identity that faced extinction along with forest, river and mother earth that sustained them. The movement proved the M.I.T economist Lester Thurow wrong who had said in as late as 1980 that poor countries and poor individuals were simply not interested in environmentalism. It was only the rich who were interested in environmentalism. Inspired by Gandhian ideals Sunderlal Bahuguna and Chandi Prasad Bhatt played a very vital role by involving the poor people into the domain of environmentalism.¹³⁹ Chandi Prasad Bhatt claimed that the movement was not against science or technology but against the misuse of science where nature used for accruing profit only. The Chipkoo Movement is an ecological movement, concerned with the preservation of forests and thereby with the maintenance of the traditional ecological balance in the sub-Himalayan region, where hill people have traditionally enjoyed a positive relationship with their environment.

On 3rd March 1973, in a remote Himalayan village named Mandal, high in the upper Gangetic valley group of peasants prevented a group of loggers from felling a strand of hornbeam trees. The trees were on a ground owned by State Forest Department. Previously the peasants were not allowed to have access to these trees which they sought to use in order to make farm implements. But the peasants were outraged when they found that a company in distant Allahabad had got a contract from the government to use the same trees for making badminton racquets. The villagers protested against this unfairness by threatening to hug the trees. As Ram Chandra Guha says, "Behind their action lay the claims of justice and tradition, the legitimate subsistence requirements of local villages against commercial outsiders."¹⁴⁰ The Mandal episode led to a series of protests throughout the 1970's where the local people prevented the felling of trees. It is collectively called the Chipkoo movement. The Chipkoo movement marked the beginning of environmental protest by the local people. The movement was totally endogenous movement and was based on non violent techniques which 'recalled freedom and Mahatma Gandhi'.¹⁴¹ Vandana Shiva makes a categorical statement that Chipkoo movement which took place in the post independence India "is historically, philosophically and organisationally an extension of traditional Gandhian Satyagraha."¹⁴² Bahuguna thought of Chipkoo movement as a humble effort to materialise the messages of Indian culture as revived by Gandhi. The tactics involved in the movement were non violent strategies like Satyagraha, fasts, rallies of protest and persuasion. Bahuguna organised several Chipkoo protests and gave wider publicity to Chipkoo cause by his foot marches, fasts, writings and lecture tours. He used popular idioms and Gandhian aphorisms in all his narratives and public meeting.

Ram Chandra Guha makes an interesting comparison between the two Chipkoo leaders Sunderlal Bahuguna and Chandi Prasad Bhatt. While Bahuguna passionately followed the Gandhi of the Hind Swaraj with his uncompromising denunciation of industrial society, Bhatt and his group worked to convey a new ecological meaning to Gandhi's ideal of gram swaraj, or village self reliance.¹⁴³ Bahuguna works in a 'prophetic mode' with his wide teaching tours, whereas Bhatt gives importance to localized reconstruction efforts and appropriate technology.

The movement's major success came in 1980, when an appeal from Bahuguna to Indian Prime Minister Indira Gandhi resulted in a 15-year ban on commercial felling in the Uttarakhand Himalayas. As the movement continued, protests became more project-oriented and expanded to include the entire ecology of the region, ultimately becoming the "Save Himalaya" movement. Between 1981 and 1983, Bahuguna marched 5,000 km (3,100 miles) across the Himalayas to bring the movement to prominence.

Chipkoo Movement came to be a signal victory for the environmental movements, providing new directions and impetus to people's movements and concerns. As a shining symbol of grassroots level activism, Chipkoo provides a blueprint for environmental movements. The leaders and the participants at the grassroots have set an example of nonviolent Gandhian resistance for indigenous and marginalized people across the world. The Chipkoo Movement has been instrumental in forming a new national forest policy which reflects more responsiveness to the needs of indigenous people and ecologically sensitive development.

ECO FEMINISM OF CHIPKOO MOVEMENT

Another very important feature of environmental movements in modern India has been the crucial role played by the women. Shiva paints the Chipkoo struggle as "explicitly an ecological and feminist movement".¹⁴⁴ Paul Routledge, however, views that even though most of the Chipkoo activists were women, they did not have a major share in the ideological leadership of the movement.¹⁴⁵ But the strongest local supporters of the movement were women. They took to streets to protest tree felling, irregular mining, and displacement and over fishing. Ram Chandra Guha has argued that women's' participation in the environmental movement may be explained by the fact that women and girls were more

involved acquiring fuel, fodder and water.¹⁴⁶ Women of all rural cultures were affected, specially the poor, marginal and small farming families. Women were more affected by paucity and shortage and hence more keen to combat and triumph over it. In this connection the role of Gauda Devi in the Chipkoo movement may be mentioned. She was the unsung heroine of Chipkoo movement.

Gandhiji's clarion call to the Indian women to take active participation in the nationalist movement had perhaps prepared the ground. According to Bahuguna, the establishment of ashrams by Gandhi's English disciples Mira Behn and Sarala Behn in the early 1950s paved the way for a new awakening among the women in the Himalayan districts. Mira Behn realized that the sporadic floods in the Indo-Gangetic plains were because of deforestation caused by replacement of oak forests with pine, a species which retains less water in the soil.¹⁴⁷ Sarala Behn trained women for social work and chose Vimla Behn who later married Bahuguna. Vimla And Sunderlal Bahuguna together continued the struggles in keeping with Gandhian ideology. In the 1960s Mira Behn and Sarala Behn established the Uttarakhand Sarvodya Mandal, which played a crucial role in organizing and empowering women to resist alcohol consumption by the adult male population¹⁴⁸. They also dealt with issues like protection of forest rights and establishment of local forest-based small industries. The women's prohibition movement, which turned successful, provided a legitimate platform for organizing women and thus it became a forerunner of the Chipkoo agitation in the 1970s.¹⁴⁹ The empowered rural women did not dither to fight non-violently for preserving their immediate environment for their survival

GANDHI AND SUSTAINABLE DEVELOPEMENT

Gandhi becomes very relevant today's world when the threat of climate change looms large and natural resources are fast depleting. Gandhi always spoke about sustainable use of resources and the least damage to the environment for the sake of future generation. He did not favour a divided world of *haves and have nots*.

But with full scale industrialisation we have a world with 6 billion people, where 1.1 billion have no access to drinking water, 2 billion have no electricity, 2.4 billion live without sound waste water disposal system. Today we realise the greater implication of Gandhi's ideology that 'there is enough in this world for everyone's need, but not for everyone's greed.'¹⁵⁰ Gandhi may be hailed as the first advocate of the doctrine of sustainable development. He said, "Nature produces enough for our wants and if everyone took enough for himself and nothing more there would no pauperism and consumerism"¹⁵¹ While advocating the thesis of sustainable development Gandhi raised the question that how much a person can consume and how much a person should consume when natural resources are limited. In Gandhian model a sustainable village

Today ironically the thesis of sustainable development is being debated globally. Today unbridled consumption and globalisation has led to the concentration of wealth in the hands of few. Jean-Pierre Lehmann has mentioned that in the early 21st century, some 20 percent of the world's population consumed 85 percent of the world's goods and services. It has also created a global elite who tend to be totally on the same page whether in Shanghai, Mumbai, Cape Town, São Paulo, Paris or Chicago, but are seen as distant and aloof by their own more local compatriots. John Kenneth Galbraith in his *The Affluent Society*, termed 1950's America, the affluent society "so dedicated to affluence that the possession and consumption of material goods was its exclusive standard of individual and collective achievement."¹⁵²

Galbraith quotes Anthropologist Geoffrey Gorcer's remarks that in modern America "any device or regulation which interfered, or can be conceived as interfering, with [the] supply of more and better things is resisted with unreasoning horror, as the religious resist blasphemy, or the warlike pacifism" While speaking to his fellow Americans that "we have not yet learned the difference between yield and loot."¹⁵³ Berkeley geographer Carl Sauer, shares Gandhian concern for an immoral and sinful development and what Gandhiji would condemn as the satanic mode of development, 'when happiness of the one is defined in terms of the suffering of the other'¹⁵⁴.

There has been a growing realization in national governments and multilateral institutions that it is impossible to separate economic development issues from environment issues; many forms of development erode the environmental resources upon which they must be based, and environmental degradation can undermine economic development. Public concern grew rapidly and forced a broad debate on environment conservation and economic growth. The possibility that the process of industrial growth would run into material resource constraints became an important theme in this debate. In the Report of World Commission on Environment and Development (1987) the concepts of sustainability and sustainable development was laid out. Sustainable Development was defined for the first time by Gro Harlem Bruntland the former Prime minister of Norway and the World Health Organisation for the first time. Bruntland defined Sustainable Development as, "Humanity has the ability to make development sustainable to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own

needs."Here we find an echo of Gandhian thought. Gandhi had always professed that a miniscule part of the world population amassed wealth by exploiting the natural resources of the world. According to Gandhi, it meant nothing but a hunger of greedy pursuit of worldly pleasure.

Today we are realising that uncontrolled exploitation of natural resources could spell disaster for the future generations. Gandhi becomes extremely relevant in this context in the world today.

1356 IMPACT OF CLIMATE CHANGE ON REGIONAL ECONOMIES UNDER RAPID POPULATION DECLINE THROUGH FLUCTUATIONS IN JAPAN'S RICE PRODUCTION: USING MULTI-REGIONAL CGE MODELS

ABSTRACT

Based on the assumption that only rice is affected by global warming under a depopulating society, this paper presented the impact of global warming on regional economies through spillover effects from other agricultural products and the industrial section having an input-output relationship with agriculture. As a result, our study found that global warming-induced climate change causes different impacts in each region and creates regional economic disparities. For example, global warming has a positive impact on regional economies in Hokkaido and Tohoku (in the case of minimum value). In addition to increasing rice production, gaps in rice prices in Kanto and the region west of Kanto will increase outflow, which in turn further increases such production. Meanwhile, global warming will reduce production in Kanto and the region west of Kanto, which will have a negative impact on regional economies. Moreover, other agricultural products will be negatively affected in all regions due to changes in rice production, and production in the food and beverage industries will be also negatively affected in Kanto and the region west of Kanto. However, when the impact of global warming becomes greater, production in the food and beverage industries will increase in Hokkaido.

RS03.2. Environmental Issues

1072 A PATHWAY TO DELIVER HEALTHY CITIES IN INDIA- A CASE OF UJJAIN CITY, MADHYA PRADESH, INDIA**N. R. Mandal, Kakoli Saha****ABSTRACT**

Indian cities are the growth engines of the Indian economy. Nearly 31% of India's current population lives in urban areas and contributes a major share of India's GDP. However, haphazard urbanization has caused severe deterioration of air and water quality of most of the major cities of India resulting to rises in vector borne, water borne and respiratory diseases. This paper aims to identify the nexus between disease occurrences and quality of built-environment in Indian cities. For the purpose of the study, Ujjain City of Madhya Pradesh has been considered as case study area. Since Ujjain is one of the identified cities for development as a Smart City under Smart City Mission launched by Government of India in 2015, substantial major urban investment in Ujjain City will happen through the Smart City Mission. Further the city will be ranked for city livability index, a first ever exercise in India. As a result, built environment interventions that promote health and well-being identified through this research may inform the development proposals under consideration.

For the study, first issues related to environment and sanitation were identified such as mode of transport used for daily commute, garbage disposal, frequency of pest control, problem of rain water drainage & water-logging, types of diseases, frequency of visits to nearest health facility etc. Information related to each such issue was collected through either primary or secondary sources and the data was transferred to GIS (Geographical Information System) platform. Disease occurrence was divided into four major categories such as water borne, vector borne, respiratory & lifestyle diseases and spatially represented through choropleth maps. In this research, built environment is represented through physical infrastructure which includes road and drainage network, garbage disposal infrastructure, open space, water bodies etc. Maps of physical infrastructure were prepared and nexus between disease occurrences and built-environment in Ujjain City was identified through overlay technique in GIS. The analysis would further help to identify built environment interventions that promote health and well-being and define a specific improvement framework to link performance determinants leading to 'healthy and sustainable communities' as inputs to physical planning and related land development processes.

Key words: Healthy city, Urban Planning, Ujjain, GIS

1. INTRODUCTION: INDIAN URBANIZATION AND POLICY

According to the 2011 Census, 31% of India's population lived in urban areas which is forecasted to increase to 40% by 2030. The Central Statistical Organisation (CSO) of India estimated in 2004-5 that 52% of GDP was produced by urban areas. MGI (McKinsey Global Institute) estimates that by 2030, urban India would produce more than 70 percent of Indian GDP (Sankhe 2010)¹⁵⁵. In the context of this kind of growing urbanization and growing economic contribution, urban areas in India have began to attract more attention while earlier, policy focus was on rural areas. Urban India should play a pivotal role in steering the transition towards a low-carbon society as well as in promoting and protecting health and well-being, but policies need to be in place to ensure that urban services function adequately, and the settlement built-environment provide an aspired quality of life. Indian urban planning faces multi-pronged challenges to deliver services and address the inadequacies of basic amenities. As a consequence, a revised policy was adopted in 2007 called the 'National Urban Housing and Habitat Policy'. The same is currently under consideration for revision. In 2011, a National mission on sustainable habitat was also launched.

2 URBAN DEVELOPMENT MISSIONS

As a national policy response, Jawaharlal Nehru National Urban Renewal Mission (JNNURM) was launched in 2005, the largest initiative since Independence to initiate urban governance reforms and fund infrastructure and service provision. Since 2014, a number of new schemes and missions have been launched to transform urban India, for example, SBM (Swachh Bharat Mission - Urban), AMRUT (Atal Mission for Rejuvenation and Urban Transformation), HRIDAY (Heritage City Development and Augmentation Yojana), HFA (Housing for All -Urban) and the Smart City Mission. While SBM focuses on urban sanitation, AMRUT lays focus on water supply, sewerage, and urban transport. The mission statement of AMRUT indicates the purpose to be threefold: (i) assure supply of water and sewerage connection; (ii) increase the amenity value by developing greenery and well maintained open spaces, and (iii) reduce pollution by switching to public transport or non-motorized movement (e.g. walking and cycling). Smart City Mission, presently targeting 98 cities, was launched in 2015 with an objective of providing core infrastructure and a decent quality of life to urban dwellers through a clean and sustainable environment. The Mission emphasized on comprehensive development of physical, institutional, social and economic infrastructure to improve the quality of life and attracting people and investments to the Cities, setting in motion a virtuous cycle of growth and development (Smart City Mission Statement & Guidelines 2015)¹⁵⁶.

3 LIVEABILITY STANDARDS IN INDIAN CITIES

In January 2018, it was announced that The Housing and Urban Affairs Ministry has decided to assess the liveability standard of 116 Indian cities, which include the identified Smart Cities and few more cities with a population of over 1

¹⁵⁵ Sankhe, S. et. al. (2010). India's urban awakening: Building inclusive cities, sustaining economic growth, McKinsey Global Institute

¹⁵⁶ Smart City: Mission Statement & Guidelines (2015). Ministry of Urban Development, Government of India

million. The concept of the 'liveability standard' is based on four main pillars of development: (i) institutional, (ii) social, (iii) economic and (iv) physical. These four pillars are subdivided into fifteen categories of indicators for preparing sub-indexes (Liveability Standards in Cities 2017)¹⁵⁷. These 15 categories are based on the features contained in the Smart City Proposals (SCPs). Of these fifteen categories, one each relate to Institutional and economic pillars, four of the categories relate to social pillar and the rest nine categories relate to physical pillar of development. A total of 79 Indicators (57 Core Indicators and 22 Supporting Indicators) for these 15 categories have been prescribed in the document for computation of the liveability index of cities. These indicators are also linked to eleven of the seventeen SDGs (Sustainable Development Goals) of UN; i.e., barring the goals numbered 2, 9, 10, 13, 14 and 15 which do not come under the purview of the Urban Development or Housing and Urban Affairs Ministry of India.

4 HEALTH AND WELL-BEING IN CONTEXT OF LIVEABILITY

Amongst the four pillars of development mentioned in the context of 'liveability standard' of cities, the social pillar includes a category of health with five indicators. Recently a National Health Policy (NHP 2017)¹⁵⁸ has been launched with the objective to achieve the highest possible level of good health and well-being, through a preventive and promotive health-care orientation in all developmental policies, and to achieve universal access to good quality health care services without anyone having to face financial hardship as a consequence.

This NHP focuses upon health service delivery, mainstreaming alternative healthcare practices but does not talk about physical planning and built-environment either in urban or rural context. However, research indicates a close link between majority of the categories included in 'physical pillar' of development [Liveability Standards] and 'health' which also is a category in 'social pillar' of development. The nine categories of indicators included in 'physical pillar' of development are for example, (i) Housing and Inclusiveness, (ii) Public Open Space, (iii) Mixed Land Use and Compactness, (iv) Power Supply, (v) Transportation and Mobility, (vi) Assured Water Supply, (vii) Waste Water Management, (viii) Solid Waste Management, (ix) Reduced Pollution.

While the Ministry of Housing and Urban Affairs will prepare city a liveability index considering, inter alia, health outcomes, related plan of actions for development will be implemented by Ministry [centrally] and Department [at state level] of Health and Family Welfare. These activities will happen in silos without adequate coordination amongst the concerned ministries or the departments.

Master plans or physical Development plans including its various statutory or non-statutory forms such as vision plans, perspective plans, sanitation plans, mobility plans are prepared under the aegis of Department of Urban development in each of the states which is also responsible implementation for all the central government missions and schemes mentioned earlier other than the NHM. These plans do not as a practice objectivise health outcomes presently. However, as existing research suggests, it is possible to identify built environment interventions that promote health and well-being and define a specific improvement framework to link performance determinants leading to 'healthy and sustainable communities' as inputs to physical planning and related land development processes.

To achieve this goal, it is imperative that nexus between key health indicators and built-environment parameters are established in the context of Indian cities.

5 BACKGROUND STUDY ON THE CONCEPT OF HEALTHY CITIES

The unprecedented growth of India's urban population exerts a great strain on an already overburdened infrastructure and for the purpose; schemes and missions are being implemented by successive governments. For the purpose of improving city-based public health and environmental hygiene, World Health Organization (WHO) evolved the concept of "Healthy Cities". The "Healthy Cities Project" was launched in Europe in 1986 and extended to India in 1990 (Goli et al., 2011)¹⁵⁹. Goli et al., (2011) identified and prioritized urban health and environmental challenges in eight selected cities in India. According to the healthy city strategy, the foundation and framework for focusing on public health in cities and towns is to overcome the environmental deterioration caused by rapid urbanization. From this perspective, it is understood that health in cities does not imply merely the absence of disease; it symbolizes harmony between humans and their environment (Goldstein, 1998¹⁶⁰; Goumans & Springett, 1997¹⁶¹; Harpham & Stephens, 1991¹⁶²). Researchers, for example, Agarwal et al., (2007), Chattopadhyay & Roy (2005), Swaminathan,(1995), Yesudian (1988) attempted to identify urban health and environmental problems unique to urban areas in India. Bardhan et al.(2015)¹⁶³ researched on the relationship between compact urban form and urban quality of life.

Till date, not much research has been done linking the concept of Healthy Cities and physical planning in India. Since substantial major urban investment in India will happen through the various missions and schemes mentioned earlier,

this research focuses on impact of built environment on public health to inform and influence objectives of future urban physical development planning in India.

6 STUDY AREA AND DATA USED:

Ujjain city of Madhya Pradesh (fig. 1) is selected as case study area because Ujjain is one of the identified cities for development as a Smart City under Smart City Mission launched by Government of India in 2015 and will be assessed and ranked in 2018 for City Liveability Index. For this study, data is collected through both primary and secondary sources. Primary sources include household level questionnaire survey. Secondary sources include census data, maps and information from various line departments and information provided by consultants engaged by the Ujjain Smart City Limited, an entity formed to help plan and roll out smart city proposals in Ujjain.

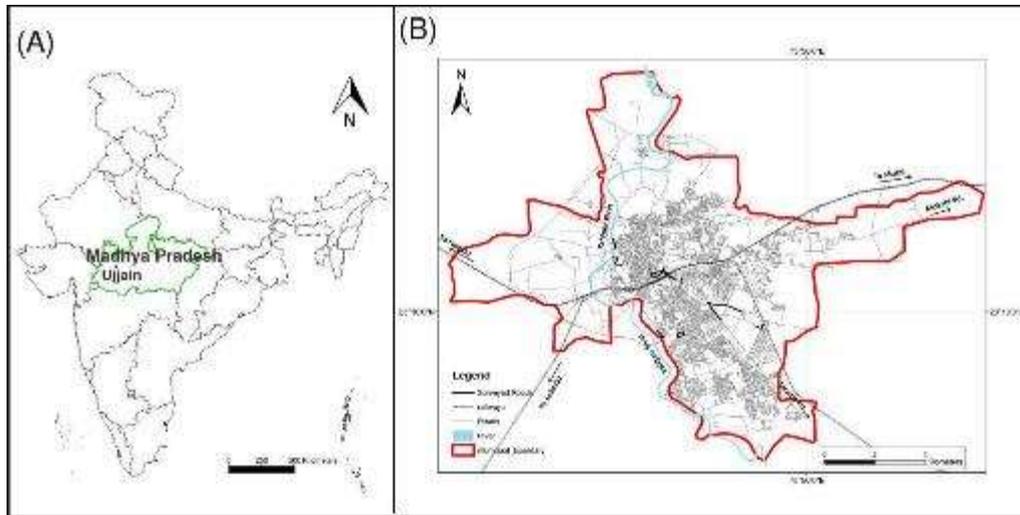

Figure 1: A. location of Ujjain city in India, B. Ujjain Municipal Boundary representing Ujjain city

7. METHODOLOGY

The Healthy Cities approach recognizes the determinants of health and the need to work in collaboration across public, private, voluntary and community sector organizations. This research has been carried out as a part of an academic exercise on preparation of physical Development Plan of Ujjain city in the third semester studio project of a PG programme (Master of Urban and Regional planning) at SPA Bhopal in 2017. The aspect of 'healthy city' is attempted to be linked as public health scenario (in terms of occurrence of diseases) with two aspects, e.g., infrastructure scenario and environmental scenario. The methodology for assessing urban health included three steps: (i) Preparation of detailed questionnaire, (ii) Conducting survey, and (iii) Spatial analysis in GIS platform.

(i) Preparation of detailed questionnaire

A detailed questionnaire was prepared to identify issues related to environment and sanitation. The questionnaire, inter alia, focused upon mode of transport used for daily commute, garbage disposal, frequency of pest control, problem of rain water drainage & water-logging, types of diseases, frequency of visits to the nearest health facility.

(ii) Survey

After preparing the questionnaire, a household survey has been conducted in a span of 10 days in August 2017 with a sample size of 550 households distributed in 54 wards of Ujjain city. Apart from answering questions, the respondents were also requested to indicate and rate health related issues resulting from physical environment in their respective wards. The issues that were frequently highlighted include un-cleaned Drains, mosquito breeding, water-logging, power supply issues, water supply service, stray animals and safety / street lighting scenario. In majority of wards, issues of un-cleaned drains, water supply service and water-logging came to the fore as causing health issues. Though not a common issue, but some wards highlighted issue of street lighting. It was also observed that the three most highly ranked issues physically coincide with the location of slums.

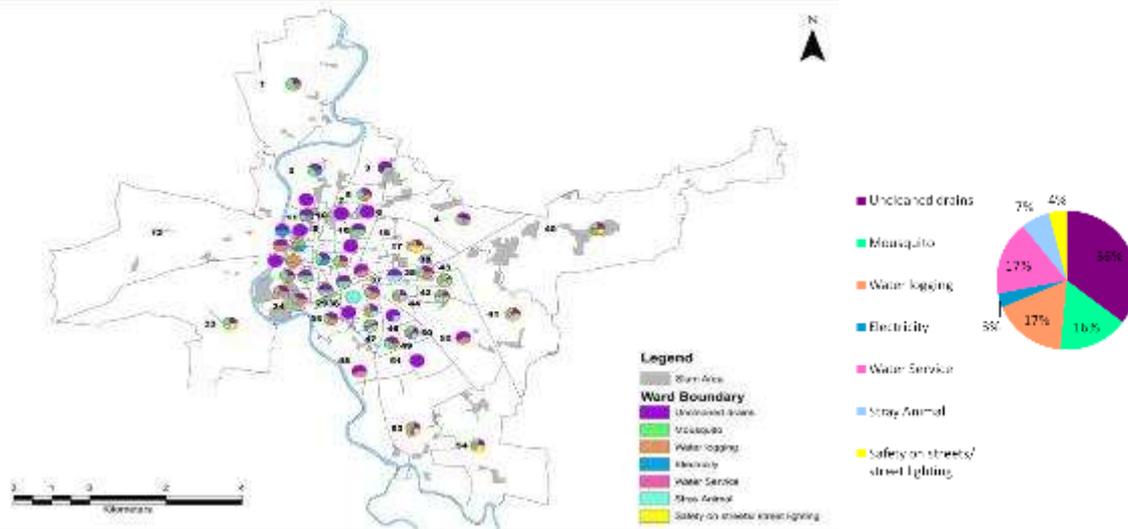

Figure 2: Percent distribution of responses by households on issues of physical environment affecting health in different Wards of Ujjain city¹⁶⁴

(iii) Spatial analysis in GIS platform

All the information collected through primary and secondary sources were mapped in GIS. Mapping was done in two steps: (a) mapping of physical infrastructure, (b) mapping of diseases and opinion responses (as in figure 2).

8. MAPPING AND ANALYSIS

a) Mapping of infrastructure related to health and sanitation

Household survey revealed that 17% of the surveyed population have to traverse more than 1.5 km to reach a dustbin. Large part of the city is not covered by any planned and systematic network for storm water drainage. 29% households of surveyed population do not have septic tanks and they discharge waste water directly into drains which catalyzes the pollution of the surroundings and spread diseases. To understand the relation between diseases and infrastructure, the first step was to map distribution of toilets, dustbins, natural & constructed drains and open spaces (fig. 3).

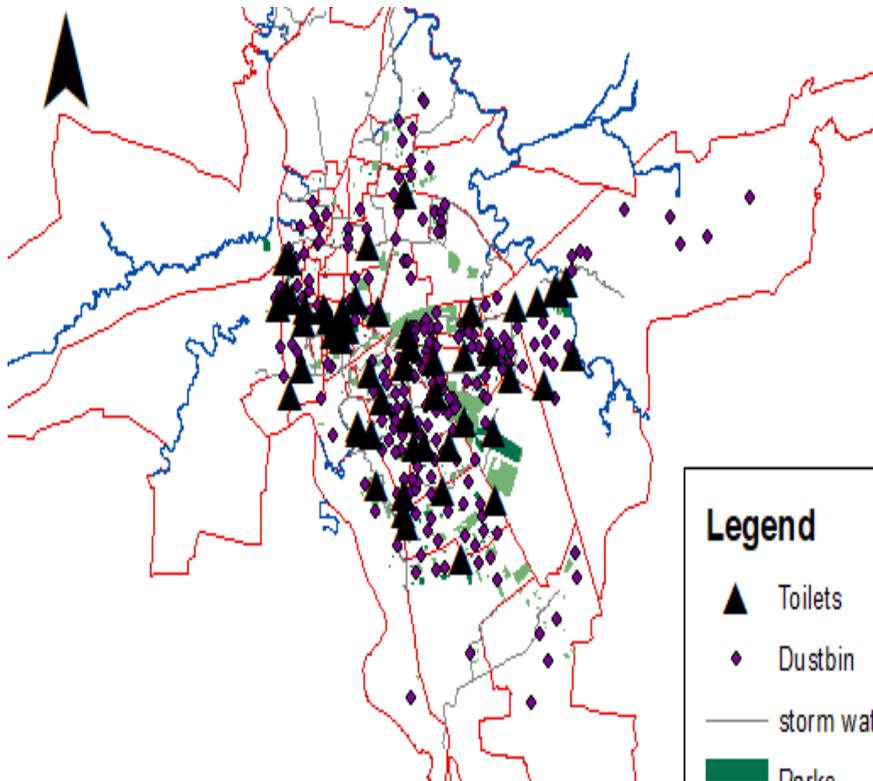

Figure 3: Map indicating natural drains, constructed storm water drains, open spaces, parks, public toilets and dustbins (solid waste bins)¹⁰

b) Mapping of diseases

¹⁶⁴ Development plan of Ujjain, India. Unpublished report, 3rd semester MPUR programme (2017), School of Planning and Architecture, Bhopal, India

The diseases identified through household survey have been divided into four categories such as: (i) Lifestyle diseases (including Diabetes, Blood sugar, Old aged problem, etc.), (ii) Water borne diseases (including Cholera, Diarrhea, Jaundice and various Gastroenterological problems), (iii) Vector borne diseases (including Malaria, Dengue etc.) and (iv) Respiratory diseases (including bronchitis, asthma etc.). Choropleth maps were generated for occurrences of these four categories of diseases. Overlay analysis was performed to find the relationship between diseases and infrastructure.

Cases of Vector Borne, Water Borne, Respiratory and Lifestyle Diseases, UMC

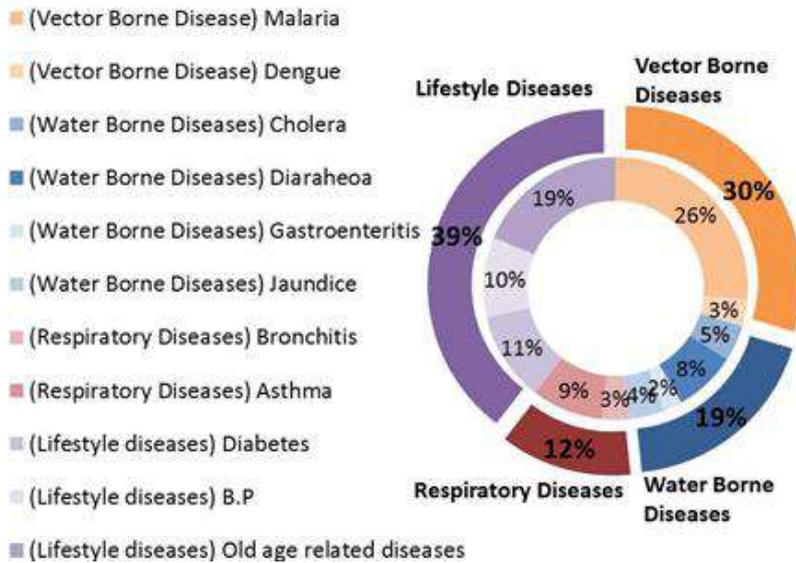

Figure 4: Percent distribution of responses by households for occurrences of diseases in Ujjain city¹⁰

c) Analysis of occurrence of vector borne diseases

Vector borne diseases are predominant in Ujjain Municipal Corporation (UMC) area, specially malaria and cerebral malaria. This leads to the issue of mosquitoes which has been reported by the residents (un-cleaned drains). To investigate the matter, an overlay analysis was performed between occurrence of vector borne diseases, slum distribution, sanitation facilities including access to toilets and natural and constructed drains (fig. 5). Overlay of maps indicate that vector borne diseases are more in areas where access to household toilet is less and slum is more. The map also shows that high occurrences of vector borne diseases follow the course of the Kshipra River (water is kept stagnant for most of the period of a year) and also Piliya khal (natural drain meeting Kshipra River).

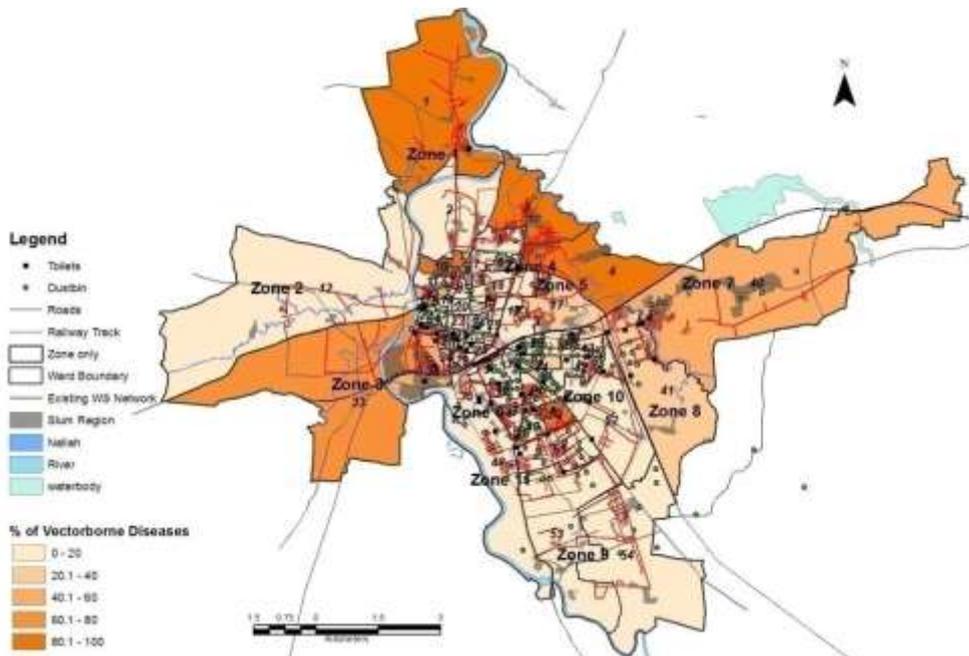

Figure 5: Overlay mapping of percent distribution of vector borne diseases, slums, watercourses, water bodies, public toilets and dustbins¹⁰

d) Analysis of occurrence of water borne diseases

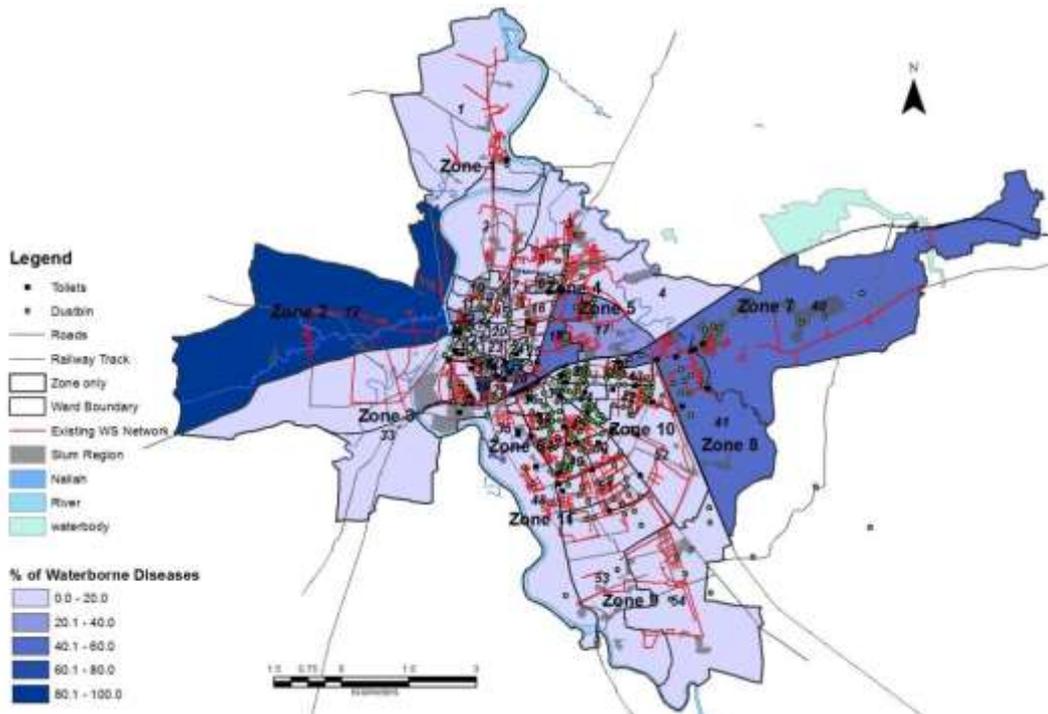

Figure 6: Overlay mapping of percent distribution of water borne diseases, slums, watercourses, water bodies, water supply network, public toilets and dustbins¹⁰

Figure 6 reveals that occurrence of water borne diseases are more in wards where primarily there is less coverage of water supply pipelines, wards with fewer dustbins [leading to accumulation of street-side litter] and where public toilets are less. It also indicates that wards / areas with less constructed and natural drains have a higher prevalence of water borne diseases. There is a high prevalence of water borne diseases in ward number 12 because of existence of a STP site within the at a place called 'Sadaval'.

e) Analysis of occurrence of respiratory diseases

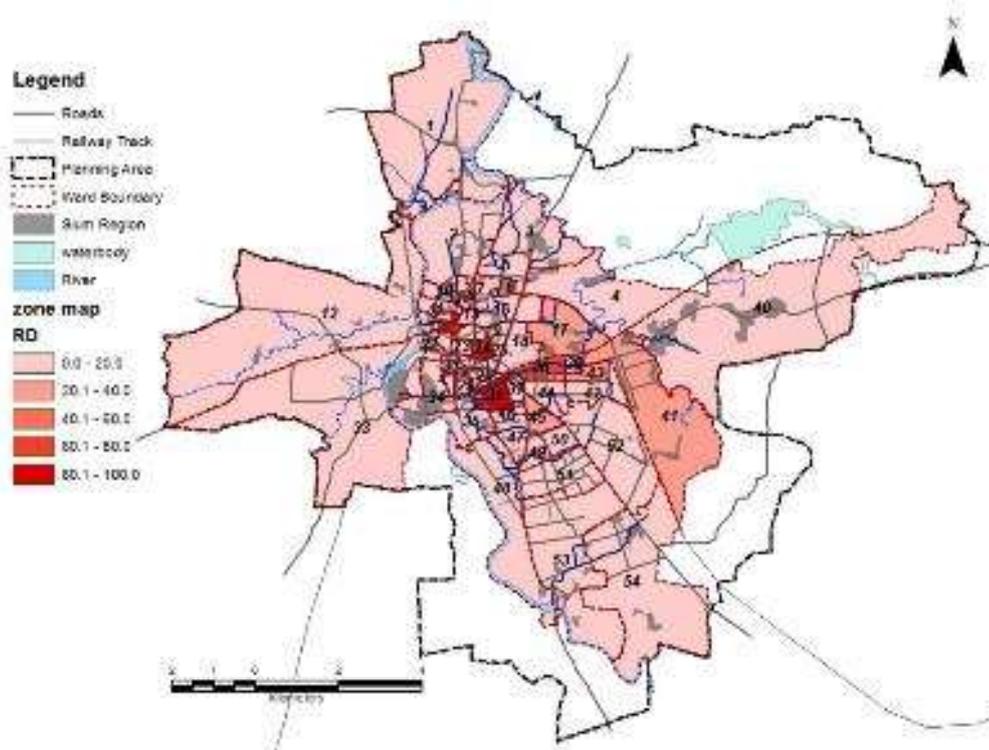

Figure 6: Overlay mapping of percent distribution of respiratory diseases and physical infrastructure¹⁰

Figure 6 shows that in Ujjain city there is no relationship between respiratory diseases and availability of public toilets, dustbins, water supply network etc. However, it indicates a relationship with location of major roads and railway track that is passing through the city. The wards which have major roads and railways line passing through have high occurrence of respiratory diseases.

f) Analysis of occurrence of lifestyle diseases

From the household survey, for the case of lifestyle diseases, mainly diabetes, blood pressure, old-age related issues were identified. Figure 7 reveals that the wards which are situated in the core area of the city have higher prevalence of lifestyle diseases. Occurrence of lifestyle diseases reduce significantly in the peripheral wards. Overlay of maps suggest wards with less availability of residential open spaces and parks are having higher prevalence of lifestyle diseases which may be further construed as a lack of opportunity for active lifestyle. The whole of the city, except for the religious area near the river Kshipra [at Ramghat area] does not have any separate pedestrian facility. Roads have a mixed mode of use, that is pedestrian, cyclists and motorists all use the same road. Hence, this factor has not been considered here. Comparisons with other maps suggest prevalence of lifestyle diseases in wards with higher population density and higher percentage of building footprints. However, age factor has not been taken into account in the analysis and in that way it is a limitation of the study.

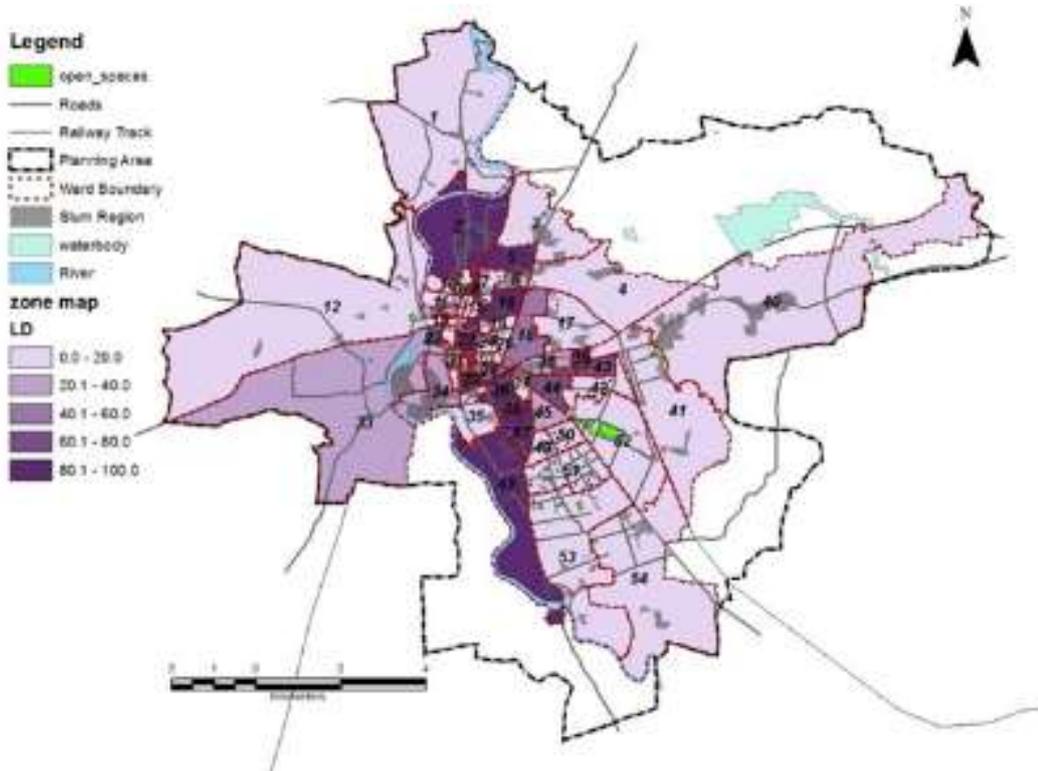

Figure 7: Overlay mapping of percent distribution of lifestyle diseases and open spaces¹⁰

g) Location and availability of medical Facilities

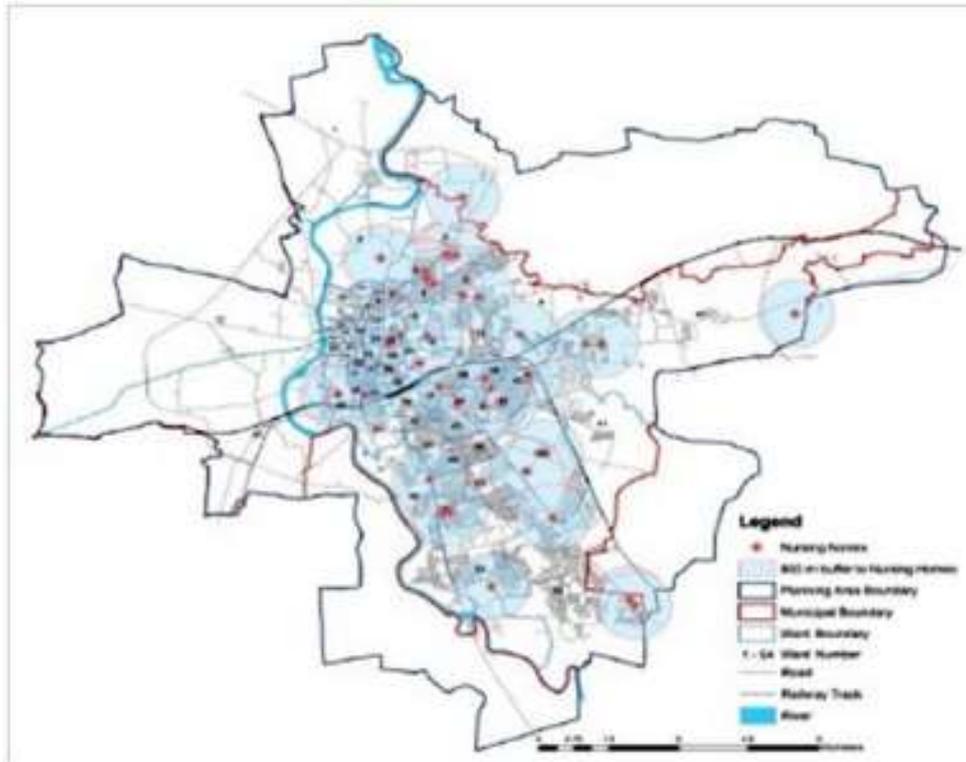

Figure 8: Location of medical facilities in different wards and Proximity Analysis using 800 m buffer distance¹⁰

Ujjain has a total of 5 government run facilities [1 district hospital, 2 civil hospitals and 2 dispensaries] and 74 private medical facilities [36 nursing homes and 38 clinics/ private hospitals]. For extrapolated population in 2017 in the city, considering URDPFI (Urban, Regional Plan Formulation and Implementation) guidelines 2014, the quantum of land used for medical facilities is a little less than as the norms suggest [less by 1.69 hectares]; whereas similarly considering 'Indian Public Health Standards', 2012, number of beds available is more than adequate. Ujjain has 4.9 numbers of doctors per 10,000 resident population, as compared to the World Health Organization Standards prescribed value of 10 [overall value for India: 5.1]. While analysis of ward-wise distribution of beds per 10,000 residents shows some amount of disparity, it was noted that wards 1, 12 and 15 have no health centres and that the facilities are concentrated in the core area of the city as is evident from figure 8. URDPFI guidelines 2014 suggests that the local level facilities to be provided at a preferable walking distance of 300 m to 800 m (located within 5-15 minutes of walk) to promote pedestrian access. A proximity analysis was carried out considering a buffer of 800 m surrounding the health facilities [Fig. 8]. The analysis indicates the areas that are not served by medical facilities within a walking distance. Also it was found that there is a lack of trauma centres in the periphery along major highways entering the city for attending to road accidents.

9. CONCLUSION

This study as a part of an academic exercise of preparing a physical development plan for Ujjain city analyzed four types of disease occurrences with relation to few types of physical infrastructure and existing physical features for example rivers and rivulets. Overlaying of disease occurrences and physical infrastructure/ features show a relation between these aspects. It may be concluded then if appropriate investments and actions are taken to improve the provision of infrastructure health and well-being, outcomes will improve. This research together with further research may provide an opportunity for evidence based planning and decision making for appropriate investments in achieving better health outcomes through physical development process. Scenario analysis for medical facilities show there is not much of deficit as per norms in terms of land being used for the purpose or number of beds. However, physical distribution of the facilities is not equitable spatially which again require attention of physical planners. Further, data of disease occurrence is maintained for the whole city and not for different zones within the city which may point to local issues as highlighted in the study.

1087 ARSENIC POISONING IN BENGAL DELTA-A GEO-ECOLOGICAL STUDY OF WEST BENGAL, INDIA

ABSTRACT

Arsenic contamination in drinking water is a serious issue and health agenda worldwide especially in Asian countries. During the past two decades, Arsenic(As) contamination via groundwater has become a major concern in the Bengal delta or Ganges Delta which includes the state of West Bengal situated at the eastern part in India. The objective of this paper is to identify the causes and the geo-spatial distribution of high As contamination in particularly Bengal Delta along with identifying the areas of high,medium and low As concentration and the people affected by it. The methodology adopted is the study of data,maps and information from different survey reports,journals,books,research papers and analysis of those data to depict the present scenario of As menace as a disaster in this region as well as field study in selected areas to survey the As affected people and their struggle of living. Districtwise study and mapping of As effected area as well as the risk,threat with health effect and mitigation are also highlighted. WHO(2011) has recommended the permissible limit of As of 0.01 mg/l whereas India consider it as 0.05mg/l.In India West Bengal has the highest As affected people.107 blocks in 9 districts are affected severely and about 80 million people are at ris- the southern part of Kolkata-the capital city has severe contamination in 141 out of 144 administrative wards.Its' main fatal effect is the health hazard.As enters human body through contaminated groundwater. Chronic arsenic poisoning, which stems from long-term exposure through drinking water cause a wide variety of diseases, including cancer of the skin,lungs, kidney, and urinary bladder and specially the development of Arsenicosis which can be lethal too.There is no specific medical treatment for these arsenic-related diseases.The study also reveals that regional distribution of this hazard lies in the geological and hydro-lithological structure of the Bengal delta.Moreover due to increasing demand of population, the water stress becomes acute leading to overuse of groundwater and reducing the piezometric level leading to As contamination. It can be concluded that the affected people are mainly poor and vulnerable section of the society and it has become an environmental threat with dense population, socio-political and economic factors exaggerating the problem.Application of knowledge in RS_GIS can help to identify geological structure, industrial effluents and other anthropogenic sources of As contamination and prepare risk map as well as sources of groundwater.

1638 GEOGRAPHICAL AND ENVIRONMENTAL ASSESSMENT OF EAST KOLKATA WETLAND REGION, WEST BENGAL, INDIA.

ABSTRACT

East Kolkata Wetland (EKW) is located adjacent to the eastern part of Kolkata in the district of North and South 24 Parganas of West Bengal. It occupies an area of 12,500 hectares and includes 254 sewage fed fisheries, several agricultural plots and solid waste farms. It is famous for having largest waste water fed aquaculture system in the world. Because of having efficient as well as eco friendly solid waste and sewer treatment system EKW is considered as kidney of the city Kolkata. Beside, the site is a harbour of diversified floral and faunal communities. Land and land cover changes has a slow but steady and prolonged effect on the loss of eco system and bio diversity. The total area EKW is 12,500 hectares of which approximately 45.93% is the water body and 38.92% is the agriculture land. The remaining portion is occupied by urban and rural settlements. The anthropogenic threat to bio diversity has been noticed through the fast changing land uses by destroying typical habitats for such resource base. While regulatory control is being attempted in the forest area, loss of greeneries in forest areas especially in wetland and its adjacent areas is now an issue of nature concern. A geographical analysis was done by questionnaire schedule for the study of people’s perception and array. Data and other information’s available and generating on the field have been quantified , compiled , analyzed using appropriate modern techniques like GIS and standard statistical methods and various diagrams to satisfy our objectives. In developing countries especially population pressure, food demands, urbanization etc. have compelled conversion of wetlands to build up an agricultural lands. EKW is a unique example where intense and rapid land cover change is going on. The changes in the quality of solid waste and sewer along with human neglect have put this Ramsar site under threat.

It is therefore necessary and need based to study the extent of loss of bio diversity in this area in relation to its changes in spatio-temporal perspectives. So the aims and objectives of our investigation are 1.To study the spatio- temporal changes over the last two decades of this region. 2. Impact of growing urbanization on environment. 3. To offer useful suggestions in the light of related findings.

1751 CFD ANALYSIS OF DIFFERENT PASSIVE GUIDING SYSTEM GEOMETRIES ON A SEMI-CLOSED FISH FARM CAGE**António Maximiano¹, Luis Eça², Guilherme Vaz³, Marco Alves¹**¹ WavEC-Offshore Renewables Numerical Modeling Team, Rua Dom Jerónimo Osório, n 11, 1 andar, 1400-119, Lisboa Portugal, Email: antonio.maximiano@wavec.org, marco@wavec.org² IST-UTL, Mechanical Engineering Department Av. Rovisco Pais 1, 1049-001 Lisboa Portugal, Email: luis.eca@ist.utl.pt³ MARIN, R&D Department, P.O. Box 28, 6700 AA Wageningen The Netherlands, Email: g.vaz@marin.nl**ABSTRACT**

Salmon aquaculture is a growing industry, which can help meet the challenges of a growing population and increasing land scarcity. A challenge faced by this industry is the control of the sea lice parasite, which is estimated to account for 9%-23% of the salmon cost in Norwegian farms [1]. One promising approach to control this parasite is using enclosed or semi enclosed sea cages that severely mitigates exposure to the parasite at the expense of increased structure costs and often pumping power. A semi- closed enclosure, with a passive guiding system on the bottom of the skirt was developed by Hydra Pioneer to redirect the incoming current inside the enclosure and promote internal flow without the need for a pumping system. CFD is used to investigate the generated internal flow behaviour produced by four different design variations of the passive guiding system. The estimated water renewal time, internal flow velocity fields and current loads are compared at two different incoming current velocities. The most promising geometry variations are discussed, and further design variations are proposed that might produce better results.

INTRODUCTION

The increasing growth of the global population requires a significant increase in food production. This increase must happen within the context of growing population, where competition for land and water usage will make these resources scarcer than they are presently. So in order to do more with less, the food industry needs to become more efficient [2]. These challenges are relevant for the aquaculture industry, as one of the fastest growing field of the food industry in the past decades [2].

A particular challenge for the salmon aquaculture is the sea lice infestation. The costs to the industry stem not only from the fish lost to the infection, but also from the procurement and administration costs of treatments, often chemicals. The costs due to sea lice are estimated to range between 9 %-23 % in Norwegian salmon farms during the year 2014 [1]. Environmental concerns regarding sea lice are related with the chemicals used for its treatment, and the increased infestation pressure on local wild populations [3]. With increasing food needs, the pressure on livestock density might rise which could further increase the impact of the sea lice on salmon aquaculture. Therefore, sea lice control is one of the most important topics for salmon aquaculture.

Chemotherapeutants have been the most common way to address sea lice infestation, either through additives in fish feed or in bath-type treatments. However some drawbacks are related with the environmental impact of such agents on the local environment, particularly crustaceans, or the increasing resistance of the sea lice to the most common compounds [3, 4]. Alternative non-chemical methods have been used to mitigate the sea lice infestation, such as: fallowing, delousing lasers, or the use of cleaner fish [4, 5], with various degrees of success.

Other possible solutions include farming in closed containment systems, either onshore or floating closed cages. This restricts the contact between the salmon and the water borne parasites, typically present in the top layer of the ocean water (10 m-20 m), which mitigates the infection pressure on the farmed stocks. The use of closed systems also have potential benefits due to a more controlled environment, which can increase efficiency and reduce environmental concerns. However this comes at higher structural and/or pumping costs [6]. Several closed or semi-closed concepts have been studied and even implemented [7, 8, 9], with one in particular showing remarkable reduction in sea lice infestation levels when compared to open net cages in similar locations [6]. Within these systems, using a tarpaulin around existing open net cages is the simplest method, and has the possibility to be retrofitted to existing farms. However, it was found that without auxiliary systems, the oxygen levels inside the pen might drop below acceptable levels [7].

The design of these closed and semi-closed systems is often aided by understanding the flow behavior inside such structures, optimizing inlet-outlets arrangement, pumping power requirements or particle residence times. These questions can be tackled with the use of computational fluid dynamics (CFD), which has seen some use for salmon aquaculture [9], current loads acting on an array of closed structures [8], or understanding the flow behaviour through a compact abalone floating cage in order to design cages to withstand more energetic seas.

In this paper a semi closed fish farm design is studied with CFD. This system utilizes a passive guiding system to redirect the incoming current inside the structure, thus avoiding the use of a pumping system. This concept was developed by Hydra Pioneer and is patented in Norway and globally (PCT). Hydra Salmon Company AS has been awarded four concessions for the implementation of this technology.

Information on the passive guiding system design variations tested is given in the next section. The parameters studied are discussed in the "Variables of Interest" section, followed by a brief description of the CFD solver utilized, numerical settings and grids. Finally, the results are shown and discussed, including remarks on numerical accuracy, closing with some concluding remarks.

PROBLEM DEFINITION

A generic design of a semi enclosed fish farm is used, which consists of a circular skirt and a passive guiding system, located at the bottom of the skirt. The passive guiding system has two main elements: two horizontal flaps, to promote internal vertical flow; and several vertical flaps, positioned with an angle of attack with respect to the incoming flow, to promote a swirling motion inside the structure. The concept is shown schematically in Figure 1.

One configuration of the passive guiding system is chosen as a baseline, henceforth called "base geometry". In addition, three variations of the base geometry are tested: variation 1, where extended horizontal plates are used in the horizontal flaps; variation 2, where an increased angle of attack on the vertical flaps is used; and variation 3, with the horizontal flaps installed with a steeper angle. All these configurations are shown in Figure 2.

These configurations are evaluated at 0.25 m s⁻¹ and 0.5 m s⁻¹ current velocities, which represent typical minimum operational conditions. Due to the structure symmetry, it is sufficient to calculate a single current heading to fully characterize the internal flow on the structure.

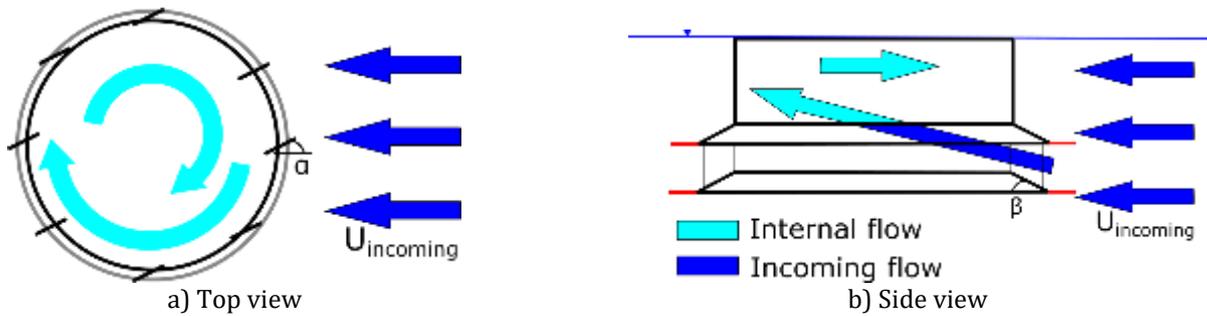

FIGURE 1: Semi-closed fish farm concept. The vertical flaps angle of attack, α , horizontal flap upward angle, β , and horizontal plate extensions (in red), used for the geometric variations are also shown. This concept is patented in Norway and globally (PCT).

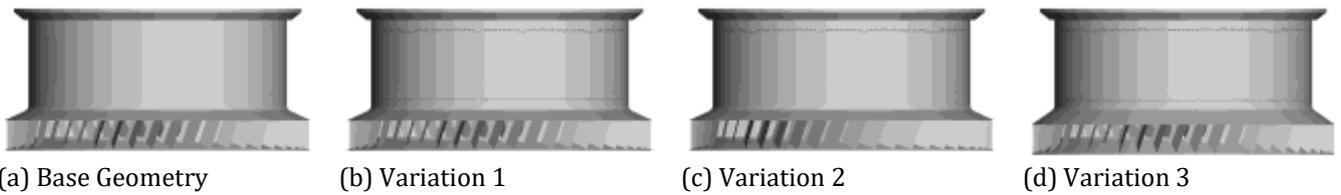

FIGURE 2: Different geometries tested.

VARIABLES OF INTEREST

Estimation of the Water Renewal Time

The time necessary to renovate the water volume inside the structure is of special interest for this application. A rough estimation of this parameter is made, based on the incompressibility assumption and mass balance. The internal volume is divided into N control volumes (CV), a sample CV is shown in Figure 3. An average mass flow rate is obtained for each CV, which is then divided by its volume to obtain an average renewal time for each CV, t_{cv_i} . A total time is computed by the summation of all CV. This time is made non dimensional by a reference time, chosen as the time necessary for a non-rigid pen of the same volume to renew its water, when exposed to the same current field.

$$t_{wrt} = \frac{4U_{ref}}{\pi D} \sum_{n=1}^N t_{cv_i} \quad (1)$$

Note that this provides an estimation for the average time for the renovation of the total volume by assuming an average flow rate per CV, i.e, a constant vertical velocity is assumed for the entire CV. However, since there are significant differences in the flow velocities inside the CV (e.g. vortices, lower velocity areas), longer times will be required to completely exchange the water volumes in these specific areas. This estimation is considered to be indicative for the comparison between the different geometries. However, it is noted that this estimation does not equal the maximum residence time of water particles inside the structure, and it serves as a rough estimation value for use in early design stages.

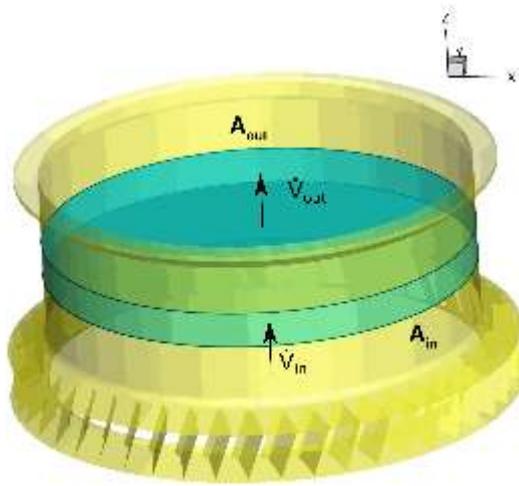

FIGURE 3: Example of a control volume.

VOLUMETRIC DISTRIBUTION OF THE VELOCITY

Another parameter used in this analysis is the local velocity magnitude nondimensionalized by the incoming current velocity, U_{ref} , defined as:

$$V_{mag} = \frac{(V_X^2 + V_Y^2 + V_Z^2)^{1/2}}{U_{ref}} \quad (2)$$

Velocity profiles at different depths are shown for flow pattern visualization, with the internal volumetric distribution of the non dimensional velocity magnitude also shown.

CURRENT LOAD COEFFICIENTS

For the current load calculations the force coefficients, CF_i , and moment coefficients, CM_i , are monitored. These coefficients are defined as:

$$CF_i = \frac{F_i}{\frac{1}{2}\rho U_{ref}^2 A_{ref,i}} \quad CM_i = \frac{M_i}{\frac{1}{2}\rho U_{ref}^2 A_{ref,i}^*} \quad (3)$$

where: $A_{ref,i}^*$ is the $A_{ref,i}$ multiplied by the moment arm; $A_{ref,i}$ is the projected area perpendicular to the i direction; F_i is the force along the i direction acting on the passive system; and M_i the moment around the i direction with respect to the center of the structure at the average depth of the passive guiding system. These forces are defined with respect to the coordinate system defined in Figure 4, with the positive Z axis pointing out of the water. The choice of presenting the loads acting on the passive system only, instead of the complete structure, is made for two reasons: first, it allows a direct comparison of the passive system design, which is the main factor of this study; and second, it avoids discussions regarding the computation of lift and drag coefficients of what is essentially a captive cylinder at a Reynolds number of the order 107.

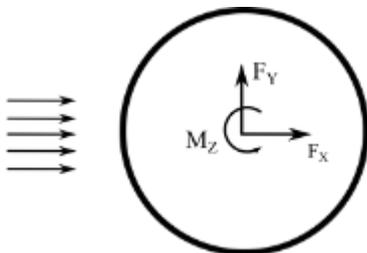

FIGURE 4: Sign convention

CFD APPROACH

Governing Equations

The governing equations are the incompressible steady Reynolds averaged Navier-Stokes equations (RANS) and the continuity equation, written as

$$\frac{\partial(\rho U_i)}{\partial x_i} = 0 \quad (4)$$

$$\frac{\partial(\rho U_i U_j)}{\partial x_j} = -\frac{\partial P}{\partial x_i} + \frac{\partial}{\partial x_j} \left[\mu \left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right) - \rho \overline{u'_i u'_j} \right] \quad (5)$$

Where U is the time averaged velocity, ρ the fluid density, P the time averaged pressure, μ the fluid kinematic viscosity and $\rho \overline{u'_i u'_j}$ the so called Reynolds stresses. The problem is not closed, as the Reynolds stresses requires additional equations to be determined. In the RANS framework, turbulence models are utilized to model the Reynolds stresses. In this work, the k- ω SST 2003 turbulence model is used, see [10], which relies on the Boussinesq Hypothesis,

$$-\rho \overline{u'_i u'_j} = \mu_t \left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right) - \frac{2}{3} \rho \delta_{ij} k \quad (6)$$

This turbulence model adds two additional transport equations, one for the turbulence kinetic energy, k , and another for the turbulence dissipation per unit kinetic energy, ω . These equations are omitted for the sake of brevity, but can be found in [10].

INITIAL AND BOUNDARY CONDITIONS

A cylindrical computational domain with a diameter equal to 10 structure diameters is used. The top of the domain corresponds to the water surface, and its bottom is located at approximately 15 structure drafts. The computational domain is presented in Figure 5. At the farfield boundary, inflow and outflow boundary conditions are applied.

At the inflow an uniform current velocity U_{ref} is prescribed. The eddy-viscosity ratio is $\mu T / \mu = 0.3$ and the turbulence intensity I is chosen equal to 10%. For the pressure a zero normal gradient condition is imposed. At the outflow boundary a constant static pressure is specified equal to p_{ref} and a zero normal gradient condition is imposed for all remaining flow quantities. At the water surface a free-slip wall condition is imposed, i.e. the normal velocity is set to zero. At the surface of the structure a no-slip boundary condition is imposed. A constant static pressure equal to p_{ref} is prescribed on the bottom surface of the domain.

The initial conditions for the calculations are defined in each computational cell by setting the velocity equal to the prescribed velocity of the inflow boundary. Furthermore, the pressure is chosen equal to the reference pressure at the outflow boundary and the eddy-viscosity ratio and turbulent intensity equal to the inflow boundary settings.

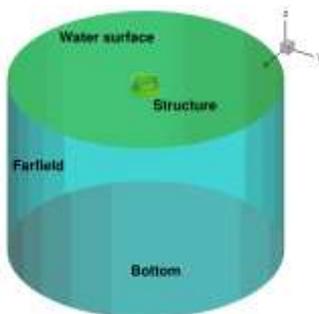

FIGURE 5: Computational domain.

Flow Solver ReFRESH

ReFRESH (www.refresco.org) is a community based open-usage CFD code for maritime applications. It solves multiphase (unsteady) incompressible viscous flows using the Navier-Stokes equations, complemented with turbulence models, cavitation models and volume-fraction transport equations for different phases [11]. The equations are discretised using a finite-volume approach with cell-centered collocated variables, in strong-conservation form, and a pressure-correction equation based on the SIMPLE algorithm is used to ensure mass conservation [12]. Time integration is performed implicitly with first or second-order backward schemes. At each implicit time step, the non-linear system for velocity and pressure is linearised with Picard's method and a segregated approach is used.

ReFRESH (v2.4.0) is currently being developed, verified and its several applications validated at MARIN (in the Netherlands) [13, 14] in collaboration with IST (in Portugal) [15], WavEC (Portugal) [16], and several other universities.

The code is targeted and optimized exclusively for hydrodynamic applications. It has already been applied, with verification and validation exercises for several offshore typical flows: current and manoeuvring coefficients for semi-submersibles, submarines and ships; roll damping; wave generation and wave loads; and for wind loads on offshore vessels.

Numerical Modeling

A first order upwind scheme is employed for the space discretization of the momentum equations and turbulence equations.¹⁶⁵ The diffusion terms are treated using central schemes. The iterative convergence criteria was defined as L2 norm $\leq 10^{-4}$ for the normalized residuals of all quantities.

The following assumptions are made when performing these calculations:

- The structure is kept stationary and fixed;
- Steady flow and forces are considered, unsteady effects are not taken into account;
- The structure is positioned in an uniform inflow velocity field;
- The effects of the free surface are assumed to be negligible, therefore the water surface is modeled with a free slip condition.
- The effects of the swimming fish and fish nets are not accounted for.

Computational Grids

Computational grids are constructed with the grid generator software package Hexpress. The grid is refined towards the hull of the structure to be able to capture the geometry. Some specifications of the grids used are presented in Table 1. The grid generated for the base geometry is shown in detail in Figure 6. The grids generated for the other geometries are equivalent to the base geometry grid shown here. Due to the large number of elements to be modeled and the high Reynolds number, grids with a large number of cells were required to perform the simulations in a reasonable manner. The cost and time constraints of the project, together with the very high cell count grids that would be required, made unfeasible to carry out a thorough Verification study [17], therefore no estimation of the numerical error is available. The lack of this estimation is discussed when interpreting the results.

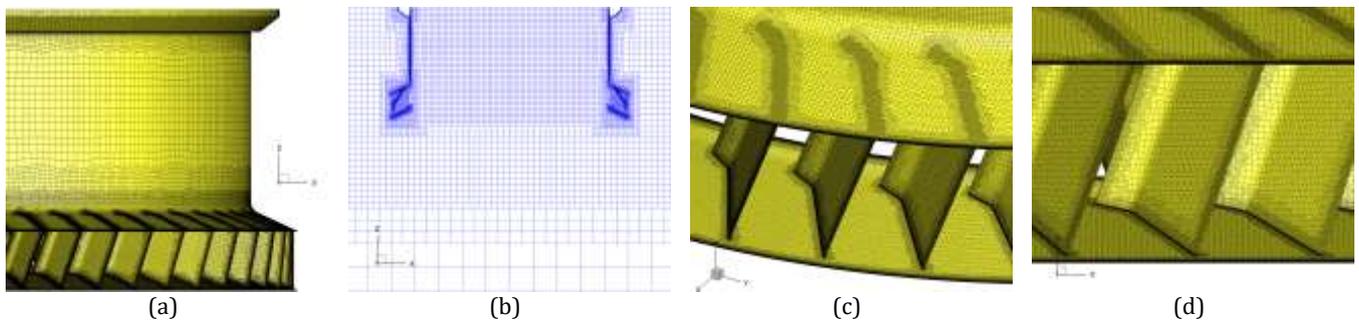

FIGURE 6: Computational grid for the base geometry. An overview of the grid is presented in (a), the grid on the interior on the structure (in blue) is shown in (b). A closer view of the grid on the guiding system is shown in (c) and (d).

RESULTS

Internal Flow Visualization

One advantage of performing CFD simulations is the physical insight provided by the availability of flow field visualization. For illustration purposes, the velocity magnitude, as defined in Equation 2, is shown for all geometries at four different depths in Figure 7. The first observation is that, for both current velocities, the non-dimensional velocity field is very similar. This similarity is observed for all geometric variations tested, which suggests that comparisons drawn between geometries are valid for current velocities between $0.25 m s^{-1}$ and $0.5 m s^{-1}$.

The incoming current flow enters the structure through the passive guiding system located at the bottom of the skirt. At this depth, velocities close to undisturbed flow velocity are present in the main inlet region, while lower velocities are present near the center of the structure. The velocity profiles extracted at shallower drafts show an overall deceleration, as is to be expected. Larger velocities occur in the continuation of a clockwise upward spiral jet, with a low velocity core

¹⁶⁵ At this stage, robustness is the key feature

present near the center of the structure. These three dimensional structures are illustrated in Figure 8 for the base geometry case, and are also present, albeit with different magnitudes, in the other geometry variations.

When the angle of attack of the vertical flaps increases (Var2), the high velocity area increases and is displaced closer to the wall due to the larger tangential component imposed by the guiding system. In addition, larger velocities are also felt at shallower drafts, when compared to the base geometry.

Conversely, when the upward flap angle is increased (Var3) this high velocity area gets smaller, but the jet has a stronger vertical component, and propagates better towards the top of the structure. However, there is also a noticeable increase of the low velocity region throughout the whole structure. This is presumably due to the increase of the blocking of the flow through the passive system (see Figure 2).

Adding an horizontal extension plate to the upward flaps (Var1) results in a more uniform flow in the passive guiding system, which produces a small increase in the high velocity area, which is also felt at shallower depths. It is interesting to note that Var1 achieves similar results to Var3, in terms of redirecting the incoming flow upwards, but with a less severe increase in low velocity areas, which favors Var1 in detriment of Var3.

Low velocity areas are generally undesirable in these applications, since it can be associated with low oxygenated areas, or particle/waste accumulation. Early identification of such flow features is valuable information to assess the design, and improve on it, should the need arise. Furthermore, the velocity profiles allow to pinpoint areas with large velocity gradients, which might not be compatible with fish safety parameters.

Velocity Distribution

As a means to quantify the observations made in the previous section, the velocity magnitude distribution, as a function of the internal volume where it occurs, is given in Figure 9. The base geometry shows the smallest volume of low velocity area: 30 % of the total volume with $U \leq 0.3U_{ref}$. Var1 and Var2 show a similar velocity distribution to the base geometry, with velocities in the range $0.7U_{ref} \leq U \leq 0.8U_{ref}$ more frequent for Var2. On the other hand, Var3 shows an increase in the occurrence of low velocities (43 % of the total volume with $U \leq 0.3U_{ref}$).

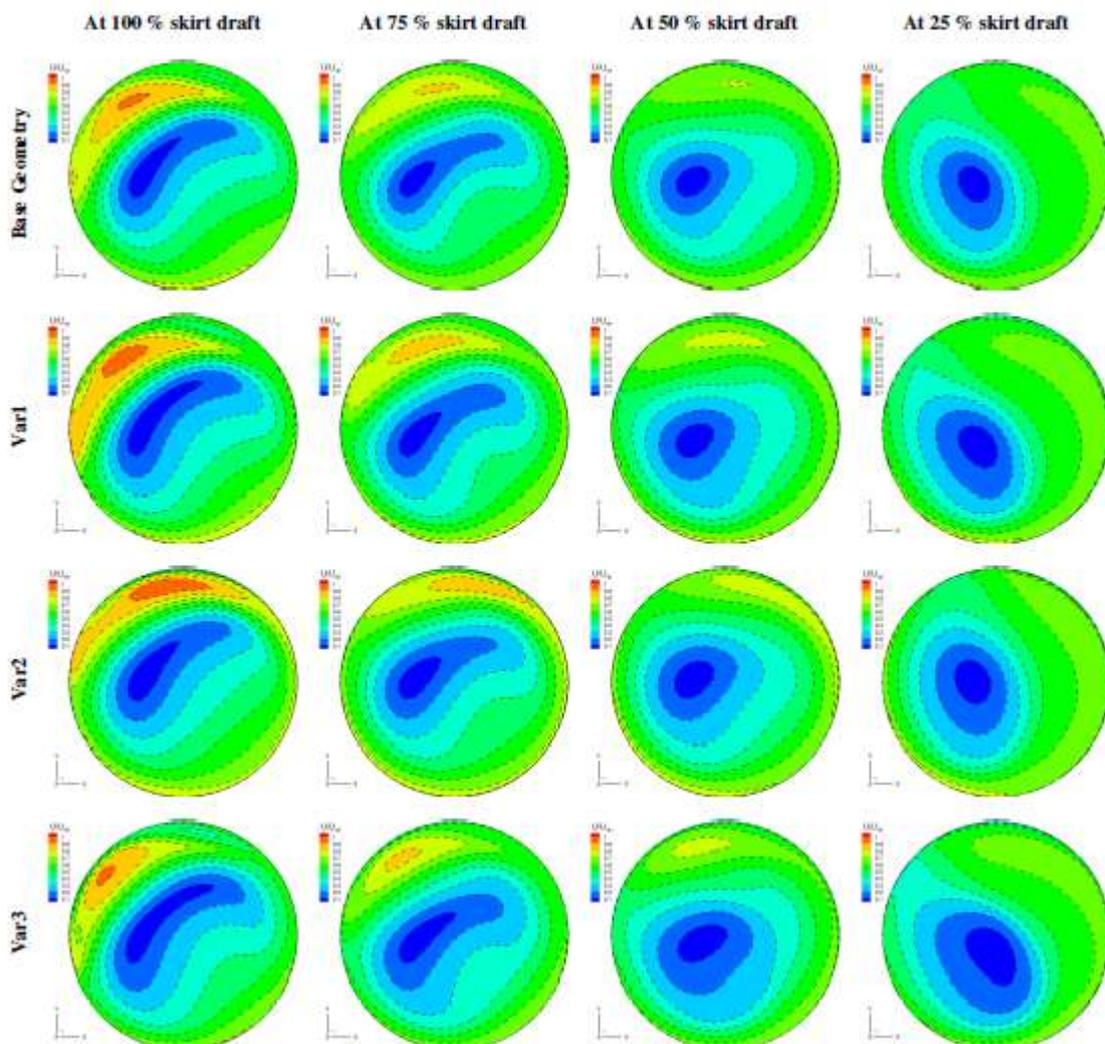

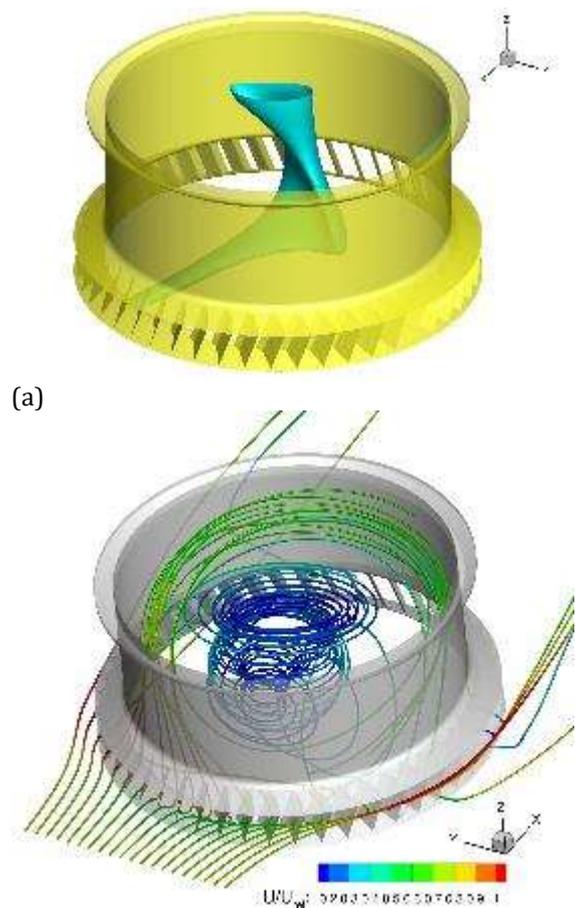

FIGURE 7: Top view of the velocity profiles extracted for all geometries tested at different depths, for a current velocity of 0.50 m s⁻¹ (colors) and 0.25 m s⁻¹ (dashed lines). The flow comes from left to right.

Estimated Water Renewal Time

The estimated time for water renewal, and average vertical velocity as function of the depth are shown in Figure 10 and summarized in Table 2 for all the variations tested. The time for water renewal is about 15-20 times larger than the open net scenario. The differences found between the base case and the geometry variations in the estimated time for total water renewal are under 8 %. The smallest time for total water renewal is found for Var3, while the longest time is found for Var2.

Based solely on this metric, one might assume that Var3 would be the preferred choice. However, as seen previously, the overall distribution of the velocity inside the structure does not favor Var3. This shows the importance of using several metrics in the assessment.

Since this metric is based on an average vertical velocity per control volume, at several depths, and Var3 promotes the vertical velocity component, it is expected that this metric shows favorable results for this geometry variation. It is also interesting to note that the average vertical velocity distribution is very similar between both Var3 and Var1, which suggests that the extension plates favor the vertical water motion, without the associated low velocity areas induced by the increased upward angle of the horizontal flaps.

(a) low velocity area ($U \leq 0.1U_{ref}$); and (b) streamlines colored by the velocity magnitude.

ABSTRACT

We develop a spatial energy model to analyze the trade-off between greening and brown expansion of electricity supply in developing countries, under influence of increasing agglomeration. We examine how the cost advantage of fossil fuels visa-vis low-carbon alternatives arises from three interrelated features: geography, power density and technology. Fossil fuels are more power dense and hence spatially more productive than renewable energy resources. Increasing concentration of economic activity in space may therefore impede the emergence of a low-carbon energy system. We calibrated our model to the case of Indonesia and find that until 2050 the expected population growth in Indonesia leads to a 1% annual reduction of the country's share of electricity produced with renewable energy sources. This result is weakened but not reversed at a substantially higher assumed power density of renewable energy sources.

Keywords: energy, electricity, geography, power density, spatial model, Indonesia

JEL Classification: O01, Q40, R12, R3

1. INTRODUCTION

In many developing countries energy scarcity and poor access to modern energy sources hamper the consumption, production and transportation of goods and services, thereby undermining economic development. Rapid expansion of (grid) infrastructure and generating capacity is therefore a key priority for policy makers in these countries. At the same time, fossil-fuel fired power plants, and those that burn coal in particular, are a leading cause of smog and local air pollution and are among the largest contributors to the emission of greenhouse gases. Developing countries therefore face a major dual “energy challenge”: the simultaneous expansion and greening of their electricity supply.

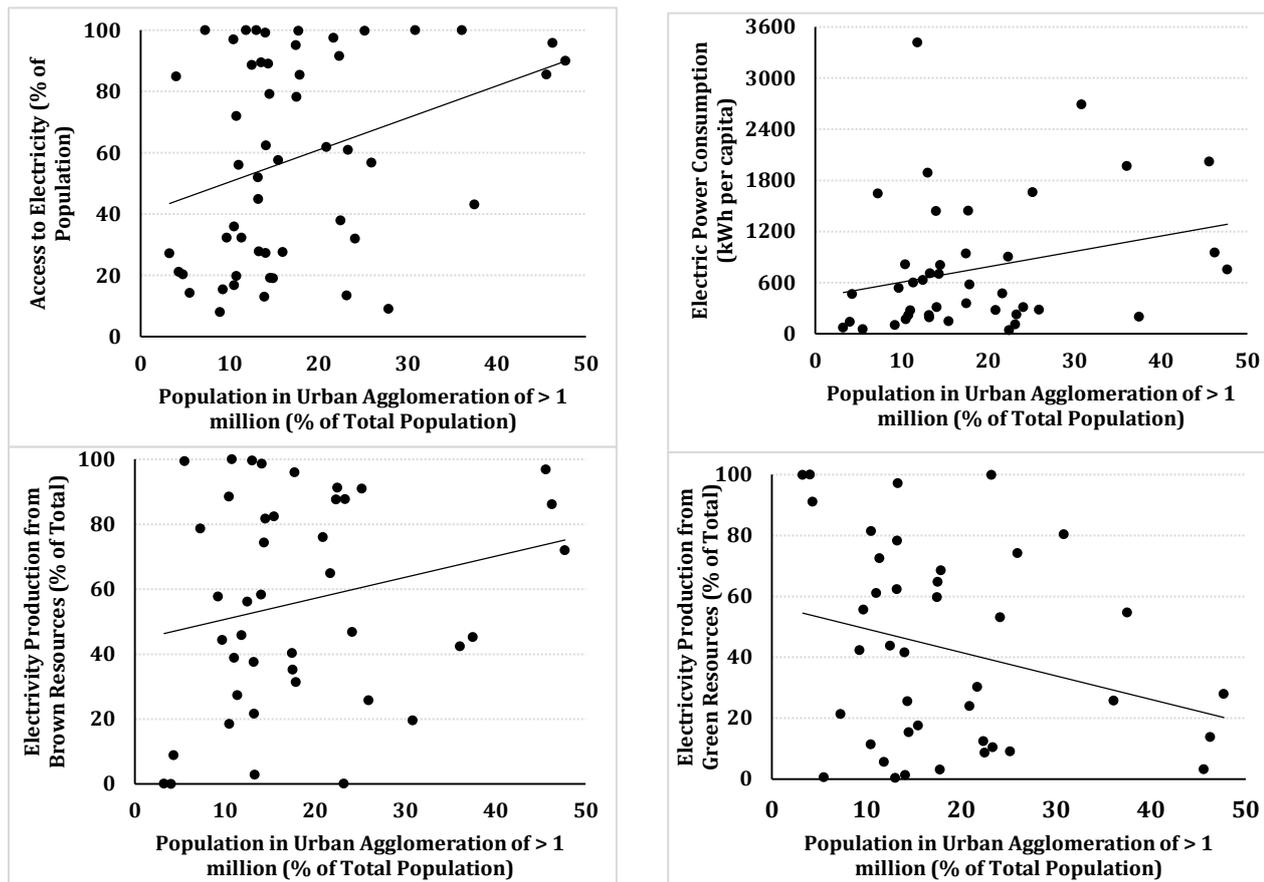

In this paper we analyze the trade-off between greening and brown expansion of electricity supply in developing countries, under influence of increasing population density. We do so by developing a spatial energy model that extends recent work by Moreno-Cruz and Taylor (2012, 2014, 2017), which we then calibrate to the case of Indonesia. In this archipelagic state, one of the most populous countries in the world, coal-fired power plants are increasingly satisfying the rising demand for electricity. Between 2009 and 2016 the usage of coal by the government-owned electricity company PLN increased from 36% to 50% (PLN, 2009 & 2017). Despite this, Indonesia's scattered geography, potentially implying large costs to transport coal, and its relatively “clean infrastructure slate”, providing the country with what Collier and Venables (2012) coined a latecomer advantage, should not necessarily predispose it towards the consumption of coal to the same extent as China and India, and in fact might even enable it to quickly exploit a range of low-carbon alternatives.

It is often argued that developing countries are in the position to leapfrog the lock-in into fossil fuels by building an energy system that meets their energy requirements from renewable energy resources (Goldemberg, 1998; Perkins, 2003; Collier & Venables, 2012). Despite this strong imperative, recent research suggests that fossil fuels are likely to remain the dominant source of energy in many regions around the world. Steckel *et al.* (2015) report that growth in a broad set of developing countries is increasingly supported by carbon-intensive power generation. As such, it appears that many developing countries are only partially meeting their energy challenge. Moreover, Steckel *et al.* (2015) show that the increase of the carbon intensity of energy production is caused mainly by an increase in the consumption of coal. Interestingly, this “renaissance of coal” is not restricted to China and India, but is quite common for emerging economies, especially for countries in Asia. As Steckel *et al.* (2015) and many others (Haftendorn & Holz, 2008; Schiermeier, 2012; Collier & Venables, 2014; Tyfield, 2014; Edenhofer, 2015) have noted, the low price of coal relative to low-carbon alternatives constitutes an important factor for its resurgence.

In this paper, we analyse how this cost advantage of coal visa-vis low-carbon alternatives arises from three interrelated features: geography, power density and technology. As economies grow and develop, the spatial distribution of population, employment and production changes. Probably the most prominent feature of spatial transformation in these countries is increased urbanization. In a few decades from now the global urban population will be larger than the entire global population today, and this urban transition is being driven by cities in the developing world, where 90% of urban growth is projected to take place. This unprecedented change in the geography of economic activity affects economic development and vice versa: an economy's degree of urbanization is not only a consequence of its development; it also determines its growth (Overman & Venables, 2005; World Bank, 2009; Desmet & Henderson, 2014; Duranton & Puga, 2014; Motamed, et al., 2014). As noted before, economic development is fuelled by access to modern energy sources, but if these sources mainly consist of fossil fuels, energy consumption will continue to be a main driver of local air pollution and global greenhouse gas emissions. Most research into the links between global environmental change and economic

development ignores the spatial dimension of both economic development and environmental degradation. In this paper, we explicitly address the role of space.

The dual challenge of expanding and greening the electricity supply relates to the degree of urbanization. Figure 1 shows that across low income and lower-middle income countries (per capita GNI \leq \$3,955) both access to electricity and per capita electric power consumption are positively correlated with concentration of population in urban agglomerations of more than 1 million people (see top left and top right of Figure 1). Also, concentration of population in large agglomerations is positively correlated with electricity production from brown (non-renewable) resources (see bottom left of Figure 1), while the opposite is true for electricity production from green (renewable) resources (see bottom right of Figure 1). In most low and lower middle-income countries, green resources are responsible for only a very small fraction of electricity production, i.e. $<58\%$ (see bottom right of Figure 1). However, in some low and lower middle-income countries, green resources are responsible for a substantial part of electricity production ($>90\%$). In those countries, population concentration in large agglomeration is less than 25% of total population (see bottom right of Figure 1).

Note: Brown resources = oil, gas and coal sources. Green resources = renewable sources, including hydroelectric

Data Source: World Bank Development Indicators (World Bank, 2017).

Figure 43. Concentration of People in Low and Lower-Middle Income Countries, in Relation to Electricity Access and Consumption (Top) as well as Electricity Production from Non-Renewable and Renewable Sources (Bottom)

The transition to a predominantly urban human population will have a significant impact on a transition to a low carbon energy system, because there are fundamental physical limits to how much energy we can extract from renewable resources for a given area of land. To measure this, we can calculate an energy source's power density in watts per square metre (W/m^2). "The power density of an energy resource measures its ability to provide a flow of power considering the area needed for its exploitation" (Moreno-Cruz & Taylor, 2017). The unit cost of transportation of an energy resource is inversely related to its power density, which implies that very power dense resources such as coal and oil will be collected at great distances, while energy resources like timber will not (Moreno-Cruz & Taylor, 2017). In sum, power density is a measure of a resource's "spatial productivity". High power density allows for concentration of people and firms in space (Smil, 2015; Wilson, 2013; Moreno-Cruz & Taylor, 2012). Economic historians have commonly held the interplay of energy density and transport costs responsible for the small city sizes in pre-industrial times (e.g. Smil, 2008, Wrigley, 2010). In a similar vein, Nunn and Qian (2011) recently linked the introduction of a new high-density energy source (the lowly potato) to population growth and urbanization in the Old World.

Following recent work by Moreno-Cruz and Taylor (2012, 2014, 2017), we develop in this paper a spatial energy model that builds on the concept of power density to analyze the potential trade-off between greening and brown expansion of the electricity supply in developing countries, under influence of increasing population density. It is a deterministic partial equilibrium model of the electricity supply chain, in which the demand for electricity in a central marketplace can be satisfied by a non-renewable energy fuel, a renewable energy source, or both. Power density differs between

renewable and fossil fuels. The non-renewable resource (coal) is more power dense and hence spatially more productive than the renewable resource (solar), which all things equal implies it is cheaper to transport coal than solar energy. Hence, for a given distance, the transport (or transmission) cost of solar should exceed that of coal. Because of this, coal will be sourced from a greater distance than solar and it will provide a greater share in total electricity production. If people, because of urbanization processes, increasingly are concentrated in space, the demand for resources with a relatively high “spatial productivity” will increase: according to the scaling law of Moreno-Cruz and Taylor (2017), the supply of energy from a particular energy source is increasing in its power density. Hence, the trade-offs between greening and expansion of electricity supply are subject to the distribution of population and economic development across space.

We find that lower population density and low growth of population density encourage the development of green electricity production and share. Population density has a bigger effect on the brown and green electricity shares for low elasticity of electricity demand and low elasticity of land investment cost for green exploitation area with regards to population density. Higher elasticity of electricity demand with regards to population density brings bigger green electricity production but with smaller share. Lower elasticity of land investment cost for green exploitation area with regards to population density, the greater the green electricity and share. The lower the brown power density and the higher the green power density, the greater the green electricity production and share. Last, we also find that changes on the brown and green power densities and on the elasticity of land investment cost for green exploitation area with regards to population density has no significant effect on the TSO’s profit but the TSO’s profit will be bigger with higher growth of population density and bigger electricity demand with regards to population density.

The remainder of this paper is organized as follows. In sections 2 and 3 we present our deterministic partial equilibrium theory and the model’s equilibrium path of the energy sector. In section 4 we briefly review recent developments in Indonesia’s energy and electricity sector and describe the calibration of our model to the Indonesian situation. In section 5 we present and discuss our main simulation results. Section 6 concludes.

2. THE MODEL

2.1 Introduction

To understand how geography, power density and technology (of fuel transportation, electricity generation and electricity transmission) influence local electricity diversification, we develop a deterministic partial equilibrium model of the energy supply chain. We extend the spatial energy model by Moreno-Cruz and Taylor (2014) by incorporating (i) both renewable and non-renewable energy sources, (ii) electricity transmission and (iii) investment in generation capacity.

Electricity can be generated by non-renewable energy fuels (e.g., coal, lignite and gas) or renewable energy (e.g., solar, wind and biomass). Two fundamental characteristics drive the supply of these resources in our model. First, wind and solar provide small amount of (free) energy per square meter of land compared to fossil fuels. In technical terms, renewable energy is characterized by relatively small power density. The diffuse nature of these resources implies that a sizeable deployment of renewable is dependent on an abundance of cheap and suitable land. Second, as wind and solar energy are free, their costs are primarily driven by the cost of capital associated with capacity investment. There are cities, whose location is fixed, demanding electricity. Electricity is generated either by the combustion of fossil fuels in thermal power plants or by renewable generators, e.g., wind turbines and solar panels. Thermal power plants are located near the cities and electricity transmission service is needed to supply electricity from producers to consumers.

We analyse four different sectors producing various intermediate goods and services. The non-renewable resource sector extracts fossil fuels from a range of locations across space and then transports these fuels to thermal power plants. Thermal power plant producers buy a non-renewable energy fuel to generate electricity using the available stock of generators. Producers of renewable electricity obtain free solar or wind energy in an amount that is proportional to installed generation capacity. Both producers sell their electricity in the electricity wholesale market to a Transmission Service Operator (TSO). In turn, the TSO delivers electricity along the electricity grid to consumers in the cities. Often, the TSO is the national electricity company, which is, especially in lower- and middle-income countries, usually owned or controlled by the state. All markets, except the consumer electricity market, are characterized by perfect competition. Since the TSO is the only supplier of electricity to consumers, the consumer electricity market is characterized by a monopoly, which we will explain in more detail later.

2.2 Geography of Electricity Production

We assume a small open economy zone, which consists of a large city (◆) and several small cities (●). The cities demand electricity, which is produced in a power plant (■) located within the small open economy, outside of the human settlements. The big city is located near the power plant and the small cities are located around the big city. Energy for electricity production is sourced from renewable and non-renewable resources. The non-renewable resources for the thermal power plant is supplied from a mine (▲) located outside of the small open economy zone. The distance between the power plant and the mine is r_B [m]. The frontier of the small open economy is located at a distance λ of the thermal power plant. This location also marks the beginning of the non-renewable resource zone, which is located outside the small open economy – implying that, in contrast to renewable resources, non-renewable resources are collected at the world market. Both the domestic and international zone are characterized by a width ω [m].

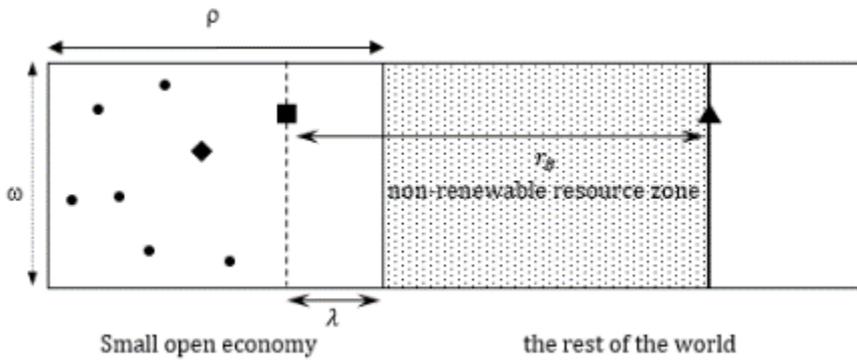

Figure 44 – Illustration of Small Open Economy and Exploitation Zone of Non-Renewable Resource

2.3 Electricity Market

Electricity Supply

The cities are supplied with the electricity produced by the thermal power plant producer and the producer of green electricity and distributed by the transmission service producer. The net supply of electricity, W_S^e [W], is the total electricity production minus the electricity loss in the distribution:

$$W_S^e = (1 - L_B)W_B^e + (1 - L_G)W_G^e \tag{1}$$

where L_B and L_G are the percentage loss of electricity generated from non-renewable resource and renewable resource respectively.

Electricity Demand

Electricity demand is the total electricity consumption of population in the small open economy:

$$W_D^e = iAD^{\beta_w} \tag{2}$$

with:

$$i = b - gp^e \tag{3}$$

$$AD = N \tag{4}$$

where i [W/people] is the electricity intensity, b [W/people] is the maximum intensity of electricity consumption, g [W²/\$·people] is the effect of the electricity price on the electricity intensity with $b, g > 0$, A [m²] is the small open economy area, D [people/m²] is population density in the small open economy, β_w is the elasticity of electricity demand with regards to population density,¹⁶⁶ and N [people] is population in all cities in the small open economy. Hence, the model can best be interpreted as a single (representative) city model.¹⁶⁷

Market Equilibrium

In market equilibrium, electricity supply W_S^e [W], equals electricity demand W_D^e [W]:

$$W_S^e = W_D^e \Leftrightarrow (1 - L_B)W_B^e + (1 - L_G)W_G^e = (b - gp^e)AD^{\beta_w} \tag{5}$$

From this definition, it follows that the consumer electricity price in equilibrium is:

$$p^e = \frac{b}{g} - \frac{(1-L_G)W_G^e + (1-L_B)W_B^e}{gAD^{\beta_w}} \tag{6}$$

Equation (6) shows that the consumer electricity price is increasing in maximum intensity of electricity consumption (b), distribution losses (L_G, L_B), the small open economy area (A), population density (D) and the elasticity of electricity demand with regards to population density (β_w). The consumer electricity price is decreasing in supply of electricity (W_S^e, W_B^e) and the price elasticity electricity intensity (g).

Moreno-Cruz and Taylor (2012) focus on explaining how the location and productivity of energy resources determine the distribution of economic activity around the globe. While the distribution of energy resources in the Asian-Pacific region may influence the distribution of economic activity both within and across Indonesia and surrounding countries, we recognize that there may be other drivers as well. We therefore take the potential demand for electricity as given and then try to explain and predict how various features of geography and technology affect both the overall supply of energy as well as the energy mix in Indonesia.

¹⁶⁶ We adjust Bettencourt's *et al.* (2007) formulation. In Bettencourt's *et al.* (2007), β_w is the elasticity of electricity demand with regards to population size.

¹⁶⁷ In principle, we could model energy consumption over a large number of cities as: $W_d^e = \sum_{i=1}^N w_0(n_i)^{\beta_w}$, where n_i is population size of city i . However, calibration of the model then requires city-specific data on the elasticity of electricity demand with regards to population density, which is yet unavailable for Indonesia. Also, on the supply side, where "D" plays a role in the transmission losses, we have a single city. A multi-city model thus requires at least to make the length of the electricity grid city specific as well, implying a need to collect city-specific data on transmission losses - which is also yet unavailable. We therefore leave this for future research.

2.4 Non-Renewable Resource Production

Producers, like mining companies, use a constant-returns-to-scale transportation technology to collect and carry energy fuels from the non-renewable resource zone to the thermal power plant located near the big city. Transport of energy fuels from the mine to the electricity power plant is costly, and costs increase with the distance and the resource weight. Let us define the physical density of the resource by f_B [kg/m²] and the exploitation area of the non-renewable resource by A_B [m²], then the resource weight x_B [kg] equals $f_B \cdot A_B$. Next, let us define the price of the non-renewable fuel set by the mine producer as p_B^m [\$/W]. Producers of brown resources earn revenues $p_B^m \alpha_B A_B$, with α_B [W/m²] the power density of the non-renewable resource. If producers pay a unit cost u_B [\$/kg·m] per total carry x [kg] over distance r_B [m] of the resource, then producer gets profit:

$$\pi_B^m = p_B^m \alpha_B A_B - u_B f_B A_B r_B \quad (7)$$

where m and B successively refer to the mine and brown or non-renewable resource. Resource producers will extract resources until the marginal revenue from the last unit extracted equals its cost of carry. The marginal supplier in the non-renewable resource zone is indifferent between supplying fossil fuels or not when profits have fallen to zero, i.e. the marginal revenue from the last unit extracted equals its cost of carry. To find the distance r_B associated with this marginal unit, we set profits equal to zero:

$$\pi_B^m = 0 \Leftrightarrow r_B^* = \frac{p_B^m \alpha_B}{u_B f_B} \quad (8)$$

$$\Leftrightarrow p_B^m = \frac{u_B f_B r_B}{\alpha_B} \quad (9)$$

The right-hand side of equation (9) represents the average cost. Further, based on equation (7) and (8), the higher the resource price and the bigger the power density of the resource, then the greater the gross revenues from the resource collection and the greater the willingness of the mine producer to explore the resource farther from the power plant.

To find the net supply of energy to the thermal power plant, note that across the whole width ω of the resource zone, a total of α_B watts can be collected every meter and delivered to the power plant. Following Moreno-Cruz and Taylor (2014), we do not model energy use in transport of resources. To obtain net resource supply W_B^m to the thermal power plant, we sum the net “physical resource rents” over the whole area of exploitation:

$$W_B^m = \int_{\lambda}^{r_B} \omega \alpha_B dr = \alpha_B \omega (r_B - \lambda) \quad (10)$$

From (10) we find that the greater the power density, the greater the supply of non-renewable resources to the thermal power plant. This is because power density not only increases the supply of energy via the intensive margin, that is, it boosts the supply of energy from infra marginal lands, but also via the extensive margin, that is, it increases the supply of energy by extending the resource frontier outwards. Equation (10) also reveals that if the non-renewable resource zone is located far away from the power plant then net supply to the power plant decreases. In the absence of new resource discoveries, the consumption of non-renewable resources will thus first peak and then decline (Moreno-Cruz & Taylor, 2014).

This boom-bust pattern has already become apparent for Indonesia where the declining production of oil fuel has forced Indonesia to become more reliant on domestic coal production and imports of fossil fuel, possibly turning Indonesia into a net energy importer before 2019 (Indonesian DGNEEC, 2012). Equation (10) explains why in some remote areas like in Indonesia, local resources with much lower power density have not been exploited and those areas are still depending more on non-renewable resources. However, the long delivery distance for the resource caused high cost. For example, the cost to provide oil fuel (including the transport cost) is \$1.52 per liter in the remote Indonesia province of Papua in 2013.¹⁶⁸ This is more than one and half times the price of non-subsidized oil fuel at \$0.8-0.9 per liter.¹⁶⁹ Inclusive of maintenance cost, the electricity production cost per kWh is 38¢, considerably higher than the average basic electricity tariff at only 7¢ per kWh (Dhany, 2013). The high cost lowers the electricity supply and makes power outage happens quite frequent in remote areas.

2.5 Wholesale Electricity Production

Brown electricity

The producer of brown electricity, i.e. the thermal power plant, buys non-renewable resource at price p_B^m , convert them into electricity at the efficiency rate η_B with $0 < \eta_B < 1$ and sells electricity on the wholesale electricity market to the TSO at price p_B^e [\$/W]. Abstracting from operation and maintenance costs, thermal power plant profits equal:

$$\Pi_B^e = p_B^e W_B^e - p_B^m W_B^m - I_B k_B \quad (11)$$

where e refers to electricity producer and I_B [\$/W] is the investment cost of the thermal power plant per unit of installed capacity, k_B [W]. Brown electricity production W_B^e [W] can never exceed full capacity so:

$$W_B^e = \eta_B W_B^m = z_B k_B \leq k_B \quad (12)$$

where z_B is the rate of production at the brown power plant, with $0 \leq z_B \leq 1$. If $z_B = 1$, then the power plant produces at full capacity.

¹⁶⁸ The IDR value was converted to USD based on the average exchange rates in 2013 (Bank Indonesia, 2015).

¹⁶⁹ In 2017, President Joko Widodo commanded to set the uniform oil fuel price in all areas in Indonesia (Irfany, 2017).

Using equation (9), (10) and (12), we can reformulate equation (11):

$$\Pi_B^e = \left(\left(p_B^e - \frac{I_B}{z_B} \right) \eta_B \alpha_B - u_B f_B r_B \right) A_B \quad (13)$$

Equation (13) demonstrates that the higher the price of brown electricity and the efficiency rate in the thermal power plant, the bigger the power density of the resource and the wider exploitation area of the resource, the greater the profit of the brown electricity producer. Equation (13) also describes that the higher the investment cost and the unit cost of carry, the heavier the resource weight collected per meter square of the exploitation area, the farther the distance between the power plant and the resource mine and the lower the production rate in the power plant, the greater the cost and the lower the profit of the brown electricity producer.

With the market for brown generation capacity being perfectly competitive, investors will increase capacity until profits are equal to zero. Setting the right-hand side of equation (11) equal to zero, and rearranging, we obtain:

$$k_B = \left(\frac{p_B^e \eta - p_B^m}{I_B} \right) W_B^m = \left(\frac{p_B^e \eta - p_B^m}{I_B} \right) \alpha_B \omega \left(\frac{p_B^m \alpha_B}{u_B f_B} - \lambda \right) \quad (14)$$

We assume that the brown electricity producer is a non-profit firm who works under zero economic profit. Using equation (9) and (12), the zero-economic profit condition can be written:

$$\Pi_B^e = 0 \Leftrightarrow p_B^e = \frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B \quad (15)$$

According to equation (15), the higher the investment cost and the unit cost of total carry, the heavier the resource and the farther the distance between the power plant and the resource mine, then the higher the price of brown electricity, but higher production and efficiency rates in the thermal power plant and greater power density of the resource, the lower the brown electricity price.

Green Electricity

The producer of green electricity collects energy from renewable energy source like sunlight, wind and geothermal heat, converts this into electricity at the efficiency rate η_G with $0 < \eta_G < 1$ and sells the green electricity on the wholesale electricity market to the TSO at price p_G^e [\$/W]. We assume that the green electricity producer only needs to cover investment cost, because for many renewable energy technologies the renewable resources (like wind and sun) can be collected for free at the power plant. Hence, the profit function of the green electricity producer is:

$$\Pi_G^e = p_G^e W_G^e - I_G k_G \quad (16)$$

where G refers to green or renewable resource, I_G [\$/W] is the investment and maintenance cost of the green power plant per unit of installed capacity, k_G [W]. We assume that the costs for generating green power decrease in the power density α_G and the efficiency rate η_G with which the flow of renewable resources can be exploited (IRENA, 2015), but increase in population density D because this reduces the potential exploitation area of the renewable resource (A_G). An increasing demand for residential land area implies increasing scarcity of suitable land to harvest green energy from hydro dams, windmills, biomass crops and solar farms, and thus higher production costs. We model these various effects as follows:

$$I_G = I_G^k + \frac{I_G^l}{\eta_G \alpha_G} \psi_G = I_G^k + \frac{A_G}{\eta_G \alpha_G A} I_G^l \quad (17)$$

with I_G^k [\$/W] the cost of the green power equipment (like solar panels), I_G^l [\$/m²] the cost of land area needed for green power production, ψ_G ($0 < \psi_G < 1$) the share of the small open economy area (A) that is used for the green energy production (so $A_G = \psi_G A$), and the other parameters as before.¹⁷⁰ Supply of green electricity production, W_G^e [W], depends on the renewable resource supply, W_G^r , and the efficiency rate of green power production, η_G . Furthermore, we assume that green power plants always run at full capacity, implying that the rate of production at the green power plant $z_G = 1$.¹⁷¹ This implies that:

$$W_G^e = \eta_G W_G^r = z_G k_G = k_G \quad (18)$$

The net renewable resource supply, W_G^r , to the green power plant(s) is defined by the amount of renewable watts that can be collected every square meter – the power density α_G – across the exploitation area A_G of the renewable resource at a cost of I_G^l [\$/m²], with the exploitation area being defined by its width ω and length ρ (see Figure 2). We do not model energy use or other costs in transport of resources.¹⁷² Hence, the net “physical resource rents” over the whole area of exploitation are:

$$W_G^r = \alpha_G \omega \rho \psi_G = \alpha_G \psi_G A \quad (19)$$

Using equation (17), (18) and (19), we can reformulate equation (16):

¹⁷⁰ We could assume that the costs for generating green power decrease in the cumulative installed production capacity K_G because of a technology learning effect (IRENA, 2016), such that $I_G^k = aK_G^{-b}$. However, this would complicate the model without yielding additional insights for the purpose of our analysis. Therefore, we take I_G^k as a fixed cost, implicitly assuming that learning effects materialize in the world market from which green power equipment is imported.

¹⁷¹ This assumption implies that solar panels and windmills are never switched off, which is a reasonable assumption (especially for solar panels, the most important source of renewable energy in Indonesia).

¹⁷² These costs are zero by definition in the case of electricity production from solar, wind and hydro, but maybe positive in the case of burning biomass.

$$\Pi_G^e = (p_G^e - I_G)\eta_G\alpha_G\psi_G A \quad (20)$$

Equation (20) shows that green electricity profits are increasing in the green electricity price and decreasing in the cost of investment, subject to the efficiency rate of green power production, η_G , the power density of the renewable resource, α_G , the size of the small open economy area, A , the share of the small open economy area that is used for green energy production, ψ_G , and the cost of land area needed for green power production I_G^k . With the market for renewable generation capacity being perfectly competitive, investors will find it worthwhile to increase capacity until the green electricity price equals the effective per unit capital cost. Setting the right-hand side of equation (20) equal to zero, using equation (17) and rearranging, we obtain:

$$k_G = \left(\frac{p_G^e \eta_G}{I_G}\right) W_G^r = \left(\frac{p_G^e \eta_G}{I_G}\right) \alpha_G \psi_G A = \left(\frac{p_G^e \eta_G}{I_G^k + \frac{I_G^l}{\eta_G \alpha_G} \psi_G}\right) \alpha_G \psi_G A = \frac{p_G^e (\eta_G \alpha_G)^2 A \psi_G}{I_G^k \eta_G \alpha_G + I_G^l \psi_G} \quad (21)$$

According to equation (21), the installed capacity of green power production increases in the green electricity price, p_G^e , the efficiency rate of green power production, η_G , the power density of the renewable resource, α_G , and the size of the open economy area, while it decreases in the cost of the green power equipment (like solar panels), I_G^0 [\$/W], and the price of land for green energy production, I_G^l .

We assume that the green electricity producer is a non-profit firm who works under zero economic profit. Using equation (17), the zero-economic profit condition can be written:

$$\Pi_G^e = 0 \Leftrightarrow p_G^e = I_G^k + \frac{\psi_G}{\eta_G \alpha_G} I_G^l \quad (22)$$

According to equation (22), the higher the land and equipment investment cost and the share of the small open economy area that is used for green energy production, then the higher the price of green electricity, but greater power density of the renewable resource and higher efficiency rates in power production plant, the lower the green electricity price.

2.6 Transmission of Electrical Power Transmission Technology and the Electricity Grid

We assume that the thermal power station is located outside of the large city (◆), creating a natural demand for the transportation of electrical power from producer to consumers. Since their inception in the 19th century, electricity grids have enabled the transportation of electrical power across long distances. The bulk of electricity is transferred, or transmitted, along high-voltage power lines from power station to electrical substations. Central to the final stage of the delivery of electricity to consumers is a more fine-grained collection of power lines, a part of the infrastructure often referred to as the distribution grid. Together the transmission and distribution grid are referred to as the electricity grid. The transmission of electrical power depends on the geographic distribution of power producers and electricity consumers. For green electricity, we assume that it could be generated by a utility-scale solar power plant which is also located outside of the city, but the green electricity generator may also be installed at the consumer's residency, e.g., a set of solar panels that is placed on the roof.

The longer the electricity grid, i.e. s_B and s_G [mc]¹⁷³, the more expensive the distribution of electricity will be. Moreover, if people cluster in the large city (◆), fewer lines are required. On the other hand, if people live scattered in small cities (●) or the countryside, more lines are needed. Therefore:

$$L_B = \tau s_B = \tau \gamma_B D^{-\beta_s} \quad (23)$$

$$L_G = \tau s_G = \tau \gamma_G D^{-\beta_s} \quad (24)$$

with:

$$s_B = \gamma_B D^{-\beta_s} \quad (25)$$

$$s_G = \gamma_G D^{-\beta_s} \quad (26)$$

where L is losses, τ [%/mc] is the effect of the distribution distance on the electricity loss, γ^{174} is the effect of population density on the length of distribution line and β_s is the elasticity of population density on electricity loss through the length of distribution lines. We assume that $\beta_s > 0$.¹⁷⁵ Since the thermal power plant cannot be in the cities then the brown electricity always needs the transmission service and so: $\gamma_B > 0$. Moreover, since the green electricity generator could be placed at the customers' residency so: $\gamma_G \geq 0$. If we assume that the green electricity is generated by solar power and the solar power is installed at the top of the customers' roof, then the transmission service is not needed. In that case, $\gamma_G = 0$, so that $s_G = 0$ and $L_G = 0$.

Transmission Service Operator

¹⁷³ mc = meter circuit

¹⁷⁴ If $\beta_s = 1$ then the unit measurement for γ is mc·people/m².

¹⁷⁵ Notice that in our model, the elasticity measured the effect of population density on the electricity loss or the length of distribution line, while Bettencourt *et al.* (2007) present the effect of population size on the length of distribution line.

The transmission system operator buys power at the price p_B^e for electricity generated from the non-renewable resource and at the price p_G^e for electricity generated from the renewable resource, and sells electricity to consumers in the small open economy at price p^e [\$/W],¹⁷⁶ taking into account that the electricity supplied suffers from transmission losses:

$$\Pi_T^e = ((1 - L_B)p^e - p_B^e)W_B^e + ((1 - L_G)p^e - p_G^e)W_G^e \quad (27)$$

Rewriting equation (27) using equations (10), (12), (15), (18), (19), (22), (23), (24) gives us:

$$\Pi_T^e = \left((1 - \tau\gamma_B D^{-\beta_s})p^e - \frac{I_B}{z_B} - \frac{u_B f_B}{\eta_B \alpha_B} r_B \right) \eta_B \alpha_B A_B + \left((1 - \tau\gamma_G D^{-\beta_s})p^e - I_G^k - \frac{\psi_G}{\eta_G \alpha_G} I_G^l \right) \eta_G \alpha_G A_G \quad (28)$$

Equation (28) defines that profits of the transmission service producer are increasing in the price of electricity, the power plant efficiency rate, the power density of the energy resources, the resource exploitation areas and the production rate at the generator. Profits are decreasing in the electricity loss per unit of the length of the distribution line, the effect of the electricity generation technology on the length of the distribution line and the cost of investment. Furthermore, greater population density and a lower elasticity of the line distance with respect to population density reduce transmission cost and raise profits.

Higher cost to deliver the resource from the mine to the thermal power plant, greater weight of the brown resource and farther distance between the thermal power plant and the mine reduce the profit but lower learning rate coefficient increases the profit.

3. MODEL EQUILIBRIUM

To close the model, we assume that it is the objective of the Transmission Service Operator (TSO) to maximize profits by choosing the optimal mix of brown and green electricity from the electricity producers, subject to the equilibrium condition (5) where total electricity supply equals total electricity demand by consumers. By substituting equation (6) into equation (27), the profit function of the TSO reads as:

$$\Pi_T^e = \left(\frac{b}{g}(1 - L_B) - p_B^e \right) W_B^e + \left(\frac{b}{g}(1 - L_G) - p_G^e \right) W_G^e - \frac{2(1-L_B)(1-L_G)}{gAD^{\beta_W}} W_B^e W_G^e - \frac{(1-L_B)^2}{gAD^{\beta_W}} W_B^{e2} - \frac{(1-L_G)^2}{gAD^{\beta_W}} W_G^{e2} \quad (29)$$

The first-order conditions for maximization of Π_T^e are:

$$\frac{\partial \Pi_T^e}{\partial W_B^e} = 0 \Leftrightarrow \frac{b}{g}(1 - L_B) - p_B^e - \frac{2(1-L_B)(1-L_G)}{gAD^{\beta_W}} W_G^e - \frac{2(1-L_B)^2}{gAD^{\beta_W}} W_B^e = 0 \quad (30)$$

$$\frac{\partial \Pi_T^e}{\partial W_G^e} = 0 \Leftrightarrow \frac{b}{g}(1 - L_G) - p_G^e - \frac{2(1-L_B)(1-L_G)}{gAD^{\beta_W}} W_B^e - \frac{2(1-L_G)^2}{gAD^{\beta_W}} W_G^e = 0 \quad (31)$$

Re-arranging equations (30) and (31) yields the optimal quantities of brown (W_B^e) and green (W_G^e) electricity, respectively:

$$W_B^e = \frac{gAD^{\beta_W}}{2(1-L_B)^2} \left[\frac{b}{g}(1 - L_B) - p_B^e \right] - \left(\frac{1-L_G}{1-L_B} \right) W_G^e \quad (32)$$

$$W_G^e = \frac{gAD^{\beta_W}}{2(1-L_G)^2} \left[\frac{b}{g}(1 - L_G) - p_G^e \right] - \left(\frac{1-L_B}{1-L_G} \right) W_B^e \quad (33)$$

From equations (32) and (33), it can be seen that the optimal quantity of both brown and green electricity increases in the small open economy area (A), population density (D), the elasticity of electricity demand with regards to population density (β_W) and the maximum intensity of electricity consumption (b). Furthermore, the optimal quantity of green (brown) electricity increases in distribution losses and production price of brown (green) electricity.

To further specify W_B^{e*} and W_G^{e*} we make use of equations (10) and (12) to define r_B as a function of W_B^e :

$$W_B^e = \eta_B W_B^m = \eta_B \alpha_B \omega (r_B - \lambda) \Leftrightarrow r_B = \frac{1}{\eta_B \alpha_B \omega} W_B^e + \lambda \quad (34)$$

and we make use of equations (18) and (19) to define η_G as a function of W_G^e :

$$W_G^e = \eta_G W_G^r = \eta_G \alpha_G \omega \rho \psi_G = \eta_G \alpha_G \psi_G A \Leftrightarrow \eta_G = \frac{1}{\alpha_G \psi_G A} W_G^e \quad (35)$$

Next, we substitute (33) and (34) into (32), as well as (32) and (35) into (33). In doing so, we make use of $p_B^e = \frac{I_B}{z_B} +$

$\frac{u_B f_B}{\eta_B \alpha_B} r_B$ from equation (15) and $p_G^e = I_G^k + \frac{\psi_G}{\eta_G \alpha_G} I_G^l$ from equation (22). After re-arranging, we get:

$$W_B^{e*} = \frac{(\eta_B \alpha_B)^2 \omega}{u_B f_B} \left[\left(\frac{1-L_B}{1-L_G} \right) \left(I_G^k + \frac{\psi_G}{\eta_G \alpha_G} I_G^l \right) - \left(\frac{I_B}{z_B} + \lambda \frac{u_B f_B}{\eta_B \alpha_B} \right) \right] \quad (36)$$

$$W_G^{e*} = \frac{(\eta_G \alpha_G)^2 A}{I_G^l} \left[\left(\frac{1-L_G}{1-L_B} \right) \left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B \right) - I_G^k \right] \quad (37)$$

Next, let us make the following assumptions:

¹⁷⁶ The electricity price in reality is the price of energy (\$/kWh) but in our model, the electricity price is the price of electrical power (\$/W). Power is energy per unit of time. We convert the price in \$/kWh into \$/W by assuming that the time is one year.

A1. The green electricity price net of transmission losses must be strictly larger than the first unit of brown electricity delivered, $p_G^e \left(\frac{1-L_B}{1-L_G} \right) > \frac{I_B}{z_B} + \frac{u_B f_B \lambda}{\eta_B \alpha_B}$.

A2. Electricity demand must be sufficiently large, that is,

$$\frac{(\eta_B \alpha_B)^2 \omega}{u_B f_B} \left[\left(\frac{1-L_B}{1-L_G} \right) \left(I_G^k + \frac{\psi_G}{\eta_G \alpha_G} I_G^L \right) - \left(\frac{I_B}{z_B} + \lambda \frac{u_B f_B}{\eta_B \alpha_B} \right) \right] < \frac{iAD^{\beta_W}}{1-L_B}$$

We can then summarize our findings in the following propositions.

Proposition 1. Assume A1 and A2 hold. The equilibrium pair (W_B^{e*}, W_G^{e*}) represented by equations (36)–(37) is then strictly interior, that is, $(W_B^{e*}, W_G^{e*}) > (0,0)$.

In equilibrium, the level of brown electricity produced is increasing (and the level of green electricity produced is decreasing) in the width of the non-renewable exploitation area, the resource and production efficiency of the thermal power plant, the power density of the non-renewable resource, the share of total land area devoted to green power production, the unit price (or cost) of green electricity, green transmission losses and population density.

On the other hand, the level of green electricity produced is increasing (and the level of brown electricity produced is decreasing) in the size of the open economy area, the efficiency rate of green power production, the power density of the renewable resource, the unit price (or cost) of brown electricity, brown transmission losses and the transport costs of the non-renewable resource to the thermal power plant.

From equation (17), (22) and (36) it follows that in equilibrium, a high share of total land area devoted to green power production, ψ_G , increases the level of brown electricity produced because the more land area used for green power produced the more scarce suitable land to harvest green energy will be, thus increasing the costs of land for green power production and therefore the unit price (or cost) of green electricity. At the same time, in section 2.5 we have argued that the potential renewable exploitation area will also become scarcer under influence of increasing population density, D , because of the implied increasing demand for residential land area. Let us assume that the costs of land for green power production, I_G^L , depend on population density, D , according to:

$$I_G^L = \theta D^{\beta_L} \tag{38}$$

with $0 < \beta_L < 1$ the price elasticity of land. Combining equation (38) with the definitions of population density and the share ψ_G of the small open economy area (A) that is used for the green energy production as given in, respectively, equations (4) and (17), allows us to define how the green electricity price (see equation (22)), depends on population size, the size of the renewable exploitation area A_G and its share ψ_G in the small open economy area (A):

$$p_G^e = I_G^k + \frac{\psi_G}{\eta_G \alpha_G} \theta D^{\beta_L} = I_G^k + \frac{\theta \psi_G^{1+\beta_L}}{\eta_G \alpha_G} \left(\frac{N}{A_G} \right)^{\beta_L} \tag{39}$$

This leads to the following proposition.

Proposition 2. The green electricity price (and thus the level of brown electricity produced) is increasing in population size, the share of total land area devoted to green energy production and the price elasticity of land.

On the other hand, the green electricity price (and thus the level of brown electricity produced) is decreasing in the efficiency rate of green power production, the power density of the renewable resource and the size of the renewable exploitation area.

Hence, we find that the role of increasing the renewable exploitation area in greening the electricity supply is ambiguous, since it depends on the price elasticity of land, β_L , and population size. Increasing the renewable exploitation area stimulates green electricity production only if price elasticity of land price and population size are modest. To further gain insight in the role of a growing population on the greening of the electricity supply we substitute equation (36) into the equilibrium condition (5), to obtain:

$$W_G^{e*} = \frac{(b-gp^e)AD^{\beta_W} - (1-L_B)W_B^{e*}}{(1-L_G)} = \frac{(b-gp^e)AD^{\beta_W} - (1-L_B) \frac{(\eta_B \alpha_B)^2 \omega}{u_B f_B} \left[\left(\frac{1-L_B}{1-L_G} \right) \left(I_G^k + \frac{\theta D^{\beta_L}}{\eta_G \alpha_G} \psi_G \right) - \left(\frac{I_B}{z_B} + \lambda \frac{u_B f_B}{\eta_B \alpha_B} \right) \right]}{(1-L_G)} \tag{40}$$

From equation (40) it follows that a higher population density, D , on the one hand increases the equilibrium level of green electricity, W_G^{e*} , through a higher demand $(b - gp^e)AD^{\beta_W}$ ($g > 0$), subject to the elasticity of electricity demand with regards to population density, β_W . On the other hand, a higher population density, D , decreases the equilibrium level of green electricity, W_G^{e*} , by increasing the equilibrium level of brown electricity (see proposition 1). The latter effect reflects the economies of scale and scope in production and distribution of brown electricity with a relatively high power density, as discussed before. We need to simulate our model to learn the total effect of population density on greening the electricity supply in Indonesia.

Finally, inserting equations (36) and (37) into equation (29) gives us the maximum profit obtained by the TSO. By substituting L_B and L_G from equation (23) and (24) we can then write the maximum profit of the transmission service producer as a function of population density:

$$\Pi_T^{e*} = \left(\frac{b}{g} (1 - \tau_{Y_B} D^{-\beta_S}) - p_B^e \right) W_B^{e*} + \left(\frac{b}{g} (1 - \tau_{Y_G} D^{-\beta_S}) - p_G^e \right) W_G^{e*} - \frac{2(1-\tau_{Y_B} D^{-\beta_S})(1-\tau_{Y_G} D^{-\beta_S})}{gAD^{\beta_W}} W_B^{e*} W_G^{e*} - \frac{(1-\tau_{Y_B} D^{-\beta_S})^2}{gAD^{\beta_W}} W_B^{e*2} - \frac{(1-\tau_{Y_G} D^{-\beta_S})^2}{gAD^{\beta_W}} W_G^{e*2} \tag{41}$$

Equation (41) can be used to determine the population density threshold for a certain level of maximum profits of the TSO.

4. MODEL CALIBRATION AND SIMULATIONS

In this section, we first describe major developments in the electricity system in Indonesia, including a brief portrayal of its institutional context. Next, we briefly describe the calibration of our model on the Indonesian situation.

4.1 The electricity system in Indonesia

As noted in the introduction, Indonesia could in principle benefit from a 'latecomer advantage' to develop a low-carbon electricity system, but currently increasingly uses coal-fired power plants to meet its rising demand for electricity. Also, it is one of the most populous countries in the world. In combination with rising per capita income, continued urbanization and its archipelagic geography, this imposes formidable challenges to its national electricity company (PLN) in terms of expanding and greening its electricity. Most Indonesian residents get their electricity from PLN, the state electricity company in Indonesia, which also buy electricity from Independent Power Producers (IPPs) and Private Power Utilities (PPUs)¹⁷⁷. Besides producing electricity, PLN is also responsible for most of the electricity distribution. Hence, PLN corresponds well with the Transmission Service Operator (TSO) in our model.

PLN is facing difficulties in realizing much needed investments in maintenance and expansion of its generating capacity and network infrastructure. An important reason for this is that the Government of Indonesia regulates the electricity prices and has for years forced PLN to sell electricity under its long-term cost price. Government subsidies to PLN were only sufficient to cover operational cost (Heriyono & Yopi, 2009), and they also have been reduced in recent years. As a result, the consumer electricity price has increased substantially over the last few years.¹⁷⁸ According to the draft of *National Electricity General Plan 2015–2034* (Indonesian MEMR, 2015), Indonesia needs to meet additional power demand at the size of 784 TWh generating capacity until 2034 (compared to 2014). During 2015–2019 the government is planning to build 35GW extra power generating capacity. PLN is responsible for realizing about 29% of this capacity increase while the rest should be developed by the private sector (Indonesian MEMR, 2017).

The national energy policy in Indonesia aims to increase the share of renewable energy from 5% in 2013 to 23% in 2025 and 31% in 2050 (Indonesian MEMR, 2015). In 2015, 90% of PLN's electricity production and purchasing came from non-renewable resources (Indonesian MEMR, 2017). Although PLN had been successful in reducing its dependency on oil fuels from 29% in 2009 to 11% in 2015, the usage of coal and gas as fuel has increased from 36% in 2009 to 52% in 2015 and from 24% in 2009 to 29% in 2015, respectively (PLN, 2010; PLN, 2017). In the longer term, this transition from oil fuel to gas and coal is under pressure, because natural gas production in Indonesia tied up in long-term contracts (Hutagalung & Hartono, 2012; Kompas, 2014) and coal reserves are depleting, while the need for gas and coal increases with the construction of new thermal power plants.¹⁷⁹ In addition, coal producers are inclined to sell their products abroad because it is more profitable (Sutianto, 2014).

Together, this raises the need for the government to keep developing new electricity generating capacity based on renewable resources. Most of PLN's current production and purchasing of green electricity is mainly generated from hydro-power (5.87%) and geothermal energy (4.3%), plus a small amount from biomass (0.2%), waste (0.008%), solar power (0.002%) and wind power (0.0016%). According to PLN's business plan (Indonesian MEMR, 2017), about 41% of additional power plant capacity in 2017-2026 will come from coal steam power. Nonetheless, about 27.7% is supposed to come from renewable resources such as hydropower (18%), geothermal (8.1%) and wind, solar, waste and biomass (1.6%).

The electrification ratio in Indonesia is 91.16% (Indonesian MEMR, 2017), but spatial distribution of electricity access is uneven. The electrification ratio in Java is 91.73% while outside of Java it is on average only 83.28%, with the lowest electrification rate in the West Papua province being 45.93% (Indonesian DGE, 2016). Most of the areas lacking access to electricity are remote areas. Their geographic conditions make it difficult to build power plant and its electricity distribution network.

4.2 Model Calibration

We calibrate the model in this paper using data from Indonesian and international sources, such that the model reflects the electricity system in Indonesia in 2015. After that, we use the model to simulate the effect of some changes on parameters in the model on the profit of the transmission producer and the share of green electricity. More precisely, we

¹⁷⁷ Independent Power Producer (IPP) is a private company that owns power plant to produce electricity for sale to the public under a Power Purchase Agreement (PPA), whereas Private Power Utility (PPU) is a private company which generates, transmits and distributes electricity to its own customer in a certain area (Austrade, 2012). The Indonesian government is also developing Energy Self-Sufficient Villages (ESSV) program. ESSV is a village which is able to generate at least 60% of their electricity and fuel need from local renewable energy resources (Indonesian MEMR, 2014).

¹⁷⁸ The increase of the electricity price sold by PLN is regulated by the Ministry of Energy and Mineral Resources. Since 2015, the basic electricity tariff for household consumer with minimum power of 1300 VA is adjusted every month. With the adjustment price, the highest price increase for household with power 1300 VA is in December 2015 with the price increase of 38.475% from the price in July-August 2014. The price adjustment for household with power of 900 VA is applied since 2017. The price increase in July-September 2017 is 123.47% compared to the price in July-August 2014. For household with power 450 VA, the price is stable.

¹⁷⁹ In 2016, coal reserve and production in Indonesia is 28,457.29 million ton and 456,197,775 ton respectively (Indonesian MEMR, 2017). Assuming that there is no new reserve found then with the same production rate, coal in Indonesia will be exhausted in about 62 years.

use the model to find the production of brown electricity (W_B^e) and the production of green electricity (W_G^e) that maximize profit of the TSO (Π_T^e), given the changes in population density (D) over time.

Land area, population size and population density values are taken from the World Development Indicator database (World Bank, 2017). Population density in Indonesia from 2016 to 2050 is assumed to grow 23%, a value that we take from the United Nations (2017) for medium growth scenario. We measure the length of the economy from the distance between Sabang (the northernmost and westernmost city) and Merauke (the easternmost regency). The effect of population density on the length of the line needed to distributed brown electricity is estimated based on estimations for the line length, population density and brown and green electricity production of Indonesia over the period 1999-2014. Because of lack of data, we assume that the length of the line needed to distribute brown electricity is proportionate to brown electricity production. We set the distance between the thermal power plant and the border between the small open economy and the exploitation area of the brown resources at zero (as if the power plant is in the border between the small open economy and the exploitation area of the brown resources). The reason is that we cannot easily obtain a true value, given that there are many power plants in many locations. By setting the value at zero, the effect of parameter changes in the simulation on the distance between the power plant and the mine (r_B) can be showed clearly. The distance between the power plant and the mining of brown resources is estimated based on brown electricity production (Indonesian MEMR, 2017), as well as the estimated brown power density and the brown efficiency rate in 2016. The share of the green exploitation area is estimated based on brown and green electricity production in 2016 (Indonesian MEMR, 2017), the estimated green power density and the green efficiency rate in 2016, the width of the Indonesia area ($\omega = \frac{A}{\rho}$) and the distance between small open economy and the exploitation area of the brown resources.

Because coal steam power is dominating in Indonesia, power density of brown resources is estimated based on coal power density in coal power plants (Donald, 2016), while power density of green resources is based on the average solar radiation in Indonesia (Indonesian DGNREEC, 2013). The value for physical density of the brown resource is based on the normal weight of coal (145 tons) from one acre area with the thickness of 30 inches (The Kentucky Foundation, 2007). The efficiency rate of the thermal power plant is based on the average thermal efficiency rate in Indonesia in 2016, while the efficiency rate for green electricity production is estimated on the basis of the efficiency rate of solar panels (c-Si type) in 2003 and 2012 (IEA, 2014; IRENA, 2015). The unit delivery cost of brown energy resource from the mine to the thermal power plant is based on maximum coal transport cost by train in Indonesia in 2016 (IDOMINING, 2016). Actual production rate in the thermal power plant is estimated based on the installed capacity and electricity production in Indonesia during 2001–2016. Unit investment cost of thermal power plant is based on an estimation of investment cost of coal steam power plants per year of lifetime. The unit capital investment cost of green power plant are based on the investment of solar power plant per year of lifetime (IRENA, 2016).

The elasticity of the electricity loss or the line length with regards to population density is estimated based on data about electricity losses in transmission and distribution and data for population density in Indonesia during the period 1990-2016. The elasticity of electricity demand with regards to population density is estimated based on the average total electricity sales and population density of Indonesia during 1989/1990-2015. Since we do not have information about the land investment cost for green power plants, we set the elasticity of the costs of green land area with regards to population density at 1. The electricity price is based on the average electricity selling price in Indonesia in 2016. The intensity of electricity consumption is estimated based on PLN electricity sales in 2016 (Indonesian MEMR, 2017). The effect of the electricity price on electricity consumption intensity is estimated based on the estimated electricity consumption intensity and the average selling price during 2001–2015. The effect of length of the line on the transmission and distribution loss is estimated based on the electricity loss in the transmission and distribution and total length of line of low, medium, high and extra high voltage of Indonesia in 2016.

Most of data used to estimate parameter values in the model come from the Indonesian Ministry of Energy and Mineral Resources, PLN, and the World Bank but some are taken from other sources (see Table B.1 in Appendix B).

5. SIMULATION RESULTS

In this section we present our most important simulation results. The simulations are presented in Figure 3–5, showing how the share and production green electricity changes over time under influence of changes in population density, the elasticity of electricity demand with regards to population density (β_W), brown and green power densities (α_B and α_G) and the elasticity of the land investment cost for green power plant with regards to population density (β_L).

A first key result, as shown in Figures 3 and 4, is that increasing population density over time leads to an expected decreasing share and level of green electricity production. The top of Figure 3 shows that in the medium population growth scenario the share of green electricity decreases from about 13% in 2016 to about 7% in 2050 (left-hand side). This equals an annual reduction of just over 1%. Over the same period, production of green electricity decreases from about 3.5 billion Watt in 2016 to 2.5 billion Watt in 2050 (right-hand side), which equals a reduction of just over 30%. The reduction of the green electricity production is accompanied by a decrease of the green exploitation area, suggesting that there indeed is a competition for land between the need for the green exploitation area and other needs, such as land needed for residential use. In the high population growth scenario, the share of green electricity drops to about 5% by 2050, corresponding with about 2 billion Watt in production. Interestingly, in the low population growth scenario, the share of green electricity follows a U-curve shaped pattern, with a minimum around the year 2040. This pattern can be explained by the opposing forces of increasing population density, increasing electricity demand and a relatively low

green electricity price because of the relatively low costs of green land area under influence of a moderate population density.

The bottom of Figure 3 shows that the model outcomes are sensitive to the elasticity of electricity demand with respect to population density, β_W . An elasticity of 1 instead of 1.29 (baseline) leads to about a four-fold increase in the share of green electricity (left-hand side). The impact on total green electricity is only marginal (right-hand side), implying that the increasing share of green electricity levels out with the relatively moderate increase in total demand. This underlines the importance of better understanding how agglomeration (increasing population density) impacts the demand for energy in general, and electricity in particular. In the literature on scaling laws (see, for example, Bettencourt et al. 2007), there is some evidence given for the elasticity of electricity demand with regards to population size in cities. In the urban studies literature some evidence is provided that both increasing urban density and increasing city size reduce households' average energy consumption (see, e.g., Glaeser & Kahn, 2010; Larson & Yezer, 2015; Sugahara & Bermont, 2016). The basic idea underlying this so-called compact city argument is that a higher population density makes cities more environmentally friendly because it decreases average commuting distance, increases public transport usage, while smaller housing units help to reduce transport and home energy use (Glaeser & Kahn, 2010). However, thus far the compact city argument received only very little attention in the context of developing countries; exceptions include Chen et al. (2008), Jenks and Burgess (2004), and Permana et al. (2008).

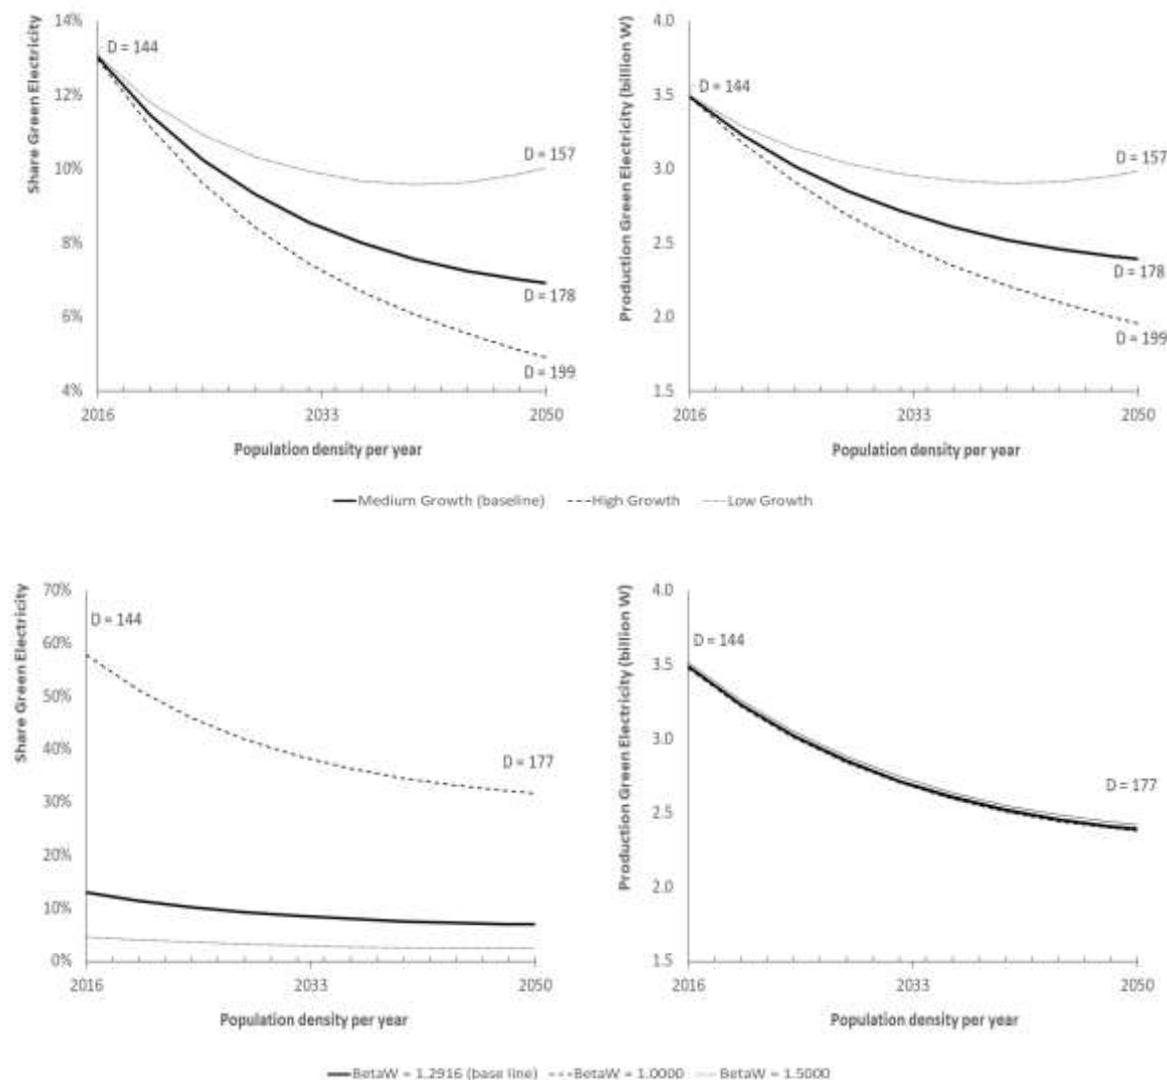

Figure 3. The share (left) and production (right) of green electricity under influence of changing population density (D) and elasticity of electricity demand with respect to population density (β_W)

The top of Figure 4 shows that the share and size of green electricity production increases 2–2.5 times if green power density (α_G) increases with 50% (from 200 to 300) or the elasticity of investment cost for green area with respect to population density (β_I) decreases with 20%. In contrast, a 70% reduction of brown power density (α_B) has almost no impact on the share and size of green electricity production. The latter can be explained by the already substantial higher power density of brown resources as compared to green resources. The bottom of Figure 4 shows that the share of green electricity production decreases below 3% if green power density (α_G) would fall with 50% (from 200 to 100) and even become almost zero if the elasticity of electricity demand with respect to population density (β_I) doubles (to 2). Again, a 50% increase in brown power density (α_B) has almost no impact on the share and size of green electricity production.

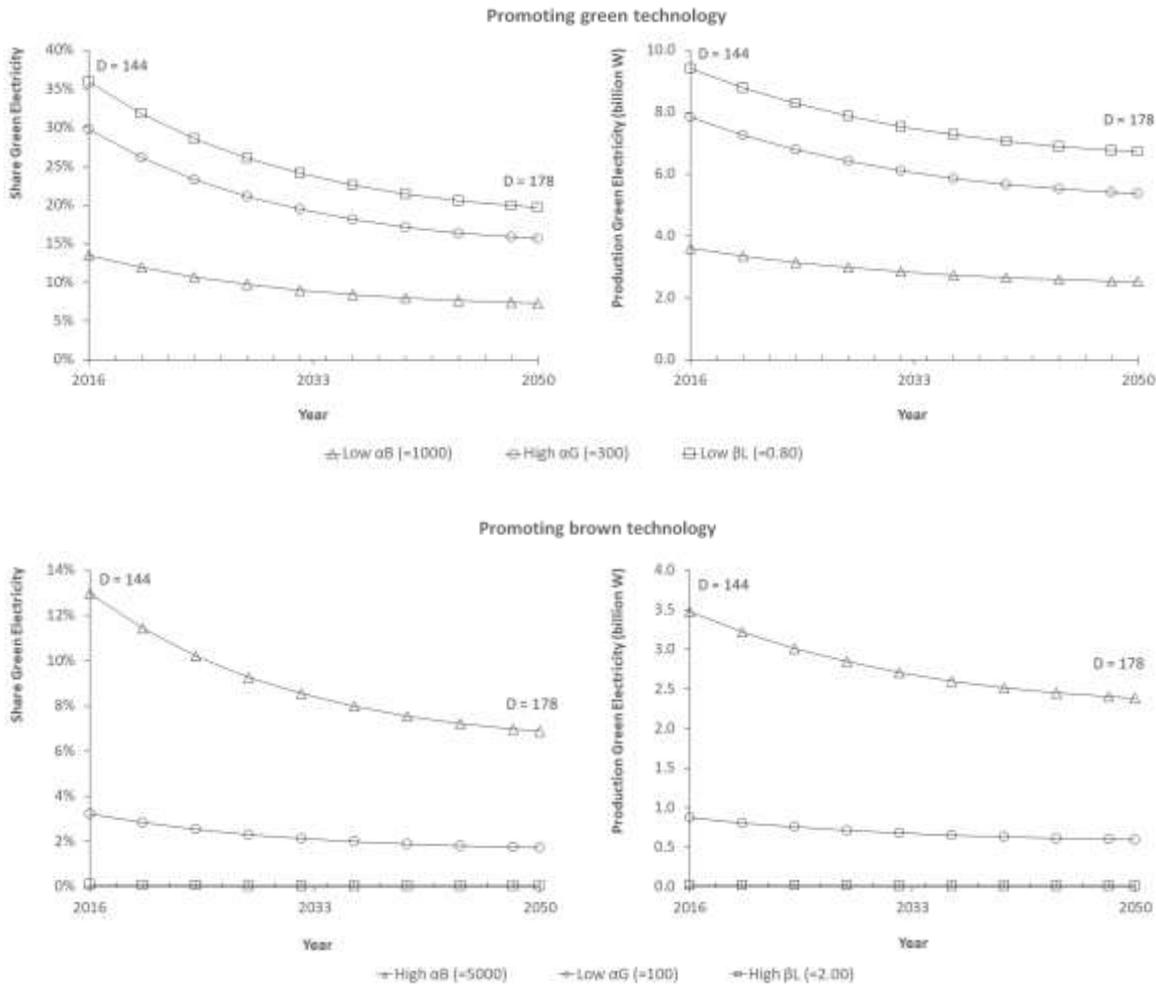

Figure 4. The share (left) and production (right) of green electricity under influence of promoting green technology (top) versus brown (bottom) technology.*

* Promoting green technology: low power density of fossil fuels, high power density of renewables, low price elasticity of green land area. Promoting brown technology: high power density of fossil fuels, low power density of renewables and high price elasticity of green land area.

Finally, we show in Figure 5 how the costs of green land area change under influence of increasing population density (left) and different price elasticity of green land area (right).

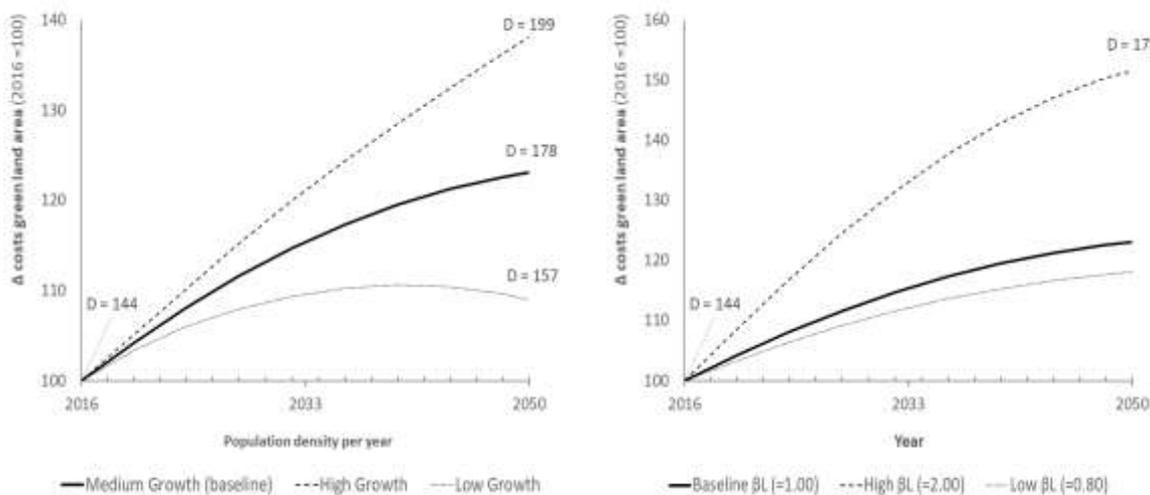

Figure 5. The increase in costs of green land area under influence of increasing population density (left) and different price elasticity of green land area (right).

From the left-hand side of the Figure it can be concluded that in the medium population growth scenario, the costs of land needed for green electricity production increase almost 25% until 2050. In the high- and low population growth scenarios, these costs increases are, respectively, about 40% and 10%. The right-hand side of the Figure shows that a doubling of the elasticity of electricity demand with respect to population density (β_L) leads to more than a 50% increase in the price of land needed for green electricity production by 2050, given the medium population growth scenario.

6. CONCLUSIONS

Poor access to modern energy and environmental concerns make developing countries often facing a dual energy challenge: the simultaneous expansion and greening of their electricity supply. We developed a spatial energy model to analyze the trade-off between greening and brown expansion of electricity supply in developing countries, under influence of increasing population density. We analyzed how the cost advantage of fossil fuels vis-a-vis low-carbon alternatives arises from three interrelated features: geography, power density and technology.

Probably the most prominent feature of spatial transformation in developing countries is increased urbanization. The transition to a predominantly urban society will have a significant impact on a transition to a low carbon energy system, because there are fundamental physical limits to how much energy we can extract from renewable resources for a given area of land. Fossil fuel are more power dense and hence spatially more productive than renewable energy resources (like solar), which all things equal implies it is cheaper to transport fossil fuels. If people, because of urbanization processes, increasingly are concentrated in space, the demand for resources with a relatively high “spatial productivity” will increase, thus impeding the emergence of a low-carbon energy system.

Our spatial energy model is a deterministic partial equilibrium model of the electricity supply chain, in which the demand for electricity in a large city can be satisfied by a non-renewable (‘brown’) energy fuel, a renewable (‘green’) energy source, or both. We find in equilibrium that the level of brown electricity produced is increasing in the width of the non-renewable exploitation area, the resource and production efficiency of the thermal power plant, the power density of the non-renewable resource, the share of total land area devoted to green power production, the unit price (or cost) of green electricity, green transmission losses and population density. In contrast, the level of green electricity produced is increasing in the size of the open economy area, the efficiency rate of green power production, the power density of the renewable resource, the unit price (or cost) of brown electricity, brown transmission losses and the transport costs of the non-renewable resource to the thermal power plant.

Also, we find that the green electricity price (and thus the level of brown electricity produced) is increasing in population size, the share of total land area devoted to green energy production and the price elasticity of land. On the other hand, the green electricity price (and thus the level of brown electricity produced) is decreasing in the efficiency rate of green power production, the power density of the renewable resource and the size of the renewable exploitation area.

We calibrated our model to the case of Indonesia. In Indonesia, coal-fired power plants are increasingly satisfying the rising demand for electricity but the country’s scattered geography, potentially implying large costs to transport coal, and its relatively “clean infrastructure slate”, may enable the country to quickly exploit a range of low-carbon alternatives. However, we find for Indonesia that an increasing population density over time causes a reduction in green electricity production and thus a falling share of green electricity production in total electricity supply. We show that until 2050 expected population growth in Indonesia leads to a 1% annual reduction of the country’s share of electricity produced with renewable energy sources. This reduction is accompanied by a decrease of the renewable exploitation area, suggesting a competition between land needed for renewable energy production and other needs, such as land needed for residential use. These results are weakened but not reversed at a substantially higher assumed power density of the renewable energy sources.

A.1. Define Profit of the Transmission Service Producer as a Function of Brown and Green Electricity Production

By substituting equation (6) into equation (27) we get:

$$\begin{aligned} \Pi_T^e &= ((1 - L_B)p^e - p_B^e)W_B^e + ((1 - L_G)p^e - p_G^e)W_G^e \\ &= \left((1 - L_B) \left(\frac{b}{g} - \frac{(1 - L_G)W_G^e + (1 - L_B)W_B^e}{gAD^{\beta W}} \right) - p_B^e \right) W_B^e \\ &+ \left((1 - L_G) \left(\frac{b}{g} - \frac{(1 - L_G)W_G^e + (1 - L_B)W_B^e}{gAD^{\beta W}} \right) - p_G^e \right) W_G^e \\ &= \left(\frac{b}{g} (1 - L_B) - p_B^e \right) W_B^e + \left(\frac{b}{g} (1 - L_G) - p_G^e \right) W_G^e - \frac{2(1 - L_B)(1 - L_G)}{gAD^{\beta W}} W_B^e W_G^e \\ &- \frac{(1 - L_B)^2}{gAD^{\beta W}} W_B^{e2} - \frac{(1 - L_G)^2}{gAD^{\beta W}} W_G^{e2} \end{aligned} \tag{27}$$

A.2. Define the Brown Electricity Production

First, substitute equations (15) and (22) into equations (30) and (31):

$$W_B^e = \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{\left(\frac{I_B}{z_B} + \frac{u_B f_B r_B}{\eta_B \alpha_B} \right)}{(1 - L_B)} \right] - \left(\frac{1 - L_G}{1 - L_B} \right) W_G^e \tag{30.1}$$

$$W_G^e = \frac{gAD^{\beta W}}{(1 - L_G)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} \right] - \left(\frac{1 - L_B}{1 - L_G} \right) W_B^e \tag{31.1}$$

Next, use equation (10) and (12) to define r_B as a function of W_B^e :

$$W_B^e = \eta_B W_B^m = \eta_B \alpha_B \omega (r_B - \lambda) \Leftrightarrow r_B = \frac{1}{\eta_B \alpha_B \omega} W_B^e + \lambda \tag{34}$$

We substitute both (31.1) and (34) into (30.1), to get:

$$\begin{aligned} W_B^e &= \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{\left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} \left[\frac{1}{\eta_B \alpha_B \omega} W_B^e + \lambda \right] \right)}{(1 - L_B)} \right] - \left(\frac{1 - L_G}{1 - L_B} \right) \left\{ \frac{gAD^{\beta W}}{(1 - L_G)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} \right] - \left(\frac{1 - L_B}{1 - L_G} \right) W_B^e \right\} \\ \Leftrightarrow W_B^e &= \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{\left(\frac{I_B + \lambda u_B f_B + \frac{u_B f_B}{\eta_B \alpha_B} W_B^e}{\eta_B \alpha_B} \right)}{(1 - L_B)} \right] - \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} \right] + W_B^e \\ \Leftrightarrow \frac{gAD^{\beta W}}{(1 - L_B)^2} \cdot \frac{1}{2} \frac{u_B f_B}{(\eta_B \alpha_B)^2 \omega} W_B^e &= \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{\left(\frac{I_B + \lambda u_B f_B}{z_B + \lambda \eta_B \alpha_B} \right)}{(1 - L_B)} \right] - \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} \right] \\ \Leftrightarrow \frac{u_B f_B}{(1 - L_B)(\eta_B \alpha_B)^2 \omega} W_B^e &= \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} - \frac{\left(\frac{I_B + \lambda u_B f_B}{z_B + \lambda \eta_B \alpha_B} \right)}{(1 - L_B)} \\ \Leftrightarrow W_B^e &= \frac{(1 - L_B)(\eta_B \alpha_B)^2 \omega}{u_B f_B} \left[\frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} - \frac{\left(\frac{I_B + \lambda u_B f_B}{z_B + \lambda \eta_B \alpha_B} \right)}{(1 - L_B)} \right] \\ \Leftrightarrow W_B^{e*} &= \frac{(\eta_B \alpha_B)^2 \omega}{u_B f_B} \left[\left(\frac{1 - L_B}{1 - L_G} \right) \left(I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G \right) - \left(\frac{I_B}{z_B} + \lambda \frac{u_B f_B}{\eta_B \alpha_B} \right) \right] \end{aligned} \tag{36}$$

A.3. Define the Green Electricity Production

Substitute equation (32) into equation (33):

$$\begin{aligned} W_G^e &= \frac{gAD^{\beta W}}{(1 - L_G)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} \right] - \left(\frac{1 - L_B}{1 - L_G} \right) \left\{ \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{\left(\frac{I_B + u_B f_B r_B}{z_B + \eta_B \alpha_B} \right)}{(1 - L_B)} \right] - \left(\frac{1 - L_G}{1 - L_B} \right) W_G^e \right\} \\ \Leftrightarrow W_G^e &= \frac{gAD^{\beta W}}{(1 - L_G)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{I_G^k + \frac{I_G^L}{\eta_G \alpha_G} \psi_G}{(1 - L_G)} \right] - \left(\frac{1 - L_B}{1 - L_G} \right) \frac{gAD^{\beta W}}{(1 - L_B)} \cdot \frac{1}{2} \left[\frac{b}{g} - \frac{\left(\frac{I_B + u_B f_B r_B}{z_B + \eta_B \alpha_B} \right)}{(1 - L_B)} \right] + W_G^e \end{aligned} \tag{33.1}$$

Next, use of equations (18) and (19) to define η_G as a function of W_G^e :

$$W_G^e = \eta_G W_G^r = \eta_G \alpha_G \psi_G A \Leftrightarrow \psi_G = \frac{1}{\eta_G \alpha_G A} W_G^e \tag{35}$$

Using equation (35) and rewriting (33.1) yields:

$$\begin{aligned}
 W_G^e &= \frac{1}{2} \frac{b}{g} \frac{gAD^{\beta_W}}{(1-L_G)} - \frac{1}{2} \frac{gAD^{\beta_W}}{(1-L_G)} \frac{I_G^k + \frac{I_G^L}{(\eta_G \alpha_G)^2} W_G^e}{(1-L_G)} - \frac{gAD^{\beta_W}}{(1-L_G)} \frac{1}{2} \frac{b}{g} + \frac{gAD^{\beta_W}}{(1-L_G)} \frac{1}{2} \frac{\left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B\right)}{(1-L_B)} + W_G^e \\
 \Leftrightarrow \frac{1}{2} \frac{gAD^{\beta_W}}{(1-L_G)} \frac{I_G^k + \frac{I_G^L}{(\eta_G \alpha_G)^2} W_G^e}{(1-L_G)} &= \frac{gAD^{\beta_W}}{(1-L_G)} \frac{1}{2} \frac{\left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B\right)}{(1-L_B)} \\
 \Leftrightarrow \frac{I_G^k + \frac{I_G^L}{(\eta_G \alpha_G)^2} W_G^e}{(1-L_G)} &= \frac{\left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B\right)}{(1-L_B)} \\
 \Leftrightarrow I_G^k + \frac{I_G^L}{(\eta_G \alpha_G)^2} W_G^e &= \left(\frac{1-L_G}{1-L_B}\right) \left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B\right) \\
 \Leftrightarrow \frac{I_G^L}{(\eta_G \alpha_G)^2} W_G^e &= \left(\frac{1-L_G}{1-L_B}\right) \left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B\right) - I_G^k \\
 \Leftrightarrow W_G^{e*} &= \frac{(\eta_G \alpha_G)^2}{I_G^L} \left[\left(\frac{1-L_G}{1-L_B}\right) \left(\frac{I_B}{z_B} + \frac{u_B f_B}{\eta_B \alpha_B} r_B\right) - I_G^k \right] \tag{37}
 \end{aligned}$$

A.4. Define Profit of the Transmission Service Producer as a Function of Population Density

By substituting equations (23), (24), (36) and (37) into equation (29):

$$\begin{aligned}
 \Pi_T^e &= \left(\frac{b}{g} (1 - \tau \gamma_B D^{-\beta_s}) - p^e\right) W_B^{e*} + \left(\frac{b}{g} (1 - \tau \gamma_G D^{-\beta_s}) - p^e\right) W_G^{e*} \\
 &\quad - \frac{2(1-\tau \gamma_B D^{-\beta_s})(1-\tau \gamma_G D^{-\beta_s})}{gAD^{\beta_W}} W_B^{e*} W_G^{e*} \\
 &\quad - \frac{(1-\tau \gamma_B D^{-\beta_s})^2}{gAD^{\beta_W}} W_B^{e*2} - \frac{(1-\tau \gamma_G D^{-\beta_s})^2}{gAD^{\beta_W}} W_G^{e*2}
 \end{aligned}$$

we can define Π_T^e as a function of D .

APPENDIX B: PARAMETER ESTIMATION

Table B.21 – List of Parameters Values in the Base Simulation

Parameter	Symbol	Value	Unit	Note
The small open economy area	A	1,812	thousand km ²	The land area of Indonesia.
The length of the small open economy	ρ	5,2491.07	km	This value in the model cannot reflect the real distances because in reality, the width of the small open economy and the exploitation area of the brown resource are different. We set ρ as the distance between Sabang (the northernmost and westernmost city) and Merauke (the easternmost regency).
The power density of brown resource	α_B	3,297.07	W/m ²	Estimated based on the coal power density in the coal power plant stated by Donald (2016) and the efficiency rate on the thermal power plant (η_B).
The power density of green resource	α_G	200	W/m ²	Based on the average solar radiation in Indonesia by Indonesian DGNREEC (2013).
The elasticity of the electricity loss or the line length with regards to population density	β_s	1.1324		Estimated based on the electricity loss in the transmission and distribution and population density of Indonesia during 1990-2016.
The elasticity of electricity demand with regards to population density	β_W	1.2916		Estimated based on the average total electricity sales and population density of Indonesia during 1989/1990-2015.
The elasticity of the price land on the green investment cost with regards to population density	β_L	1.0000		Because we do not have information about the land investment cost for green power plant, then we set this parameter into 1.
The electricity price	p^e	0.6543	\$/W	Based on the average electricity selling price in Indonesia in 2016.
The intensity of electricity consumption	i	22.1035	W-m ² /people	This parameter is estimated based on PLN electricity sales in 2016 (Indonesian MEMR, 2017), population density in 2016 from World Development Indicator (World Bank, 2017), the area of Indonesia and β_W .
The maximum intensity of electricity consumption	b	31.5667	W-m ² /people	This parameter is estimated based on equation (24).
The effect of the electricity price on the electricity consumption intensity	g	14.4621	W ² -m ² /(\$-people)	Estimated based on the estimated electricity consumption intensity and the average selling price in price 2016 during 2001-2015.
Population density	D	144.14	people/km ²	Population density of Indonesia in 2016 by World Development Indicator (World Bank, 2017).
The effect of population density on the land price on the green investment cost	θ	9.7440e+7	\$/people	This parameter is set so that the electricity supply and the share of brown and green production close to the real data.
The efficiency rate on the thermal power plant	η_B	30.33%		Based on the average thermal efficiency rate in Indonesia in 2016.
The efficiency rate on the green power plant	η_G	23.83%		Estimated based on the efficiency rate of the solar panel (c-Si type) in 2003 and 2012 by IRENA (2015) and IEA (IEA, 2014).

Parameter	Symbol	Value	Unit	Note
The physical density of brown resource	f_B	1,075	kg/m ²	Based on the normal weight of coal (145 tons) from one acre area with the thickness of 30 inches by Kentucky Fondation (2007).
The effect of population density on the length of the line needed to distributed brown electricity	γ_B	2.5936e+8	kmc-km ² / people	Estimated based on estimation for the line length, population density and brown and green electricity production of Indonesia in 1999–2014. Because there is no available information, we assume that the line needed to distribute the brown electricity is proportionate to the brown electricity production.
The effect of population density on the length of the line needed to distributed green electricity	γ_G	0	kmc-km ² / people	It is assumed that the green electricity is generated by solar panel that can be put in the consumer's roof.
Unit investment cost of thermal power plant	I_B	0.0385	\$/W	Based on the estimation of investment cost of coal steam power plant in Indonesia in 2016 price per year of lifetime from some sources.
The unit capital investment cost of green power plant	I_G^k	0.0746	\$/W	Based on the investment of solar power plant by IRENA (2016) in 2016 price per year of lifetime.
The distance between the thermal power plant and the border between the small open economy and the exploitation area of the brown resources	λ	0	km	Because this value in the model cannot reflect the real distance where there are many power plants in many locations, then we set $\lambda = \text{zero}$ (as if the power plant is in the border between the small open economy and the exploitation area of the brown resources) so that the effect of parameter changes in the simulation on the distance between the power plant and the mine (r_B) can be showed clearly.
The distance between the power plant and the mining of brown resources	r_B	67.5505	m	Estimated based on the brown production in 2016 (Indonesian MEMR, 2017) , the estimated brown power density (α_B) and the brown efficiency rate (η_B) in 2016.
The share of the green exploitation area	ψ_G	4.0393e-5		Estimated based on the green production in 2016 (Indonesian MEMR, 2017), the estimated green power density (α_G) and the green efficiency rate (η_G) in 2016, the width of Indonesia area ($\omega = \frac{A}{\rho}$) and the distance between small open economy and the exploitation area of the brown resources (ρ).
The effect of length of the line on the transmission and distribution loss	τ	1.0179e-8	%/mc	Estimated based on the electricity loss in the transmission and distribution and total length of line of low, medium, high and extra high voltage of Indonesia in 2016.
The unit delivery cost of brown resource	u_B	5,3284e-7	\$/kg.m	Based on the maximum coal transport cost by train in Indonesia in 2016 Price by IDOMINING (2016).
Production rate in the thermal power plant	z_B	49.14%		Estimated based on the installed capacity and the electricity production of thermal and green power plants of Indonesia during 2001-2016.
Production rate in the thermal power plant	z_G	100.00%		The green production is assumed to be at full capacity.

Note: (1) All monetary values are converted into price in 2016. (2) kmc = km circuit.

$L_B + L_G$	%	9.4822	9.4800	

Note: (1) Data in 2016 and data used to estimate data in 2016 are from the Indonesian Ministry of Energy and Mineral Resources or PLN. (2) Unit measurement in Wh is converted to W where hours in year t = number of days in year t × 24 hours/day. (3) The simulation is based on the assumption that the production rate on the green power plant is at full capacity, In reality, the production is not at full capacity.

1193 THE IMPACT OF URBANIZATION ON ENERGY CONSUMPTION IN THE GLOBAL SOUTH. EVIDENCE ACROSS COUNTRIES, CITIES AND NEIGHBORHOODS.

ABSTRACT

We analyze how city size and urban form impacts residential energy use in low- and middle-income countries. Traditionally, energy consumption and emission levels are highest in rich countries, but, nowadays both urban and GHG emission growth is largely driven by countries in the global South. By 2050, around 80% of total urban population is expected to live in cities in low- and middle-income countries. Despite the importance of urban areas for energy use and global emissions, data on urban energy use worldwide are in short supply. The data scarcity is even worse when it comes to urban areas in the developing world. This paper aims to reduce this knowledge gap by presenting new evidence on how city size and urban form impact energy use in the global South. In contrast to most of the energy studies literature on residential energy use in low- and middle-income countries (cf Barnes et al. 2004), we focus on the role of the spatial distribution of population and economic activities on energy consumption and vice versa. Existing urban economics research on the relationship between energy use and city structure suggests that per capita energy consumption decreases when urban density increases. The basic idea underlying this so-called compact city argument is that a higher population density decreases average commuting distance, increases public transport usage, while smaller housing units help to reduce transport and home energy use (Glaeser and Kahn 2010, Muniz and Galindo 2005). But, the evidence for this compact city hypothesis comes almost exclusively from rich countries. In contrast, we focus on low- and middle-income countries. Our dataset combines information at three levels of spatial aggregation: i) 60 low- and middle-income countries; ii) 136 cities in Indonesia and Mozambique; iii) 62 neighborhoods within the metropolitan areas of Yogyakarta (Indonesia) and Maputo (Mozambique). This allows us to combine different levels of aggregation in our analysis, including an assessment of the role of city size, population density, distance from the CBD and commuting behavior within two large metropolitan areas. Furthermore, in contrast to existing studies on the relationship between urbanization and energy across developing countries (cf Poumanyong & Kaneko 2010, Martinez-Zarzoso and Maruotti 2011, Sadorsky 2013), we use a sorting model (cf Combes et al. 2008) and an IV regression approach to identify causal mechanisms in the relationship between urbanization and energy use. At all levels of spatial aggregation, we find that in the global South urbanization leads to increasing per capita energy use through an income-effect. This robust positive income effect dominates weak evidence of a negative impact of population density on per capita energy consumption. At the country level, we find no evidence that urbanization has a direct effect on energy use.

Yet, for Maputo we found evidence that a 1% increase in commuting distance increases per capita transport energy use with 5%. For Indonesia, our data for Yogyakarta city include evidence that population density has a negative impact on total and dwelling energy consumption per capita, thus lending support to the compact city theory.

1529 THE MUTUAL RELATIONSHIP BETWEEN REGIONAL INCOME AND DEFORESTATION: A STUDY ON TURKEY

ABSTRACT

This paper addresses the bilateral relationship between growth and environment. It aims to show how regional economic growth causes environmental deterioration, while the environmental resources function in turn as a supply factor for economic development. A simultaneous-equations model is developed and applied to test this two-way relationship statistically, where economic growth is measured by regional income, and environmental deterioration by deforestation. Using data from 26 NUTS 2 regions in Turkey between the years 2004 and 2014, the results of the two-stage least squares (2SLS) regression analysis reveal strong evidence on the presence of a mutual relationship between deforestation and regional income, while lagged deforestation is a statistically significant positive determinant of income growth, and vice versa.

1354 LIVELIHOOD DEVELOPMENT FOR SUSTAINABLE FOREST MANAGEMENT

ABSTRACT

Rural economy of India in agriculture based with tremendous success in productivity since independence. But livelihood of agro-based region of many parts of India still remain under developed. In west Bengal the plateau district is relatively backward because of low productivity, drought, insufficient irrigation system, poor soil quality, lateritic waste land, lack of proper planning. Forest is the main natural capital of livelihood development as this region has low agricultural productivity and more than 35% land fall under forest. Here more than 80% protected forest is Under JEM program since nineties. But lack of proper planning, lack of knowledge, fund scarcity, and sever poverty are the main reason for failure of JFM program which further leads to forest degradation and deforestation, and forest land conversion. The aim of this paper is to discuss the present scenario of forest and to find out how forest can be conserve with fulfilment of economic benefits from the forest to sustain the livelihood of the poor forest fringe villagers in Rupnarayan Forest Division, West Bengal emphasizing Non Timber Forest Products production.

1331 ASTHMA PREDICTABILITY INDEX AMONG CHILDREN OF ATOPIC PARENTS LIVING IN AND AROUND KOLKATA METROPOLIS AND ITS CO-RELATION WITH VARIOUS AIR POLLUTION INDICES

Jayati Das

Associate Professor in Geography, Shri Shikshayatan College, Kolkata. jayati04@yahoo.co.in

ABSTRACT

Asthma is not just a public health problem for developed countries. In developing countries, however, the incidence of the disease varies greatly. Although heredity plays a major role in asthma and in other allergic diseases, mechanisms underlying the inheritance of these disorders are poorly understood, as is the relative contribution of maternal and paternal conditions to risk of disease. Asthma attacks all age groups but often starts in childhood. It is a disease characterized by recurrent attacks of breathlessness and wheezing, which vary in severity and frequency from person to person. In an individual, they may occur from hour to hour and day to day. This condition is due to inflammation of the air passages in the lungs and affects the sensitivity of the nerve endings in the airways so they become easily irritated. In an attack, the lining of the passages swell causing the airways to narrow and reducing the flow of air in and out of the lungs.

Objectives: We tried to evaluate the relationship of new-onset asthma with pollution and an attempt to draw a predictability index for children below 6 years of age with atopic parents.

Methods: Children below 6 years of age with atopic parents are the subject of study. Parent-reported physician diagnosis of new-onset asthma ($n=82$) was identified during one year of study. We assessed traffic-related pollution exposure based on automatic data generated by Central Pollution Control Board, Kolkata and local meteorology.

Results: The adverse effect of air pollution on respiratory health has been well established in, but our results are not consistent with this evidence. The concentration of pollutants such as PM₁₀ and NO₂ no longer provides a statistical explanation for variations in asthma prevalence across urban units. Interestingly, the relationship between childhood asthma and SO₂ was consistently negative. And surprisingly, these annual mean levels of PM₁₀ (0.091mg/m³), NO₂ (0.042mg/m³), and SO₂ (0.042mg/m³) detected during the sampling period did not conform with. Asthma risk increased with modeled traffic-related pollution exposure from roadways near homes. Traffic-related pollutant levels may also be considerably higher during the morning hours, when children are arriving at school, especially during temperature inversions that occur largely in the winter months when children are attending school ([Kim et al. 2002](#); [Ning et al. 2007](#)). The odds of having a child with asthma were three times greater in families with one asthmatic parent and six times greater in families with two asthmatic parents than in families where only one parent had inhalant allergy without asthma; furthermore, inhalant allergy in one parent also conferred additional risk in the presence of asthma in the other parent.

Conclusions: Our results indicate that children exposed to higher levels of traffic-related air pollution at school and home are at increased risk of developing asthma. Hereditary factor plays a major in asthma among children.

Keywords: air pollution, asthma, child

INTRODUCTION

Asthma is one of the most chronic inflammatory disorders characterized by recurrent attacks of wheezing, breathlessness, cough, and/or chest tightness, which vary in severity and frequency from person to person. The prevalence of allergic airway diseases, such as asthma and rhinitis, has been increasingly common to epidemic proportions worldwide. About 334 million people worldwide are now suffering from asthma.

A large number of studies have confirmed that respiratory diseases are related to the physical characteristics of the living area: multiple factors affect asthma including exogenous factors like air pollution and climate. The link between urban air pollution, climatic factors, and asthma is established. However, there are merely a few analyses developing a comparative approach of differences in asthma morbidity among places, such as cities. In addition, levels of outdoor air pollutants have been associated with asthma incidence but not clearly with asthma prevalence at the population level. Under this circumstance, this paper investigated the local disparities' correlation with air pollutants and climatic factors in different areas of Kolkata.

Respiratory viruses and symptoms of early asthma may be hard to tell apart, making diagnosis and treatment tricky. But doctors and parents now have a tool to help them predict with reasonable accuracy if the child will develop asthma or simply outgrow it.

The asthma predictive index (API) is a guide to determining which small children will likely have asthma in later years. Children younger than 3 years who have had 4 or more significant wheezing episodes in the past year are much more likely to have persistent (ie, lifelong) asthma after 5 years if they have either of the following:

- Parent with asthma
- Physician diagnosis of eczema (atopic dermatitis)

- Sensitivity to allergens in the air (as determined by physician through positive skin tests or blood tests to allergens such as trees, grasses, weeds, molds, or dust mites)
- Wheezing is very uncommon during the first two months of life, but in the next few months, first-time wheezing increases, peaking between two and five months of age. Infants' airways (compared to older children and adults) are smaller around, have less smooth muscle and make more mucus, which can lead to more coughing, wheezing, chest tightness, shortness of breath, or rapid breathing.
- The 2007 National Heart, Lung and Blood Institute (NHLBI) Guidelines for the Diagnosis and Management of Asthma describes the Asthma Predictive Index (API), a guide to determining which small children will likely have asthma in later years.

The API was developed 10 years ago by using data from 1246 children in the Tucson Children's Respiratory Study birth cohort. It was based on factors that were found during the first 3 years of life to predict continued wheezing at school age

OBJECTIVE

The aim of this study was to investigate the potential role of city-average air-pollutant levels and climatic factors in explaining regional differences in asthma prevalence among children below 6 years of age with atopic parents in Kolkata. To evaluate the development of asthma in children below 6 years who were seen for an acute wheezing episode in infancy and to determine the effectiveness of the API in predicting the development of asthma in this group of children.

METHODOLOGY

Asthma Data

Asthma data in this study was collected from outdoor department of Allergy and Asthma Research Centre, Kolkata, Missionaries of Charity, Kolkata. The selected data of asthma prevalence were defined as children who had experienced at least one asthma attack in the last two years or have not experienced any but have atopic parents.

Informed consent was obtained from the next of kin, caretakers, or guardians on behalf of children. The consent on behalf of the children enrolled was written. The study design was approved by the ethics committee of the Allergy and Asthma Research Centre, Kolkata.

Air pollution data was in the form of seasonal concentrations of air pollutants and other climatic factors were obtained for the same period from several government departments. Data analysis was implemented with descriptive statistics, Pearson correlation coefficient, and multiple regression analysis.

Parents provided informed consent and completed a baseline and yearly questionnaire with information about demographic characteristics, respiratory illness, and risk factors for asthma at study entry. To ensure that the study population was free of any previously undiagnosed asthma, I also excluded children with a history of wheeze ($n=24$, 29.3%) and additional children with missing information about wheeze, or missing or a "don't know" answer about asthma ($n=12$, 14.6%).

A positive API score by the age of 3 years was associated with a 77% chance of active asthma from ages 6 to 13 years; children with a negative API score at the age of 3 years had less than a 3% chance of having active asthma during their school years.

Major Criteria	Minor Criteria
1. Parental MD asthma	1. MD allergic rhinitis
2. MD eczema	2. Wheezing apart from colds
	3. Eosinophilia

- Loose index for the prediction of asthma: early wheezer plus one of the two major criteria or two of three minor criteria.

New-onset asthma and covariates

The date of new onset of asthma could not be precisely defined. Therefore, the date of onset was assigned to the midpoint of the interval between the date of the questionnaire when asthma diagnosis was first reported and the date of the previous questionnaire reporting asthma status, and this date was used for estimating follow-up time in all statistical analyses. Socio demographic characteristics, exposure to cigarette and wildfire smoke, health insurance, housing characteristics, history of allergy, and parental asthma were assessed by questionnaire.

DISCUSSION

Causes

Asthma cannot be cured, but could be controlled. The strongest risk factors for developing asthma are exposure, especially in infancy, to indoor allergens (such as domestic mites in bedding, carpets and stuffed furniture, cats and cockroaches) and a family history of asthma or allergy.

Exposure to tobacco smoke and exposure to chemical irritants in the workplace are additional risk factors. Other risk factors include certain drugs (aspirin and other non-steroid anti-inflammatory drugs), low birth weight and respiratory infection. The weather (cold air), extreme emotional expression and physical exercise can exacerbate asthma.

Urbanization appears to be correlated with an increase in asthma. The nature of the risk is unclear because studies have not taken into account indoor allergens although these have been identified as significant risk factors.

Experts are struggling to understand why rates world-wide are, on average, rising by 50% every decade. And they are baffled by isolated incidents involving hundreds of people in a city, who suffer from allergies such as hay fever but who had never had asthma, suddenly being struck down by asthma attacks so severe they needed emergency hospital treatment.

The way forward and the role of the WHO

WHO recognizes asthma as a disease of major public health importance and plays a unique role in the co-ordination of international efforts against the disease. International action is needed to increase public awareness of the disease to make sure patients and health professionals recognize the disease and are aware of the severity of associated problems; organize and co-ordinate global epidemiological surveillance to monitor global and regional trends in asthma; develop and implement an optimal strategy for its management and prevention (many studies have shown that this will result in the control of asthma in most patients); and stimulate research into the causes of asthma to develop new control strategies and treatment techniques.

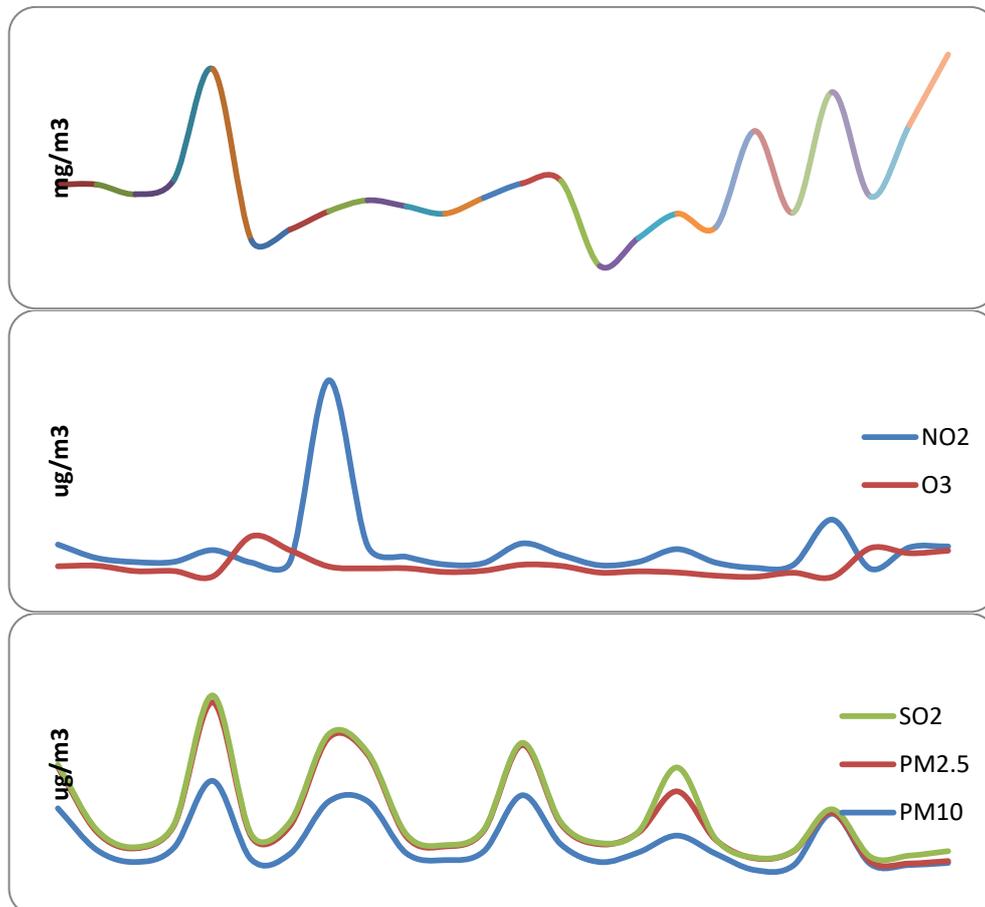

Among children < 5 yr of age, the proportion with asthma was 8.2%. Among children ≥ 5 yr of age, this proportion was greater: 17.9% among children between 5 and 10 yr of age.

The proportions of asthma and other allergic conditions were higher among mothers than among fathers . Of the 56 families, 11 (19.6 %) had both parents with asthma, 38(67.8%) had 1 parent with asthma, 7(12.5 %) had both parents with asthma.

Air pollution

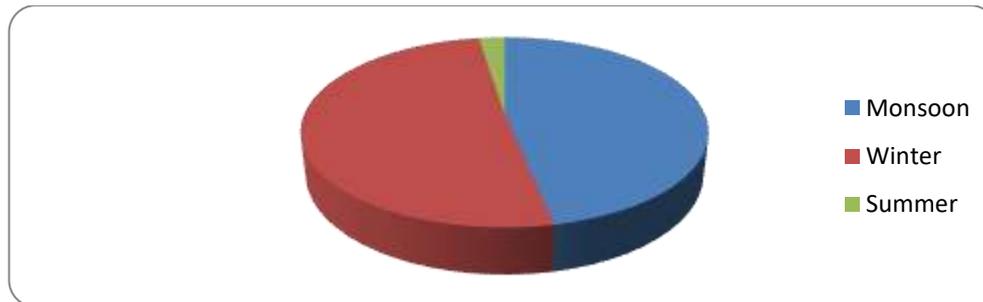

Air pollution data included the annual (January 2017 to December 2017)) average values for particulate matter less than or equal to 10 μm PM10 (μg/m³), sulfur dioxide SO₂ (μg/m³), and nitrogen dioxide NO₂ (μg/m³). All the data were obtained from the Central Pollution Control Board, Kolkata which collected monthly average concentrations of air pollutants through automated fixed-site monitoring stations. The data were regularly recorded from January 1, 2017, to December 31, 2017. The World Health Organization Air Quality Guidelines for annual mean concentrations of PM10 and NO₂ and for 24-hour mean concentrations of SO₂ were 20 μg/m³, 40 μg/m³, and 20 μg/m³, respectively.

Seasonal variation of air parameters in different locations in Kolkata were monitored for a year.

Evidence of a school effect comparable with that associated with the much larger amount of time spent at home could potentially be explained by physical education and other exercise at school that may increase ventilation rate and dose of pollutants to the lungs and thereby increase the risk associated with exposure.

Traffic-related pollutant levels may also be considerably higher during the morning hours, when children are arriving at school, especially during temperature inversions that occur largely in the winter months when children are attending school (Kim et al. 2002; Ning et al. 2007).

Incidence rate is much higher in winter months. This is due to the trapping of air pollutants because of temperature inversion.

Correlations between asthma prevalence, air pollutants, and climatic factors

According to Pearson correlation analysis, there were significant associations between asthma prevalence and several factors including SO₂ ($r = -0.323, p < 0.05$), relative humidity ($r = -0.351, p < 0.05$), and hours of sunshine ($r = -0.476, p < 0.05$). As can be seen, these correlations between PM₁₀, NO₂, air temperature, precipitation, and asthma prevalence were not statistically significant.

The adverse effect of air pollution on respiratory health has been well established, but our results are not consistent with this evidence. The concentration of pollutants such as PM₁₀ and NO₂ no longer provides a statistical explanation for variations in asthma prevalence. Interestingly, the relationship between childhood asthma and SO₂ was consistently negative. And surprisingly, these annual mean levels of PM₁₀ (0.091mg/m³), NO₂ (0.042mg/m³), and SO₂ (0.042mg/m³) detected during the sampling period did not conform with.

Regarding the effect of climatic variables, a large number of studies have confirmed that temperature is related to asthma. However, for our study, there has not been shown any statistically significant association between annual mean temperature and asthma prevalence. Thus, a direct comparison of results is not possible.

There is no confirmation in the literature that the association between climate and asthma prevalence reflects a causal relationship or that correlations are a result of indirect relationships and linked to other factors like air pollution levels. Little is known about the long-term influence of climate on asthma prevalence, but the findings from our study do not suggest that climate, at least in children, plays a major role.

CONCLUSION

To conclude, our study showed associations between long term exposure to urban air pollution and climate conditions, using Pearson correlation coefficient and multiple regression analysis capturing variations within communities, and asthma. First, the study shows the surprising results for the contribution of pollution factors. In contrast to reports from within-community studies of individuals exposed to traffic pollution, we found no evidence of a positive relation between air pollution and asthma prevalence. Meanwhile, our results suggest that climate may affect the prevalence of asthma, yet climate does not play a major role, at least in terms of children.

The most impressive aspect of the API is its ability to rule out the likelihood of asthma by school age in young children with wheezing. For children who are “early wheezers during the first 3 years of life,” API negative predictive values ranged from 93.9% at 6 years of age. For children who are “early frequent wheezers during the first 3 years of life,” the negative predictive values were 91.6%.

Factors such as genetic polymorphisms, environmental and socioeconomic factors and family health beliefs might also be taken into account. Even if an index is accurate, it must be easy to apply, validated in different populations, and shown to improve patient outcome to be used by busy clinicians. The simplicity of the API allows its use in every health care setting worldwide.

1764 PROMOTING THE DIFFUSION OF ENVIRONMENTAL INNOVATIONS ACROSS DEVELOPING NATIONS: THE IMPACT OF INNOVATIVE AND ABSORPTIVE CAPABILITIES

ABSTRACT

Environmental policies and regulations play a central role in promoting technological innovation. However, in order to achieve sustainable development, not only developed but developing countries must also be involved in promoting and spreading those innovations. In this research we first analyze the trends on environmental patent activity (air pollution abatement, water pollution abatement and waste management) in 6 selected countries: the top three inventors of the past including Japan, US and Germany and the most rapid developing nations in the last two decades. The patent activity was analyzed for the last decade of the 90s and first decade of this century. The study also analyzed the innovation dissemination and indigenous innovation trends by using claimed priorities and priority applications as proxies respectively. Findings suggest that while in developed nations environmental regulations have played a central role in inducing innovations the case has not been the same for developing or mid income countries. The study argues that diffusion of technologies can be determined by domestic technological capabilities (R

1014 HOW CAN CROSS-SECTOR PARTNERSHIPS BE MADE TO WORK SUCCESSFULLY? LESSONS FROM THE MERSEY BASIN CAMPAIGN, 1985-2010

ABSTRACT

Experience suggests that cross-sector partnerships can turn out to be a big disappointment: a cozy talking shop with plenty of warm words but not a lot of action to show for it. The Mersey Basin Campaign, however, was a major exception. As a government-sponsored 25-year initiative to clean up the rivers, canals and estuary of the Mersey river basin in North West England, the Campaign was a pioneer in public-private-voluntary partnership working and, in the period it was active (1985-2010), made great progress in improving water quality, promoting waterside regeneration, and engaging stakeholders, in a region with a history of severe industrial dereliction and pollution. In this paper, by a former leader of the Campaign, a number of themes are explored: Why was a Campaign needed? What did it try to achieve? How did it do this? What impact did it have? What are the critical success factors for partnership working? The story ends with an interesting twist: the present speaker brought the Campaign to a close in 2010, arguing that, after its planned life of 25 years, it had done what it set out to do. Now, much to the surprise of many people, several aspects of the Campaign are being re-created, albeit in a quite different institutional and financial context.

1239 THE SQUARES OF OLD GOA: THEIR ROLE IN THE ORGANIZATION OF THE CITY**Manuel C. Teixeira**CIAUD, Lisbon School of Architecture, Universidade de Lisboa
Rua Sá Nogueira, 1349-063 Lisboa, Portugal**1. INTRODUCTION**

Urban squares play an important role in the structure and the image of cities built by the Portuguese, or which they rebuilt, restructured or had some type of intervention. Goa is no exception. There, one may find examples of the different types of squares that occur in cities of Portuguese origin, and fulfilling similar roles in the organization of the urban fabric. For this survey of the squares of Goa, one shall take as reference the late sixteenth century. The best known representations of Goa from this period are the plan by Georg Braun and the plan included in the *Itinerario* of Linschotten.

2. GOA'S URBAN STRUCTURE

Goa was an affluent port city when in 1510 Afonso de Albuquerque conquered it to the sultan of Bijapur, Adil-Shah, also called the Sabaio in Portuguese chronicles. A former Hindu city, Goa had been conquered by the Muhammadan princes in 1469 (1). The wealth of Goa, its role as an important entrepôt for the commerce of Asia and its strategic location were amongst the main reasons for the Portuguese control of the city.

Although considerably smaller than under the Portuguese rule, the city had a consistent urban structure. Located in a moderate slope, oriented north, Goa was surrounded by a wall with a rounded perimeter and a ditch filled with water. The main city gates were located at the cardinal points, and articulated with the main streets within the city, defining a classical organization of two main axes, crossing each other at right angles. The main buildings and public spaces were located at their intersection. This was the location of the Palace of the Sabaio, in the centre of the city, in front of a vast open square called the Terreiro do Sabaio. The Great Mosque was located nearby. The most important axis had the north-south direction; it was called the *Rua Direita*, and was the main structuring element of the city. As one of the principal emporiums of trade on the western coast of India, the area by the river Mandovi was occupied by shipyards, warehouses and other buildings related to maritime and merchant activities.

The intersection of two main axes within a walled enclosure is the fundamental structure of a city, which one may find in urban settlements built in different historical times, different cultural contexts and geographical settings located wide apart. This is the basic structure of a city from the earliest periods of urban civilization. It is the physical translation of principles that relate to the very concept of a city, and at the same time the expression of basic principles of man's conception of the world, which was rooted on the observation of the course of the sun through the skies and the four cardinal points. These principles were similar in different cultures and the urban structure of Goa fits into this matrix.

Cities are expensive infrastructures and human and material resources were always scarce in colonial contexts. Goa was a prosperous, and a well-established functioning city, with an urban structure to which the Portuguese could easily adapt, and as a consequence of that the city's basic structure and its main buildings were maintained. Within the walled-in city, the fundamental transformations that occurred over the years consisted either in functional changes of existing buildings or in the construction of new institutional buildings. These were built in locations that reinforced the existing urban structure and the hierarchies of the city. The palace of the Sabaio, became the palace of the Viceroy and later, in 1560, the siege of the Inquisition, whereas the new Vice Royal palace would occupy the Sabaio's fortress by the river, in 1554. Other buildings were occupied by new functions or its site rebuilt, like the convent of São Francisco that was built where Goa's principal mosque had stood. The Jesuitical college of São Paulo was also built over a former mosque.

New Portuguese buildings included the *Misericórdia*, built just within the south city gate, which reinforced the importance of *Rua Direita* as the main axis of the city, linking this southern gate to the Viceroy's gate, in the north. The institutional centre of the city, formerly made up of the Palace and *Terreiro do Sabaio*, saw its role as the institutional centre of the city greatly increased with the construction of the Cathedral, the Bishop's Palace, the Municipality, and the Franciscan convent.

Within the city walls, there were two types of urban fabric, on one side and the other of *Rua Direita*. On the western side, the urban fabric consisted of an orthogonal street network, where *Terreiro do Sabaio* and the nearby buildings occupied a central position. On the eastern side, the urban fabric was made up of a number of arching streets that converged on the *Misericórdia* and the square to which it was associated.

The city soon grew beyond its old limits. The city walls disappeared, either demolished or engulfed by constructions: "the wide ditch that surrounded its walls were filled up, and the additional space thus created was (...) assigned for new buildings. Once the old barriers were overstepped, the city rapidly grew in size in almost every direction" (2). Whereas the old city, within walls, had been built in a gentle slope surrounded by hills, now the city grew over this hilly land. The logics of location of new institutional buildings in this new territory, the layout of the new street network and the design strategies adopted were identical to those of other Portuguese urban settlements. The rounded perimeter of the city walls influenced the way the city developed in the immediate periphery, outside its old limits. In the cartography of Goa one may see one or two circular, concentric streets, which were built following the curving of the old city walls.

Beyond this first area of expansion, that followed the rounded contour of the old city, there were two different types of urban layouts. One, in the south, was fairly orthogonal, continuing the orthogonality that characterized the western part of the old city. Another type of urban layout, in the eastern and the western parts of the city, was made up of streets that converged into important institutional buildings built in singular locations of the city. In the east, the main focuses of these converging streets were the college of São Paulo, the Dominican convent and the church of Santa Ana. In the western part of the city, the convergence of streets was made towards the site of the former city gate, where the chapel of Santa Catarina and the Franciscan convent had been built.

The most important roads built outside the former city limits followed the natural lines of the territory, being built either along the valleys or along the ridges. Other streets made the connection between them, articulating the different levels. The most important topographic features of Goa's territories of expansion were a wide valley in the south-eastern direction that led to the lagoon, and a narrower and less pronounced valley in the south-western direction. The first valley was limited by two roads implanted at the foot of the hills, on one side and the other of the valley. The second valley was defined by a road that was the continuation of *Rua Direita* and went on into the hinterland.

These two valleys separated three main elevations, each one of them punctuated by religious buildings. One, in the east, where the chapel of Nossa Senhora do Monte was implanted; another in the south, with the convent of Cruz dos Milagres; and another elevation in the west, where a significant number of religious buildings were located: the nunnery of Santa Mónica, the convents of Santo Agostinho and São João de Deus, the church of Nossa Senhora da Graça and the chapel of Santo António. The main streets that led to these religious enclosures were built along the ridges, or climbed the hills diagonally.

Religious buildings were located in singular points of these natural lines, usually at the end or at points of divergence or inflection of ridges. Churches and convents were built in these topographically dominant locations both for symbolic reasons and to ensure their role as urban landmarks and focal points for the organization of the urban fabric. While the natural lines of the territory were integrated into the urban fabric as major streets, the construction of religious buildings in dominant locations, their association with squares and their careful positioning in relation to other urban elements, meant that these sites were reinforced as singular points of the urban structure and these buildings became the natural foci of street perspectives or views from afar.

In Goa, both convents with their *terreiros* and churches and chapels with their *adros* played an important role in the structuring of the city and the organization of the urban fabric. Their location was never casual. Singular buildings were either built in topographically dominant locations, in places imbued with a symbolic meaning and that ensured their visibility or in dominant locations in terms of the logic of the urban fabric. The convents' *terreiros* were larger and they were, or would become, major ordering elements of the city. The smaller *adros* of churches had a structuring role rather at the scale of the neighbourhood. Both these two types of spaces were sometimes punctuated by *cruzeiros* or other architectural elements which, together with the singular buildings in front of which they stood, became landmarks in the city, elements of reference for the alignment of streets, the definition of perspectives, the rotation of streets, the articulation of different sectors of the urban fabric, or references for the identification of singular urban situations, or the functional or symbolic importance of those buildings.

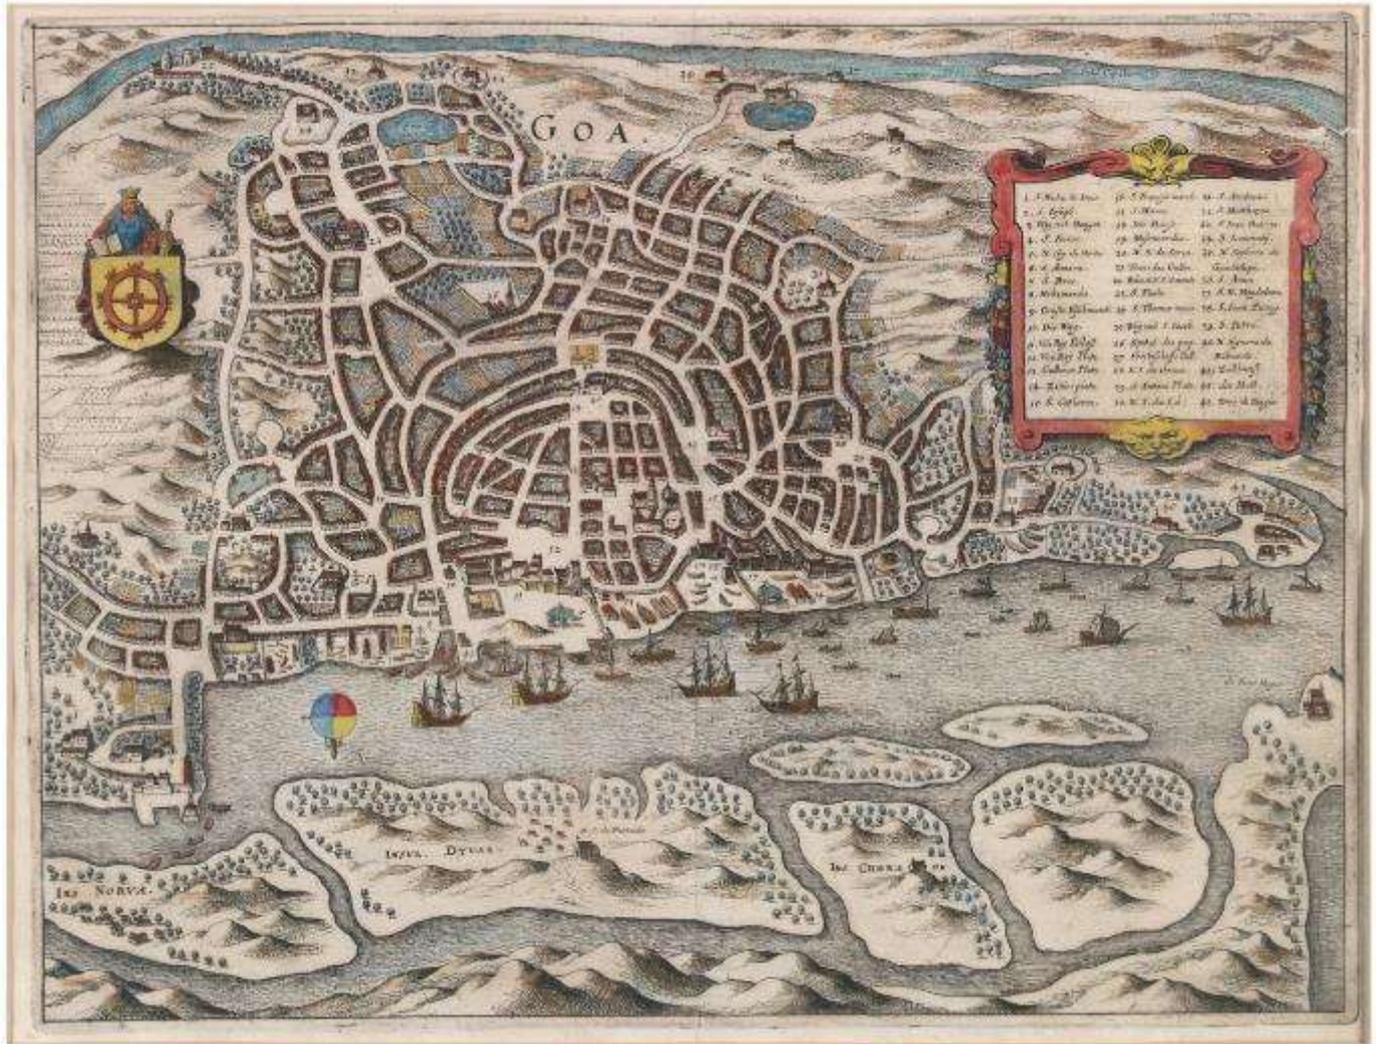

Convents, with their enclosures, needed a large amount of space and therefore they were often built on the periphery of the built-up city, where empty land was available. When the city grew, some of them were incorporated into the urban fabric, whereas others became obstacles to the growth of the city, and remained in their outlying situation. In the city of Goa, in the late sixteenth century, the Dominican, the Carmelites, the Jesuits, and the Augustinians convents, with their *terreiros*, were close to the limits of the city, in the east, the south, and the west. The only convent in a more central location was São Francisco, which had replaced the great mosque.

The existence of *terreiros*, or *campos*, on the periphery of walled towns, often associated with the city gates, was a characteristic of Portuguese cities. In the sixteenth century plan of Braga, in Portugal, one can see a number of these outlying *terreiros*, used for markets and festivals, still without the formal organization they would acquire in latter years. Usually, these spaces were dominated by churches and convents, in relation to which they were organized. As the city grew, these *campos* became the new squares of the expanded city.

Churches with their *adros* were located in different neighbourhoods, fulfilling their role of rotulas of the city structure at a local scale. Amongst these, the chapels of Nossa Senhora do Monte, Santo Amaro and São Lázaro on the eastern part of the city, Nossa Senhora da Luz on the south, and the chapels of Santo André, Nossa Senhora da Graça, and São Pedro on the west. They were focal points in relation to which the streets were oriented and elements of reference of the neighbourhoods in which they were located, sometimes of the whole city. Other chapels, located further out in the open countryside, were meant to fulfil this role later on, becoming focal elements for new urban developments if the city grew in their direction. Amongst these, São Brás, São Tomé-o-Novo, São Mateus, São João Baptista, São Lourenço, Nossa Senhora de Guadalupe, Santa Ana, Santa Maria Madalena, São João Evangelista.

The riverside of Goa, occupied by the vast area of *Ribeira* was one of the areas where the Portuguese invested the most. The original functions of the *Ribeira* were kept and consolidated and along the different quays were built, amongst other buildings, the rope factory, the new customs house, the foundries, the main Hospital, the Mint, the jails and the church of Chagas. This became the actual new centre of the city, which culminated in the transference, in 1554, of the Viceroy's palace to the Sabaio's fortress in the *Ribeira*, mimicking Lisbon, where a similar transference of the Royal palace had occurred in the early sixteenth century.

The *Ribeira* was subdivided in four different compounds. First, coming upstream from the bar, one reached the *Ribeira Grande*, “the workshop of the city, for here were the arsenal and the gun foundry, the mint, the naval dockyard, the offices of the *Vedor da Fazenda* (Comptroller of the Treasury) and also the elephant stables” (3). The church of the Cinco Chagas was also located here. To the east of *Ribeira Grande* lay the *Cais de Santa Catarina* (St. Catherine’s Quay), with the fish market. On its western side was located the Archbishop’s prison and on its south side was the Chapel of São Martinho and, overlooking the river, the Royal Hospital, run by the Jesuits. Next to St. Catherine’s Quay was located the *Ribeira das Galés*, where galliots and foists were built, and which was also used as a landing-stage. The largest and most important of the compounds that made up the *Ribeira* of Goa was the *Terreiro Grande*, or Quay of the Viceroy, in front of the Viceroy palace, between the palace and the Mandovi River.

GOA, Georg Braun, Museu de Angra do Heroísmo.

3. THE SQUARES AND *TERREIROS* OF GOA

Terreiro Grande, Bazar Grande

The *Terreiro Grande* was “the centre of the official life of the city, containing as it did the Viceroy’s palace and its dependencies (...). Here stood the *Alfândega* or Custom’s House (...), the *Bagançal*, or the great go-down, where the incoming cargo was stored; here, too, was the *Peso*, or weigh-house where the goods were put on scales. Equally functional was the *Tronco*, or the civil prison (...). But by odds the most important structure in the area was the Vice regal Palace itself” (4). To the east, across a narrow creek, was located the *Bazar Grande*, the great market of Goa.

Terreiro Grande was the equivalent of other maritime or riverside squares of Portuguese cities, which developed next to the intersection of the first street that run parallel to the river or the seaboard, with the main street that run perpendicular to it, often beyond the city limits towards the interior. These squares were usually associated with some of the city’s most important buildings. That is the case, amongst others, of the main squares of Ponta Delgada, in the Azores islands, of *Ribeira Grande*, in the islands of Cape Verde, of Rio de Janeiro in Brazil, or Lisbon in Portugal. In many of these cities, these squares were developed between the marginal street and the river, or the sea. Sometimes, a building or a series of constructions stood between the street and the square. That was the case of Goa, as well as of Lisbon, before the earthquake. In both cities, the Royal and the Vice-royal palaces had similar locations.

Terreiro do Vice-Rei

From the *Terreiro Grande*, across the Arch of the Viceroy, one entered the old city through another square, the *Terreiro do Vice-Rei*, or Palace Square. This was located behind the Viceroy Palace, which made up its north façade. The Viceroy Palace was built against the old city walls, and the square lay within these walls. *Terreiro do Vice-Rei* was indeed an enlargement of the street that run east to west, parallel to the river, and it belonged to the type of squares that, in Portuguese walled-in towns, were built just inside the city gates, usually associated with a larger *terreiro* located outside. This duality was present in Goa, with the associated *Terreiro Grande* and *Terreiro do Vice-Rei*.

The Arch of the Viceroy and the Palace Square marked the beginning of *Rua Direita*, the main street of Goa, which run perpendicular to the river. This was one of the main axes of the city, running north to south until the old limits of the city and beyond into the hinterland. Its course was punctuated by several squares.

Square of Misericórdia, Terreiro do Pelourinho Velho

The duality of *Terreiro Grande* and *Terreiro do Vice-Rei* was mirrored, on the south side of the city, with the duality of the Square of Misericórdia, inside the south city gate, and the *Terreiro do Pelourinho Velho*, outside. The square of Misericórdia was located at the site of the principal gate of the Moslem city. In this square, in addition to the Misericórdia, stood the church of Nossa Senhora da Serra.

The building of the Misericórdia protruded into the street, making it the focus of *Rua Direita*. This was a design strategy employed in Portuguese urban layouts: buildings would be purposefully implanted out of alignment, in such a way as to become more visible and offer themselves as focal points of street perspectives or other views one wished to emphasize. Together with the squares to which they were usually associated with, these buildings punctuated singular points of the urban fabric, like the end or the rotation of important axis, important intersections or the articulation of different sectors of the urban fabric.

Just across the city gate stood the *Terreiro do Pelourinho Velho*, surrounded by shops. Usually, this association of two squares followed a similar pattern: a smaller square on the inside, associated with more formal buildings and functions, whereas the square or *terreiro* on the outside was larger, less formally organized and often associated with merchant activities. This was a well established pattern in Portuguese cities, reproduced in Goa.

Square of Pelourinho Novo, Square of Nossa Senhora da Luz

Rua Direita continued beyond the *Pelourinho Velho*. Halfway along this last leg of *Rua Direita*, and located marginally to the left of this street, was the small square of *Pelourinho Novo*. *Rua Direita* finished in the small square – little more than an *adro* – in front of the church of Nossa Senhora da Luz, which marked the southern limit of Goa. This small square, and the limit of the built-up city were further announced by a *cruzeiro* located in front of the church, on the perspective of the street. This north-south axis linked the city to the hinterland, and went on through the countryside, punctuated at intervals by other churches or chapels. One last urban event was the square in front of the church of Nossa Senhora da Luz.

Terreiro do Sabaio

Returning to the old city limits, if one stood on *Rua Direita* facing south and took a turning to the right two blocks after the *Terreiro do Vice-Rei*, one would enter another square, the *Terreiro do Sabaio*, associated with some of the most important institutional buildings of Goa: the palace of the Inquisition facing *Rua Direita* – which had previously been the palace of the Sabaio and later the palace of the Viceroy – , the Sé or Cathedral of Santa Catarina, the Archbishop's Palace, the *Casa de Câmara* and the *Casa dos Contos* or treasury. The old *Terreiro do Sabaio*, before the Portuguese, had probably been larger, flanked by the palace of the Sabaio on one side, and the mosque – later replaced by the Franciscan convent – on the other side. The Cathedral would have been built in the centre of the *Terreiro*.

This was the institutional square of the city, dominated by the Cathedral. Fittingly, it stood next to the intersection of the main north-south axis – the *Rua Direita* – and the east-west axis that started at the eastern city gate and exited the old city on *Terreiro de São Francisco*. Although this was not a unique situation, this square had a singular characteristic. In Portuguese cities, different squares were usually associated with different functions, and in most cases the Cathedral square was separated from other civic squares. This was not the case in the *Terreiro do Sabaio*.

Terreiro de São Francisco, Terreiro dos Galos

The convent of São Francisco was built next to the Cathedral, on the site where Goa's main mosque had stood, just inside the old city gate. Outside, was located the *Terreiro de São Francisco*. To the south, next to it, also outside the city walls, was located the *Terreiro dos Galos*, dominated by the church and the Jesuitical convent of Bom Jesus. Both these *terreiros* had probably their origin in the Moslem city, being consolidated as urban squares with a religious content by the Portuguese.

Terreiro de Santo António

Further out, located upon a hill – the *Monte Santo* – and defining the western limit of the city, was the *Terreiro de Santo António*, surrounded by several religious buildings, including the nunnery of Santa Mónica on one side, and the convent of Santo Agostinho on the other.

Terreiro de São Paulo, Terreiro de São Domingos

The *Terreiro de São Paulo*, next to the Jesuitical college of São Paulo, located in the south-eastern part of the city, and, further north, close to the *Bazar Grande*, the *Terreiro de São Domingos*, associated with the convent of São Domingos, were on the eastern side the outermost squares of sixteenth century Goa.

4. THE ROLE OF SQUARES IN THE ORGANIZATION OF THE PORTUGUESE CITY

One may conclude that the squares played an important role in the reorganization of the city of Goa. Within the old limits of the city, the *Terreiro do Sabaio* grew in importance by means of the implantation of a number of new institutional buildings, either in the *terreiro* or close by. Other urban spaces acquired a greater importance, as well. That was the case of the open spaces associated with the city gates. The *Terreiro do Vice-Rei* acquired a greater status after the Viceroy moved in there and, at the other extreme of *Rua Direita*, the square of Misericórdia, gained a greater distinction with the construction of this building, which articulated the square and *Rua Direita*. The *terreiros* located outside the city gates became ordered squares associated with the construction of convents, like the *Terreiro de São Francisco* and *Terreiro dos Galos* in the west, or associated with other functional or symbolic roles, like the *Terreiro do Pelourinho Velho* in the south, a market square where the symbol of municipal authority stood.

The outlying areas of the city were developed by the Portuguese from the beginning. Whereas one may find a geometrical logic in the urban layout of the old city and in the organization of its various components, in these outlying areas of expansion topography was the main element that structured the urban fabric and the formal logic of these new urban areas has to be found primarily in the physical characteristics of the territory. Topography suggested the locations of singular buildings, the directions and the implantation of the main roads and the sites for the development of squares. These became the main elements for the structuring and hierarchization of the city. Three large squares defined the limits of this territory: the *Terreiro de São Domingos*, in the east, the *Terreiro de São Paulo*, in the north-east, and the *Terreiro de Santo António*, in the west. Each sector of the city was organized in relation to them.

The Portuguese city was always the synthesis of two different components. One erudite component, that arose from a set of rational principles and was translated into geometrical layouts, which were usually called planned, and one vernacular component, that arose from a close relationship with the territory and was usually translated into non-geometrical layouts, usually called organic. Different cities were more or less regular depending on historical circumstances, the topography, the resources available or the social actors involved. In Goa, one has a singular juxtaposition of these two components, in which the more regular corresponds to the pre-existing Indian city, whereas the less geometrical corresponds to the areas developed by the Portuguese. In these outlying areas, religious buildings and their squares, located and developed in close relationship with the natural characteristics of the site, played a determinant role as focal points in the organization and hierarchization of the city structure.

1712 DEMAND AND CIRCULATION ANALYSIS OF FISHERY RESOURCES AS FOOD IN JAPAN

ABSTRACT

In this study we analyze the food distribution industry in Japan, and focus the eel resources in the domestic food market. We have 19 species of eel in the world. Japanese has the history by which eel resources were put on as edibility from the past, and they use Japanese eel (*Anguilla japonica*). *Anguilla japonica* is one of the eel species that lives around East Asia, and that is designated 'vulnerable.' Eel resources are natural resources. We capture young eel in estuaries to use as the food resources, and cultivate them to raise. Recent years, although edible use has been increasing in East Asia countries such as China, it is said that about 70% of the world eel resources are consumed in the Japanese market. Japanese eel is now very popular as a food, and it has been eaten by the recipe called spitchcock for three hundred years. However, recent years the catch volume of Japanese eel is drastically decreasing, and the eel resources are concerned about exhaustion. The purpose of this study is to build a flow model of eel resources in the food market of Japan, and estimate the demand function of the eel resources as a food. From the result of our study, we discuss the management policy of eel resources considering the balance between supply and demand of Japanese eel in the domestic food market of Japan. If the supply and demand balance of eel resources in Japanese food market and the influence on price are clarified, we can concretely discuss the measures of the eel resource management in the market of Japan, which can be taken according to the change in captured amount of natural glass eel.

1116 GOOD FISHING, BAD GOVERNANCE: LESSONS OF TRANSFORMATIONS FROM COASTAL GOA

Sebastiao Anthony Rodrigues

Department of Humanities and Social Sciences, BITS Pilani Goa Campus, Goa. Email: p20130411@goa.bits-pilani.ac.in

ABSTRACT

Goa, currently a State on West coast of India is a *de facto* maritime territory bordering Arabian Sea. Sea and Rivers have not only been channels of its various Political Conquests in history but are also volatile and dynamic spaces of regional conflicts played out due to various dominant, ecologically hostile political and economic ambitions. At the core of challenge to the State powers and the elite economic projects is Goa's widespread fisher people engaged in variety of forms of successful oppositions in the past and fierce ongoing resistance that deserves serious academic attention.

This paper traces and evaluates conflicts on coastal Goa divided in two categories *intra-fishing conflicts* and *inter-fishing conflicts* unfolding in watery territories of Goa. Intra-fishing conflicts are contested amongst fishermen based on sustainability factors that determine types of fishing nets and types of fishing techniques in sustainability induced State banned territories. State role enmeshed in ambiguity as the defender of sustainable fishing practices and as promoter of unsustainable fishing practices will be critically examined based on evidence and field data. *Inter-fishing conflicts* represents confrontations between fishing and other competing industries such as *tourism* desiring to use water for water sports, marinas and casinos, *mining* aiming to transport ore through barges from rivers where fishermen carry on fishing, *sand mining* that digs to sell river sand for *real estate*, *Coal import* for steel plants threatening life and livelihood of fishing community along with others, and raging conflict over Goa's six rivers after Indian Government brought them under the National Waterways Act 2016 creating tyrannical legal architecture for dredging and fencing of rivers sounding warning to fishermen to benefit *Shipping* and *tourism* industries.

The large scale state wide protests over rivers have witnessed participation beyond fishermen with other people too involved. The threats inherent in the legislations itself releases draconian signals for the future of not only fishermen but also other actors too. This understanding has helped to evolve a large network of interest groups, public groups and media to mount a formidable challenge to the State plans at various levels.

Historical analysis method is adopted to treat textual documents while interview techniques are deployed for data gathering purpose. The paper will conclude with lessons of grassroots actions that have triggered important political awareness across Goa as important contributor offering credible challenge to bad governance in place.

1. INTRODUCTION

Goa's ecology has shaped its identity. Rivers flow downwards from the mountains of Western Ghats Forest into Arabian Sea often through plains and around islands forming river systems with their tributaries covering several kilometers. The river system includes Tiracol, Harmal, Mandrem, Chapora, Baga, Mandovi, Zuari, Sal, Saleri, Talpona and Galgibaga¹⁸⁰. Out of these eleven river nine has river basins¹⁸¹ People ever since they settled in this territory that is currently known as Goa has always interacted with Rivers and the Arabian Sea for various reasons. In fact livelihood itself got shaped by Rivers, Arabian Sea and connected Mountains together with plains and reclaimed land on the banks of rivers known as Khazan lands. Fishing and cultivation on riparian lands¹⁸² was most common interactions with Rivers that has come under attack with bad governance leading to constant breaches, flooding of paddy fields in riparian lands. In some villages people even cultivated paddy in the middle of river like in Vantem village in Sattari in the middle of potable water flowing Mhadei river that is known as Mandovi. This practice is known as Puran Shethi and is discontinued after river was dammed in 2005 to augment water.

Besides fishing and cultivation people also interacted with rivers while in journey across river in canoes and later on in launches and ferry boats before bridges were constructed. Still this practice continues. People and particularly soldiers interacted with rivers for warfare purpose. Soldiers guarded river banks as they were also international borders invaders often had to negotiate fortified banks of Arabian Sea and rivers. Notably Goa's Forts are located at these sites signifying conflicts of past involving various kingdoms and fiefdoms, empires and nations that staked their claims on Goa. The Seat of Power too has been located at various coastal venues in Goa of various rulers. Places such as Chandor, Ela¹⁸³, Panjim which are sites of Seats of Power of various rulers in Goa are all located on different river banks of Goa. Wind powered ships were source of navigation for the purpose of war, peace and commerce. Few rivers that flow into Goa have their source in neighboring States of Maharashtra and Karnataka and there are disputes on potable water sharing. One of them is Madhei river water diversion by Karnataka government¹⁸⁴. Diversion of rivers are known to have impact on fisheries¹⁸⁵. In addition commercial fishing itself globally is known to have wider ecological impacts¹⁸⁶.

¹⁸⁰ See Alvares (2002) Pp 13-17

¹⁸¹ See Sonak (2014) Pp 41-42

¹⁸² Riparian lands are lands adjacent to river

¹⁸³ Ela was a regional seat of Power of Adil Shah rule till Portuguese defeated his armed forces and began ruling from the same place from November 25, 1510 till plague forced to relocate to Panjim after few centuries. Its currently known as Old Goa located on the banks of Mandovi River.

¹⁸⁴ See Sonak (2014) Pp 40-61

¹⁸⁵ See Drinkwater (1994)

¹⁸⁶ See Moore and Jennings (2000)

However in the entire maritime context people who are indulging in fishing are mostly silent in history of Goa for they did not know to write their history and caste wise they were classified as Shudras¹⁸⁷ who were historically denied education. 'Shudras' is a Sanskrit word that mean slaves as per text of Manusmriti¹⁸⁸ imposed on fishers and others due to historical process of caste hierarchy formations through conquest of one set of native people who are referred as Shudras. So even if fishers struggled their initiatives did not find place in written history for they were not considered as subject of history. Fisher people's occupations and livelihood has ecological identity while caste has imposed another identity as slaves. However with the Introduction of Constitution of India¹⁸⁹ and annexure of Goa to India, the rule of manusmriti has been theoretically abolished¹⁹⁰ and principle of equality¹⁹¹ enforced. However it is tragedy that even the scholars continue to refer to fisher people of Goa as Shudras¹⁹². Goa's movement of fisher people especially against mechanized fishing is well known and has some scholarly attention¹⁹³. This paper moves interior intensely to trace fishing related conflicts in Goa's rivers.

2. RIVER FISHING AS SOURCE OF REGIONAL CONFLICTS

Even though Goa's fishing conflicts in Arabian Sea are well known its river based fishing that has come into increased public attention over the past five years with consistent articulations of concerns by fisher people on the banks of River Zuari. The paper is based on participant observation method since 2014. However qualifier is needed:

We must remain ready to revise our judgment, not only in the light of new factual information but also on the basis of further critical reflection¹⁹⁴.

Writing is based on primary data in the form of letter written by fisher people on the Zuari Coast to various government authorities mainly to the Directorate of Fisheries, Government of Goa. In this sense factual issues are well known to the Goa Government. This paper is only a trigger for further reflection and more importantly action. The conflict scenario of Zuari river that also serves as political boundary between the two districts: North Goa and South Goa. There are two types of conflicts classified based on the nature and dynamics involved.

2.1 Intra-fishing conflicts

The intra-fishing conflicts are amongst those engaged in fishing but with different nets and techniques.

2.1.1 Mechanised Trawlers

One conflict is well known: mechanized boats carrying on fishing in rivers. The magnitude and intensity of this conflict is indeed huge affecting entire coast of Goa. Mechanised trawlers coming closer to the shore and carrying on fishing led to depletion of fish, damage to the ecology and loss of livelihood to the coastal fisher people who carried on fishing on non mechanized canoes without trawling in co-operative manner. After protected agitation by the fisher people¹⁹⁵ led by late Mathany Saldanha¹⁹⁶ the Government of Goa framed law named Goa, Daman and Diu Marine Fishing Regulation Act, 1980. However it came in force only on 7th July 1981¹⁹⁷ when even Department of Fisheries was not formed and notifications was signed by Under Secretary (Forest and Agriculture). On the same day Mechanized fishing within five kilometers from shoreline was banned. Notification read:

In exercise of the powers conferred by clause (h) of section 2 of the Marine Fishing Regulation Act, 1980 (3 of 1981), the Government of Goa, Daman and Diu hereby specifies an area of 5 kilometers from the coast in the sea along the entire coastline of the Union Territory as the 'specified area' for the purpose of the said Act.¹⁹⁸

Simultaneously State banned Mechanised fishing vessels in a 'specified area' of five kilometers. Government order read:

In exercise of the powers conferred by sub-section (1) of section 4 of Marine Fishing Regulation Act, 1980 (3 of 1981), the Government of Goa, Daman and Diu having regard to the need to conserve fish and to regulate fishing on a scientific basis, hereby prohibits fishing with mechanized fishing vessels in the specified area declared as such under Government Notification No. 2-1-81-FSH (iii) dated 7-7-1981.

Explanation:- "Mechanised fishing vessels" means a fishing vessel propelled by mechanical means¹⁹⁹.

Earlier²⁰⁰ Indian Fisheries Act, 1897 was applied in Goa from 1st February, 1965 clearly was not serving the needs of he agitating fisher people against mechanized trawlers. This also indicate that from 19 December 1961 to 1st February 1965

²⁰⁰ See Balkrishnan (1965)

Goa fishing was without any legal regulations. This period duration amounts to three years one month and eleven days. Prior to 19th December 1961 it was Portuguese rule and only scanty references²⁰¹ are available for the kind of laws prevalent during colonial regime such as ban on nylon fishing nets and specific size of fishing nets thereby allowing smaller fish to escape along with strict enforcement of law extend of burning of seized nylon fishing nets.

The passing²⁰² of the Goa, Daman and Diu Marine Fishing Regulation Act 1980 has a specific mandate to frame rules to protect small scale fishing people under Section 4 (2) (a) that reads:

The need to protect the interest of different sections of persons engaged in fishing, particularly those engaged in fishing using traditional fishing crafts such as catamaran, country craft or a canoe.

There is also mandate to for conservation. Section 4 (2) (a) empowers State to frame rules to wards:

the need to conserve fish and to regulate fishing on scientific basis.

Both the above provisions of law are sufficient legal backing to protect small scale traditional fisheries in Goa.

2.1.2 Purse Seine fishing

Many fishing boats use Purse Seine nets in Zuari river that contributes to massive depletion of fish stock as well as drastically reduced fish catch to those using Gill net fishing. A study published by British Ecological Society point out interesting aspect²⁰³:

Gears like purse seines are used to capture free-swimming (pelagic) fish in the water column. This gear is capable of taking perhaps 400t of catch per single deployment.

This amount of catch is more than total yearly catch of the traditional fisher in Zuari River. One fisher pointed out in an interview to this author:

Here in Zuari they came without fear, they don't have to navigate too much in river as it is small. They can get fish faster while if they go out in Sea they have to release longer net. It's not like that in river, here in Zuari where they release shorter net and catch bumper catch. And they have fish finder screens inside their boats. They can know the existence of fish at a particular spot but they cannot identify the variety of fish. Screen shows tiny dots indicating fish. If the fish is bigger in size then dots are bigger in size. Then these boats encircle with their nets around fish.

The Study also points out facet of this encirclement²⁰⁴:

The circle enclosed by some purse seines can have a diameter of over 600 m and the base of the net is drawn closed to enclose the shoal.

Further it must be noted that Government has power to restrict the size of mesh of fishing nets. Section 7 reads:

The Government may having regard to the nature and mode of fishing and the need to conserve fish and to regulate fishing on a scientific basis by an order notified in the Official Gazette regulate or restrict the size of mesh of a fishing net.

This is very important to note; as one of prevailing conflict in Zuari River is that traditional fishers complained about the small size fishing nets used by fishing boats engaged illegally in trawling as well as purse seine nets causing damage to the ecology and depletion of fish stock of river that is known for breeding of fish.

State authorities have enough powers to enforce its laws when violations takes place, yet it is seldom done. Here is what the Section 18 state:

The authorized officer may, if he has reason to believe that any fishing vessel is being or has been used in contravention of any of the provisions of this Act, or of any order or rule made thereunder or any of the conditions of the license, enter and search such vessels and impound the same and seize any fish in it.

Further it must be noted that in order to implement this law notified rules²⁰⁵ in 1981. Rule 3 (1) prohibits fishing with net operated from a mechanised boat:

No person shall take fish in inland waters with a net operated from a mechanised boat

Rule 3 (2) deals with penalty for the offenders:

If any person is found taking fish in inland waters with a net operated from a mechanized boat, the net alongwith the mechanized boat shall be confiscated by the Director or any other officer authorized by the Government in this behalf which shall be without prejudice to the penalty which may be under rule 14.

There is also proactive element in the rules for Fishing in Inland Waters. Rule 3 (3) provides that

The director or any officer authorized by the Government may carry out the patrolling of the inland water to detect any violation of the rules.

In spite of such tight laws illegal fishing in Zuari has flourished. Several fisher people continuously has filed compliant before Director of Fisheries, Secretary to Fisheries who is the Administrative head of the fisheries department in Goa, to

²⁰¹ See Somayaji and Coelho (2017)

²⁰² See Sharma 1981

²⁰³ See Moore and Jennings (2000) Pp 11

²⁰⁴ See Moore and Jennings (2000) Pp 11

²⁰⁵ See Gaunekar (1981d)

the Minister of Fisheries. Governments changed with times but problem of illegal fishing threatening very livelihood of the fisher people and danger to the river ecology has remained.

Observations in Zuari River reveal that even after thirty six years of the enactment of this law enforcement is pathetic. River is included within the definition of Inland Waters which reads as per Rule 2 (f):

"Inland Waters" means a creek, river upto the boundary where it meets the Sea, canal, stream or any other water including stationary water collected in a paddy field or Khazan lands.

There are routine violations of this law. Its illegal because of two reasons. The first: mechanised fishing is banned in inland waters. In case of Zuari river both trawlers and purse seine boats are mechanized fishing vessels. "Mechanised fishing vessels"²⁰⁶ means a fishing vessel propelled by mechanical means. "Mechanised fishing" means *fishing by a boat which uses mechanical power for actual fishing operations* as per Rule 2 (g) of Goa, Daman and Diu Fisheries Rules, 1981. This definition is surrounded with ambiguity as Goa Fisheries department has partly funded several traditional small scale fishers in Goa through subsidies fuels costs as well as purchase of fiber canoes fitted with outboard motors that functions on Petrol or Kerosene. As a result most of the boats in rivers are mechanized and fishers are dependent upon State subsidies.

In 2016 Director of Fisheries Dr. Shamila Monteiro attempted to enforce this rule and told traditional fishers who are registered with department and recipients of subsidies as illegal because they filed several complaints against banned trawlers and purse seine boats fishing in Zuari river. One leader of the fisher Union narrated this incident to this author in Konkani. Here is an English translation

Due to our repeated complaints against illegal fishing Director of Fisheries Dr. Shamila Monteiro targeted us and told us that we cannot use out board motor to go for fishing in Zuari. You'll have to row and go in the waters. I answered her "we don't have any problem with anyone fishing in Zuari coming with outboard motors. Our problem is not on their mode of navigation but kind of fishing nets they use and kind of fishing techniques they deploy in Zuari. Both Trawler nets and purse seine nets are banned for use in rivers. If they want they can come and do fishing like how we do by using Gillnet. You objecting our mode of travel to Sea also makes us question your mode of travel. Why don't you instead of using car to come to the office daily shift to walking? Director got angry on us.

The Second reason why it is illegal is due to use of banned fishing nets. As Per the Rule 10 use of nets with certain mesh sizes are prohibited. Rule 10 (1) states:

No person shall use a net the mesh size whereof is less than 24 mm. for catching fish and 20 mm for catching prawns

There is no accountability on the size of nets used by Trawlers and purse seine boats in Zuari River who are prohibited in the first place to enter rivers for fishing. Oral narration to author by one fisher revealed that net size used by Purse Seine boats are below 12 mm. there by catching fish life very small in size. Gillnet fishers use different mesh sizes in Zuari estuary within limits prescribed by law. One study has documented nine mesh sizes in Zuari river. 30 mm, 36 mm, 40 mm, and 46 mm for mix catch, 52 mm and 60 mm for mixed catch of big size, 120 mm for crabs and catfish, 160 mm for Seabass and snappers, and 200 mm for Rays (footnote).

Legal ambiguity has been eliminated as far as use and site of various fishing nets in the license itself. In Form "E" issued under sub-rule (12) of rule 11 instructions are printed to this effect²⁰⁷:

(a) The Rampon operators including the non-mechanised traditional fishing crafts shall operate freely without any restrictions. However, waters upto a distance of 5 kms. From the shore shall be reserved exclusively for those operating the rampon nets and non-mechanised traditional fishing craft and no other type of vessels shall be allowed to fish within a distance of 5 kms, from the coast and inland waters.

(b) Mechanised fishing vessels shall operate beyond 5 kms. Line from the coast.

When rules are clear cut as above the question of violations is a sign of bad governance in Goa. Gillnet fishing is preferred fishing practice for Zuari estuary as per the scientific study²⁰⁸. It reported:

The results suggest that this estuary is an immature developing ecosystem and it has adequate strength in reserve to adjust perturbations. Simulations of relative changes in biomass for major fishery groups under two different fishing effort scenarios indicate that gradual increase of fishing effort in gillnet fleet through motorisation will be ecologically sustainable for this estuary.

2.1.3 Politics of River Patrolling

Zuari River has ongoing fishery but is facing certain hitch. According to study²⁰⁹:

The gillnet fishery represent majority of the landed catch. The region holds a medium fish landing centres like Siridao, Cakra, Odxal, Bambolim and Nauxim which lands about 1000 tonnes of fish every year...However the intrusion of mechanised vessels into the coastal zones as well as the exposure of motorised fishermen beyond 5 km have created a critical social concern in fishing operations and resulted in fishing conflicts... recently the fisheries department has introduced a fisheries patrolling boat and become functional since October, 2014.

206 See Gaunekar (1981c)

207 See Gaunekar, N.P. (1981d) FORM, "E"

208 See Sreekanth, G. B (2016)

209 See Sreekanth G.B. et al, (2015)

However in spite of introduction of fisheries patrol boat, conflicts has not ceased. Ground investigations revealed the following about patrolling in Zuari:

- a) Patrolling in Zuari river is shared by Department of Fisheries and the Coastal Security Police.
- b) Often both the departments – Police and Fisheries - has been responsive in attending to calls of the fishers from Zuari river as there has been several lapses in the form of delayed response resulting in continues illegal fishing.
- c) There been cases of complete non-response to fisher's calls by police citing brake down of patrolling boat or lack of fuel for boat or boat is busy elsewhere.
- d) Penalty imposed on booked vessels for illegal fishing is negligible and suspension period is short. No fishing vessel proved in illegal fishing has faced cancellation of its license.
- e) Political pressure from officers in State administration and politicians to allow illegal fishing to continue and keep patrolling boats standstill.

The above five points were particularly intense from 2013 up to 2017. Fishers from Zuari coast filed several complaints with Fisheries department and Police; complaining about illegal fishing but due to political patronage to the illegal fishing fisheries administration itself in Zuari river remained in collapsed state. As far as fisheries are concerned governance in Goa was bad.

Pressured by continues complaints from Fishers Goa Fisheries department in early January 2017 extended the ambit of Goa, Daman and Diu Fisheries Rules, 1981 and empowered eleven more officials to act against illegal fishing in Goa²¹⁰. This includes:

1. Deputy Director, Directorate of Fisheries
2. Superintendent of Fisheries, Directorate of Fisheries
3. Assistant Superintendent of Fisheries, Directorate of Fisheries
4. Fisheries Officer, Directorate of Fisheries
5. Police Inspector
6. Police Sub-Inspector
7. Assistant Police Sub-Inspector
8. Head Constable
9. Mamlatdar
10. Joint Mamlatdar
11. Block Development Officer (B.D.O)

Situation improved in 2017 after the elections. The new minister²¹¹ who took the department took some very bold and dramatic steps soon after taking over charge of department in March 2017. After studying the department for few months he rolled out series of steps to restore administration and political will to check illegal fishing in Zuar river. Here are some of the steps Goa Fisheries Minister initiated from September 2017.

- a) Served 48 hours notice to the Director of Fisheries and other officers of the fisheries department citing that fishermen from Zuari have phoned him to complaint about rampant illegal fishing in Zuari and it must be stopped.
- b) Suspended Director of Fisheries Dr. Shamila Monteiro and gave charge of the department to Secretary Fisheries, Govind Jaiswal, I.A.S. for six months. Meanwhile Dr. Monteiro was transferred as Officer On Special Duty (OSD) in the office of Director General of Police (DGP).
- c) Acted strictly against trawler fishing vessels indulging in illegal fishing in Zuari by way of administrative action and media statements.
- d) After fishers mobilized (in mid November 2017) and got the local Member of Legislative Assembly²¹² from Talegao Constituency to oppose illegal fishing in Zuari accompanying in the Secretariat for joint meeting with Town and Country Planning Minister²¹³ and the Fisheries Minister. Fishers were given two weeks time by the two ministers to act and also promised to change law to increase penalty for those caught in illegal fishing.
- e) After two weeks Fisheries Minister acted on illegally fishing purse seine boats in Zuari River, compounded one boat and gave media statements against illegal fishing in Zuari River November 2017 end. Ministry of Fisheries also cancelled VAT and Fuel subsidies of the fishing boats reported by Coastal Security Police and Fisheries department Patrolling boat though according to law their fishing licensed should have been cancelled.

The above five steps to a great extend reduced illegal fishing in Zuari both by Trawlers and by Purse seine boats. Illegal fishing however has not stopped completely. Here is way it still continues:

210 See Monteiro (2017)

211 Vinoda Palyenkar

212 Jennifer Monserrate

213 Vijay Sardessai

- a) On holidays like Good Friday there was massive illegal fishing by 35 purse seine boats in Zuari river. There was no response to Fishers' telephonic calls from Police as well as Fisheries department and fisheries administration resembled collapsed again in 2018.
- b) Night fishing by trawlers is rampant every night between 8.00 pm to 3.00 am. According to information furnished by fishers between four to five trawlers are carrying on this activity that is both ecologically damaging to Zuari estuary and legally banned.
- c) One purse seine boat are carrying on illegal fishing daily evening from 3.00 pm onwards.

State government has not been successful if eliminating illegal fishing totally though it has made some sincere efforts. In March 2018 Fisheries department has a new Director²¹⁴ and the challenge of illegal fishing is huge and fisheries department has to put its act together to stop it. A study has pointed out that if illegal fishing by mechanized boats in Zuari River is not stopped then it will have will have negative impacts on the populations of resident species, semi-resident species

and migrant species in the coastal system²¹⁵ besides law and order problems as like emergence of unrest amongst fishers.

2.2 Inter- fishing conflicts

Inter-fishing conflicts represents tensions and confrontations between fishing and other competing industries. This creates additional burden on fishing communities that are already burdened with issues if illegal fishing as discussed so far in this paper. Short introductions to various inter- fishing conflicts are attempted here to know these additional burdens imposed by political and economic system in place.

2.2.1 Tourism

Goa's tourism promotion has now come to aggressively target rivers in multiple ways. Ground study reveals interesting trend. Water surface is used for water sports, docking of off shore casino boats, plans for marinas to park yachts of the financially privileged jeopardizing fishing communities to a great extent. This section takes a bird's eye view of the various tourism related issues that are in direct confrontation with fishing communities in Zuari River.

2.2.1.1 Water Sports

In 2013 Government of Goa issued permissions to a corporate to start water sports activities in Zuari river. Department of Fisheries granted No Objection Certificate (NOC) to Aquasail Distribution Company Pvt Ltd. *Aquasail* has an agreement with Goa Hotels and Club Private Limited (GHCPL) inked in 2011 for profit sharing and space sharing. Aquasail to use premises of five star hotel Grand Hyatt at Zuari river front, conduct water sports activities in Zuari river and share earnings with GHCPL. When boats entered Zuari river fishers' livelihood got disrupted. They petitioned Director of Fisheries and permissions were revoked for nine months. Zuari estuary being a breeding site for fish noise began to push away the fish. Nets of fishers began to get cut off by water sports boats²¹⁶. One fisher from the Zuari river puts it succinctly:

Fishermen there in Zuari put out Gill nets in the morning and pull back in the evening. These nets gets entangle with under water fans of water sports boats and gets cut off.

Cutting of nets certainly creates a financial loss to fishers but impact transcends fishers to reach fish. Another fisher points different dimension:

Water sports boats causes leakage of oil from their engines. Their oil deeps into water and reaches river bed. Fish then does not get oxygen to breath. Fish food spaces get damaged. Fish then moves to some other location. Some fish dies with oil leakage, with oil odors, we have seen fish dying in river due to this reason. When fish gets affected with oil, it rotates around itself.

Power politics at play is rather glaring. One fisher put it in an interview with this author:

When we fishermen are there actively fishing it was duty of the Fisheries department director to consult us prior before granting NOC. She has not consulted us at all. NOC was given in secrecy with Ministerial influence. They tell us that we have orders from above (Delhi) to grant NOC to Water sports. We refused to accept this reasoning. We went to Fisheries department and met Director. We asked as her as to why they are telling us that orders have come from Delhi when the elections are in Goa and how come these rules are coming from Delhi? She told me that I am speaking too much. I retorted back to her saying that she is the one who is compelling me to talk too much. Every decision making is in Goa and how can orders come from Delhi? We told her that we will never allow Water sports boats in Zuari because that is the breeding spot of fish at Nauxim and we carry our fishing there.

In November 2017 Fishers called for the revoking of permissions granted to the water sports in Zuari to Aquasail (no body else has permissions for water sports in Zuari). Their requested was complied neither by Captain of Ports nor by Department of Fisheries whom they petitioned. Then in February 2018 they wrote to the Minister of Fisheries to initiate action against director of fisheries for ignoring their letter²¹⁷ on water sports. In March 2018 first two weeks Director of Fisheries called two meetings with fishers. Second meeting included Scientists from Indian Council of agricultural

217 Fishers of Zuari correspond with the State Authorities under the names 'Bharat Mukti Morcha' and 'Shree Sahntadurga Fishermen co-operative society'.

Research, and National Institute of Oceanography. Decision that was arrived at is to carry on scientific study of fish breeding sites in Zuari and only then to ban water sports.

2.2.1.2 *Marinas*

In May 2000 Government of India brought Zuari River under the jurisdiction of Mormugao Port Trust (MPT)²¹⁸. Then in 2010 MPT leased out 1,00,000 square meters each of river fronts of Zuari to two corporate Yatch Haven (Goa) Private Limited, and Kargwal Constructions Private Limited. One site belongs to Nauxim- Bambolim Panchayat and second site belongs to Sancoale Panchayat jurisdictions provoking intense protests. Words of opposition resonates in fishers:

We are the fishermen and they should have consulted us but they did not. We are 120 fishermen in our organisation itself but still they ignored us. We they came to know about it from other sources. Then MLA Vishnu Surya Wagh came to support us against Marinas. Francis Silveira too came and had joint meeting with us in Nauxim. It was very good meeting. After that protest meeting in Nauxim Marinas stopped and till now there is no sign of them. We will not allow these Marinas to be installed under any circumstances.

Technical analysis has pointed out various flaws in conceptualizing of marinas in Zuari river²¹⁹. However it is important to know the perceptions of threats from Marinas from local fishers themselves. One fisher responded:

First of all our people do not know exactly what is the meaning of marina. I heard that marina mean a big company will construct boats/ships and dock boats/ships from outside, they will dredge the river. When ships will navigate in river we will not be able to put our nets for fishing. This will impact us most.

Another fisher had more insightful picture of how marinas could impact fishers in Zuari:

When we put our nets in river it does not remain static in one place. It flows. And if marinas were there then our fishing nets would have gone and touched the parked boats. We would face lots of hardships if marinas are installed. It is loss for us. There will be no fish available. Look at the example of Panjim under the bridge, there are no more tisreos there. Entire river Mandovi from Miramar to bridge used to be full of tisreos, they are untraceable now.

According to his perception this has happened because of stationing of Casinos in Mandovi river:

2.2.1.3 *Casinos*

Gambling is promoted in Goa to attract tourists and all the casino boats are located in River Mandovi. Although there are Court cases involvement of fishers against casinos is minimal. However fishers from Zuari shore who also used to come for fishing in Zauri has narrated that Shell fish *Tisreo* has gone extinct in Mandovi. Here is his narration:

It is because of stationing of casino boats in Mandovi river, their oil leaks in river. Oil is bad of life in river and so tisreos have gone untraceable. Also there is direct release of sewage into Mandovi river in Miramar and Campal. There is one such outlet near Kala Academy. One Ramponkar from Aivao, Dando has told fisheries Minister Palyenkar to stop letting out of city sewage into river near Kala Academy. Minister is aware of this and has promised to stop it. Fish dies with sewage and oil release in river. Fish gets no food to eat or fish moves further away due to pollution.

The above concerns of fishers on floating casinos if addressed calls for removal of these boats from Mandovi river.

Recently government announced that public comments on the State plans to shift Casinos from Mandovi into Zuari. Zuari fishers opposed. Here is one argument:

If casino boats are installed then we will not be able to carry on fishing activities. If, all the six boats are shifted to Zuari then where we would be going for fishing? Fish habitat is the same that they wanted to station casino boats on Bambolim shore. It is a breeding site for fish. Casinos would have released sewage into river then our fishing nets would have got entangled with casino boats, its all round disruption and there would not been any fish left in Zuari.

Fishers from across the river Zuari, from Vasco too opposed shifting of Casinos in Zuari river and finally they have stayed in Mandovi.

2.2.2 *Mining*

Goa State Pollution Control Board was created in 1988. Very first meeting was held on October 05 chaired by the Chief Secretary of the newly formed State of Goa. Out of the six areas that are listed as deserving Board's attention three are relevant to note from the minutes here²²⁰:

1. *Mining Industry being a major polluting industry in Goa*
2. *Pollution of inland waterways by movement of barges and other vessels*
3. *Education of masses on the aspect of prevention of pollution*

It is inland waterways being polluted by barges that has impact upon fisheries and fishers of Zuari river. Barges are used in Goa to transport ore from hinterland to MPT for export purpose. Some barges also import Coal to industrial plants located in hinterland of Goa particularly in North Goa's Vedanta Plant in Amona village. It's a transportation of ore through barges using Mandovi, Zuari, Cumbharjua and Mapusa river that pollution of inland waterways of Goa occurs. According to insights ground insights barges not only pollute rivers through leakage of oil but also conflicts with fishing nets in river. Mining companies has filed complaints before Captain of Ports and with Director of Fisheries to keep fishers

218 See Rao (2000)

219 See Rodrigues (2017)

220 See Parulekar (1988)

away from the river as they obstruct barge transportation and delay in operations. One fisher commented in while interviewing:

Barges passage is same as our fishing venues. The difficulties arise when we put our fishing nets in river and if barge happen to come. We are unable to quickly remove our nets from the river because barge is approaching. We put lighted torches on barges to indicate our fishing nets so that they can move slightly sideways. If the staff of barges awake then they oblige otherwise they go over our fishing nets. That time our net gets torn up completely. At the Siridao shore water is shallow, so if barges go over our gill net it definitely tears up.

Besides direct conflicts like these there are also problems of pollution of rivers particularly through dumping of ore in River. One Fisher narrated his observations:

They do dump remaining ore in Zuari while returning from MPT. Some of Coal blocks are small while other are big, they get entangles with our fishing nets. Barges we have seen many times throwing left over ore in Zuari river near Siridao coast where it is shallow.

In addition to this fishers observed large amount of fish life dead every time barge pass though river as the bottom of it scrapes on riverbed and disturbs breeding fish life in Zuari estuary.

2.2.3 Sand mining for real estate

Sand mining is being carried on in rivers of Goa, particularly Chapora river and Mandovi where it is intense. Supply of sand goes mainly for real estate constructions etc. While constructions are booming there has been increasing public discomfort rising from the visible impact on marine river ecology and fishing. According one study²²¹ sand mining has prowess to destroy the cycle of ecosystem. In Goa there are also additional reports of police intimidation of those who complain about illegal sand extraction in Mandovi river²²².

2.2.4 Goa's rivers as National Waterways for Shipping and Tourism

In March 2016 Government of India through an Act of Parliament included Goa's six rivers – Chapora, Moira/Mapusa, Mandovi, Cumbharjau, Zuari and Sal - as national waterways without holding any consultation with any of the democratic decision making bodies. There was no discussion on Goa State Legislative Assembly, Goa Cabinet, Any of the Panchayats. Goa Chief Minister Laxmikant Parsekar secretly consented to the Central Government to include Goa Rivers as national waterways and conveyed to Central Government through Captain of Ports. Only known consultation was in 2010 that too by IWAI only with select few: Goa Chamber of Commerce and Industry (GCCCI), Mormugao Port Trust (MPT), and Captain of Ports and most importantly Goa Barge Owners Association (GBOA). According to information posted on the website²²³ of IWAI, they were invited to Goa by mining connected interests.

This decision granted control of Goa's rivers to the Inland Waterways Authority of India (IWAI). According to its past Chairman Amitabh Verma²²⁴, Inland water transport expansion is for two reasons: Cargo transportation in cheap manner, and for tourism. Government of India then went aggressively campaigning for this purpose. IWAI approached for permissions before Expert Appraisal committee to dredge three rivers (Mandovi, Cumbharjua and Zuari) of Goa on behalf of 228 mining barges as per the minutes of 24 October 2018 meeting²²⁵. Treating rivers as 'Highways' for transportation ignoring everything else including those who carry on fishing in rivers is colonial and is acknowledged with regard to European settlers in New Zealand and use of Whanganui river in section 69(17)(c) of Te Awa Tupua (Whanganui River Claims Settlement) Act 2017²²⁶. Crown has apologized in section 70 of this law. And India is launching similar initiatives and turning colonial against its own people. It's truly a paradox unfolding. However in case of Goa ruling elites has already been conceived as colonialists subjugating native people. Ruling elites includes those carrying on mining aggression on ecology and people on mass scale including corporate. In fact mining companies has been historically accused of promoting through political back up to Portuguese who ruled over varied Geographies of Goa for 451 years and 24 days from November 25, 1510 to December 19, 1961. Mining began in 1929 with Portuguese granting first lease of total 710 leases covering nearly 30 per cent of Goa's Geography. However it is unlikely that Portuguese has conceived damage that it could inflict on ecology including on marine ecology through barge transportation of iron ore and manganese.

3. PUBLIC DISSENT OVER GOA RIVERS AS NATIONAL WATERWAYS

The Fishermen perceive themselves as first casualty of getting Goa's rivers as National Waterways as they were not consulted before taking this decision neither by Government of Goa nor by government of India. Here is one narration from fisherman:

We were not consulted. It is wrong on the part of the State to ignore us. We are fishing in river and others are fishing in other rivers. Without consulting us they do whatever they want. Parrikar²²⁷ is doing whatever he wants to, but he should consult public as public has elected him. They say they will dig all six rivers of Goa. We told them that we will not allow you'll to dredge and will hit the streets in protest. Our leader Agnelo from Vasco told us that they will go on dredging mouth of Zuari.

227 Parrikar refers to Manohar Parrikar, Chief Minister of Goa

First they will dredge the mouth and then they will come dredging inside the river. They must be stopped right away. They should not be allowed to dredge.

Dredging is one of the main activities to be undertaken by IWAI to sufficiently deepen rivers for large ships to navigate through as current depth is not sufficient and on low tide barges cannot even navigate and has to be halted. Fishers are up disturbed about this. One fisher expressed about dredging:

If river is dredged then we will get no fish at all. Dredging will end all food stock available for fish to feed upon. After dredging everything will change. It will be very difficult for us to survive as feeding stocks of fish will be removed from river. Fish will not be able survive in river after that. Secondly if they give depth of 40 to 50 meters to rivers then both side edges will face risk of caving in and houses on coast will be shaken up. Gradually edges will descend into river. Its hardship for us in all sides; from threat to our fishing activities as well as threat to our habitat, and this is going to affect all the people of Goa.

Scientific study²²⁸ on dredging confirms assertions for fishers of Zuari River. It has been found that marine ecology and coral reefs are negatively affected in situations of dredging of rivers even though there may be differences due to site specific differences in evaluations. Rivers of Goa that has intense fishing activities are bound to get affected due to dredging of rivers and this is also widely held view in the State of Goa against State projects and plans for rivers to benefit tourism and shipping, mining and coal transportation.

Public dissent on rivers has spread across the State of Goa. Nearly 100 Panchayat Gram Sabhas (Village Assemblies of citizens) has passed resolutions against inclusion of Goa's six rivers as National Waterways. Various organizations has opposed it and several politicians has been confronted over the issue. Several objections has found their way to various government offices such as Directorate of Fisheries, Captain of Ports, Chief Minister, Governor of Goa, IWAI office in Gurgao and Ministry of Shipping in Delhi, Prime Minister's office in New Delhi and other places of importance. Documents ultimately find their way in the office of Captain of Ports and are accessible to Public via Right to Information Act 2005 (RTI).

This issue of Rivers has found its way very deep amongst people and is preparing to gather momentum for a major political revolt in the State of Goa. On April 27, 2018 major confrontation broke between protestor and the State Government over the issue of Rivers as national waterways, Regional Plan-2021, Outline Development Plan (ODP), Planning and Development Authorities (PDA) Coal handling with opposition led by Indian Armed Forced retired officer naming corrupt politicians publicly. Situation for has further turned out to be tensed as Government of India has proposed to reduced Coastal Regulations Zone (CRZ) to 50 meters from the shoreline to facilitate commercial hotels on river fronts.

The direction the opposition is finding is unusual. It has called for the scrapping of Town and Country Planning Department, Introduction of New law that opposition has already drafted and scrapping of Regional Plan 2021, stoppage of Coal Handling at MPT, Salvaging of fish in rivers from "nationalized rivers", and scrapping of PDA all over Goa. Issue of fishermen and rivers has found integrated in wider political consciousness of the State of Goa with ever consolidating opposition.

4. CONCLUSION

Fishing and Fisher's determination to speak out and struggle in spite of all the odds at hand has pushed Goa State into tremendous political churnings. However without restricting to issues there is a need to question the asymmetries ingrained in the very process of State formation including Annexure of Goa to India through conquest. There is a need to re-visit the archives of history to freshen up the collective memory of the people and the scholars who neglect watershed event in the life of Goa: Liberation that is contested through every dissent. It is unlikely that any long term solution for problems faced by people of Goa would emerge without questioning nature of democracy and nature of freedom and without understanding most significant debate Goa at United Nations Organization in December 1961²²⁹. The question of Regions Development of Goa in intricately linked to the available avenues of freedom whose spaces shrinking spaces in subtle manner needs scholarly attention as without spaces for articulations any kind of development at Regional level is an exercise in tyranny. Fishers of Goa in General and those of Zuari River are facing tremendous pressures from the forces discussed in this paper.

ABSTRACT

We are ignoring the significance of water for our life. Increasing demand due to fast and multidimensional development along with the modernization the water has been over looked. Anthropogenic activities caused the pollution of surface water bodies which has increased the dependency on the underground water. Less rainfall and recharging of ground water along with the over exploitation of ground water have forced ground water level to go down abnormally. Ground water is a major source of drinking water in India. Ground water health is deteriorating with the time. In the present study Pingla Block, Kharagpur sub-division, Paschim Medinipur, West Bengal has been taken. The total area of Pingla Block is 224, 48 Sq.km. The temperature varies from 43°C to 7° C and the average rainfall is about 1750 mm. The population of Paschim Medinipur is 5943300 (Census 2011) which is unevenly distributed among 7600 inhabited villages. Naya village is a unique Indian village which falls in Pingla Block. Naya village is also famous for 'Pot Chitra'. 41 lakhs households have their own drinking water source out of 01 crore 37 lakhs rural households in West Bengal. 43 lakhs households have to cover a distance not less than ½ k.m. for collecting drinking water. Data shows that Indian village women waste 15 crore working days for the purpose of collection of drinking water and in terms of money Rs. 1000 Crore has been lost per year. Water is obtained for agriculture from the ground water which results the fall of ground water level to 110 meter in April 2015. Present study reveals, ground water exploitation has increased for various needs. Very erratic rain fall, increasing demand of water, over exploitation, decreasing surface water bodies and their pollution, poor recharge of ground water have not only caused the fall of ground water level but also dried up dug and shallow bore wells. To provide safe drinking water to the village people Central Government has introduced 'Village Level Operation and Maintenance' (VLOM) System. It is suggested that for proper use and to minimize the misuse of water there must be water tax which will also help to execute VLOM system properly. Still today there is no water Tax. A survey has shown that maximum quantity of water is wasted by poor and illiterate persons. Awareness about water and fear of water tax will definitely generate a positive movement in the direction of controlling the misuse of water and also to minimize water problem.

Key Words : Domestic water tax, VLOM system, Misuse of water.

INTRODUCTION

Water, Whom are you made for ? This question has variegated answer. The Bushman community of South Africa replies that the water belongs to those who live beside the water bodies. But this water does not belong to them permanently as they have to migrate some other place. Same question asked to any farmer community of all over India, we can have different answer. They will say that the pond and wells situated in the village belongs to all but these pond and wells are situated in side the own boundary that will be possessed by the head of the family. When this question is asked to any Govt. officer of any country, he will answer that water bodies made by the Govt. belongs to common people but any time the right of the people can be restricted by the Government. If this question is asked to officers of Coca Cola Company, they will answer that they can use the ground water and underground water occurring in their leased area, according to their needs and in their own way .Actually by asking this question from Bushman (South Africa) to Coca Cola Company, It is discovered that how men uses as it is their own property.

All types of natural water sources including river water are a precious gift of nature. Yet it is never bought by any businessman or monarch. Water was never sold in the historic period by any businessman or monarch. But in the present age of globalization it is being sold by renowned business man. In present time people are misusing drinking water. If they are not made conscious about the values of water, water business will be biggest business in India in coming day. People are not only misusing drinking water but also polluting it in an unscientific way. As a result these people have to make a domestic budget for buying drinking water in the beginning of the month in near future. From the above discussion we may arrive at conclusion after Koffi Anna that our world will experience the World War – III for nothing but water. If Government brings domestic drinking water under taxation, people will understand the real value of water.

It is said that life originated in water according to our religious and mythological books, and it is also believed that life will end with water. Comments have also made that the III rd world war will be for water. With the multidimensional developments and modernization along with the increase in the population the demand and use of water has been tremendously increased. In present situation all over the globe water scarcity may be observed. In the world about 2.7 billion people face water problem at least for one month every year. The water available in India per capita was 3000 m³/year in 1951 which decreased to 1800 m³/ year in 2010 and still it is decreasing. Due to lack of awareness and mismanagement the surface water bodies have been polluted. Although the deep water tables are not affected by pollution due to anthropogenic activities but shallow, hand pumps, dug wells etc. yields polluted water. With the development of the conscious about health in the people the use of bottle packed water has been developed.

Water ATM is gradually coming up. In India in 11 states water ATM has been successfully launched. Till 2015 about 2800 water ATM have benefitted 70,000,000 people. Due to pollution of surface water bodies people who were using the surface water for their common use, now unable to use. This has resulted the extra pressure on the supply water.

STUDY AREA

The Pingla Block is included in Kharagpur sub – division of Paschim Medinipur district of West Bengal. The block is enclaved by Kharagpur – II and Narayangarh block in west, Debra block in north, Sabang block in south and part of the Purba Midnipur district in east. The Pingla Block is dominated by rural population and it has 184 villages. The nearest Railway station is Radhamohanpur but the road is not good. So it is easy to come from Balichak railway station and it is about 12 k.m. The Pingla Block is included in the Survey of India Topographical sheet no. 73 N/11 and it's extension is 22°12'58"N to 22°20' N latitude and 87°29'22"E to 87°43'36" E longitude. The total area is about 224.48 km² with a general slope towards SE and S direction (5° gradient). It is in the 17 m elevation.

SOURCES OF DATA & METHODOLOGY

Primary Data: Primary data is collected from:

1. Field Survey: Primary data were collected from the observation method and consultation with village people.

The lack of published literature on Pingla Block especially about the water is one of the important handicaps. So to overcome this problem available literature were consulted and certain important point are noted and kept for the discussion with the people who are residing near the over head tanks and ponds during the field work. Several questions have been asked to the local people relevant to the over head tanks, to know detailed about the drinking water problem. Fields photographs have been taken and local people gave several informations related to over head tanks. Viable discussion with the local people was made to know various aspects about the over head tanks, especially about the utility of over head tanks and also the water problems.

2. Secondary data: Data were collected with the help of Topographical Sheet and published ground water prospects map prepared by NRSC (ISRO) Department of Space, Govt. of India.

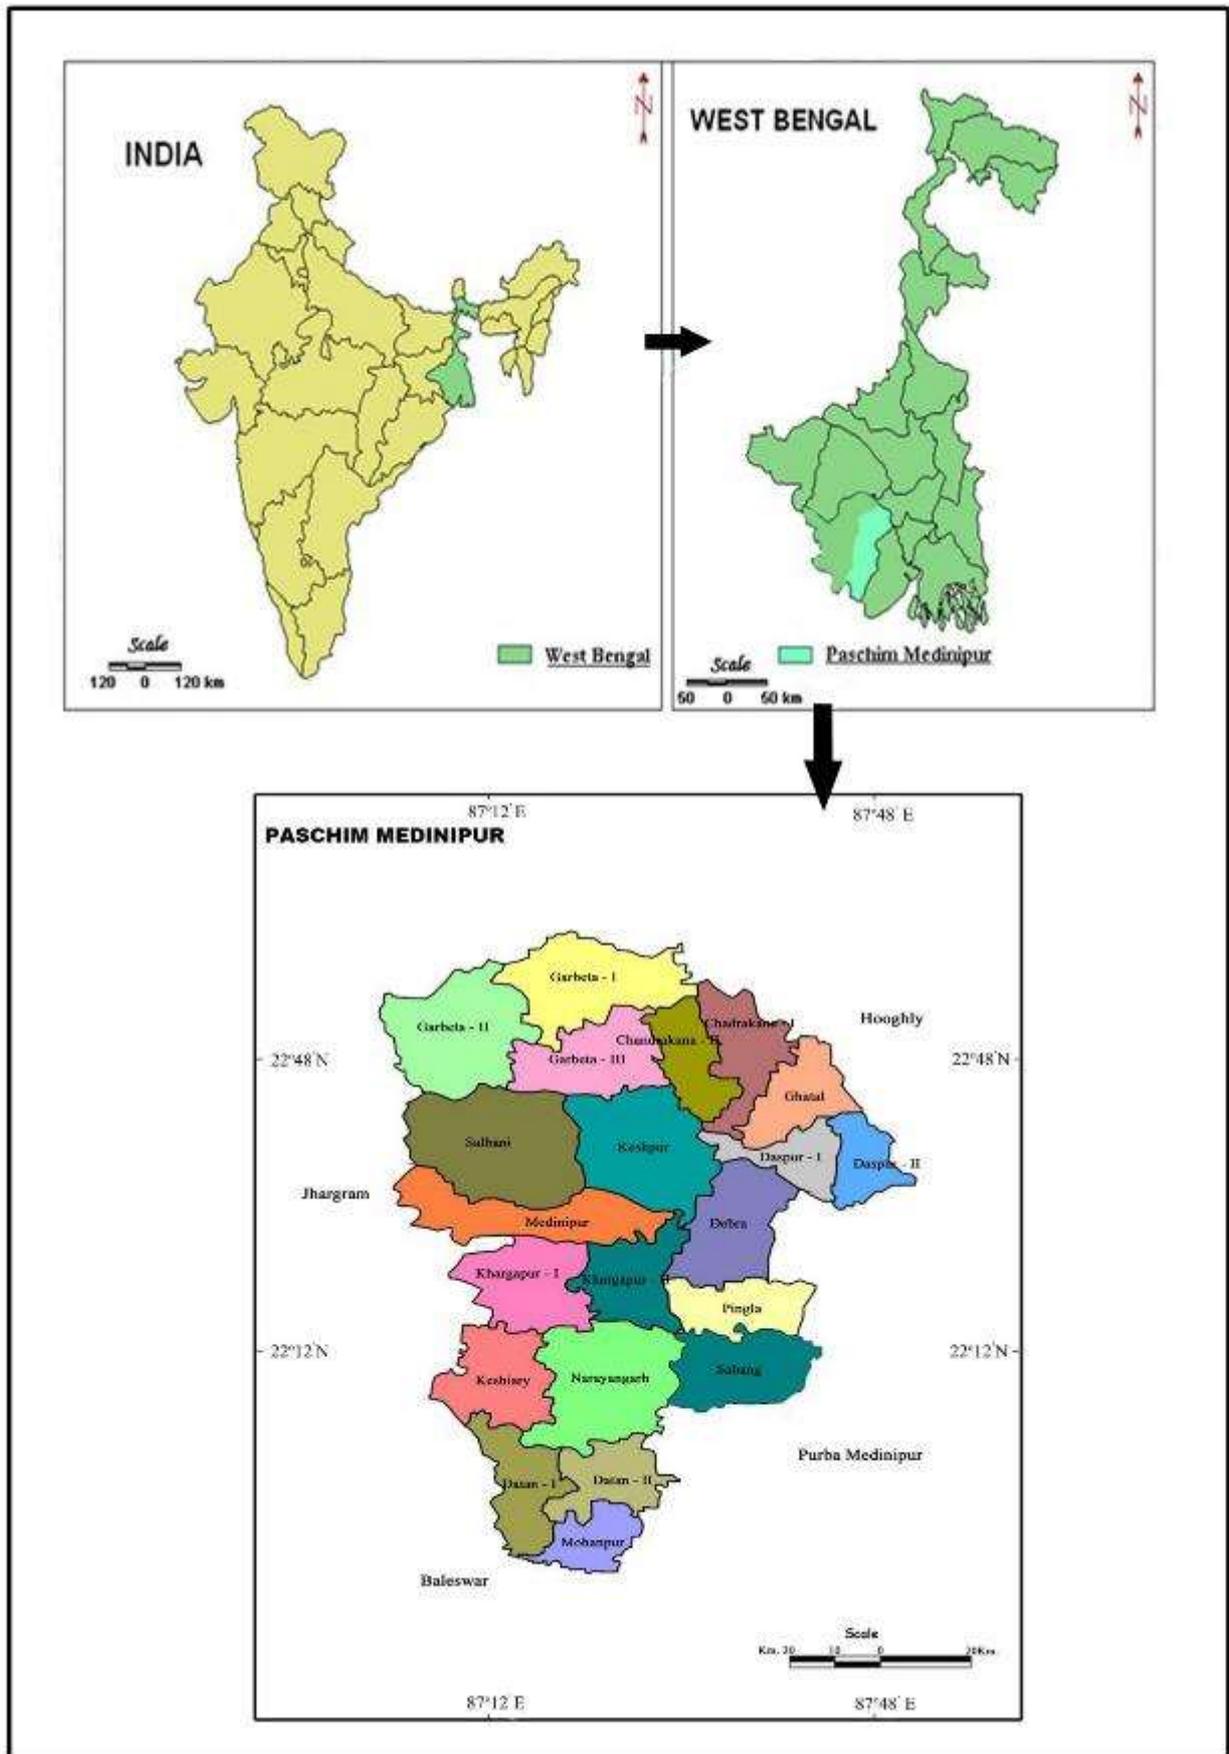

Fig.1. LOCATION MAP

CLIMATE

The Pingla Block falls under tropical climate, winter season occupy from November to February, from March to May period is included in summer season and rain occurs commonly in the period between June to October. This area experiences average maximum temperature about 34.76°C in June and the minimum temperature is 13.37°C in January. Average temperatures of January is 22 °C , February is 24 °C , March is 28 °C , April is 30 °C , May is 30 °C . The average rainfall annual is 1750 mm.

DEMOGRAPHY

According to the census 2011 total population of Pingla Block has 1,94,809, in which male is 99,988 and female is 94,821. Scheduled Castes population includes 16,428 in which male is 8,338 and female is 8,090. Scheduled Tribes population is 19332. In which male is 9,788 and female is 9,544. Total worker is 99,286, in which male is 62,452 and female is 36834. For agriculture related work more than 40,000 people are engaged in which some workers work for 3 to 4 months.

OCCUPATION

Drinking water is mostly obtained from the stored groundwater which accounts for about 40% of our total water with demands. The people of Pingla Block are mainly engaged in agriculture. The other works which they do includes fishery, diary, poultry etc. Surfaces as well as groundwater are mostly used for agriculture. But the agriculture mostly rice (Amon, Boro and Ause) is almost totally depends on the groundwater. Rice is produced three time in a year.

An ancient art still alive in the village as Naya (Patachatra) . In this very earlier stage about 60 years back, people prepare these colorful paintings on paper supported old cloths. These they show slowly and explain the story with dialogue or song. The story may from our religious matter or may be for entertainment. They were very poor and were doing this for their food and other requirements. Lots of struggles had been made for their survivals and also for this art. Now with the recognition in the international market it is gradually flourishing.

PRESENT DOMESTICS WATER TAX STRUCTURE

There is no water tax till the day.

PIPED WATER SUPPLY SCHEME (PWSS)

Public Health Engineering Department (PHED) has lodged 11 schemes, which covers the 8 panchayat. Normally these tanks are filled twice in a day. Water of 1st layer is not suitable for drinking purpose because of pollution due to anthropogenic and agricultural activities. After 2011 Public Health Engineering Department introduces several overhead water cemented tanks for supply of hygienic drinking water. There are 11 over head cemented tanks, in which commissioned is 7 (PWSS) and ongoing is 4 (PWSS). 1,15,600 people of 93 villages under eight panchyat of Pingla Block, namely 1. Kusumda, 2. Dhaneswarpur, 3. Jamna, 4. Kshirai, 5. Gobardhanpur, 6. Maligram , 7. Karkai and 8. Jalcjak are getting supply water till the day. Maximum local people do not use the supply water because they have their own tube well and hand pump. They commonly face Jaundice, Diarrhea disease. People are not aware of the quality of the water of 1st layer which they are using till today.

OBSERVATION

The Pingla Block is dominated by agriculture hence people commonly have cows and buffaloes. A good quantity of milk is produced. Its some quantity is locally consumed and 'chhana' is prepared from the rest. This area cater the needs of 'chhana' is used for sweets and other delicious foods.

Water is not an acquit problem in Pingla Block because good quantity water is available. Along with the surface water maximum people have their own borings. General depth of boring(1st layer) is 70 feet . Overhead tanks present in the area regularly supplying the water to the people but people are not using the water strictly for drinking and cooking purposes but it is used very carelessly for other works for which this water is not needed at all. Supply pipe is not maintained properly ,which gives many a time polluted water because of inflow of polluted water from the joints and cracks present in the supply pipe. Water supply project mainly implemented for drinking purpose but some people make the water in nonsensical way for example cleaning, bathing of cow, gardening and vegetables etc.. Some thickheaded and illiterate person do not stop tap after collection of water. At many places it is also noticed that to fill their bucket quickly they break the tap , so water goes waste.

In 2018 Govt. of West Bengal introduces a rain water harvesting project in Pingla Block, which is situated at Pingla Thana Mahavidyalaya, Maligram , Pingla, Paschim Medinipur. This rain water harvesting project will be fruitful for water recharging in surrounding area in near future.

SUGGESTIONS

- i) Supply pipes should be checked regularly to repair the damages well in time.
- ii) Awareness about the significance of water and its conservation may help to solve some extent to save the water from pollution and wastage.
- iii) Implementing water tax may help to save the water and this will also increase the fund of the project. The collected money may be utilized for the improvement of the water supply system

- iv) They use any amount of supply water without any restriction. Loss of supply water due to evaporation, flow and percolation. This water loss can be controlled by lodging water tax in logistic way may be installation of meter as it is present in many other places.

1792 ECONOMIC CHARACTER OF DATA GAPS IN THE ILLNESS STUDIES OF DEMENTIA

ABSTRACT

Data Gaps arise due to lack of awareness of society and state to realize the implications of immensities of fast progressing mental health problems due to multiplicity of causes. This paper looks at dementia related issues in a fast changing world. Dementia is a chronic or persistent disorder of mental processes caused by disease or injury. Conventionally, it was thought of as a medical condition especially affecting elderly people, causing cognitive impairments, destroying socio economic stability of households. However, research showed multi dimensional causes impacting it. This paper looks into the data gaps that impact economic planning for its mitigation. Presently dementia healthcare services require a rebalancing act with more emphasis on community health care. This would increase ability /capacity, limit the increased costs associated with scaling up coverage of care and coupled with the introduction of care pathways improve the coordination and integration between agencies and professionals at both macro- and micro-levels. Cost for dementia treatment is difficult to account for, in terms of opportunity cost foregone or Cost-of-illness (COI). The principal aim is to measure the economic burden of illness to society. This study mainly aims at analyzing the data gaps in the cost of illness analysis of Dementia. For this purpose, correlation between the cost of healthcare and the per capita GDP of a country is analyzed as to provide a first level methodological way to show how data collection exercises can be attended to.

1795 PROSPECTIVE IMPACT OF LAND COVER CHANGE ON THE PROVISION OF THREE ECOSYSTEM SERVICES IN OURIKA WATERSHED, HIGH-ATLAS MOUNTAINS OF MOROCCO

ABSTRACT

Ecosystems preservation is important for a consistent provision of ecosystem services. In Ourika watershed, High- Atlas Mountains of Morocco, human pressures through fuelwood harvesting and overgrazing has led to a decline of vegetation and by consequence to high rate of erosion and water flows, generating frequent and intense floods. Ecosystem services, mainly carbon storage, sediment retention and water yield are negatively impacted. The quantification of these services and their potential evolution can help decision makers to plan for future development of the watershed. This study deals with the evaluation of these services at the current state of land cover, and how they can evolve in the future with respect to four land cover scenarios. InVEST (Integrated Valuation of Ecosystem Services and Trade Offs), a decision support system, was used to perform this evaluation. The current land use map for the Ourika basin was used to assess these services for the present and for four land use scenarios, based on degrees of forest cover restoration, were used to model future ecosystem service provision. The scenario generator tool, which is a part of the InVEST, helped to develop maps of future land-use. Four spatially explicit land-use scenarios were generated for the year 2030: a business as usual scenario, catastrophic scenario, an ideal scenario and a concerted scenario. The results show that the watershed suffers presently from a great soil loss and sediment exports, while the capacity of sediment retention is low. The vegetation cover was able to retain more sediment while the non-vegetated areas showed more soil loss and sediment export. Carbon storage is lower in the watershed and less important compared to the contribution of other ecosystem services. In general, the water yield is higher in the watershed since evapotranspiration is low at the forest zones. For the future, the results show that the ideal scenario is able to retain the most sediment and produce the lowest water yield. In summary, the study shows that ecosystem services are highly affected by the land cover change. This study will be useful for policy-makers and stakeholders for better planning and management of ecosystem services in order to ensure the best welfare of the population.

RS03.7. Environmental Issues

1339 SPATIAL ANALYSIS OF SUSTAINABILITY OF EAST KOLKATA WETLAND**Biraj Kanti Mondal**Assistant Professor of Geography, Netaji Subhas Open University, Kolkata, West Bengal. E-mail: birajmondal.kolkata@gmail.com**ABSTRACT**

Wetland is one of the most productive ecosystems of the earth and it has immense importance to maintain the biodiversity and ecological balance of the biosphere. The wetland covered area of the globe is dropped by almost 6% in last two decades. The fact is that wetlands have not been given due importance that they deserve and they are being degraded due to lack of appreciation of their role. The East Kolkata Wetlands which is extended up to the Bidyadhari and Matla River confluence, effected frequently by the human encroachment along with the dynamics of Hugli, Bidyadhari and Matla River. East Kolkata Wetlands (Ramsar Site) act as an absorber basin for huge amount of contaminants drained from the Kolkata Metropolitan City. The degradation and transformation of wetlands is a slow poisoning risk made us think about its past history and hopes and doubts about its future. Reclamation of land for agriculture, aquaculture and urban expansion occur which threatened different sites of this wetlands since last 20 years. Likewise, huge population pressure, rapid growth and their increasing economic demands, the wetlands area has been victimised by different ways as an aftermath. Therefore, an in depth study was attempted for the spatial analysis of the sustainability of the East Kolkata Wetland and ten selected blocks of North and South 24 Parganas districts of West Bengal. Geoinformatics is the key solicitation technique to recognize the spatial pattern of change detection of the East Kolkata Wetland.

Key words: Wetland, spatial pattern, change detection, geoinformatics

INTRODUCTION

Environmental degradation associated with development and population explosion is a cause of concern in the present day context. Environmentalists, scientists, economists are very much concerned about the environmental consciousness of wetland that has emerged in the context of development debate. Wetland ecosystem provides goods and services to the society and play vital responsibility in maintaining environmental sustainability. Wetlands, which have multiple utilities is essential to maintain the biodiversity and ecological balance of the biosphere. This unique part of environment is considered as one of the most productive ecosystem of the earth, from environmental as well as socio-economic point of view. But the paradox is that wetlands are being degraded due to lack of appreciation of their deserving role. There are a large area of wetland expands towards the eastern fringe of Kolkata and extended up to the Bidyadhari and Matla River confluence covering part of North and South 24 Parganas. The sustainability of the wetland areas is being pretentious adversely not only by the dynamics of Hugli, Bidyadhari and Matla River but also by the human infringement. Most of the wetlands area (swamps, marshes, lake) of the globe has dropped by nearly 6% in last 20 years. The East Kolkata Wetlands, recognized as a Ramsar Site, is one of the most significant parts of West Bengal. This wetlands act as an absorber basin for gigantic amount of contaminants drained from the Kolkata Metropolitan City. Therefore, an in depth study was endeavour to swot up the spatial analysis of transformation and deprivation of the East Kolkata Wetland and the wetlands extended in ten selected blocks of North and South 24 Parganas.

Definition of Wetland

According to the Ramsar Convention definition (1971) of wetland is *"areas of marsh, fen, peat land or water whether natural or artificial, permanent or temporary, with water, i.e. static or flowing, fresh, brackish or salt including areas of marine water, the depth of which at low tide does not exceed six meters"*. Later in addition to that Ramsar site committee add *"may incorporate riparian and coastal zones adjacent to the wetlands, and islands or bodies of marine water deeper than six meters at low tide lying within wetlands"*. Ramsar is the first modern global inter-governmental treaties on the conservation and sustainable use of natural resources. This convention on wetlands (Ramsar, Iran, 1971) has come to widely known as the "Ramsar Convention".

STUDY AREA

The present study is concentrate on East Kolkata Wetland along with the wetlands of surrounding 10 selected blocks of North and South 24 Parganas. Haroa, Minakhan, Deganga, Barasat-II and Rajarhat blocks of North 24 Parganas were included in the northern part whereas in the southern part Canning-I & II, Bhangar-I & II, Sonarpur blocks were taken into consideration. The present study area extended to 22°10' 00" North to 22°50' 00" North and 88°20'00" East to 88°50' 00" East latitude and longitudinally.

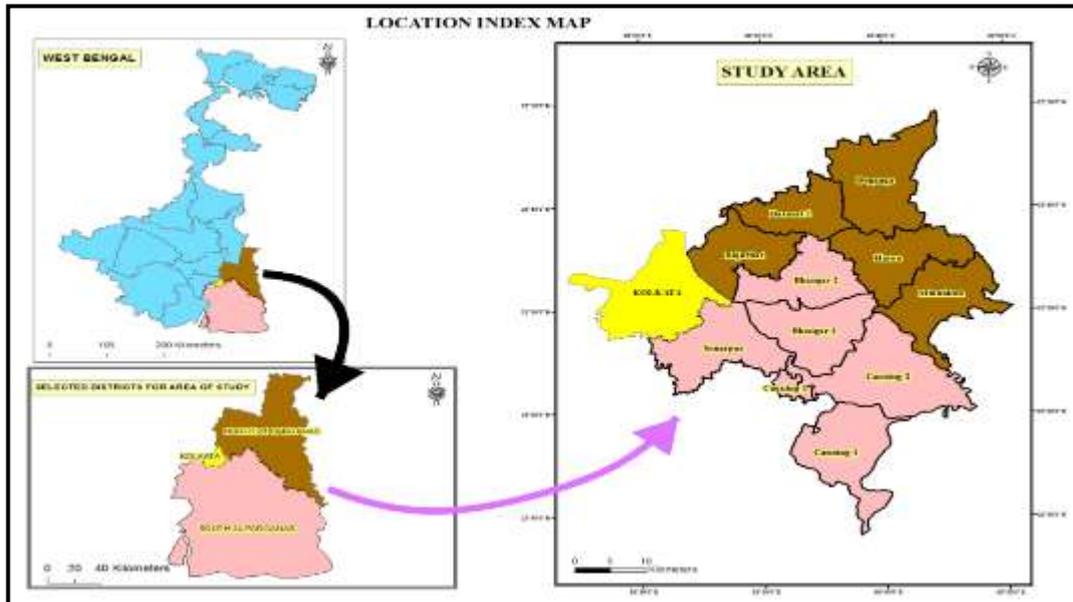

Fig. 1

OBJECTIVES

The prime objective of the present study is to analyse the degradation of wetlands of the study area. The specified objectives are:

- a. To depict the wetland transformation of the study area.
- b. To find out the change detection and degradation of wetlands of the study area.
- c. To evaluate the cause-effect relationship of various aspects of changing wetlands.
- d. To revise up the impact of population dynamics to alteration scenario of wetlands.

DATABASE AND METHODOLOGY

The present study was emphasized on the RS and GIS data from Toposheets and satellite images to find out the bona fide picture of the wetlands of East Kolkata wetland and its surroundings study area. The concrete primary survey was conducted to find out the grass root level scenario along with the consideration of recent satellite image (2012). The Remote Sensing and GIS techniques were applied for the preparation of maps along with the statistical analysis. The detail of the database is mentioned below:

- a. **Topo sheets (SOI):** 79^B/₆, 79^B/₇, 79^B/₁₀, 79^B/₁₁ (Surveyed in 1958-59 and 1959-60)
- b. **Satellite Images:** LANDSAT TM 10 Jan., 2001 and IRS P6 LISS IV data (No. 108-56, Date: 5 Feb., 2012)
- c. **Census Data:** Village level census data of 2001 and 2011 of the 10 blocks
- d. **Software Used:** Arc GIS, MS WORD, MS EXEL
- e. **Primary survey:** Questionnaire survey and photographs

SPATIAL ANALYSIS OF WETLAND

Scenario of 1960s: The scenario of 1960s was done by the on screen digitization from the four SOI topo sheets surveyed in the period of 1958 to 1960. The wetlands of the 10 blocks were marked out minutely. This includes wetlands of different sections, like:

- a) Natural Wetland, Inland (Include Swamp, Bil, Tank)
- b) Pisciculture, Aquaculture land (Include Fishery, Bheri)
- c) Lake

Scenario of 2001 and 2012: In the year 2001, the wetland area was misshapen as we found in the LANDSAT TM data/image of 2001. The wetland area was supplementary customized and rather changes drastically in 2012.

The phase-wise analysis of spatial changes in wetland is prepared to validate the transformation of wetland from 1960 to 2001 and 2001 to 2012 (fig.2). In 2012, most of the study blocks along with the EKW the wetlands are condensed and malformed to aquaculture whereas it is initiated to amplify in Haroa and Canning-2 block.

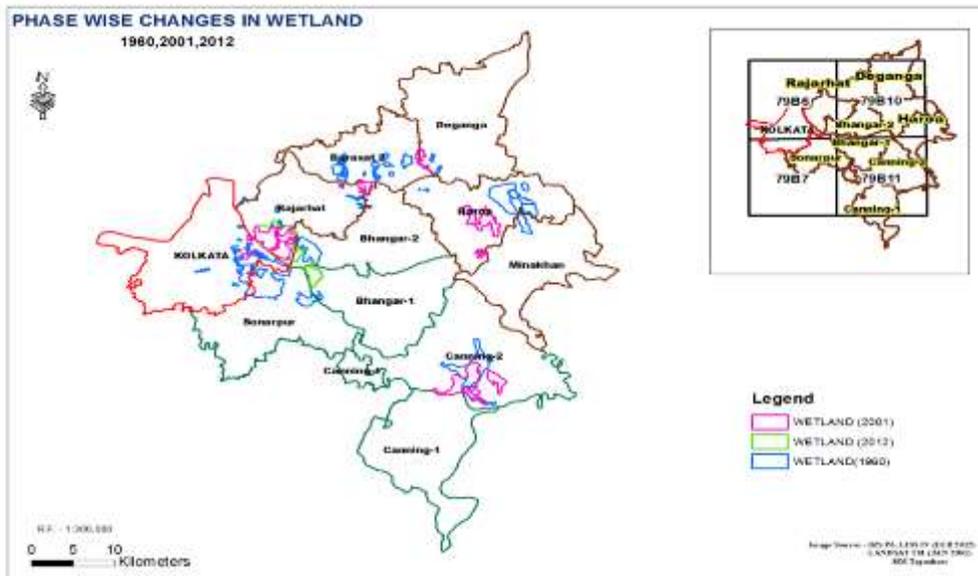

Fig.2. Source: Prepared by the author

The map of phase-wise changes in aquaculture/Pisciculture represents the alteration of wetland in the study area and it has been increased in Canning-2 from 1960 to 2012 (fig.3). It has also been distorted in Minakhan, Haroa, Barasat-2 with escalating value. But, in EKW, the area has been abridged periodically with larger proportion. In Haroa, Minakhan, Bhangar-2, Canning-2 block fishery covers the larger area in 2012. But, in 2001 the fishery was found in greater quantity in Barasat-2, Minakhan and Haroa block.

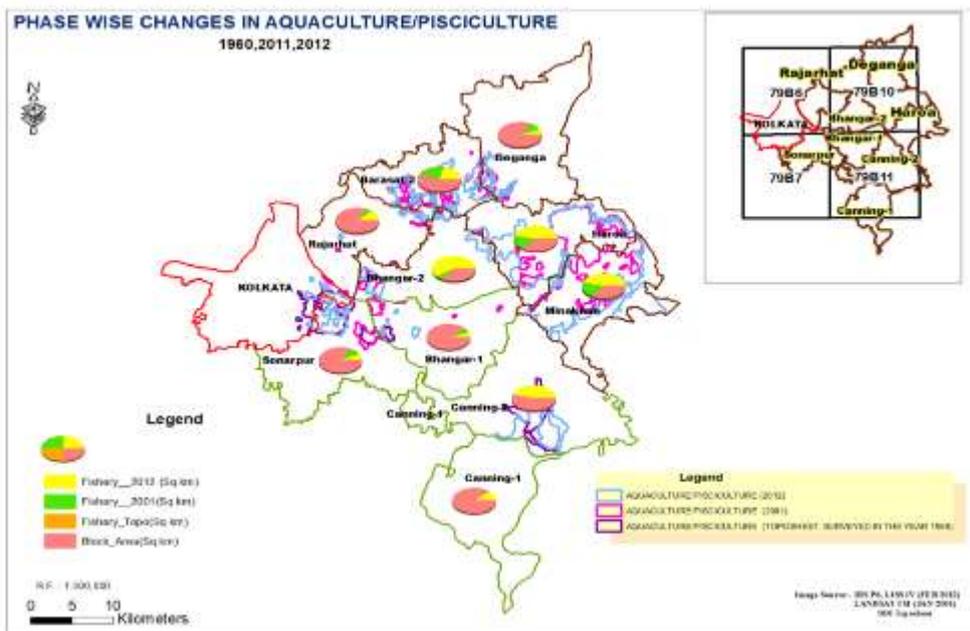

Fig.3

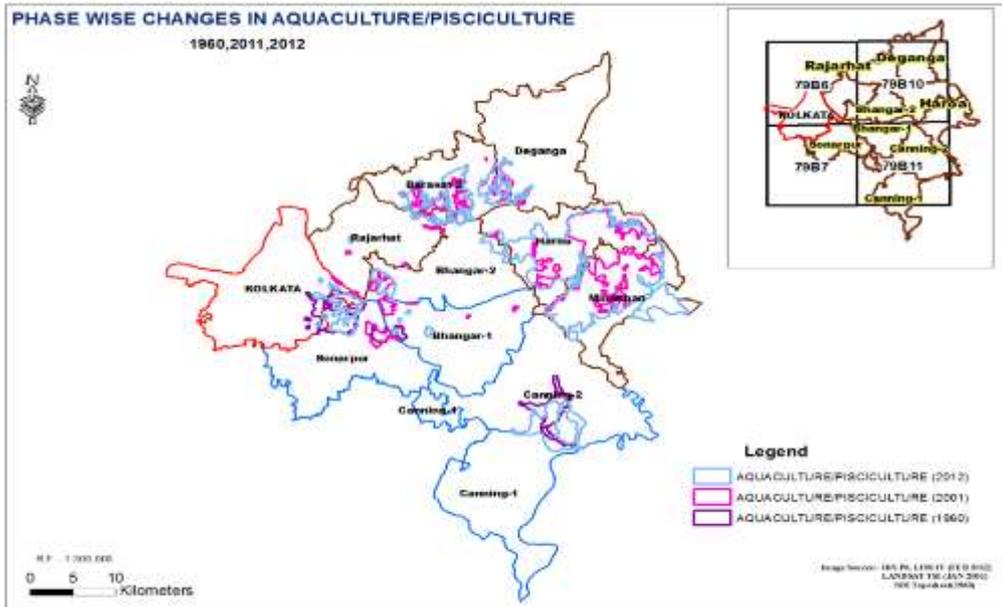

Fig.4

The map (fig.4) represents the phase wise changes in aquaculture/ Pisciculture. In 2012, Minakhan and Haroa block covers outsized quantity for aquaculture. In 2001, the area was found utmost in Minakhan, Haroa and Barasat-2 block.

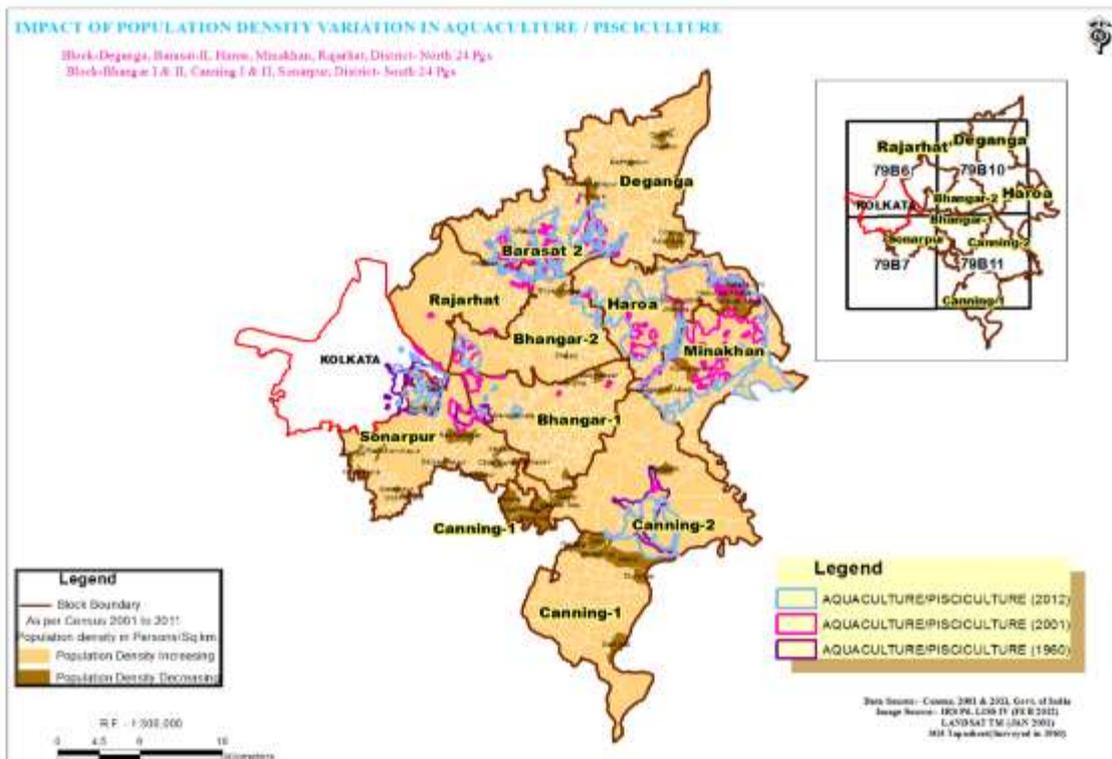

Fig.5

The map (fig.5) represents the changes of aquaculture or Pisciculture from 1960 to 2012 mostly due to increase of population density of the study area. The aquaculture or Pisciculture of the part of Kolkata, Canning-2, Minakhan, Haroa, Barasat -2 are mostly affected. In canning-2 the aquaculture area has increased drastically.

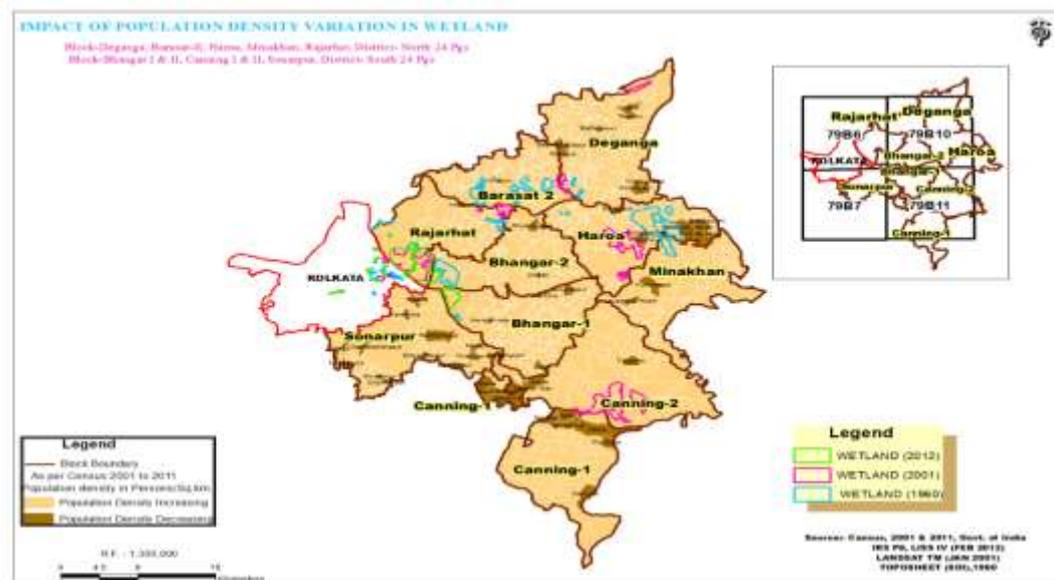

Fig.6

The map (fig.6) indicates the collision of population dynamics on the transformation of wetland in the study area. The wetland area is reduced in Haroa, Barasat-2 blocks, whereas, in is increase in Rajarhat, Canning-2 block from 1960 to 2012 due to the changes of population density dynamics over the area.

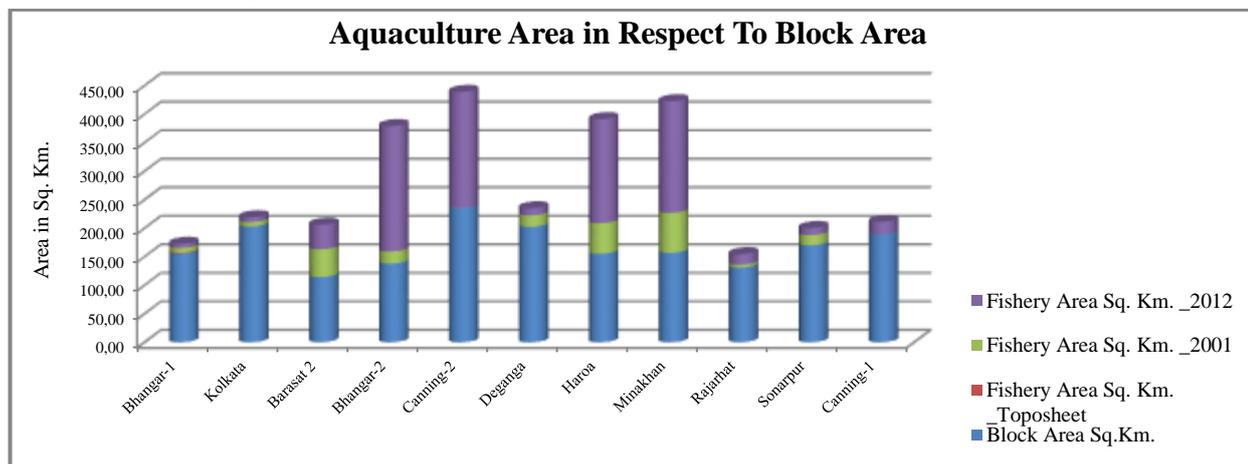

Fig.7

There is an appreciable increase in the aquaculture in Bhangar-2, Canning-2, Haroa and Minakhan blocks (fig.7). Other blocks have not experienced by such drastic changes in aquaculture area. The entire thematic maps and graph represent the cause-effect connection of wetlands and demographic character of the study area. The demographic attributes is somehow associated impolitely with the changes of wetlands openly or obliquely and sustainable stature of the area along with its socio-economic atmosphere.

EAST KOLKATA WETLANDS (EKW) AT A GLANCE

The EKW has become the ‘Kidney of Kolkata’ and its covers an area of 12,500 hectares. In August 2002, the EKW area was recognized as a ‘Wetland of International Importance’ by the Ramsar Convention for its uniqueness as a waste recycling region (WRR). This protected area, encompassing approximately 125 sq. km., includes sewage-fed fisheries, agricultural lands, horticulture, garbage dumping fields and some built-up areas (Kundu et al. 2008). However, only the wetlands encompass approximately 40 sq. km. (Information Sheet on Ramsar Wetlands 2002), of which about 45.93% area is manmade wetlands. This EKW provides goods and services to the society and therefore comprehensive and comparative assessment of the value of land vis-a-vis of this wetlands is utmost important to us. East Kolkata Wetland Management Authority (EKWMA) is entrusted with the statutory responsibility for conservation and maintenance of this wetlands area.

Area and Proportion of East Kolkata Wetland

The area and proportion of wetlands in the EKW area is tabulated below. Bhangar police station occupied the utmost proportion (36%) of EKW followed by the Sonarpur (35.50%).

Table 1: The area and its proportion under EKW under different police stations:

Police Station	Area (Hectares)	Percentage (%) Area
Bhangar	4548.58	36.00

Sonarpur	4416.83	35.50
Bidhannagar (S)	2100.00	17.00
Tiljala	1426.73	11.50
Total	12492.14	100.00

Source: Basu A. (2013)

The primary survey conducted in the area (in Rajpur Sonarpur Municipal Area, 2017) shows decreasing trends of wetland area. In most of the study area, the transformation and conversion of wetlands for the sake of development are strongly noticed. The fisheries, locally known as Bheris vary between 50 and 150 cm in depth and 0.4–0.5 sq km in size (Ray Chaudhuri et al. 2008), are mainly recharged with sewage water during 270–300 days of the year through the regulator gate at Bantala. The EKW includes around 254 sewage-fed fisheries and the conversion of some fish farms (bheries) are tabulated below:

Table 2: The conversion of some fish farms of EKW:

Name of the Bheries	Present Status
Bidyadhari Spill Cooperative Fisheries	Vidyasagar, Laboni B.S. market
Kakrimari	Atomic Research Centre
Boro	Baisakhi, Digantika
Daser	Mayukh Bhaban
Nortala Khas	Salt Lake
Kansar	Baisakhi housing
Bager	Jhilmil
Kajar	Industrial Estate
Hansar	Industrial Estate

Source: Basu A. (2013)

The EKW has been described as ‘one of the rare examples of environmental protection and development management where a complex ecological process has been adopted by the local farmers for mastering the resource recovery activities’ (Kundu *et al.* 2008) by the Ramsar Convention on Wetlands. However, in effect of land conversion and encroachment, the total area of the East Kolkata Wetlands has reduced significantly compared to the past. Moreover, unavailability of reliable wetland status data is also aggravating the problems of management of EKW.

Land use Pattern of EKW

The land use category of EKW was occupied by the water body, agricultural area, garbage farming area and settlements (Fig. 8) and it has changes very frequently over time. The pattern of land use along with the area in hectares is given below:

Table 3: The land use pattern of EKW

Land use	Nature	Area (Hectares)
Water body	Water body oriented area	5852.14
Agricultural area	Agricultural land	4718.56
Garbage farming area	Productive	602.78
Settlement	Urban/Rural	1326.52
Total		12500.00

Source: Kundu *et al.* (2008)

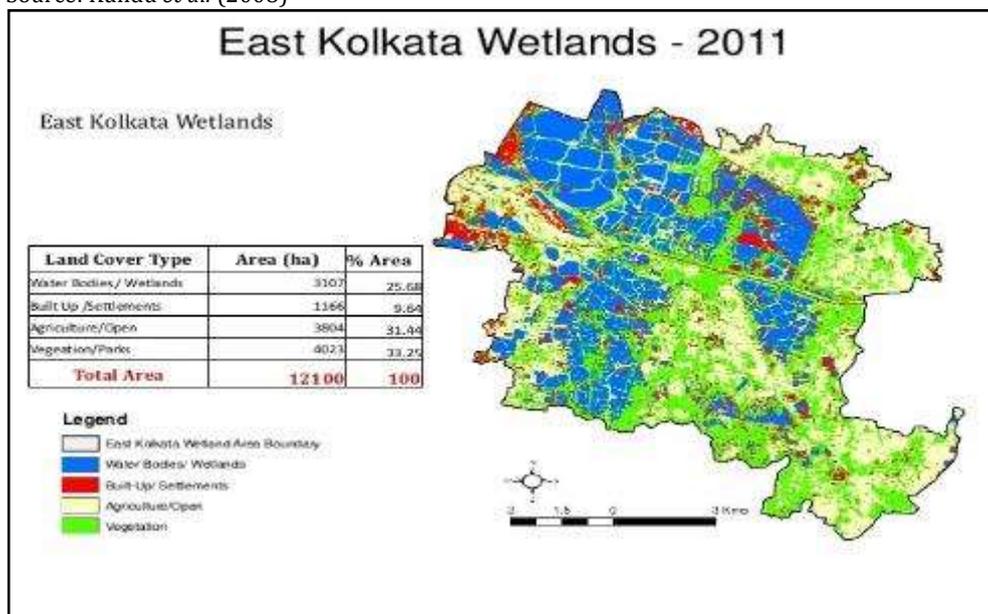

Fig. 8

Source: www.iwmi.org

The land use types of EKW are shown the graph (Fig.9) and it stated that the agricultural lands occupied the higher proportion (38%) after the water body which occupied almost 47% of the area. Rural and urban settlement holds about 10% and their encroachment in the wetland area threatened its protection and conservation. The primary survey in Sonarpur block in the Rajpur Sonarpur Municipal area reveals that due to huge population pressure (growth rate almost 30 % in 2011 census) the land use pattern is rapidly changed. Sky kissing buildings are taken place of wetlands and greenery in the region. Moreover, most of the respondents are stated (Fig. 10) that housing is the culprit for wetland conversion rather than industrial development, agricultural development or development of super markets in the area. Therefore, it reveals that non-agricultural cause also strong affect the wetland area for their conversion which hampers the environmental sustainability.

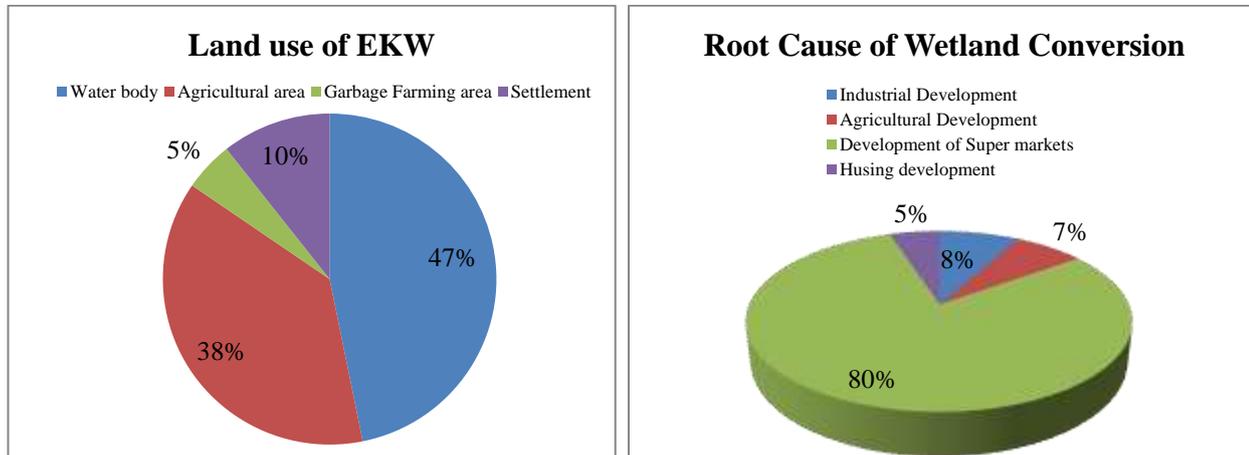

Fig. 9 Fig. 10

Root Cause recognized

The present study is also able to find out some of the root causes of such wetland transformation and conversion of wetlands which are listed below:

- a) Increasing population pressure.
- b) Direct human interventions by reclamation of land for agriculture and utilization of pesticides.
- c) Encroachment of urban settlement threatening the wetland area and its health.
- d) Transformation of wetlands into aquaculture.
- e) Increasing rate of siltation in the wetlands decreasing the volume of water.
- f) Uncertain wastewater supplies into the wetlands.
- g) Tendency of public agency to encroach upon the wetland area for development related activities, like locating commercial hubs, industries or public utilities.
- h) Pollution by the unregulated industries in the adjacent area by adding their untreated effluent into wetland.
- i) Poor quality sewage reduces quality of nutrients and induces a higher toxic load.
- j) Absence of the proper policy and regulatory mechanism.

MAJOR FINDINGS

- a) The study area contains huge wetlands in different form and most of them are associated with Hugli, Bidyadhari and Matla River. Huge swamp area was found in and around river. The sewerage water of the land area particularly the Kolkata Metropolitan area was passing through several canal to the river.
- b) Barasat-II, Haroa, Minakhan, Rajarhat, Canning-II, Bhangar-II blocks have the maximum wetlands.
- c) Some part of the wetland area was converted to aquaculture in recent times.
- d) Some wetland area was encroached by population, and somewhere it was completely vanished.
- e) Anthropogenic effects are the root cause for such transformation of wetlands.
- f) The increasing population density was found as a major cause of concern regarding the reduction of the wetlands.
- g) Some of the wetlands were replaced by the human settlements. Rapid growth of sky-kissing buildings in the study area is support the truth that difficulty was increasing to protect the wetlands from the developers and real estate agents.
- h) Most of the wetlands of the entire region were not conserving properly. Moreover, the various regulations for the conservation of wetlands are often flouted.

RECOMMENDATIONS

- ✓ The pollution of the aquatic environment should be control by bleaching and cleaning the wetlands with lime, potassium and organic material like cow dung.
- ✓ Need dredging work to remove siltation particularly in dry parts of the bils. Reduction of soil degradation particularly in the wetland areas is also necessary.
- ✓ Pension schemes for old fishermen, improve pisciculture and water quality management etc become essential to aware the locale so that they are willing to conserve the wetlands. Arrangement of adequate training for fish-farming in saline environment to protect the wetland area.
- ✓ Need development of eco-aquaculture to strengthen the wetland's environment.
- ✓ Human encroachment in the wetland area should be restricted.
- ✓ The East Kolkata Management Authority should be more active to protect its deformation and conserve the wetlands properly.

CONCLUSION

Wetlands play vital responsibility in maintaining environmental sustainability. The wetland of the study area is no exception. It acts as the soul of city to maintain the ecological balances as well as sustainability of its environment. Thus, wetland conservation is an important issue, which needs to be addressed through protection, catchment area development, siltation control and pollution control. Therefore, full implication of the values and losses of wetlands to be undertake in perspective of attempt for its conservation and development by government and non-government organisations. The critical analysis of the wetland issue with the help of geoinformatics have informed us about the recent threats and menaces of environment, caused particularly due to the anthropogenic activities and have also laid down the potentialities of 'Sustainability' as a concept in promulgating awareness about dealing with the such maledictions. The recent observations and findings have revealed a complex array of problems and issues facing by the wetlands community in the perspectives of sustainability. It is hope that the findings, analysis and recommendations made in these present study on wetland may also be helpful to the environmentalist, scientists as well as policymakers in order to frame policies and introspect into the different ways of protecting the environment through a more sustainable approach.

1497 THE ROLE OF URBAN MOMENTUM IN URBAN TRANSFORMATION OF NORTH 24 PARGANAS DISTRICT, WEST BENGAL, INDIA

ABSTRACT

Urban areas are dynamic in nature and they respond to every dynamic need of urban society. Urban area changes because life does change. Urban form does adapt the changes with various characteristics of changing socio economic structures of urban lives. Often this change creates transformations in urbanicity. Urban transformations are taking place at a rapid pace; it aims to social, economic and spatial quality of post modern societies. Some time transformation does occur with a momentum. Each and every urban centre has a dynamic momentum of its own. This paper aims to compute the momentum of urban centres of North 24 Parganas district of West Bengal in India. Three types of parameters i.e. socio-economic, commercial real estate and future proofing capacities like education, innovation and environment etc. were considered as main indicators to predict the momentum value of urban centres of this district. After going through in detail understanding about the present dynamic conditions on different types of urban centres in North 24 Parganas district, this paper includes only Municipal towns for analysis. It shows that emergence of huge numbers of sub-urban centres and outcome of tertiary sector’s economy mostly affect the momentum of urbanicity of this district.

INTRODUCTION

Due to the rapid growth of population and the non renewable resources decreases and disposal of effluent and toxic waste indiscriminately increase, these are the major environmental issues posing threats to the existence of human being (Allen et al; 1997). The most common problems associated with improper management of solid waste include disease transmission, fire hazards, odour nuisance, atmospheric and water pollution, aesthetic nuisance and economic losses (Jilani et al).

Waste management is a global environmental issue which constitutes a very significant problem in today's world. The environment is heading towards a potential risk due to unsustainable waste disposal. There has been a significant increase in solid waste generation in India over the years to nearly 500 grams per persons per day as a worldwide problem it is becoming more and more complex day to day (Singha et al., 2011).

According to World Health Organization (W.H.O) any unwanted, useless discarded material that is not a liquid or gas, that arising out of man's activity which is not free flowing is called solid waste.

As per the report of the Ministry of Urban development (MoUD) and Pollution Control Committees/State Pollution Control Board that in India 1,00,000 MT of Municipal solid waste was generated daily and 1,27,486 TPD (Tones per day) solid waste is produced during 2011-2012 in our country, but only 89,334 TDP (70%) of municipal solid waste is collected and 15,881 TPD (12.45%) is treated or processed (CPCB, 2012). The current population of India is 1.252 billion (2013) and it will continue to grow at the rate 3-3.5% per year and per capita waste generation increased 5%. Due to the growing amount of solid waste generation and cost effective management process the Government is under pressure to effectively and fruitfully handle the solid waste (Rathor et al., 2010). It can be said that in India management of municipal solid waste is going through a carping phase for poor collection, insufficient transportations, unavailability of suitable facilities to disposal and treat So the disposal of municipal solid waste is a one of the central parts of solid waste management.

LOCATION AND HISTORY OF THE STUDY AREA

The study area Krishnanagar is a municipality, and an administrative headquarter of Nadia district. The latitude of Krishnanagar is 23°04'N to 23°24'N and longitude is 88°05'E to 88°31'E. It has an average elevation of 14 meters (45 feet). Krishnanagar located at the left side Ofjalangi River, (locally known as "Khore" about 9 km above its junction with the "Bhagirathi". The town is well connected by road to different parts of the state and also a railway junction. Krishnanagar municipality was established on 1st November 1864 (Garrett, 1910). It is one of the oldest municipality in West Bengal as well as in India. The town had an area of 7 km², and its population was only 24547 in 1901. In 2001, the areal coverage of Krishnanagar increased to 15.96 km², and the population also grew rapidly to 139110. In 2011, there were 24 wards in the municipality, but the population increased to 153062, and the density became 9590 persons/km². Besides, the enormous population pressure of its own, thousands of people visit the district headquarters for various administrative, social, and economic reasons.

Fig 1: Location of the Study area

STATEMENT OF THE PROBLEM

Solid waste management is an essential part of urban society and it also a fundamental key to environmental sustainability and susceptibility. The common observed problems in this area are:

- The waste collection capacity is less in comparison with the amount of waste generation in the municipality.
- There is a shortage of manpower, machinery, and equipments and trained staff.
- There is only one facility for re-using or re-cycling process in this study area Krishnanagar.
- Lack of private sector participation or involving of community based organization.

- Insufficient fund allocation for processing and dumping is a challenging problem in this area.
- There is no segregation of solid waste such as plastic, kitchen waste, metal, others etc.
- Lack of public awareness about the need of solid waste segregation.
- Lack of proper dumping facilities in this area. A dumping site is located near the river Jalangi which degrade the river water quality. Once a river Anjana flow through the municipality has become a shallow Khal due to solid waste dumping by the stack holder of the municipality.

OBJECTIVES

- To find out the nature and typology of the solid waste in this municipality.
- To find any relation between population and household in respect of inter ward disparity of generation solid waste.
- To find about the awareness of the people in respect of solid waste and evaluate the ward wise aesthetic environment and criticality by the perceptual study in this study area.

METHODOLOGY

A perception based questionnaire was formed to collect data about ward wise solid waste generation, collection process, awareness and used to collect information from the household of Krishnanagar Municipality. The data thus obtained were compiled and processed to assess the capability of data for strategic planning of solid waste management.

A. Data Entry

The spatial data and attribute data are entered into a database to create maps and analysis by Arc map 10.3.1 software. This includes photos, ward boundaries, quantity of waste, waste generation etc.

Thematic Mapping

Thematic maps show the distribution pattern of a particular theme objective. Thematic mapping involves data classification methods, which is known as the most common method for manipulation of data. Perceptions of people have been systematically analysed and give weight to them. Mean and standard deviation set the class breaks in the units of standard deviation above and below the mean. The method of natural breaks uses a computing algorithm to minimize the difference between data values in the same class and to maximize the difference between classes. For the present study, natural break classification techniques were used to classify the waste generation for thematic mapping.

RESULTS AND DISCUSSION: QUALITATIVE AND QUANTITATIVE ANALYSIS OF SOLID WASTE:

There are many categories of MSW in Krishnanagar such as food waste, rubbish, commercial waste, institutional waste, street sweeping waste, industrial waste, construction and demolition waste, and sanitation waste. MSW contains recyclables (paper, plastic, glass, metals, etc.), toxic substances (paints, pesticides, used batteries, medicines), compostable organic matter (fruit and vegetable peels, food waste) and solid waste (blood stained cotton, sanitary napkins, disposable syringes) (Jha et al., 2003; Reddy and Galab, 1998; Khan, 1994). The quantity of MSW generated depends on a number of factors such as food habits, standard of living, degree of commercial activities and seasonal variability. Data on quantity variation and generation are useful in planning for collection and disposal systems. The amount of MSW generated per capita is estimated 300 to 500 gm daily. The amount of MSW generated per capita is estimated to increase at a rate of 1–1.33% annually (Pappu et al., 2007; Shekdar, 1999; Bhide and Shekdar, 1998).

Types of solid wastes	Description	Sources
Food waste (garbage)	Wastes from the preparation, cooling and serving of food, market reuse, waste from the handling, storage and sale of meat and vegetables.	Household, institutions and commercials such as stores, hotels, restaurants, markets etc.
Bulky wastes	Large auto parts, tyres, stoves, refrigerators, other large appliances, furniture, tree branches etc.	Hotel, auto mobile centres,
Construction and demolition wastes	Lumber, roofing and shedding scrapes, crop residues, broken concrete, pipe, wire, insulation, paper, cardboard, cartons, wooden boxes, plastics, rags, cloth, bedding. Leather, rubber, grass, Metals, Tin can, metal foils, stones, bricks, ceramics, crockery, glass bottles etc.	Construction and demolition sites, repairing sites, shopkeeper, market, automobile repairing centres etc.
Dead animals	Small animals: cats, dogs, poultry, etc. Large animals: cow, buffalo	
Street waste	Street sweepings, dirt, leaves, animal droppings. Contents of litter receptacles, dead animals.	Streets, alleys, vacant lots, etc.
Industrial waste and sludge	Solid waste resulting from industrial processes and manufacturing operations such as food processing wastes, boiler house cinders, wood, plastic and metal	Factories, brick fields, automotive service centres.

	scraps and shaving, etc. Effluent treatment plant sludge of industries and sewage treatment plant sludge, septic tank.	
Hazardous wastes	Pathological wastes, toxic wastes, hospital wastes	Household, hospitals, institutions, industrial stores.

Table 1. Types of solid wastes present in krishnanagar municipality

Ward wise study of Krishnanagar municipality shows that there are very peculiar situation about the nature of solid waste generation. Door to door study shows that a very decent amount of solid waste is produced by the household every day in this municipality. The range varies from 300 gms to 600gms/capita every day. Table 1 shows us different kind of solid waste producing nature in this municipality. Most of the solid wastes are domestically based. As some important transport routes meeting point is Krishnanagar, automobile sludge and any automotive waste also generated on a regular basis. With the normalized value of ward wise solid waste generation data (weekly basis) the wards were divided the whole municipality into 5 groups, fig. 2 and from the table 2 it is observed that the total waste generation ratio is higher in ward no 24, 5, 6 and 8 whereas 1,3,4,10,18 no wards are falling in the second higher order group. In the rest of the wards solid waste generation record is comparatively lower than these words. Mainly the market area location, different district level administrative offices like district collectorate, district magistrate office, municipal, and post office is the main cause for huge number of population influx in those wards. The Ward wise nature of variability about the generation of solid waste weekly basis is known from table 2. Ward wise census data (2011) show us that the density of population is high in ward 1 and 6 whereas household density is high in ward no 1 and 6 and 19 but the nature of solid waste generation normalized value shows that these wards fall under moderate nature in respect of solid waste generation. It shows no relation between the population density or household density and the waste generated in these wards. Coefficient of determination ($R^2 = -2.46$) between population density and waste generation and household density and waste generation ($R^2 = -2.55$) implies that there is no significant relation between the variables.

Table 2: Ward wise waste generation

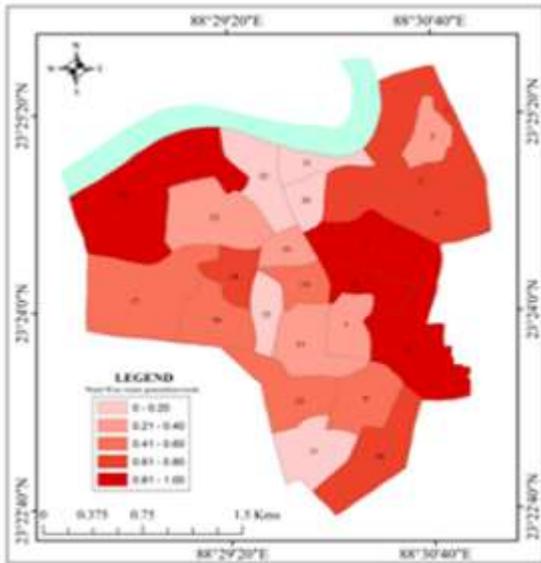

Fig 2: Ward wise waste generation

Fig 4: Landuse map

Ward wise survey conducted to locate the exact location of the bins in the municipal area. There are two kinds of bins, mobile bins and walled public bin. 25 Mobile bins which were given by “MISSION NIRMAL BANGLA” to the municipality in 2014. The Ward wise survey finds that there are only 11 bins are in a working condition. The rest of the bins are not in proper condition. These bins are mainly seen in the govt.hospital area, and in busy road side or in market area only. Walled public bins or vat were constructed by the municipality in some of the wards road side places. These bins are open in nature and causes the filthy smell to the surrounding neighbours.

Public perception about the bin is most unpleasant. Different perception about bins has been identified, including solid waste management processes in the municipality. It is quantified by giving score on the nature of the cleanliness of the bins.

Fig.3 shows that there are a very few number of public bins and vat in each ward. As a result of this, the public is generally prone to through their waste materials into the roadside. Nevertheless bins could not be emptied in a proper way regular on basis also. Survey shows bins or vat overflowed by waste materials as the municipality does not clean the bins in regular basis.

Municipal day by day waste collection process is not adequate here. Perception study shows in only few of the wards like 13,12,6 and 19 have the municipal door to door collection (though it is limited in few wards only) process by special types of tri-cycle van. As a result all the households they either dumped their solid waste in their respective home area or throw the materials into the vat. As the vats are few, most of the cases they even throw the materials on the open road, or elsewhere without knowing the environmental polluting fact. This causes a serious problem to the environment. The aesthetic view is totally absent in this municipality.As a result of very few of the waste vat or dumped station in the municipality causes a habit of the people, they dumped the waste particles everywhere, beside the road, at the pond side, Khal or canal side and riverside. As a result of this the water quality in pond, Khal is significantly affected. Khal side garbage dumping prevalent here as a result Anjana river became a degraded canal which flowed through ward no

24,17,16, 15, 13,12 and 11. Shaktinagar hospital located in ward no 11 besides of Anjana Khal. Pathological materials are thrown into the Khal very often by the hospital authority. The roadside, the canal side slum area also generates huge amount of solid waste which directly causes environmental pollution. In bejikhali area slums in ward no 15, the open defecation prevalent in and around Anjana Khal. This scenario is also prevalent other than slum besides of road or besides of the pond. Land use map helps us to show the actual frame of the location of the slum and the most prevalent waste generating area in the municipality. People used to dump solid waste in and around in the roadside area most of the time. People's perception about bin shows us a significant nature of the cleanliness and, other than the aesthetic view of the wards. From the perception study of the household it is clearly visible that the public bins don't get clear every day by the municipality. Some of the vats are clear only in a month. Generally marginal wards are getting a very low amount of services in respect of clearing vats. At the survey time it is often seen that most of the waste bins are filled and overflowed by the wastes, a typical bad odour coming out which most of the household raised voice over it. Generally waste pulling tractors are engaged in this work. Only 3 tractors are in working condition and there are only 35 labourers who are working by getting only 110 rupees per day basis in managing this huge solid waste. It is also a cause which reflects that waste bins are not clean daily by few amount of labour.

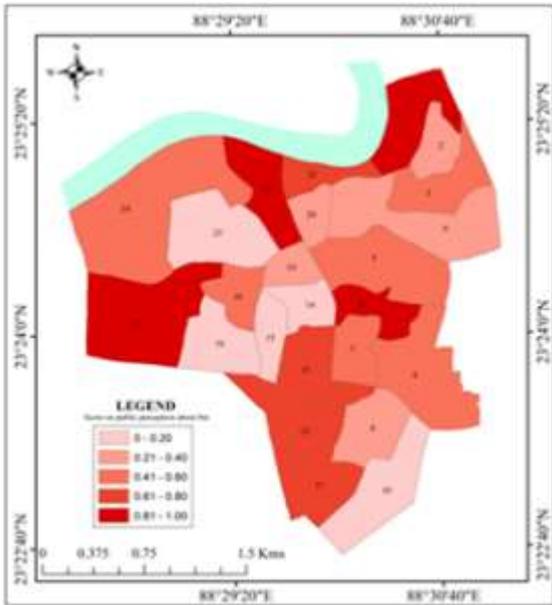

Fig 5: Perception about bin of the Household

In respect of waste generation, perception study (Table-3) generates a significant view about the nature of the wards which reflects the awareness level of the population in the municipality. In a few of the wards municipality waste bucket has been given to the household, but it has been observed that the waste bucket is used for water storage bucket. All the waste material deposited along the roadside where any kinds of waste bin exist.

It reflects the low awareness of the people in those wards

Different types of perception based weekly basis score card generated by different awareness oriented factors. Fig 6 shows that the near central business district wards like 20, 4, and 6 no wards people's awareness level is pretty low. Literacy level is also a significant factor for reducing the awareness level in those wards.

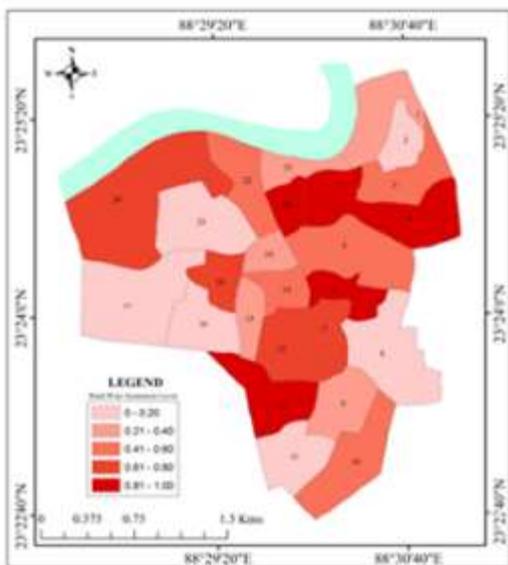

Fig-6 Ward wise awareness level

- Study the statistics of the quantity of waste generated in different areas of planning, waste management in a more precise manner.
- Analysis of further requirement of recyclable waste bins for any specific land use or any area.
- Study of improvement in the system due to proposed waste segregation and analysis to see if there is any requirement of segregation of waste into further more categories and how adoptable can it be.
- The study of revenue generation by the composting the organic waste and selling the recyclable waste would give the statistics about the economic response to the proposal of segregation of municipal waste. Further improvements can be suggested in the planning policies.
- Utilizing the manpower of rag pickers by providing them with work responsibilities in the waste management system and giving a secured livelihood and a social status in the society.
- Route planning for waste collection vehicles can be done and implementations of vehicle tracking systems like GPS on the vehicles calculate waste collection timings.

The main aim is to provide good SWM facilities to the citizens which could maintain a healthy clean and sustainable environment.

1739 URBAN ECOLOGICAL CRISIS IN A HIMALAYAN TOWN: A CASE STUDY OF MIRIK, WEST BENGAL, INDIA

ABSTRACT

At the beginning of the 20th Century, less than 15% of the world’s human population lived in urban areas. Today, more than half do. Between 1980-2010, the world’s population increased by 2.4 billion and half of that growth took place in cities (UN, 2009). By 2030, demographers expect global population to increase by another 2 billion with nearly all of that population increase in urban areas of developing countries due to urban migration and high birth rates. In this perspective, the future for our next generations will be predominantly urban and this provides immense challenges in the planning, management and sustainability of urban areas (UN-Habitat, 2003). Urbanisation has affected all geographical regions with variable impacts – but it challenges sustainability in ecologically sensitive locales – this paper is an attempt to assess the ecological crisis in a small town located in the Darjiling Himalayas in West Bengal, India. Early ecologists simply defined ecology as the study of organism and their environment. But urban ecology has evolved as a unique field of study through the integration of several disciplines that investigate the ecological and human dimensions of urban ecosystems. Urban ecology is a constantly evolving discipline that can help us to identify and face the challenges that an increasing urbanization will impose on essential ecological systems, locally and globally. The latest advances in urban ecology conceive cities in comprehensive and systematic ways where socio-economic and biophysical dynamics merge in an evolutionary process. The concept of creating sustainable cities has become a major focus of urban ecology research. With this understanding, ecologically sensitive. The selection of the Mirik town in Darjeeling district has been made with a specific objective in mind. The Himalayan and Sub-Himalayan region constitutes a rich ecological heritage of the country. The urban regions of the ecological zone have evolved historically for tourism demands of the population. The exquisite beauty and rich biodiversity attracts a large number of domestic and international tourists and the pressures of this tourist flow falls directly upon the small towns which host them. Development of transport and communication networks, rapid growth of hotels and other tourist attractions have created pressures upon the ecological capacities of these towns. The changes in the ecological parameters of these towns have never been studied in a holistic manner. This study is primarily aimed at the analysis of two major aspects, the status of ecological degradation and the rate of urban ecological degradation between core and periphery areas of the town and examines its spatial, social, economic and environmental impact by analysis of primary and secondary data as well as Geographical Information System (GIS) and Remote Sensing (RS) techniques.

RS04.1. Infrastructure, Transportation and Accessibility

1237 SPATIAL EQUITY OF ROAD INFRASTRUCTURES. AN ANALYSIS OF THE PORTUGUESE ROAD CONSTRUCTION PROGRAM BETWEEN 1991 AND 2011

ABSTRACT

Road infrastructure investments are believed to improve regional competitiveness given the enhancement of accessibility they offer and increase social welfare and regional cohesion. Investments in road infrastructure have been promoted as means to increase spatial equity. The notion that equity over space should be taken into account in the planning and policy-making process has been strengthened as it has been found to govern the distribution of a number of these broader effects. The methodological framework for evaluating equity in transportation policy has been shaped by several indicators ranging from more complex indicators like the Gini coefficient to simpler approaches that include variance, mean absolute deviation, etc. This approach for measuring spatial equity of accessibility is insufficient due to two main reasons. First, it doesn't take into account the limitations imposed by geography and the actual foundations of network development. The evolution of road networks is mainly based on the extension or growth of the existing network. A geographically central location would always be more accessible than a peripheral location. The omission of geographical limitations leads to misinterpretations, as it does not realistically represent highway allocation capabilities. It would never be possible for a peripheral location to have the same accessibility as a central one. This difference cannot be directly linked to inequity in the allocation of transportation infrastructure. This paradox results in an unrealistic definition of spatial equity as it does not express geographical differences. A second source of misconception is related with the fact that equity impacts are mainly estimated assuming a static environment. The dynamic effects of accessibility on population growth will not be incorporated, resulting in biased conclusions about the equity appraisal. The focus of this paper is to define a framework to address these shortcomings concerning the effect of accessibility indicators in the equity evaluation procedure. To achieve these objectives a set of accessibility indicators including economic potential, weighted average distance, and cumulative opportunities are built. We use data from Portugal for 3 different periods – 1991, 2001 and 2011. In the last 20 years Portugal embarked in an ambitious road construction program aimed at increasing regional cohesion. We estimate the aforementioned accessibility indicators for the 3 periods and respective equity levels, and compare them with accessibility indicators assuming equal population distribution and direct distance travel times to have benchmarks to account for the geographical limitations and population uneven distribution. Preliminary results indicate a decrease in spatial equity due to population uneven growth. Its intensity is dependent on the type of accessibility indicators. This highlights the pitfalls of not incorporating population forecasts in accessibility analysis. They also indicate the role of geography in preventing perfect spatial equity, illustrating the limitations of infrastructure policies. These and other results and their implications will be discussed and contrasted with the policy objectives which supported the road construction program. The obtained results and its implications will be discussed, and contrasted with the policy objectives put forward in the official documents which supported the road construction program.

ABSTRACT

The impact of transport infrastructure in regional economic development is a largely studied issue. Recent studies reveal that developing countries need a large amount of investment in infrastructure to cope with their demand. There is an urgency to understand how transport infrastructure investment impacts regional economic development in the case of developing countries. Despite a long and growing body of research in academic fields such as regional science, economic geography, planning and development economics, one of the major issues remains unresolved: Does transport infrastructure investments lower the regional economic disparity in developing countries?

New Economic Geography (NEG) theory suggests that transportation cost is a major determining factor for the concentration or dispersion of populations and economic activities in a location that in turn shapes regional economic development. According to NEG theory, cities in developing countries, which have better transport access, emerge as larger hubs that determine the size of the cities. A city with 'superior access', transport infrastructure 'peter out' with distance, attracts both consumers and producers and emerges as a primate city. The size of cities positively correlates with the regional income per capita, because of agglomeration benefits and economies of scale.

In order to understand the role of transport infrastructure in urbanization- and regional economic development processes in developing countries, we analyzed the change in transportation cost and a population of cities since 1961. We used intercity travel time, a calculation based on the design speed, length of sections and pavement type as an indicator of the quality of infrastructure (transportation cost). Next, we computed hubness and accessibility indices of cities defined by gravity model and a function of transportation cost, to compare among cities. Computation of the GINI index helped us to measure regional income inequality.

With this study, we empirically tested the ability of core mechanisms of NEG theory to explain longitudinal patterns in transport infrastructure investment, urbanization and regional economic development in developing countries. Results of our Nepal study show that (1) cities with higher hubness and accessibility did not all grow into a big city and (2) a region that has larger urban population can have a higher regional income per capita but some other regions can have higher regional GDP without containing a city. These findings have major implications for the applicability of NEG theory, which is still often the dominant theory behind reports of important institutions, such as the OECD and World Bank.

Keywords: Transport investment; developing countries; regional economic development; new economic geography.

1 INTRODUCTION

The impact of transport infrastructure in regional economic development is a largely studied issue but yet inconclusive. Focusing on the issues of developing countries need more research. In the developing countries, on the one hand, in more urbanized areas; there is massive rural-urban migration, rapid growth in city size and increasing incomes, and exploding travel demand, which current transport infrastructures are not able to accommodate. On the other hand, in more peripheral areas, where any transport means, like roads, are yet to be realized, people are struggling to access food, health, education, and other basic resources, services and markets. For instance, in rural communities in Nepal, one of the major causes of food insecurity is high transport cost for food (NFSMS 2016). At the same time, local agriculture products from these areas (for instance, apples from remote regions of Nepal) rot in the field due to a lack of road access to the market. These rural areas of developing countries have little opportunity for the economic activities.

Transporting goods and services to and from the peripheral areas is relatively very costly. Because of a higher cost of producing goods and services, investment is less attractive in non-connected or poorly connected regions. Thus, while as a result of the specular dynamics, urban or semi-urban areas enjoy higher economic growth, attracting people and private investment, rural areas feel the stagnation or, in some places economic decline. Consequently, the regional income inequality becomes more extreme.

A large and growing body of literature has investigated on the impact of transport investment on economic development. There is a general consensus that transport investment facilitates economic growth, however, in a well-connected region with a good quality of infrastructure might have an only limited impact (Banister and Berechman 2000; Piet Rietveld and Bruinsma 1998; Lakshmanan 2011; P. Rietveld et al. 2001). Transport connectivity can create the environment for urbanization, a growth of employment density and economic growth in a location (Lin 1999; Cervero 2001; Motamed, Florax, and Masters 2014; Kasraian, Maat, and Van Wee 2015; Kasraian et al. 2016). There is also a debate on various issues, such as the regional economic impact of transport infrastructure investment. The regional inequality might be bigger between the high-speed railways and expressways connected and non-connected regions (Vickerman 1997; Ortega, López, and Monzón 2011; Kim, Lee, and Park 2013; Yin, Bertolini, and Duan 2015; Jin, Wang, and Liu 2004; Roberts et al. 2010; Hou and Li 2011). Various studies focused on developing countries argued that one of the bottlenecks of economic growth is inadequate transport infrastructures (Bhattacharyay 2010; Dash and Sahoo 2010; Sahoo and Dash 2012; Sharma and Vohra 2009; Ghani, Goswami, and Kerr 2012; Alder 2014; Ndulu 2006; Nedozi, Obasanmi, and Ighata

2014). Infrastructure is argued to be a necessary but not a sufficient condition to achieve the economic growth (World Bank 1994).

Despite a long and growing body of research in academic fields such as regional science, economic geography, planning and development economics, one of the major issues remains unresolved: 'Does infrastructure investments lower regional economic disparities in developing countries?' The aim of this study is to understand how most dominant theory the NEG can explain the transportation investment, urbanization and regional economic development in the context of a developing country. In the following section, a brief introduction of the NEG theory is presented. Three hypotheses based on NEG theory particularly from the paper from (Krugman 1993, 1996), and other NEG theorist (Fujita and Mori 1996) and Ideas from the World Development Report 2009 published by the World Bank (World Bank 2009), are formulated to test the mechanism of the theory. In the method and data section, the operationalization process is introduced. Section 4 presents the results from the case study of Nepal. The paper closes with the discussion and conclusion in the final section.

2 THEORY

Study on economic development in a space has a long history since Von Thunen (1826). Interest is expanding these days from economic geographer and mainstream economist to urban and regional planners. A key question in regional economic development is 'Why some regions are economically prosperous whereas some regions lag behind within a country's boundary? After long negligence of this issue in mainstream economics, Krugman (1991) introduced New Economic Geography (NEG) for the explanation of 'how a country is divided into the industrialized core and agriculture periphery within a neoclassical framework. In the late 1990's Evolutionary Economic Geography (EEG) has been discussed by Boschma and Lambooy (1999) first and proposed a theoretical framework by Boschma and Martin (2007) under the disequilibrium framework and Generalized Darwinism. However, the EEG is still developing. Despite some critical views from geographers (for example Ron Martin and Sunley 1996; R Martin 1999), the NEG has been the dominant theory for the case of regional development analysis (for example World Bank 2009; OECD 2009) however, empirical studies are still limited. The developing countries, where infrastructure development policy has been influenced by the international donors such as the World Bank, has been using the NEG (for example World Bank 2009). Therefore, we prefer to choose the NEG to test in the case of developing country, Nepal.

The new economic geography (NEG) theory answers as to why a country is divided into industrial core and agriculture periphery and the causes of regional income disparity within a boundary of a country. The main argument of this theory is regional concentration and diversion of economic activities happen in locations because of the interaction of economies of scale with transportation cost (Krugman 1991b). According to Krugman (1998), the regional concentration or divergence of economic activities is a result of "tug of war" between centripetal and centrifugal forces. Centripetal forces are market size effects; labor market and external economies (lower average cost including transportation of input and output materials etc.) while land and other immobile factors and other external diseconomies (higher average cost etc.) are the centrifugal forces. The relative strength of centripetal forces determines the concentration of economic activities in a location (ibid).

After Krugman first introduced the new economic geography in 1990's this theory has evolved considerably. Krugman (1996) argued that the NEG is more relevant to the developing countries to understand the urbanization and uneven regional growth. Based on the NEG, particularly from (Krugman 1993, 1996), and other NEG theorist (Fujita and Mori 1996) and Ideas from the World Development Report 2009 published by the World Bank (World Bank 2009), three hypotheses have been developed to test the relevance of the NEG in the context of developing countries.

Hypothesis 1: The size of the cities is determined by their Hubness.

The transportation cost between locations determines which place (transportation node) can be a Hub (Krugman 1993). The transportation hub agglomerate (attracts) firms and labor. Krugman explains with the help of figure 1. In general, given three locations (nodes) are entitled to produce and consume both goods and services. A node can emerge as a big city from where transportation cost to the other locations is lowest. For example, if the transportation cost between nodes 1 and 3, 1 and 2 are lower than the cost between nodes 2 and 3; node 1 can be a transportation hub.

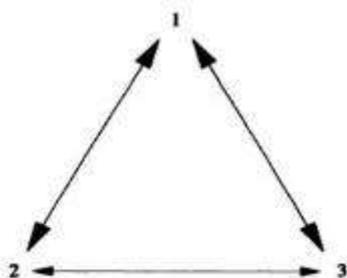

Figure 1: Krugman (1993)

The main mechanism of the hub formation is "the interaction between transportation cost and increasing return in production leads to the indigenous formation of Hubs" that is cities (Krugman 1993). According to Fujita and Mori (1996), port and other transport nodes have an extra advantage of access. Transportation nodes dominantly grow as compared

to non-transport nodes. Eventually, non- node cities get absorbed by the cities in the transportation nodes. The World Bank report 2009 which is based on the 'New Economic Geography' argued that cities are located near the most efficient transport systems.

Hypothesis 2: A city in a developing country, which is most accessible (superior access), emerges as a big city.

If one of the cities has better access with respect to the other cities, it leads to a concentration of population in the 'superior access' city(Krugman 1993). In developing countries, transportation cost is higher if one moves away from the big (capital) city because roads often 'peter out quickly' away from such city. This transportation system centered to the single city promotes the concentration of economic activities in the primate city. Because of Hub effect of a single city, most of the production and consumption of goods and services are concentrated in the primate city(Krugman 1996).

Hypothesis 3: Regional inequality exists because the region that contains bigger city has a higher GDP per capita.

Uneven urban distribution and the growth of cities lead to the regional inequality. In developing countries, the region that contains big city has higher regional GDP per capita (Krugman 1996).

3 METHODS AND DATA:

3.1 Hubness Index

Krugman (1993) defines Hub as a place from where transportation cost is a minimum. Hubness is a measurement of a city in terms of transportation cost between cities. Transportation cost is the cost of transporting goods or raw materials, commuting cost of workers between two locations (Krugman 1993, 1996). Transportation cost is a function of distance which impacts accessibility as expressed from a geographical point of view, in terms of length, travel time, economic cost or amount of energy required(Rodrigue 2017). Therefore, lower the transportation cost greater the Hubness. The major determinant of transport cost is infrastructure, that is, remoteness and poor quality of infrastructure isolate the locations(Limao and Venables 2001).

Hubness of each city is measured by the simple formula of accessibility index. Travel time is taken as a proxy measure of transportation cost. Travel time is based on the infrastructure quality and design speed. This formulation is widely used for accessibility measures for example(F. Bruinsma and Rietveld 1993, 1998; Spiekermann and Wegener 2006; Spiekermann and Neubauer 2002). Here we term the Hubness index of a node as:

$$H_i = \sum_{i \neq j} \frac{1}{t_{i-j}}$$

Hi= Hubness index of a city i

ti-j =Travel time between city i and j

Travel time depends on the quality and design speed of transport infrastructure. Travel time is estimated based on design speed of the roads. Average travel time of a public transport vehicle is estimated based on the sample survey of some sections of national highway and through expert interviews. Hubness index is calculated in time series to understand the change in hubness, city size and regional economy.

3.2 Accessibility index

The city from where larger markets are accessible is an accessible city. That is transport cost to the larger market is minimum (Krugman 1993, 1996). A form of accessibility indicates the opportunities available to the people and firms that are affected by the impedance (transportation cost). That is, more distant market (city) reduced the opportunity (Linneker and Spence 1992; F. Bruinsma and Rietveld 1998; Gutiérrez 2001). Accessibility index compares the advantage of locations that depends on the quality of transport infrastructures (Hansen 1959; Linneker and Spence 1992; F. R. Bruinsma, Rietveld, and others 1997; F. Bruinsma and Rietveld 1993; Vandenbulcke, Steenberghen, and Thomas 2009) We term the Accessibility Index of a city as:

$$A_i = \sum_{i \neq j} \frac{P_j}{t_{i-j}}$$

A_i= Accessibility index of city i

P_j= Population of destination city j

t_{i-j}= Travel time between city i-j

This formulation has been proposed and used by (F. Bruinsma and Rietveld 1993, 1998; Spiekermann and Wegener 2006; Spiekermann and Neubauer 2002) to measure the accessibility of each agglomeration. The bigger city will have a greater

opportunity to the people and firms. Therefore, the population is taken for comparison among cities. The impedance (transportation cost) affects the accessibility of the opportunity. That is distant city has less opportunity.

4 THE CASE OF NEPAL

Nepal is a least developed country in South Asia with the population of 28.7 million (in 2017, estimated based on 2011 census). In 2017, the average GDP per capita income was US\$ 853(Economic Survey-2016/17, MOF, Nepal). Transport Infrastructure in Nepal is in a developing stage. There were 259 Km all-weather roads out of 624 Km in 1956, prior to the start of the planned development process in Nepal. People were living all over the country in numerous scattered villages. With the gradual expansion of roads, people have migrated to the transportation nodes and formed numerous cities. There were 238,275(3% of national population) people residing in 6 urban settlements (Kathmandu Valley considered as a single settlement) in 1952; most of them were border- towns having an easy access to the Indian cities. The border towns were growing up to supply imported and exported goods to and from the inland hills and mountains through walking or mule routes. Only two roads connected the inland hill urban centres to the southern border towns in 1961. As road construction started from East to the West in the southern plain first and South to North in the hills and mountains later, cities gradually grew along the highway alignment. By the end of fiscal year 2015/16, the National Highway had expanded to 4670 Km that includes 3380 Km of paved roads and 7500 Km of feeder roads including 3300 Km paved roads (DOR, 2016). These roads connect the 217 designated urban areas.

4.1 The data

According to the 2011 census, 17.1% population resided in the 58 designated municipalities. After the declaration of additional municipalities in 2014 and 2015, the total urban population reached 40 % in the 217 designated urban areas. In March 2017, the local level restructuring commission further increased the number of municipalities to 293. However, the declaration of municipalities being political in nature, many declared municipalities are in spirit rural settlements. Therefore, we have taken only the cities declared until 2015 and having a population greater than 50,000 while including at least one city from each regional unit. Total of 25 cities have been selected for the analysis- of them, 21 cities have a population greater than 50,000 and 4 are regional urban centres that are not included in the group of greater than 50,000. Nepal is divided into 15 regional units based on 3 ecological regions and 5 development regions. Figure 2 shows the 15 regional units including the regional urban centre.

**NEPAL
15 REGIONS AND THEIR LARGEST URBAN CENTRES**

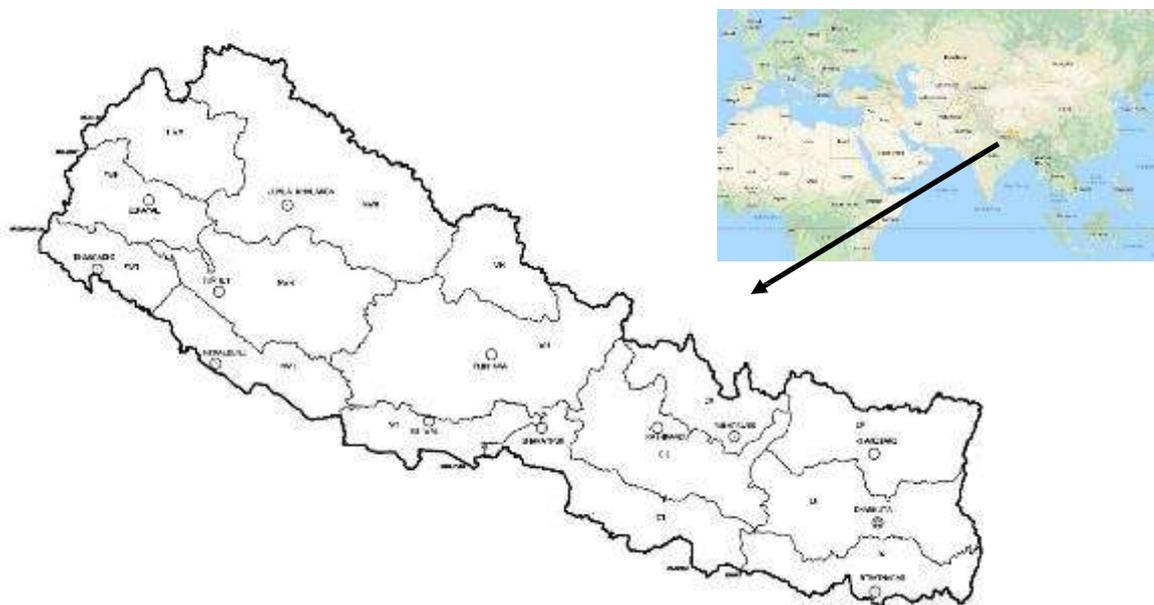

Figure 2: Nepal: Regional Division

The average travel time of road section is estimated based on design speed, sample survey and expert interviews. The average speed of roads is estimated as 50% of design speed for paved roads, 25% of design speed for gravelled roads and 15% for the earthen roads. Due to the availability of regional economic indicator (GDP per capita) of three years 1985, 2001 and 2011, comparative analysis of regional economy is limited to those years.

4.2 The Results

4.2.1 Hubness and Accessibility

We have selected 25 cities that had a population greater than 50,000 in 2015 and at least one city of each region even if they do not meet the population criteria. Hypotheses 1 and 2 are tested by computing the Hubness and Accessibility indexes of each city. Figures 3, 4 and 5 show the road development pattern, emergence of cities and their population, accessibility and Hubness indices.

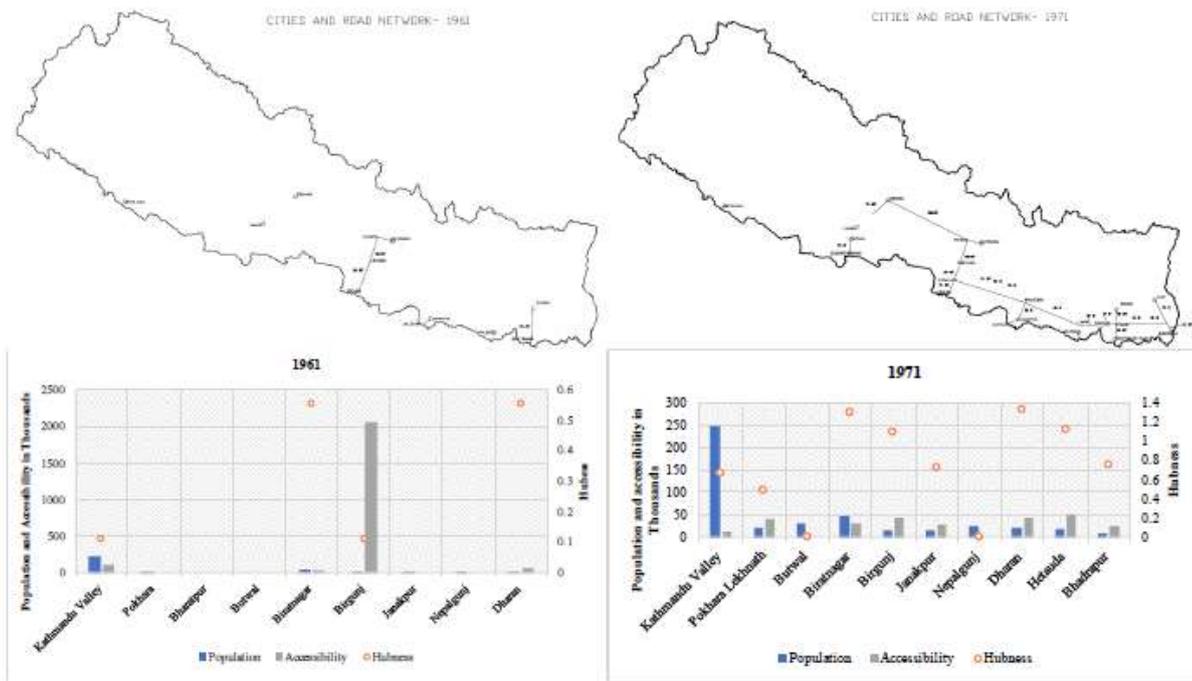

Figure 3: Transport connectivity and population, Hubness and accessibility of cities in 1961 and 1971

In 1961, the capital city, Kathmandu was connected to the border city Birgunj and another border city Biratnagar in the east is connected to inland Terai city Dharan. The Hubness and accessibility of those 4-cities do not show much significant meaning. More roads appeared in 1971 particularly connecting the South-East plains to the capital city. In spite of a higher population growth in the Kathmandu Valley, many cities appeared in the southern plains along the highway corridor. Significant Hubness and accessibility were achieved by the southern cities despite the population growth being modest. Asimilar pattern can be clearly seen in the following figure 4 and 5, that is Hubness do not affect the growth of cities.

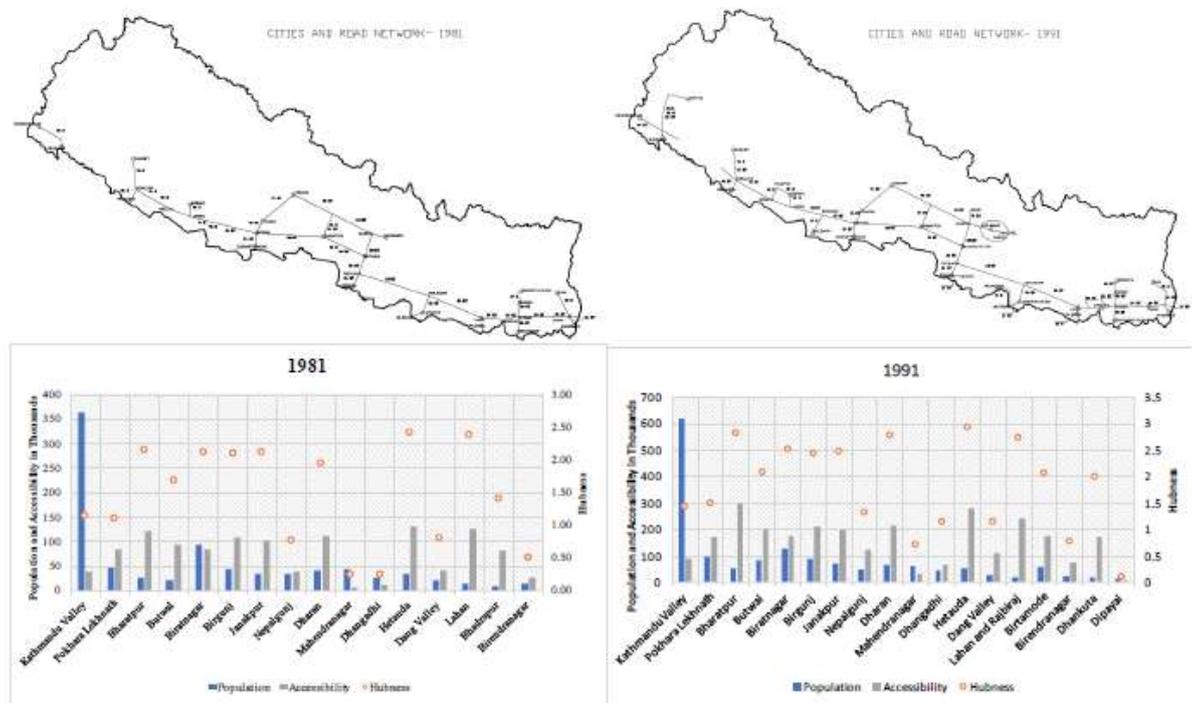

Figure 4: Transport connectivity, population, Hubness and accessibility of cities in 1981 and 1991

Transport connectivity significantly improved in the following years, but the Hubness does not influence the city growth and bigger cities do not necessarily have higher Hubness.

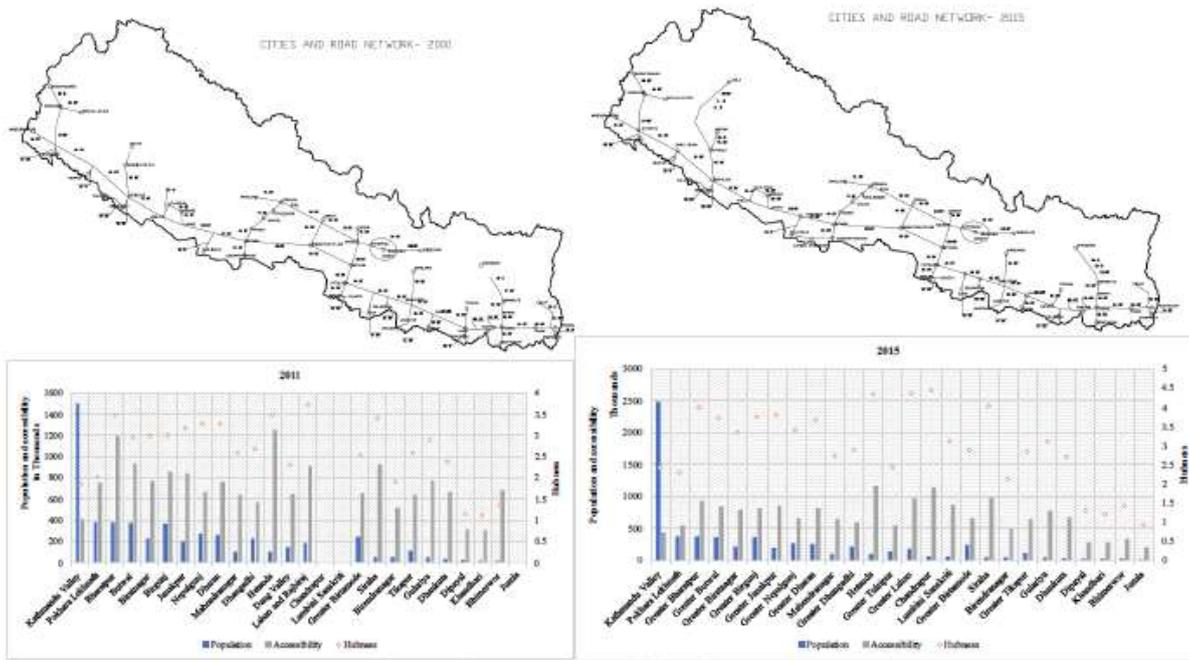

Figure 5: Transport connectivity, population, Hubness and accessibility of cities in 2000 and 2015

Table 1 below shows the ranking of cities based on population, Hubness and accessibility. What is interesting in these figures and table is the growth of cities is not determined by Hubness and accessibility. For example, the city, Hetauda was established in 1971 and already connected to the capital city before 1961 always scored high in accessibility and within the third position in the Hubness over the time but the size (population) has not increased significantly as compared to other cities. Similarly, Kathmandu, the primate city of Nepal is top-ranked in terms of population but far below in terms of Hubness and accessibility.

P=Population Rank, H=Hubness Rank, A=Accessibility Rank

The chart below shows the relationship between the Hubness and the population of cities in 2015. What can be clearly seen in this chart is the growth of cities and Hubness do not have any correlation.

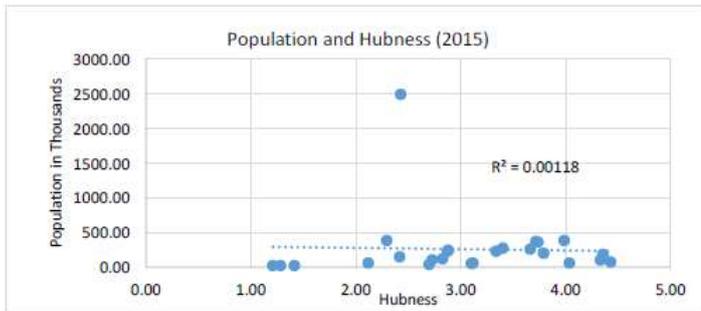

Figure 6: Correlation between Hubness and Population

From above time series analysis of Hubness, accessibility and population growth of cities, the hypotheses 1 and 2 that are drawn from the NEG are not significant in the case of Nepal.

4.2.2 Regional Inequality

For the regional analysis, the entire country is divided into 15 regions based on 3 ecological regions (Mountains, Hills and Plains) and five development regions (Eastern, Central, Western, Mid-Western and Far-Western). Figure 7 shows the comparative chart of regions between urban population, Hubness and accessibility and Regional GDP per capita.

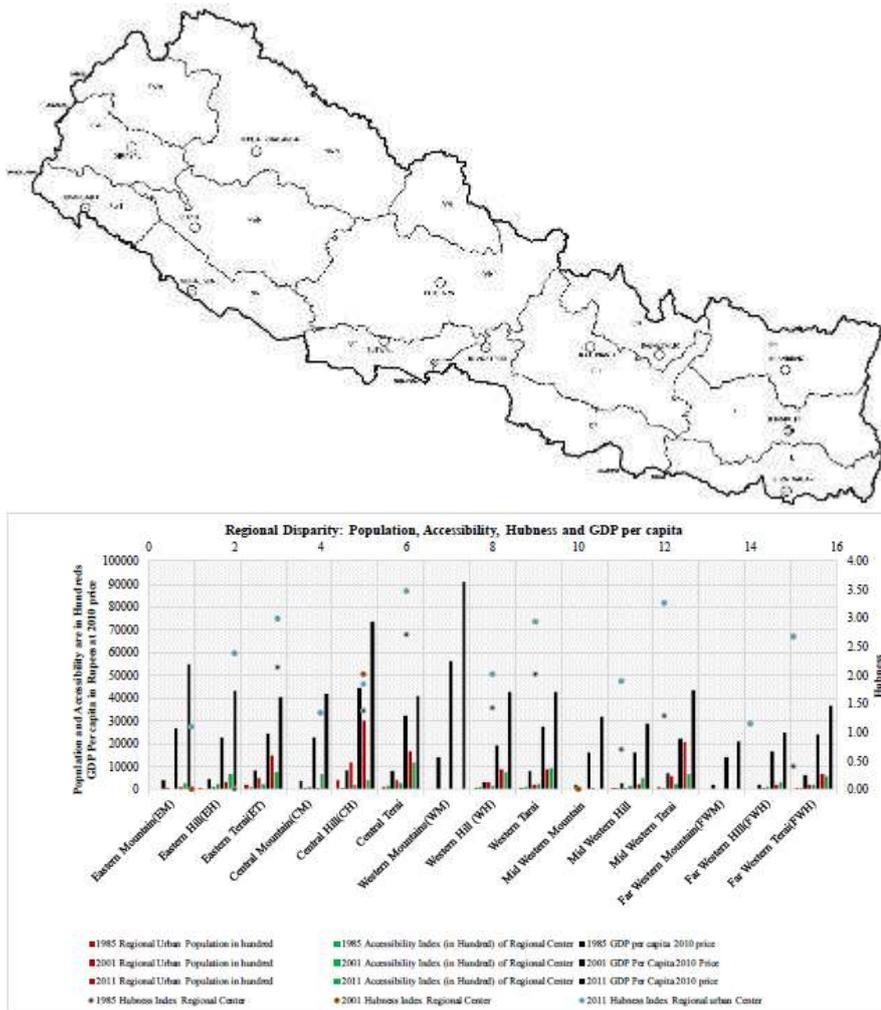

Figure 7: Regional Comparison of Urban Population, Hubness and Accessibility from 1985 to 2011

GDP Data source: Gurung (2005) for 1985 and 2001; UNDP, 2014, for population CBS

It is found that the central hill has the highest share of urban population and scored the second position in terms of Regional GDP per capita. The western mountains which do not contain any city yet secured highest regional GDP per capita since 1985. It seems that the region which has a higher share of urban population can have a higher regional GDP but it is not an essential condition.

Figure 8 below shows that the regional income inequality as measured by GINI coefficient. It can be seen that the regional income inequality has been declining smoothly over time, however, the level of inequality is severe.

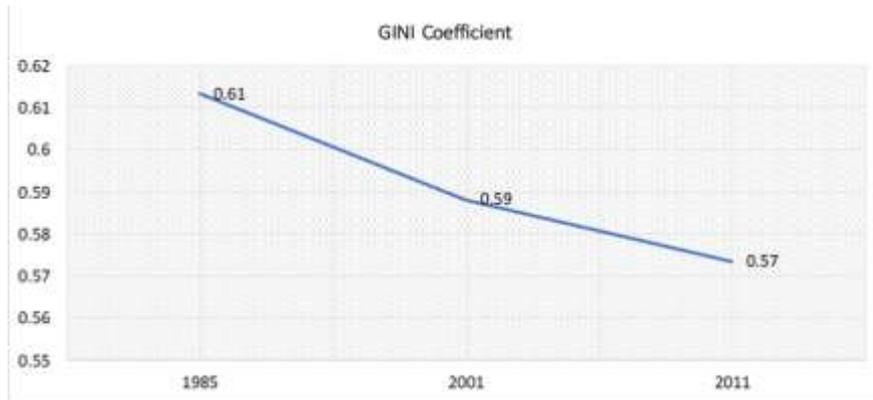

Figure 8: Regional Inequality

From above discussion, our third hypothesis is also falsified as a region that contains a bigger city might have a higher regional income per capita whereas other regions can have higher regional GDP without having a single big city. Transport investment might have a positive impact, since inequality has been declining over time. A possible explanation for the declining inequality might be transport connectivity in the later years in the lower income western regions. However, a more complex mechanism might be associated.

5 CONCLUSION AND DISCUSSION

This paper has conducted an empirical study on the impact of transport investment in urbanization and regional economy. We contest the three hypotheses that are formulated based on the New Economic Geography (NEG) in the context of a developing country, Nepal, where transport is in developing stage. The first hypothesis is 'the size of the cities is determined by their Hubness'. The Hubness of a city is calculated based on the intercity travel time. The primary hub is the city which has the highest Hubness index that is total travel time to reach the other city is lowest. We find that the cities which scored higher Hubness index are not always bigger cities. However, transport connectivity facilitates the formation of cities. The capital city Kathmandu and other bigger cities do not score higher hubness. The second hypothesis is 'a city in a developing country, which is most accessible (superior access), emerges as a big city'. We computed the accessibility index of each city for the comparison. We have found that the most accessible city is not the biggest city. The size of the most accessible city, Hetauda, does not lie even in the top-5 rank in terms of population. Therefore, this hypothesis is also invalid in the case of developing country Nepal. The third hypothesis is 'regional inequality exists because the region that contains bigger city has a higher GDP per capita. We find that this hypothesis is partially true for the case of Nepal. The highest income region does not have any city yet. But the other region that contains larger urban population has higher GDP per capita. Therefore, it can be concluded that the region that contains large urban population can have higher regional GDP per capita but it is not necessary to have a big city in the region to have higher regional GDP per capita. In addition, we found that GINI coefficient shows a smooth declination of inequality, however, the level of inequality is severe in developing countries. It is also found that the earlier connected eastern regions have higher GDP per capita as compared later connected western regions.

The falsification of the formulated hypothesis in the context of a developing country does not mean a complete rejection of the NEG theory. The NEG gives several important concepts, ideas and methods such as an introduction of transportation cost for the regional analysis. The possible explanations for the Nepal study findings might be associated with complex mechanism-for instances, the availability of natural resources which is an immobile factor, the timing gap between transport connectivity and city formation etc. Another possible direction for the improvement might be the introduction of an evolutionary concept into the NEG which is already started by Fujita and Mori (1996). There would, therefore, seem to be a definite need for further research and development of the NEG theory that can explain the phenomenon of developing countries.

1399 IMPACT OF VEHICLE PARKING ON THE ROAD NETWORK SYSTEM OF AGARTALA CITY, TRIPURA

ABSTRACT

Diversified traffic flow and continuous demand for choosing particular vehicle in Agartala City has been increased due to the economic growth of the citizen. Vehicles require street space to move as well as the occupants require space to park. But at present, spaces are a big problem in the city. With the increasing number of motor vehicles, the problem of parking has been introduced as a serious issue in the road network system of Agartala City. Presently, out of the total road network of Agartala City 88 per cent are minor and only 12 per cent are the major roads. The present paper attempts to identify the nature of parking as well as highlight the effect of parking in the road network system in Agartala City. For the Foundation of the research work ground level survey like measuring of roads, collecting different features associated to parking through structured questionnaires, transport survey etc. were carried out at different locations of the city. Moreover, different instruments like GPS, SL4010 has also been used to locate and measure the effect of parking in the urban environment of Agartala City. From the field survey the collected data were analysed with the help of geometry of parking, measuring of Peak Hour Factor (PHF) value, Time Series Analyses of vehicle movement, statistical tools such as mean, deviation and covariance level using SPSS Software and interpretation wherever necessary with logical elucidation of the present research work. The result shows that the space required for parking are very few in Agartala City. Most of the roads are narrow in width and are incapable to facilitate the on street-parking of vehicles. This had resulted hindrances to smooth mobility in the roads causing congestion and unprecedented noisy environment. Relevant preventive measures have been suggested for reducing the problem of parking in Agartala City. Key Words: City, GIS, Parking, Traffic Flow

1645 ROLE OF PMGSY TO CONNECT RURAL BHARAT TO URBAN INDIA: AN EVALUATIVE STUDY OF MURSHIDABAD DISTRICT

ABSTRACT

Pradhan Mantri Gram Sadak Yojana (PMGSY) is a dream project of Govt of India. Among many other objectives, developing connectivity of unconnected habitations to propel social transformation through improvement of transportation was one of the prime one. With initiation of the project in the Murshidabad in the year 2000, the connectivity with the unconnected habitations numbering 828 PMGSY schemes have been established in phases. Out of 331 PMGSY roads constructed so far in the district, presently connect as many as 5 Census Towns (CT) as terminal nodes, 3 CTs along the road and 1 statutory town as terminal end point. All together 10 roads (those constructed at least 5 years back) and adjoining areas are surveyed to assess the role of PMGASY roads in establishing connectivity of Rural Bharat to Urban India. Two roads are selected randomly from each sub-division (total sub-division in the district is 5) making a total of 10 roads. Both geographical and potential accessibilities are calculated to assess the role of PMGSY. Similarly, the change of dependency on service centres for fulfilling different needs such as health, education, marketing of agricultural produces and purchasing of agricultural inputs etc. is evaluated to see the PMGSY induced transformation of habitations. The study shows that though the schemes have been running for quite a few years, it has not been able to bring the desired change in terms of social transformation to a satisfactory level. Though the connectivity and also accessibility have improved noticeably yet the prime goal of connecting Rural Bharat to Urban India has not happened to a desired level. The present study makes an effort to assess the role of PMGSY to bring desired change of bringing visible social transformation along with bringing Rural Bharat and Urban India more close through enhanced connectivity.

RS04.2. Infrastructure, Transportation and Accessibility

1037 UNIVERSAL ACCESS ASSESSMENT AT RELIGIOUS TOURIST SPOTS OF INDIA USING GEOSPATIAL TECHNIQUE**Kakoli Saha¹, N.R. Mandal², Rachna Khare³**^{1,2}. Department of Planning,³Department of Architecture, School of Planning and Architecture, Bhopal-462030, India.Email: kakolisaha@spabhopal.ac.in.**ABSTRACT**

Religious tourism to sacred places has a long history in India. 'Tirthayatra', or pilgrimage, has been an important practice in Hinduism since ancient times. All the other old religions which have roots in India, such as Buddhism, Jainism and later, Sikhism also have practices of pilgrimage making it an important element of social life in the country. While differently abled and aged are a significant part of the pilgrims, most of the sacred sites in India lack facilities required for universal access. To address this and related other issues, lately, there has been an initiative by Government of India: 'Accessible India Campaign' (launched in December 2015) in consonance with the Article 9 of UN Convention on the Rights of Persons with Disabilities. This paper discusses the possibilities offered by geospatial technologies with the aim of assessing universal accessibility at religious tourist spots. Ujjain City of Madhya Pradesh, India has been selected as a case study. With more than 5000 years old history, Ujjain is one of the renowned Hindu places of pilgrimage in India. The sacred sites of Ujjain City include temple complexes, ancient monuments, lakes, bathing steps (*ghats*) along the river Kshipra, pilgrim routes, historic urban squares and townscapes. Major road stretches at some of these pilgrimage sites, locations of disembarking from inter-city vehicular /railway travel and pilgrim routes within Ujjain city were selected and mapped in GIS platform. An accessibility audit was performed along the selected road stretches/locations using a purpose made checklist suitable in the Indian context and the same has been spatially represented. Further, a hierarchy of accessibility issues has been developed to identify dominating factors and prioritize actions. The proposed method would help the local authority to plan for making Ujjain City more accessible for differently abled and aged visitors and help in increasing its revenue from tourism. The proposed method may be adopted by other such cities endowed with religious destinations.

Key words: universal accessibility, religious tourism, GIS**1. INTRODUCTION**

An architect and disability advocate Ron Mace, first gave the term universal design and defined it as "The design of products and environments to be usable by all people, to the greatest extent possible, without the need for adaptation or specialized design" (Mace and Lusher, 1989). The concept has been re-thought and re-defined by diverse writers around the world. Today, it is recognized that the goal of universal design must go beyond usability to address promotion of health and wellness and also promotion of social participation for all citizens.

Unlike western countries where the concepts of accessibility and universal design originated, Indian disability is ingrained in poverty, rural life and social difference (Mullick, 2011). Today, in India, majority of elderly, people with disabilities and children live in a physical environment which is either unplanned or underdeveloped. Every person develops his concept of 'self' by the interaction with his environment and get educated, encourage and inspired by the series of experiences he has with his surroundings. If his/her access to environment is limited, his self image is negatively impacted. Religion being reflection of our history, culture and identity, it is important to make religious buildings and sites accessible for all members of the society including person with disabilities.

In Indian community, traditions are deeply rooted despite modern lifestyle. One such traditional practice is pilgrimage that almost all religions follow, in one form or the other. The ancient city of central India, Ujjain is situated in the Malwa region of Madhya Pradesh, on the eastern bank of river Kshipra. The religious importance of the town has made it one of the most prominent pilgrimage sites for Hindus with the divine presence of Mahakaleshwara Jyotirlinga and auspicious Mahakumbha mela that is held after every twelve year. With an annual pilgrimage volume of 75 million there is utmost need to make Ujjain accessible to everyone including people with functional limitations. Greater accessibility will benefit everyone and contribute also to the quality of life of its residents, and residents with disabilities in particular.

This paper discusses the tools, planning and implementation processes of accessibility assessment in the unique and complicated nature of the old city of Ujjain, a model for other historic pilgrimage cities of India.

2. BACKGROUND STUDY

The concept and framework of accessible tourism is a neglected area both in the academics and industry in India. As a result, very little information and knowledge is available in this context. At the government level also, hardly any credible documentations are available to provide clear understanding of the subject (Problems and Prospects Of Accessible Tourism In India, 2010).

A study by National Council of Applied Economic Research (NCAER) was indeed revealing of the socio-economic and touring behaviour of Indian households but it was short of specific information on persons with reduced mobility and the disadvantaged groups. Indian Institute of Tourism and Travel Management has recently (October, 2010) published a report on problems and prospects of accessible tourism in India (Problems and Prospects of Accessible Tourism in India, 2010). Main objectives of the study were set to examine various socio-economic and travel-related attributes of the tourists with reduced mobility, their major issues and constraints during different stages of travel and the potential of

developing inclusive tourism market as special-interest visitor segment. Six attractions, essentially historico-cultural in nature, such as Taj Mahal (Agra), Amber Fort (Jaipur), Qutab Minar (Delhi), Sun Temple (Konark), Mamallapuram (T.N) and Old Goa churches were selected for this study. A total of 1205 tourists with reduced mobility were surveyed as part of the study. To finalise the sample size at each location, quantum of visits in a year at each one was considered.

The study found that disabled tourists have to face many barriers at booking stage itself. The major ones are poor understanding of their specific problems and requirements by the booking staff and the inhospitable attitude; a pattern commonly reported by both domestic & foreign tourist. During journey in general, intra-destination travel is most difficult part indicating the lack of accessible taxis & local transport infrastructure and facilities, followed by other constraints like lack of proper information and inadequate signages at necessary points and intersections. There are other noticeable constraints as well such as non-availability of personal aids and equipments at the stations and in the vehicles, locating affordable and accessible accommodation and lack of knowledge about their specific problems among ground staff. However, till date, universal accessibility assessment has not been performed for any pilgrimage city in India (Problems and Prospects Of Accessible Tourism In India, 2010).

The problems encountered at places of stay equally also merit serious attention. Major ones falling in the group are lack of necessary facilities in the rooms meant for tourists with disabilities/reduced mobility, lack of understanding about their special needs and inappropriate location of such rooms. Absence of lift and inaccessible lobby also call for major interventions. At tourist attractions also, there are many barriers such as absence of accessible toilets or its unhygienic condition, non-availability of public utilities and the like. Their easy movement inside the site is also hampered due to the constraints attributable to scarcity of ramps, lifts, signage and slippery/coarse tracks (Problems and Prospects Of Accessible Tourism In India, 2010).

The above mentioned findings helped to select parameters to be included in Universal Accessibility Assessment of Ujjain City. The detailed methodology is explained in section 4.

3. STUDY AREA AND DATA USED

Ujjain city of Madhya Pradesh is selected as case study area because with more than 5000 years old history, Ujjain is one of the renowned Hindu places of pilgrimage in India (fig1A).

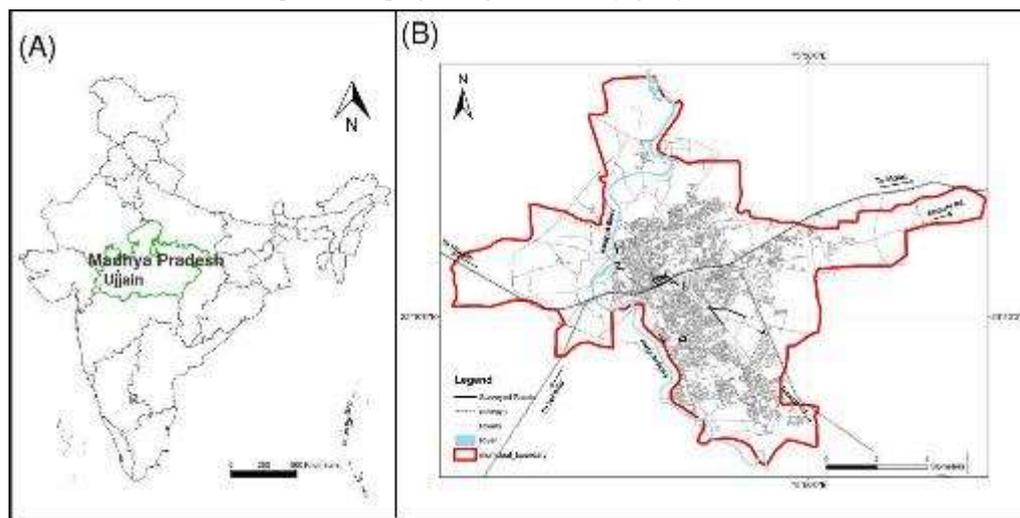

Figure 1: A. location of Ujjain city in India, B. Ujjain Municipal Boundary representing Ujjain city

Since the study was aimed to assess accessibility of religious tourists, the accessibility audit has been performed along the roads within the road network of the city. Since all roads of Ujjain City can not be covered, 17 road stretches was selected to perform the accessibility audit survey (fig1B).

For this study, data is collected through both primary and secondary sources. The road network of Ujjain City is digitized in the GIS platform. To assess the universal accessibility of identified road stretches an accessibility audit checklist was prepared from secondary sources (refer section4.2.1).

4. METHODOLOGY

The methodology for Universal Access Assessment of road stretches within Ujjain city is comprised of two steps -1) Selection of Road Stretches 2) Preparation of Audit Checklist and Performing the Universal Accessibility Survey using the checklist.

4.1. Selection of Road Stretches

The study was aimed to assess accessibility and to make the city accessible, roads play a very important role. Since all roads of Ujjain city could not be covered due to resource constrain, the roads stretches were divided into three categories such as, 1. Road stretches along city entry points, 2. Road stretches along city entry points to accommodation points, 3. Road stretches along heritage sites.

Six road stretches were selected for the first category, eight were selected for second category and three were selected for third category. The selection was done on the basis of footfall of religious tourists. To map the selected road stretches, a road network map of Ujjain City was prepared in GIS platform and then the identified road stretches were marked (fig.1B).

4.2.1. Preparation of an Audit Checklist for Universal Accessibility Assessment of Ujjain City

Two types of checklists were prepared to assess universal accessibility of selected road stretches such as one for City Entry Points including railway station and bus stand and another is for Public Realms including road stretches along arrival points in the city to accommodation points and along accommodation points to heritage sites. The checklists were prepared referring relevant guidelines and checklists such as, Access-improving the accessibility of historic buildings and places (2011), Code of Practice-on Accessibility of Public Services and Information provided by Public Bodies – National Disability Authority, Dublin, Ireland, Improving Access to Heritage Buildings (1999), Accessible Route in Historical Cities (2013), Harmonised Guidelines (2016). Main parameters of the checklists are mentioned in the table 1.

Table 1 Showing Parameters for Access Audit at City Entry Points

At city entry points (railway station, bus stands)	Standard
<p>1. Reservation and information counters</p> <p>1.1. Should have clear floor space in front of the counters of at least.</p> <p>1.2 There should be at least one low counter at a height of from the floor with clear knee space.</p> <p>1.3. The counters should have pictographic maps indicating all the services offered.</p> <p>1.4. On entry and exit should have a minimum width and is level or ramped.</p> <p>1.5. Approach walkway should have tactile pavements for persons with visual impairments.</p>	<p>900 x 1200 m 750 to 800 mm</p>
<p>2. Toilet Facility</p> <p>2.1. Are the toilets accessible to all user groups?</p> <p>2.2. Are the toilets easily identifiable?</p> <p>2.3. Can the grab bars withstand the user load ?</p> <p>2.4. Can doors be locked from inside and releasable from outside under emergency situations?</p> <p>2.5. Is there a unisex accessible toilet ?</p> <p>2.6. Is there colour contrast between the floor, wall and sanitary fittings?</p> <p>2.7. Are there proper signages installed defining the toilet location?</p> <p>2.8. Are signages provided in braille and tactile format?</p> <p>2.9. Are these switches installed at operable height?</p> <p>2.10. Is it a firm, levelled, slip-resistance, free from trip hazards ?</p> <p>2.11. Is it provided with tactile paving/tiles or not for visually impaired persons?</p>	
<p>3. platforms (train)</p> <p>3.1. Should have a row of tactile warning blocks installed before the track edge.</p> <p>3.2. Should have non-slip and level flooring.</p> <p>3.3. Should have seating areas for people with ambulatory disabilities (paralysis)</p> <p>3.4. Should Be well illuminated.</p> <p>3.5. There should be no gap or difference in level between the train entry door and the platform.</p>	<p>400mm-600mm</p>
<p>4. Signages</p> <p>a Does the signages inform the user a route, a hazard, or a facility.</p> <p>b. Are the signs clear, concise, and consistent?</p> <p>d. Information may take the form of visual information (e.g. signs, notice boards)</p> <p>4.1. Signages provision</p> <p>4.1.1. Information and direction signs should be provided at junctions of circulation routes and key destinations.</p> <p>4.1.2. Directional signs should readily identify and provide a logical sequence from a starting point to a point of destination.</p> <p>4.1.3. A clear indication of named exits.</p> <p>4.1.4. A clear indication of the existence of steps or ramps on a route should be provided at both ends of the route.</p> <p>4.1.5. Signs to facilities for Persons with Disabilities should incorporate the International Symbol for Accessibility</p> <p>4.1.6. Colour to be Navy Blue with White lettering.</p> <p>4.1.7. Signs should be provided to inform persons with hearing impairment (eg. hearing enhancement systems).</p> <p>4.1.8. A wall mounted or ceiling hung information board should be provided at lift landings, floor level landings of staircases, junctions/intersections and in main circulation routes.</p> <p>4.2. Directional Signage</p> <p>Signages include directional arrows to direct users to specific areas or elements within an area</p> <p>4.3. Information</p> <p>Information signs include directions, maps, building identification signs, notices and interpretative signs.</p> <p>4.4. Identification</p> <p>Should identify entrances, street addresses, buildings, rooms, facilities, places and spaces.</p> <p>4.5. Location</p> <p>4.5.1. Signs should be provided at all sites, campus, developments and buildings.</p> <p>4.5.2. Signage including approach to building / facility / service, entrance / exit, main lobby or reception, public facilities.</p> <p>4.6. Universal Signage</p>	

<p>4.6.1.Colour Contrast Signs 4.6.1.1. The commonly employed colours are white for the figure and blue for the background. 4.6.1.2. Safety signs use primarily red, yellow and green as information colours.</p> <p>4.6.2. Basic principles 4.6.2.1. Should be Tactile embossed with Braille. 4.6.2.1. Minimal use of bold letters.</p> <p>4.6.3. Pictograms 6.6.3.1. Signage should incorporate a combination of lettering and symbols. 6.6.3.2.Signs should be located where they are clearly visible. 6.6.3.3.Wall-mounted signs that contain timetables,maps or diagrams, should be centered from the ground around. 6.6.3.5.Are ceiling suspended signs above head height at from floor level?</p> <p>6.6.3. Pictograms 6.6.3. 1.Signage should incorporate a combination of lettering and symbols. 6.6.3. 2.Signs should be located where they are clearly visible. 6.6.3. 3.Wall-mounted signs that contain timetables,maps or diagrams, should be centered from the ground around. 6.6.3.4.Are ceiling suspended signs above head height at from floor level?</p>	
<p>5. Seating Area 5.1.Persons in wheelchairs should have a clear and level floor space. 5.2.Clear knee space of at least,wherever a forward approach is used.</p>	
<p>6. Kerb ramps 6.1.Should provided where the vertical rise is less than 150 6.2. Should have a slip-resistant surface; 6.3. Should be designed not to allow water accumulating on the walking surface; 6.4. Should not project into the road surface; 6.5.Should be located or protected to prevent obstruction by parked vehicles 6.6. Should be free from any obstruction such as signposts, traffic lights, etc.</p>	>150m
<p>7. Ramps 7.1. General 7.1.1. Should provide accessibility by both steps and ramps. 7.2.Gradient 7.2.1. It should be noted that the gradient should be constant between landings. 7.3.Width 7.3.1. The minimum clear width of a ramp should not be less than 1800mm 7.4.Surface 7.4.1.Ramps and landing surfaces should be slip resistant 7.4.2. Ramps surface should be designed to prevent water from accumulating on the walking surfaces. 7.5. Landings 7.5.1.Ramps should have a level landing at the top and bottom of each run. 7.5.2.Landings should be at regular intervals 7.6. Handrails 7.6.1. A ramp should have handrails which run with a vertical rise. 7.6.2. Handrails should be provided with Braille/ tactile markings 7.6. 3. Should be slip-resistant with round ends. 7.6.4. should have a circular section in diameter of 7.6.5. Should have a minimum clear space from the walls of</p>	1800mm 900mm from ground
<p>8. Walks and paths 8. 1.Walks should be smooth, hard and have levelled surface suitable for walking and wheeling. 8. 2.Minimum walk way width for two way traffic should be more than 1500mm 8. 3.Pathways should have rest areas at equal intervals 8. 4.Seat height should be between seats should have a backrest and hand rests at height. 8. 5.Texture change should be provided for persons with vision impairment. 8. 6.Gratings and manholes in walks should not be provided. 8.7.Is the route clearly defined and visible? 8.8.Are these accessible by different user groups? 8.9.Is the width of pathway sufficient for all users? 8.10.Is the width sufficient for single wheel chair user? 8.11.Is the width sufficient for single wheel chair user with one person? 8.12. Is the route clearly defined and visible? 8.13. Are these accessible by different user groups? 8.14. Is the width of pathway sufficient for all users? 8.15. Is the width sufficient for single wheel chair user? 8.16. Is the width sufficient for single wheel chair user with one person? 8.17. Do they have proper gradient ? 8.18. Is it a firm, levelled, slip-resistance,free from trip hazards ? 8.19. Is it provided with tactile paving/tiles or not for visually impaired persons? 8.20. Are accessible spaces identified by the signages? 8.21. Are signs clear,simple,and easy to read? 8.22. Are the signages in contrasting colours?</p>	1800mm 450-500mm 900MM 900MM 1200MM

8.23. Are these signs placed at sufficient height? 8.24. Do the signages comply with the standard size? 8.25. Are the signs supplemented by braille formats? 8.26. Is the tactile layout plan available with audio system? 8.27. Are all the signs properly illuminated?	
9. Stairs 9.1. Treads should be deep not less than 250mm 9.2. Risers not higher than 150mm 9.3. The stairs landing should be not less than 1000mm 9.4. Steps should be of a consistent height and depth throughout the staircase. 9.6. There should be colour contrast between landings, and the steps.	
10. Lifts 10.1. Lifts should be marked with the symbol of accessibility and directional signs. 10.2. The sign should incorporate a representation of the International Symbol for Access.	
11. Tactile Guiding & warning blocks 11.1. Single row of tactile warning blocks should be placed at beginning and end of each ramp. 11.2. Warning blocks should be installed in the beginning and end before end of each flight of step. 11.3. Approach walkway should have tactile pavements for persons with visual impairments. 11. 4. Is toilet provided with tactile paving/tiles or not for visually impaired persons? 11.5. 4. Braille and tactile signage should be placed at a height above the finished floor level between 11. 6. tactile information (e.g. signs with embossed lettering or Braille). 11.7. Is Visual and tactile information is reinforced by audible information? 11.8. There are no obstacles, such as trees, poles or uneven surfaces, along guidance blocks.	

Same checklist has been made for road stretches at public realm. While parameters like Signages, Kerb Ramps, Tactile Guiding & warning blocks remain constant other parameters like Traffic signals, Parking Space, Approach to Building, Planned Pedestrian routes, Subways and Foot Over Bridges are added. Details of added parameters are shown in table 2.

Table 2. Parameters for road stretches in Public Realm

At road stretches	Standard
1. Subways and Foot Over Bridges 1.1. Should have provision of signage at strategic location. 1.2. Should have provision of slope ramps or lifts at both the ends to enable wheelchair accessibility. 1.3. Is the width of the walkways at least? 1.4. Should have provision of tactile guiding and warning blocks along the length of the walkway. 1.5. Providing for seats for people with ambulatory disabilities at regular intervals along the walkway and at landings.	
2. Traffic signals 2.1. Pedestrian traffic lights should be provided with clearly audible signals. 2.2. Acoustic devices should be installed on a pole at the point of origin of crossing. 2.3. The time interval allowed for crossing should be programmed according to the slowest crossing persons.	
3. Kerb Ramps (Already mentioned in table 1)	
4. Tactile Guiding & warning blocks (Already mentioned in table 1)	
5. Barriers and hazards 5.1. Obstacles such as lighting columns, bollards, signposts, seats and trees, should be located at or beyond the boundaries of walkways. 5.2. Protruding objects in the access route should contrast visually with the background environment. 5.3. Free-standing columns should not be positioned within the width of an access route. 5.4. Bollards should be avoided but where necessary be at least at the height of 5.5. Provide a wheelchair passage width of at least. 5.6. Hazard protection should be provided. 5.7. finished walk surface should not protrude more than.	1000mm 900 mm 100 mm
6. Parking Space 6.1. Are they located nearest to the entrance? 6.2. Are there signages installed? 6.2. Is the parking area provided with shelter? 6.3. Is the parking area levelled? 6.4. Is the parking area non-slippery? 6.5. Is there a tactile floor guidance in the parking area available for independent mobility for persons with blindness and low vision? 6.6. Is there a tactile floor guidance from the emergency exit to the parking area? 6.7. Gradient along the pathway not less than 1:12? 6.8. Is there a parking lot available for visitors and staff? 6.9. Are there bays reserved for person with disabilities? 6.10. illumination level minimum 40 lux 6.11. lighting is available with 4 mtr radius? 6.12. Any Public telephone available 6.13. Alternative mode of transport to entrance from long way parking 6.14. Is there any other mode of transport if parking on site is not present? 6.15. If it's outside the site, then at what distance? 6.16. Are there signages installed?	

6.17. Is there a tactile floor guidance in the parking area available for independent mobility for 6.18. persons with blindness and low vision? 6.19. Is there a tactile floor guidance from the emergency exit to the parking area? 6.20. Gradient along the pathway not less than 1:12? 6.21. Is there kerb ramp provided in case of level change?	
7. Approach to building 7.1. Should not project into the road surface; 7.2. Should be located or protected to prevent obstruction by parked vehicles; and 7.3. Should be free from any obstruction such as signposts, traffic lights, etc. 7.4. Minimum width of the walkway should be. 7.5. Walkway should be constructed with a non-slip material. 7.6. The walkway should be cross vehicular traffic. 7.7. Warning blocks at before and after finishing of the walkway should be provided. 7.8. Should be provided at the level of approach for Persons with Disabilities to alight from and board a vehicle. 7.9. Difference in level between the driveway and footpath level surface should be avoided. 7.10. The driveway and the pavement or footpath surfaces should be blended to a common level or ramped. 7.11. Passenger alighting and drop off points 7.12. Should provide an access aisle of adjacent and parallel to the vehicle pull-up space at least width and height of. 7.13. The accessible aisle must be at the same level as the vehicle. 7.14. There should be kerb ramps provided. 7.15. Should have identification signage. 7.16. Wherever possible, it should be sheltered. 7.17. Tactile floor guidance be provided from the building drop off area leading up to entry.	1800mm 300mm
8. Planned Pedestrian routes 8.1. Is there any arrival plan or route described? 8.2. Do these points are provided with sittings or not? 8.3. If yes, are these covered? 8.4. Do they have provision for people like pregnant woman, elderly, etc. ? 8.5. Is there any assistance provided by the staff?	
9. Signages (Already mentioned in table 1)	
10. Sidewalks and footpaths 10.1. Is it non-slip floor surface? 10.2. Is it along the entire length of the road? 10.3. Should be not more than height of 10.4. Should be at least width. 10.5. Is it tactile guiding blocks for persons with visual impairments provided? 10.6. Is it have well defined edges of paths and routes by use of different colours and textures? 10.7. Do the footpaths have a clear headroom of at least height from the floor level. 10.8. Should have tactile warning blocks installed next to all entry and exit points from the pathway.	120mm 1800mm 2000mm

4.2.2. Performing Universal Accessibility Survey

Using the checklist mentioned above, surveys to assess universal accessibility was performed. The distance of road stretches were within 1 km. Students were sent to each stretch with appropriate audit checklists mentioned above. At city Entry points, students record information against each sub-parameter in the check list (Table 1) in the form of “Yes” and “No.” Each “Yes” is counted as one and the ones are added up to give total score for that parameter. After giving scores to individual parameter, total accessibility score was calculated in percentage for each stretch and then a comparison was performed within stretches.

Each stretch belong to Public Realm stretch was divided into six points and six students record information against each sub-parameter in the check list (table 2) in the form of “Yes” and “No.” Each “Yes” is counted as one and the ones are added up to give total score for that parameter. After giving scores to individual parameter, total accessibility score was calculated in percentage for each stretch and then a comparison was performed between stretches.

5. ANALYSIS AND DISCUSSION

Since the road stretches were divided into three categories the analysis of was also performed in three steps.

5.1. Analysis of survey at road stretches along City Entry Points

Since rail and road are the two prime modes of transportation at Ujjain city, railway stations and bus stands were considered as city entry points. 6 stretches were selected within Ujjain Railway Station, Vikram Nagar Railway Station, Nanakhera Bus Stand, and Raja Bhau Bus Terminal (fig.2).

Figure 2. A. Map showing platform no. 1, 2, 3, 5 of Ujjain Railway station and Vikram Nagar station. B. Platform Number 1, C. Platform number 2, 3, D. Platform number 5, E. Vikram Nagar station, B1 and B2 is Nana Khera Bus Terminal, C1 & C2. Raja Bhau Bus Terminal.

After performing accessibility audit and total accessibility score in percentage was calculated for each stretch (Table 3).

Table 3. Comparison of accessibility score between City Entry Points Stretches

		Ujjain Railway Station PF-1	Ujjain Railway Station-PF2,3	Ujjain Railway Station-PF-5	Vikram Nagar Station	Nankhera bus terminal	Raja Bhau Bus Terminal
	Maximum score	Accessibility score	Accessibility score	Accessibility score	Accessibility score	Accessibility score	Accessibility score
Reservation and Information Counters	5	2	0	1	1	2	2
Toilet facility	11	2	2	2	0	0	2
Lifts	2	2	1	1	0	0	2
Seating Area	2	2	1	2	1	2	2
Ramps	13	3	7	9	9	4	0
Tactile Guiding & warning blocks	8	3	0	3	3	0	0
Stairs	6	4	3	4	1	3	3
Kerb ramps	6	4	0	1	5	1	4
Signages	27	11	16	6	8	6	6
Walks and paths	27	11	3	13	16	15	7
Platforms	5	0	4	5	4	2	0
Total Audit Score	112	56 (50%)	59 (53%)	47(48%)	35 (32%)	35 (31%)	28 (25%)

According to the table 3 platform (PF) no. 2 and 3 of Ujjain Railway Station has scored highest with 53% of total accessibility score and Raja Bhau Bus Terminal scored lowest with 25% of total accessibility score. High score in signages contributed to the highest score of PF no.2 and 3. On the other hand, nil to low score in every parameter has contributed to the lowest score for Raja Bhau Bus Terminal. Detail investigation of accessibility status of stretches in individual parameters reveal that though PF no. 2 and 3 scored highest among other stretches, it scored nil in some of the individual

parameters like Reservation and Information Counters, Tactile Guiding & warning blocks, and Kerb ramps. Both of the bus stands scored zero in the parameter Tactile Guiding & Warning Blocks. To investigate the matter more closely total accessibility score in percentage was calculated for each parameter (fig.3).

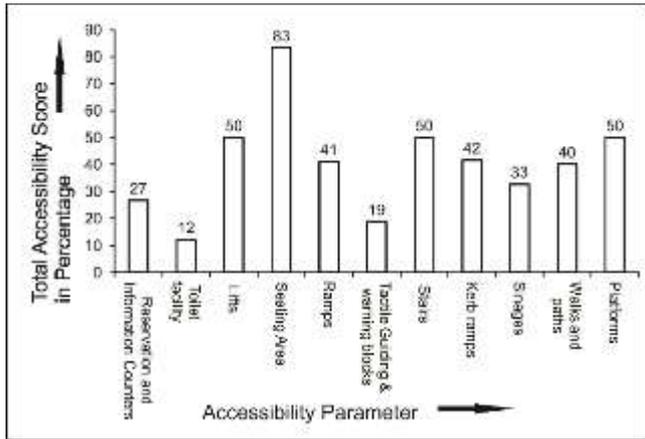

Figure 3: Parameter wise total accessible score in percentage for major City Entry Points

According to fig.3, Toilet Facility and Tactile Guiding & Warning Blocks have lowest accessibility scores (12% and 19% respectively). Since railway stations and bus stands are the transit places, tourists spend quality time in these locations. Considering this fact, toilet is a must have facility for these locations.

As Hindus belief in rebirth, there is a deep rooted belief that disability is the god’s way of punish people for their previous life’s sin and by performing pilgrimage is the way of get rid of the curse. As a result, Ujjain City is visited by a huge number of religious tourists with disability. In this context, improvement in Tactile Guiding & Warning Blocks is necessary for this area.

5.2. Analysis of survey at road stretches along city entry points to accommodation points

Eight such stretches were selected throughout the city where majority of accommodation centres including hotels and lodges are located (fig.4).

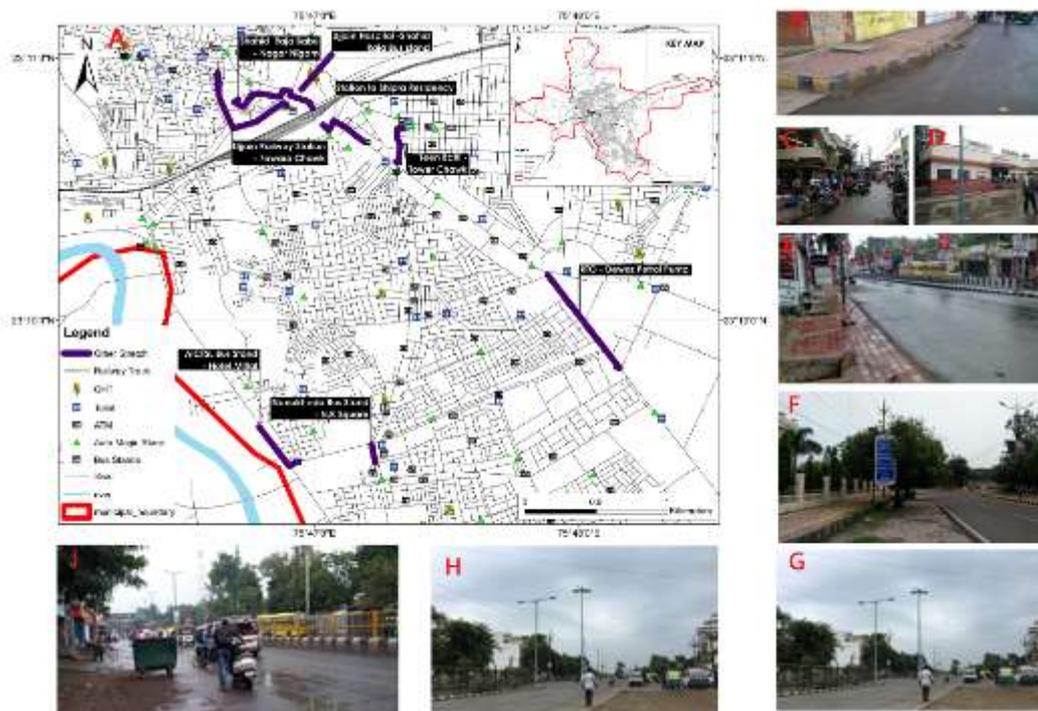

Figure 4. A. Map showing eight stretches including arrival points to accommodation points. B. Ujjain Hospital to Shahid Raja Babu Bus Stand, C. Shahid Raja Babu Bus Stand to Nagar Nigam (Municipality), D. Ujjain Railway Station to Shipra Residency (hotel), E. Teen Batti to Tower chawk (stretch along most of the accommodation points are located), F. RTO to Dewas Petrol Pump, G & H Nankhera Bus stand to N.K. Square, I, Ujjain Railway Station to Fawara Chowk.

The survey was conducted and total accessibility score in percentage is calculated for each stretch (table4).

Table 4. Comparison of accessibility score between different stretches along city entry points to accommodation points

Stretch	Ujjain rly station to	RTO to Dewas	Ujjain hospital-Shahid	Shahid Raja bhau bus	teen batti to tower chalk	Nana khera bus stand to	Ujjain Raily station to	AICTSL bus stand

		shipra residency	Petrol Pump	Raja bus stand	stand to Nagar Nigam		nanakhera bus stand square	Fawara chalk	to hotel Mittal
	Maximum score	Accessibility score	Accessibility score	Accessibility score	Accessibility score	Accessibility score	Accessibility score	Accessibility score	Accessibility score
Subways and Foot Over Bridges	30	0	0	0	0	0	0	0	0
Traffic signals	18	0	0	0	0	0	0	0	5
Kerb ramps	36	0	5	0	0	0	0	0	24
Tactile Guiding & warning blocks	36	0	0	0	0	0	0	0	0
Barriers and hazards	42	0	20	0	0	0	2	0	8
Parking Space	126	3	24	8	2	7	6	1	37
Approach to building	102	4	34	3	0	0	6	0	54
Planned Pedestrian routes	30	0	6	0	5	0	0	0	9
Signages	186	8	54	6	29	6	20	0	40
Sidewalks / Footpaths	48	8	35	10	16	10	0	0	21
Total Audit Score	654	23 (4%)	178 (27%)	27 (4%)	52 (8%)	23 (3.5%)	44 (6.7%)	1 (0.15%)	198(30%)

According to table 4, the stretch from AICTSL bus stand to hotel Mittal score highest with 30% of accessibility score and Ujjain Railway Station to Fawara Chowk (fig.4) scored lowest with 0.15% of accessibility score. High accessibility score in the parameters like Parking Space, Approach to Building, Sidewalks/Footpaths contributed to the high accessibility score. On the other hand, zero score in every parameter other than Parking contributed to the lowest score for road stretch along Ujjain Railway Station to Fawara Chowk. All seven stretches scored zero in three important parameters like Subways and Foot Over Briges, Traffic Signals, Tactile Guiding & Warning Blocks. To investigate the matter more closely, total accessibility score in percentage was calculated for each parameter (fig 6).

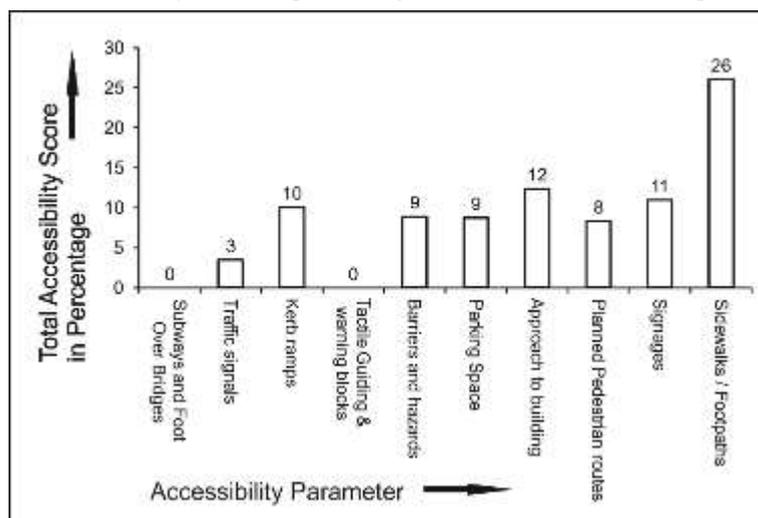

Figure 5. Parameter wise total accessible score in percentage for road stretches along City Entry Points to Accommodation Points

According to fig 5, parameters like Subways & Foot Over Bridges and Tactile Guiding & Warning Blocks scored nil as none of the road stretch has it. It implies the fact that the city lacks those accessibility infrastructure where high investment is required.

5.3. Analysis of survey at road stretches along Heritage Sites

Out of 17, 3 stretches were selected at heritage sites which include temples, bathing ghats along river Kshipra, and palace of the old ruler of Ujjain (fig.6).

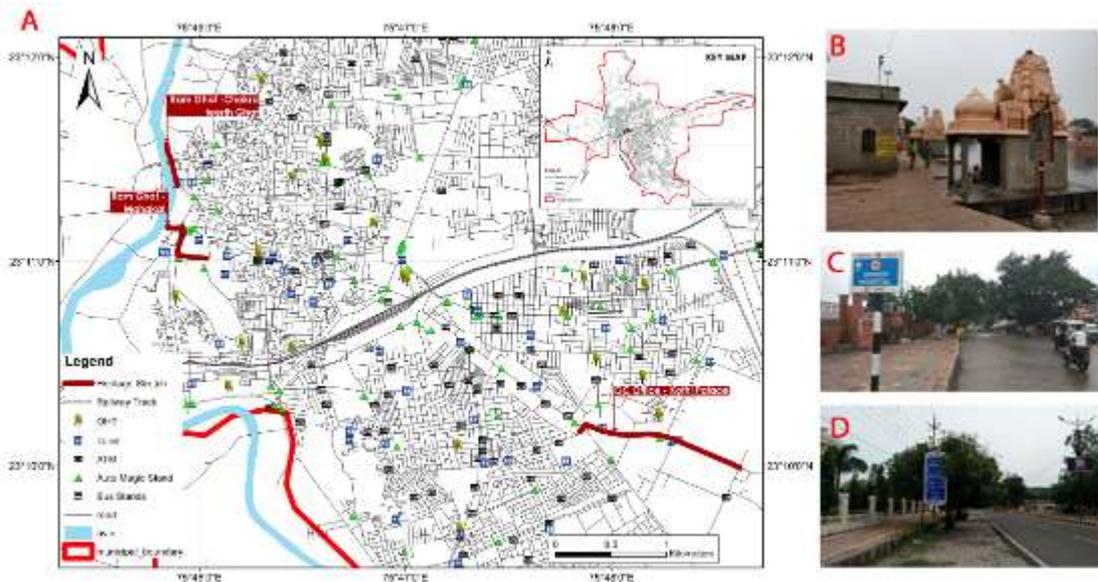

Figure 6. A. Map showing heritage stretches, B. Ram Ghat to Chakra Teerth Ghat (heritage bathing places), C. Ram Ghat to Mahakal temple, D. DC office to Kothi Palace.

After performing the accessibility survey and total accessibility score in percentage was calculated for each stretch and comparison was done (table5).

Table5. Comparison of accessibility score between heritage stretches

		Ramghat to Mahakal	Ramghat to Chakrateerth Ghat	DC Office to Kothi palace
	Maximum score	Accessibility score	Accessibility score	Accessibility score
Subways and Foot Over Bridges	30	0	10	0
Traffic signals	18	0	0	0
Kerb ramps	36	0	0	0
Tactile Guiding & warning blocks	36	0	5	0
Barriers and hazards	42	2	16	0
Parking Space	126	3	26	15
Approach to building	102	4	25	15
Planned Pedestrian routes	30	6	5	3
Signages	186	15	32	34
Sidewalks / Footpaths	48	93	22	16
Total Audit Score	654	128 (19%)	141(21%)	83(12%)

According to table5, Ramghat to Chakrateerth Ghat scored highest (21%) among three stretches. Highest score in multiple parameters such as Subways and Foot Over Bridges, Tactile Guiding & Warning Blocks, Barriers and Hazards, Parking Space and Approach to Building has contributed to the high score. On the other hand, the stretch representing DC Office to Kothi palace scored lowest (12%) because the stretch scored nil in parameters like Subways and Foot Over Bridges, Traffic signals, Kerb ramps,. To investigate the matter more closely, total accessibility score in percentage was calculated for each parameter (fig.7).

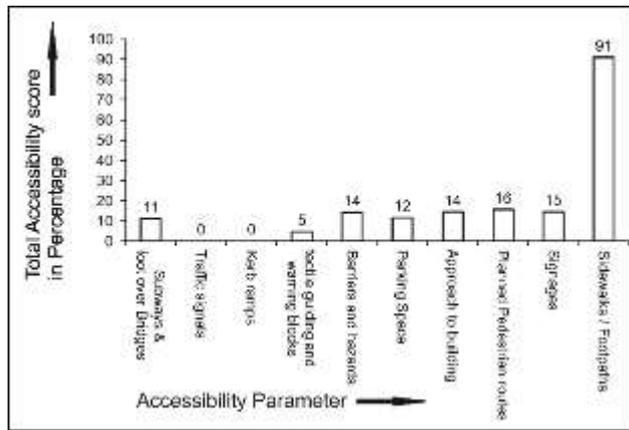

Figure7. Parameter wise total accessible score in percentage for road stretches along Heritage Sites

According to figure7, parameters like Traffic Signal, Kerb Ramp and Tactile Guiding & Warning Blocks needs attention as these parameters scored nil to lowest (5%). Ramghat is a bathing area along Kshipra River, where Hindu pilgrims takes holy dip. Due to this reason, the road stretch along the Ramghat experience huge crowd during every religious occasion.

While undertaking actions for improving accessibility, city authorities would find a multitude of issues to be addressed. However, since fund has to be allocated to bring improvements, these issues can be prioritised according to the monetary allocations so city authorities can improve these issues according to priority list. For that purpose, a hierarchy of accessibility issues has been developed from above analysis to identify dominating factors and prioritise actions. Table 6 summarises the issues for each stretch type.

Table 6. Accessibility issues in each stretch which needs to be addressed on priority basis

Stretch type	Issues needs to be addressed priority basis
1. Road stretches along city entry points	Toilet Facility and Tactile Guiding & Warning Blocks
2. Road stretches along city entry points to accommodation points	Subways & Foot Over Bridges and Tactile Guiding & Warning Blocks
3. Road stretches along heritage sites	Traffic Signal, Kerb Ramp and Tactile Guiding & Warning Blocks

6. CONCLUSION

According to Census India- 2001 figures, the size of the accessible market i.e. disabled persons, their family members/ dependents and other potential people with reduced mobility like those above 60 years works out to be 18.11% of India's population (Problems and Prospects Of Accessible Tourism In India, 2010). It is further estimated that 46.58 million Indian people with reduced mobility is economically significant from tourism angle. It means, promotion of accessible tourism in India can contribute significantly in revenue generated by tourism.

This paper aims to assess universal accessibility at religious tourist spots of India. Ujjain City of Madhya Pradesh, India was chosen as a case study since Ujjain is one of the renowned Hindu places of pilgrimage in India. Accessibility assessment of Ujjain was performed along the road stretches, as roads play an important role to improve the accessibility of a city. For that purpose, entire road network of Ujjain city was mapped in GIS platform. Further, road stretches were categorized into three types such as 1. Road stretches along city entry points including railway stations and bus stand, 2. Road stretches along city entry points to accommodation points, 3. Road stretches along heritage sites including temples and bathing *ghats*. From these three types of road stretches, six, eight and three road stretches were selected respectively on the basis of footfall of religious tourists. To assess the Universal Accessibility of these road stretches, two access audit checklists were prepared from secondary sources. The checklist for assessing accessibility of road stretches along City Entry Points include parameters which are relevant to its location such as Reservation and Information Counters, Platforms etc. On the other hand, the checklist prepared to take care of other two type of stretches has relevant parameters like Traffic signals, Parking Space, Approach to Building, Planned Pedestrian Routes, Subways and Foot Over Bridges etc. Each parameter has five to thirty sub-parameters on the basis of which road stretches were given scores. Road stretches having most of the parameters exist on ground got maximum score. In this way, PF No. 2 and 3 of Ujjain Railway Station were found most accessible within city entry points category. The stretch from AICTSL bus stand to hotel Mittal scored highest in terms of accessibility within the category of Road stretches along City Entry Points to Accommodation Points and road stretch along Ramghat to Chakrateerth *Ghat* scored highest among Heritage Stretches.

A hierarchy of accessibility issues has also been prepared by calculating parameter-wise total accessibility score for each category and dominating factors were identified for prioritizing actions. Among those dominating factors, Tactile Guiding & Warning Blocks is the common for all three kind of stretches. It seems authorities need to emphasize on this factor along with Toilet Facility, Traffic Signal, Kerb Ramp etc to make Ujjain Universally Accessible. If Ujjain City becomes more accessible for differently abled and aged visitors, it will get more revenue from religious tourism. Greater accessibility will also improve the quality of life of the residents of the city.

Though the research has focused on selected road stretches of Ujjain, further development can be done in two ways. Firstly, the access audit can be performed in more robust way, i.e. including more road stretches in each category. Secondly, the proposed method may be applied to other such cities to verify flexibility of the method.

ACKNOWLEDGEMENTS

The authors would like to thank and acknowledge Mr. Sauvik Adhikari, Mr. Udit Sarkar and all the students of Masters of Urban and Regional Planning Studio, SPA Bhopal for conducting the survey. The authors also like to thank Ministry of Human Resource Development for funding part of the the research through Design Innovation Centre (DIC) project titled "Universal Design Innovation for Heritage."

1071 WHO DISPLACED? HOW IMPLEMENTED THE RESETTLEMENT

ABSTRACT

Jamuna bridge project plays an important role in socio-economic and cultural development of the country, at the same time it causes widespread traumatic psychological and socio-cultural consequences. A huge number of development activities have been undertaken during the development programme of the Jamuna Bridge construction. Displacement, resettlement and rehabilitation programme are the major software issues that addressed the responsibilities of the Jamuna Bridge Authority to the affected people with proper compensation in cash or in kind. In the reality, there are so many suffering both socio-economic and psychological issues involved in the process of resettlement and rehabilitation programme. This paper tries to review the policy of the Bangladesh Government towards the resettlement and rehabilitation programme undertaken for the affected people by the construction of Jamuna Bridge. It is found that the resettlement and rehabilitation programme is different from traditional one and has been introduced for the first time in Bangladesh. In this programme priority has been given to social and economic rehabilitation. As a new type of activity the programme could not be able to avoid different type of problems like providing lower compensation rate for the land than its actual value, construction of temporary houses or cultivating vegetables and crops in fallow land during the period of land acquisition. Deprivation of actual land owners right on the basis of false land records also displayed in the study. In spite of such problems, the importance of the resettlement and rehabilitation programme is placed within its exceptional viewpoint and newness. Key Word: Displacement, resettlement, rehabilitation and Jamuna Bridge

1161 INTERNATIONAL TRADE AND CAPITAL ACCUMULATION IN AN OVERLAPPING GENERATIONS MODEL WITH A PUBLIC INTERMEDIATE GOOD

ABSTRACT

We investigate the effects of a public intermediate good on trade patterns, capital accumulation and the gains from trade in a two-country, three-sector overlapping generations model. Because a public intermediate good affects not only the productivity of the private production but capital accumulation, the results are opposed to those obtained by previous researches: First, opening to trade may accelerate capital accumulation in the higher-savings country. Second, it is possible that a country with more public intermediate goods supposed to be labor-intensive imports an investment good supposed to be capital-intensive. Third, the lower-savings country may lose from trade.

RS04.3. Infrastructure, Transportation and Accessibility

1163 URBAN CONGESTION AND HOUSEHOLDS' VULNERABILITY WITHIN THE BORDEAUX METROPOLITAN AREA

ABSTRACT

This paper is part of a research project supported by three local authorities in France (Région, Département and Metropolitan area). The research project focus on interactions between land use and transport in the Bordeaux metropolitan area with a particular attention paid to the social and economic aspects of sustainable mobility in suburban areas. The interaction of mobility constraints with location choices and access to housing is essential to understand contemporaneous patterns of spatial inequalities. The growth in house prices in French urban areas during the last decade (an increase of about 100% between 1998 and 2008) has considerably impacted housing accessibility for a large spectrum of households. Consequently, a growing part of medium and low income families have been led to move away from city centers to find a place to live and particularly to achieve ownership in suburban or exurban areas, thus reinforcing the connexion between owner-occupied housing tenure and car-based suburbanization. This phenomenon of urban relegation has important negative effects on the mobility of these households: lengthening of travel times and distances and consequently increasing travel costs combined with growing automobile dependency (Dupuy, 2011). Therefore, suburban congestion may have a disproportionate impact on medium and low income households located in exurban areas. The combination of exurban relocation of low income households with increased suburban congestion and oil vulnerability creates a risk of increased vulnerability of exurban low income households, defined as the combined increased of social isolation and poverty due to housing and transport increasing costs and irreversibility of location and mobility choices. This research aims to contribute to a better understanding of the combined impact of increasing land and house prices and suburban congestion on the vulnerability of exurban households within the metropolitan area of Bordeaux. It seems thus essential to develop a spatial approach of the impact of urban congestion on households' mobility and location choices. For that, our approach consists of the following three main steps. In the first part of the paper, we will develop a set of spatial indicators of urban congestion based on GPS data Tom Tom in 2009 and 2013 provided by the local authority Bordeaux Metropole. Then, these spatialized indicators of congestion are "territorialized" ie computed for each territory according to the specific profiles of residential areas and the characteristics of local households. Combining information about travel flows from each zone and data about the level of congestion of each road section of the transportation network allows to quantify the impact of congestion on different income groups and territories. An indicator of vulnerability to congestion is thus computed to identify the more impacted populations and areas. In the last part of the paper we propose an evaluation of the consequences of congestion on household's behavior. Can households vulnerable to increased congestion modify their mobility/housing choices in order to adapt, and if they do how do they adapt? We expect to find possible local effects of congestion in three domains: mobility patterns, location choices and housing demand

ABSTRACT

This paper provides an analysis of the regional freight market structure with regard to the urban hierarchy. Urban hierarchy, which we define by the combination of the size in population and economic activities, impacts freight volumes and freight rates. Using a survey on freight flows between 45 Japanese regions, from 1990 to 2010, we find evidence of economies of scale in truck transportation. The findings show inter-urban freight rates to be negatively related to population size of the Urban Areas (UAs) of origin and destination. Thus, shipping cargo from large to small UA is significantly more costly than in the reverse direction. A regression model is used to explain these differences, controlling for variations on time and cargo types. Part of the explanation appears to be related to economies of scale, agglomeration and distance in freight transportation, which seem to be common to many countries and urban systems. Regional-specific factors, such the incoterms most commonly chosen by Japanese firms, seem to play non-negligible roles as well.

Keywords: Urban hierarchy – freight flows –freight rates - Japan

1. INTRODUCTION

Freight transport plays an essential role in the development and competitiveness of cities and urban systems. It is vital for urban firms, enabling their material connections with markets and suppliers. While some of these relationships take place within the same city, many others do not. Indeed, for urban firms efficient connections with firms from other cities are indispensable for growing beyond their local markets and moving up the value chain.

Given its importance and geographical scope, the implementation of logistics policies requires integrated planning implying not only local but also national authorities. However, the bulk of research works on urban freight is focused on intra-urban flows, giving limited attention to inter-urban exchanges and to the roles cities are currently playing as transit centers between cities.

The purpose of this paper is to help to fill this void by analyzing the structure of interurban freight flows and rates. It measures in which extent they are determined by the positions of urban areas within the urban systems. The results of this work could be helpful for countries considering to support the development of logistics activities for promoting regional development.

Freight volumes and rates are analyzed within the different levels of the urban hierarchy. The aim is to identify the regularities observed within a freight system and which can eventually be later compared to those observed within other countries. By providing insight on the spatial patterns of inter-urban freight, this paper also aims to contribute with empirical evidence on one of the less observed dimensions of urban systems, which has been overlooked by the literature.

The paper is structured as follows. The next section reviews the relevant contributions in the literature. The third section develops the theoretical framework. The data and geographical context are described in section four. Section five presents the results of a regression analysis. The sixth section concludes by highlighting the main implications of this paper.

2. LITERATURE REVIEW: URBAN HIERARCHY AND FREIGHT

The urban hierarchy has been empirically analyzed by Zipf (1940), who observed that the distribution of urban agglomerations in India, Germany and other countries including United States followed a simple rule. The population size of a city is proportional to its rank within a country urban hierarchy. In other words, the size of the largest urban area is twice the size of second largest one, three times the third and so on. This regularity in the urban hierarchy is considered to be the result of a common effort of distance minimization both within industrial linkages and to markets. In one of its works, Zipf (1949) showed regularities on the spatial organization of rail cargo flows between US cities. The tonnage of flows was found to be proportional to the population of the cities of origin (P1) and destination (P2) and inversely proportional to the distance between both (D) ($P1 \cdot P2 / D$ p. 393).

More recently, an analysis of interurban freight movements has been carried out in France (Guerrero and Proulhac, 2014). In France, as a result of different periods of industrial expansion in the 19th and 20th centuries, manufacturing activities are mostly located in small and medium-sized urban areas. These generate a large share of the freight movements to other manufacturing firms and markets in Paris and large urban areas. The prominence of upward freight movements within the urban hierarchy seems to be common to many countries and urban systems. But, when considering activities others than manufacturing, such distribution, the hierarchical pattern is a strongly contrasting one. Many of the major freight movements in the distribution system are flows down the urban hierarchy, although highly differentiated patterns are noted depending on the types of distribution activities involved. While some of them serve their markets from a small number of places, usually within the largest urban areas, others are more ubiquitous. Therefore, the movements of cargo in the distribution system are represented as a waterstream falling step by step from the top to the bottom of the urban hierarchy. This hierarchical pattern is strongly suggestive of the concept of *step*

migration introduced by Ravenstein in the 19th century to explain migration patterns in Great Britain, from rural areas to towns, and then to large cities (1885, cited by Plane et al, 2005).

Without making specific reference to urban hierarchy, Tanaka and Tsubota (2017) showed that in Japan freight rate imbalances largely resulted from the differences of population size of the urban areas of origin and destination. This paper aims to expand the former works by taking in account different levels of urban hierarchy in the organization of freight flows and rates.

3. THEORETICAL FRAMEWORK

To analyze the hierarchical structure of freight flows and rates between cities, the following hypotheses are tested:

3.1. Distance and inter-urban freight rates

Road transport cost consists of several components. Some of them vary with distance and others not. Among the former we find the driver's salary, fuel, maintenance and use costs, or the tolls paid for using motorways vary with distance. Distant-invariant components are, for example, loading and unloading operations, the movement of the truck from the parking to the pick-up point in shippers' establishment, complying with administrative formalities, and so on. Given the above, the following hypothesis is expected to hold:

- *Hypothesis 1: The longer the distance of the freight movement, the lower are the freight rates (by ton km).*

The relationship between distance and freight rates has already been verified within other regional contexts. In France, using a survey with 53 000 truck movements, Jeger and Thomas, (1999) (cited by Reme-Harnay, 2012) underlined that distant trips were comparatively much cheaper than short distance ones, particularly for small loads. Indeed, the impact of distance on freight rates was found to be higher for heavy shipments than for light ones.

3.2. City size and intra-urban freight rates

The trucks performing the collection and distribution of load units usually move in the densely urbanised and/or industrialised zones. They may experience congestion and the consequent private delays and may also impose delays on other vehicles whose costs are counted as an externality (Janic, 2007).

- *Hypothesis 2: The larger the UA, the higher the intra-urban freight rate*

This results from the price index (including, in particular, labor and land costs) which is higher in larger urban areas.

3.3. City size and inter-urban freight rates

- *Hypothesis 3: Shipping downwards is more expensive than upwards.*

This results from the difficulty for truck companies to find back-haul cargo when going to less populated areas, where the local demand for truck transportation is lower (Tanaka and Tsubota, 2017). Since the probability of finding backhaul cargo locally is lower, the front haul freight rate will be higher. Conversely, the opportunities for back haul cargo in large urban areas are higher, because of a higher local demand, which will contribute to lower the front haul freight rates.

- *Hypothesis 4: The wider the population gap between origin and destination by UA, the wider the gap between front haul and back haul rates.*

When the population sizes of the UA of origin and destination are very different, the front and backhaul freight rates tend to be very different as well. The freight rate gap between L+3 and L-3 will be higher than between L-1 and L+1. The explanation is the same that for Hypothesis 3.

3.4. City size, volume, and inter-urban freight rates

- *Hypothesis 5: The larger is the volume between an od pair the lower are the freight rates.*

This is related to scale economies in truck transportation, namely the opportunities to optimize the capacity of trucks. Moreover, since the market is larger there is also more room for competition between truck companies.

- *Hypothesis 6: The characteristics of the origin UA have a stronger impact on freight rates than the characteristics of destination UA.*

The most common incoterm in Japan is CIF, meaning that the transport to the destination is usually included in the price of the good. Therefore, the characteristics of the shippers' UA would determine more the freight rates than the characteristics of consignees' UA.

4. DATA AND GEOGRAPHIC CONTEXT

Japan provides an interesting area for studying the patterns of inter-urban freight rates for several reasons. First its insular context and the extensive use of road transport implies few interference of transit flows and other modes. Second, the monopolar structure of Japan, should help to see the regularities in the relationships between cities along the urban hierarchy (Mori et al., 2008). Third, the large size of the top 3 metropolitan areas, covering each of them several prefectures, allows the analysis of freight flow movements at intra-metropolitan level. Last, but not least, this work has been made possible by the availability of two reliable data sources providing detailed information on the movements of cargo between regions.

4.1. Data: RCMS and CFS surveys

To measure the intensity of freight flows between the different levels of urban hierarchy we use two different data sources. First, we have tested the Regional Cargo Movement Survey (RCMS), carried out annually by the Japanese Ministry of Transport. The flows, in tons, have been converted to tonnes-kilometers (tk). The latter unit allows to put the focus on inter-urban flows, reducing the noise generated by intra-urban flows which represent most of flows in tons. The distance as the crow flies has been calculated between each pair of prefectures, using the location of prefecture office as reference. Intra-prefecture distances have been estimated on the basis of their surfaces.

It is essential to clearly understand the limits of RCMS data prior to analyzing inter-urban freight flows. The first restriction is on the scope of the survey, which is transport supply (transport leg) instead of transport demand (shipment from shipper to consignee). This implies that a large part of inter-urban flows, especially by road, would eventually be counted as many shorter distance flows. The use of tk instead of tonnes allows to mitigate somewhat this problem. The second restriction, partly derived from the first, is the lack of information about the activities generating freight flows. This is particularly problematic when studying the urban hierarchy, since one of the main assumptions of central place theory is that the services located at the top of urban hierarchy tend to serve larger areas than those located at the bottom. The segmentation of flows by type of cargo provides only a partial solution to the lack of information of the activities of shippers and consignees.

4.2. Data: Identification of freight areas and definition of the hierarchical levels

Figure 1 shows a map representing the largest freight flows between prefectures. It highlights largest cities and the relationships over short distances, mainly along the Fukuoka-Tokyo manufacturing belt. It confirms the metropolitan structures also revealed by commuting, migrations, or firms' headquarters (Fujita and Tabuchi, 1997). Many of the freight flows involve the prefectures around Tokyo area, which seem to constitute an urban system in itself. Suburban prefectures are strongly interconnected not just with the capital but also between them. Other specificity of Tokyo is the direction of flows: inbound movements are larger than outbound ones.

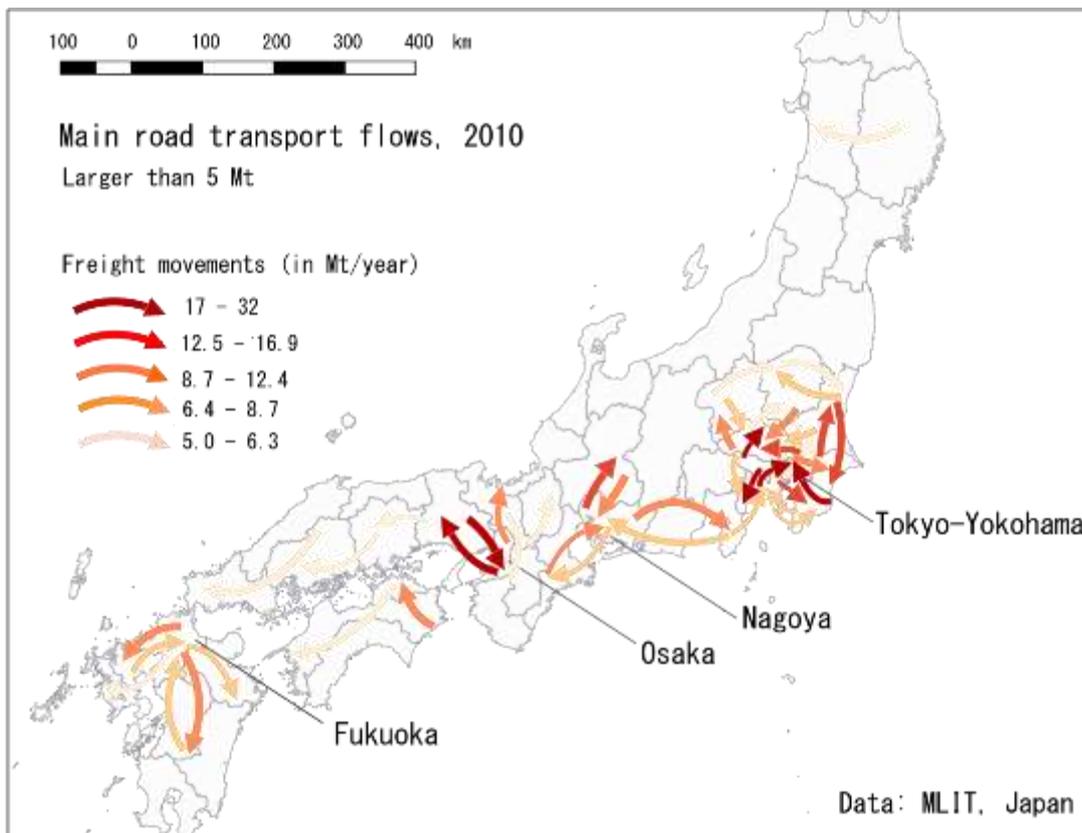

Figure 1. Main road transport flows. Source: Authors

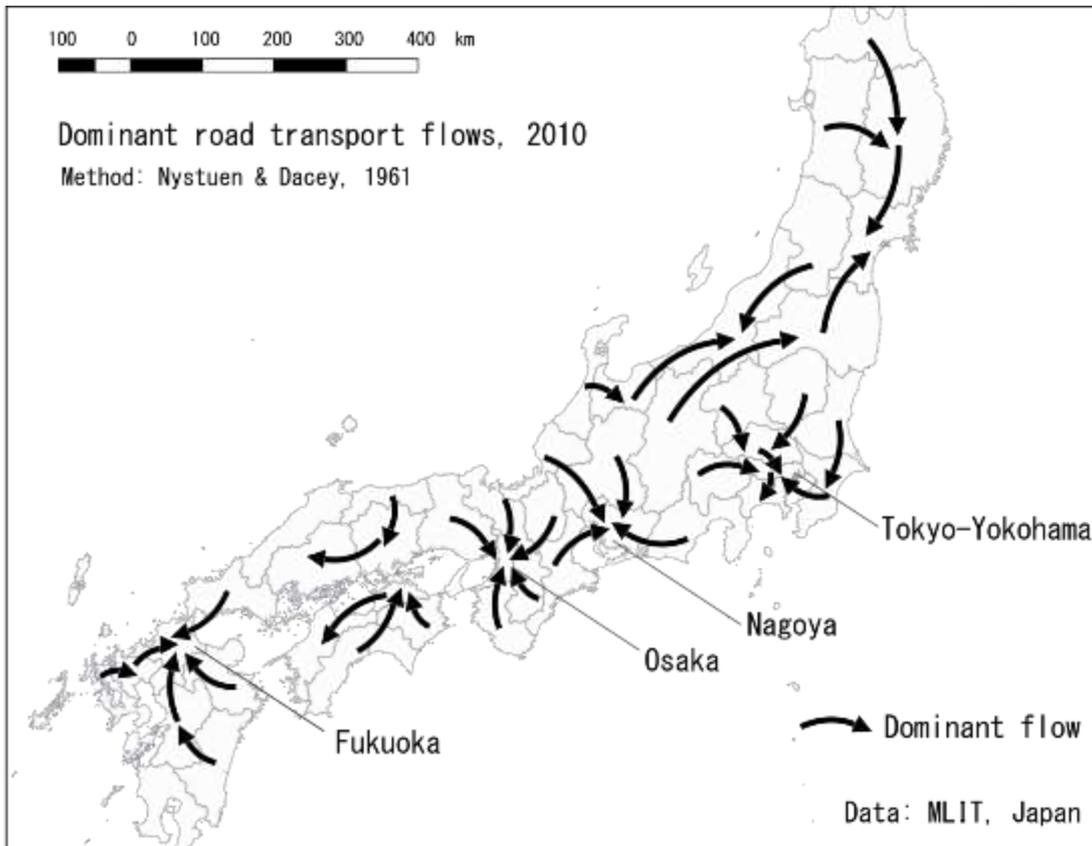

Figure 2. Dominant road transport flows. Source: Authors

The map of the figure 2 represents the dominant freight flows. It provides an alternative view to the main flows by highlighting the hierarchy between prefectures, even outside the top cities. According to this method (Nystuen and Dacey, 1961), a prefecture *i* is dominated by a prefecture *j* (a) if the most important flow from *i* is emitted towards *j*, and; (b) if the sum of the flows received by *j* is greater than the sum of the flows received by *i*. It shows that while on the East Coast freight movements are generally organized around large cities, on the West Coast the freight flows are less polarized. Again, the prefectures around Tokyo exhibit a complex hierarchical pattern with several levels, converging to the core. Paradoxically, the core of the Tokyo freight system is not dominated by Tokyo prefecture but by Yokohama (Kanagawa prefecture). This result, which may seem counterintuitive, is related to a relative specialization of prefectures within Tokyo MA in freight flows of different scope. While Tokyo prefecture polarizes most of the - short-distance - flows of the neighboring areas, Yokohama acts as a gateway to the whole Tokyo MA for many distant prefectures.

Based on the former maps and on the definition of the *Major Metropolitan Areas* of the Statistics Bureau of Japan, data on freight movements has been aggregated in five hierarchical levels. The first two levels (1 and 2) contain the three Major Metropolitan Areas of Tokyo, Osaka and Nagoya. Suburban prefectures have been included when most of their municipalities belonged to one of the three Major Metropolitan Areas, whose definition rely on commuting patterns. A third level (3) has been defined with the other prefectures containing MAs of more than 2 million people: Fukuoka, Hiroshima, Shizuoka and Sendai. Additionally, all other prefectures have been assumed to constitute another two groups (4 and 5) corresponding to least intensively urbanized levels of the hierarchy. Hokkaido and Okinawa, which are islands in the far North and South of the country, have very specific freight patterns resulting from their size and peripherality. Both have been excluded from the analysis. The population of the prefectures in the five hierarchical levels is shown in figure 3. The map in figure 4 indicates their location.

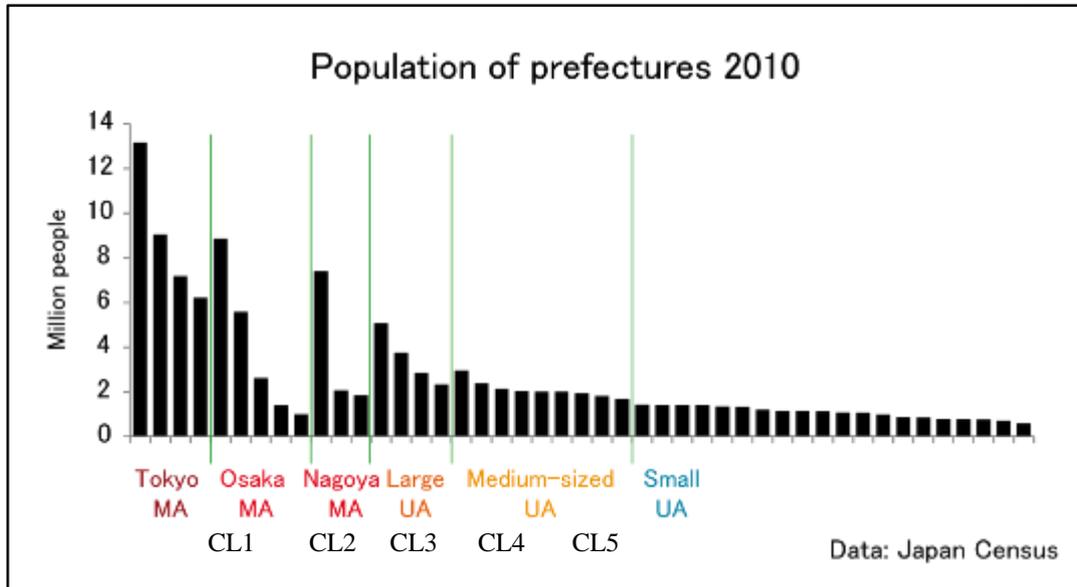

Figure 3. Population of prefectures of the five-level hierarchy. Source: Authors

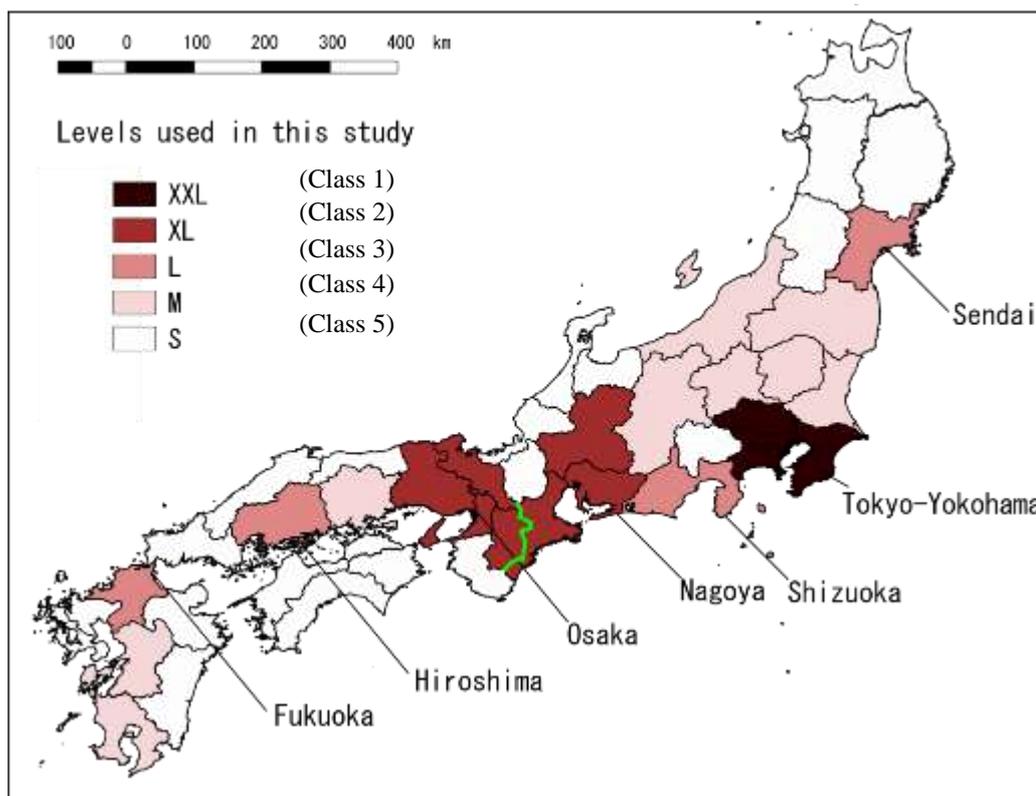

Figure 4. Location of the prefectures in the five-level hierarchy. Source: Authors

Within this five-level, size-based hierarchy, there are 25 possible directions for cargo movements to take place between any pair of levels. For ease of interpretation, these directions have been aggregated in six categories, as shown in the legend of the figure 5, following a method previously used by Guerrero et al., (2014). Thus, it is possible to distinguish the scope of movements (intraurban or interurban), their direction within the urban hierarchy (horizontal, upward, downward) and the number of hierarchical steps over which cargo is carried (neighboring levels or not).

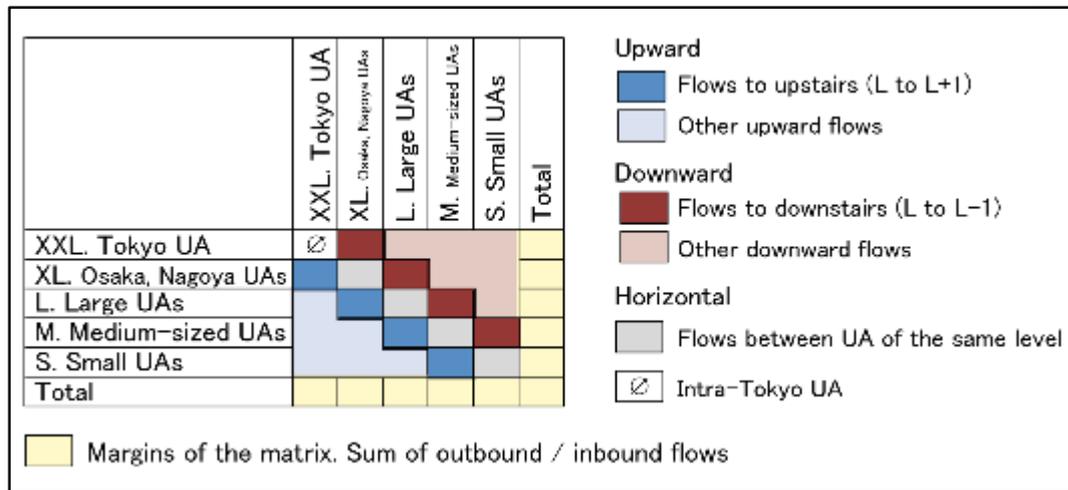

Figure 5. O/D Matrix of freight flows between hierarchical levels. Source: Authors

Table 1 contains average freight rates and distances for the flows between the different levels on 2010. It provides a first overview supporting the hypotheses of this work. For a more rigorous verification, a regression analysis is carried out on the following section, controlling, among other things, for time and commodity-type effects.

5. REGRESSION ANALYSIS

5.1. Specifications

In this section the hypotheses are tested through regression analysis. Freight market can be captured from two aspects; freight volume and freight rates. Both variables are critical in the determination of structure of regional and national freight transport markets. It is obvious, however, that freight volumes and freight rates are simultaneously determined. One starting point is the structure of the trade flows among regional markets. As the distributions of manufacturing activities and population are typically stable across time, the demand for freight market may be well shaped in advance, suggesting that, given a certain structure of trade flows, freight rates may be determined. As is discussed in the section 3, six hypotheses are to be examined where freight rates are the main concern. It is, however, important to understand the trends of freight volumes. Thus, freight volumes are estimated before freight rates. From the preliminary analysis, it become clear that there are distinct differences between inter-regional and intra-regional freight. Thus, two samples for each of them.

On the inter-regional freight, the following equation is estimated,

$$\ln Q_{rsct} = \alpha + \sum_{u=N} \beta_r \text{Class}_u + \gamma X_{rt} + \theta_t + \delta_c + \epsilon.$$

Q_{rsct} is the freight volume from region r to s of commodity c at year t , Class is a categorical dummy variable of urban hierarchy discussed in section 4 where total number of categories is N and X_{rt} is a vector of regional variables capturing the regional characteristics. Fixed effects in time, θ_t , and commodity, δ_c are also included.

On the determinants of freight rates, the equation to be estimated is written as follows;

$$\ln P_{rsct} = \alpha + \sum_{u=N} \beta_r \text{Class}_u + \sigma \ln Q_{rsct} + \gamma X_{rt} + \theta_t + \delta_c + \epsilon,$$

where P_{rsct} is the freight rates from region r to s of commodity c at year t .

It should be noted that the total number of categories of urban hierarchy is 20 for inter-regional freight and 5 for intra-regional freight. Table 2 summarizes the statistics on freight volumes and freight rates.

Table 2. Summary statistics of freight volume and rates by direction between UA

Movements of freight	log of freight volume			log of freight rates		
	Mean	Std. Dev.	Freq.	Mean	Std. Dev.	Freq.

Total	8.12	2.58	5,359	5.14	1.27	5,359

5.2. Regression results

Table 3 summarizes results on inter-urban volumes and freight rates. Results are shown to make it easier to compare the estimates for upward and downward flows and rates. Entire estimation results are shown in the appendix 1. To control regional characteristics, distance, log of population, log of per capita income for both of origin and destination have been included.

Table 3. Inter-freight market: freight volumes and freight rates

Notes: Robust standard errors are clustered at pairs of origin-destination prefecture. Detailed results are shown in the Appendix. The number of stars indicate the statistical significance at *** p<0.01, ** p<0.05, * and p<0.1.

The population sizes of origin and destination UAs largely determine the freight volumes. Log of per capita GDP of origin is positive and statistically significant while the one of destination is negative and statistically significant. These are the most important variables to explain the variations of freight volumes.

After controlling these factors, there are some other time-invariant factors which can capture the regional differences. By employing our urban class categories, the results of these dummies are shown in table 3. All of these coefficients are the difference from the benchmark which is the freight shipped from class 1 to class 3. One of the observed trends is that higher classes have smaller coefficients and lower classes have larger coefficients. These trends are mostly found in the shipments among class 3, 4, and 5. The differences between upward and downward are found statistically significant for the shipments between class 1-5, 2-3, and 4-5.

Freight rates are negatively correlated with freight volumes, meaning that 10% increase in freight volume is associated with 2.1% decrease in freight rates. This demonstrates that there are economies of scale in truck transportation. Given the large variations in freight volumes among regions, this negative relation is substantial.

A further look at the results on the class dummies, shows, in most cases, a smaller size for coefficients of upward flows. This means that after controlling for the population size, size of economies and freight volumes, freight rates remain cheaper for the upward shipments. The differences between upward and downward are found only for shipments between 1-4, 1-5, 2-4, 2-5, and 3-5.

Further analysis of inter-urban freight results is shown in Appendix 2 where the interaction of class dummy with freight volume has been introduced. By comparing the coefficients, differences in economies of scale can be found, showing the extent of price reduction by increase in volume. The cases of downward 1-2, and upward 3-2, 3-5, 4-2, 5-1, 5-3, 5-4 deserve to be highlighted.

Table 4 presents the results for intra-regional freight markets. From column (1), freight volume is positively correlated with population size. Namely, 1% increase in population is associated with 1.35% of freight volume. Column (2) shows negative relations between freight rates and volume. Instead of all in one specification, an interaction term of urban level with freight volume has been introduced. This result suggests that the extent of economies of scale is largest in the class 1 and secondarily in class 2.

Table 4. Intra-regional freight market: freight volume and freight rates

	(1) freight volumes	(2) freight rates	(3) freight rates
freight volume		-0.257*** (0.039)	
freight volume x class1			-0.337*** (0.073)
freight volume x class2			-0.265*** (0.055)
freight volume x class3			-0.253*** (0.059)
freight volume x class4			-0.200*** (0.052)
freight volume x class5			-0.262*** (0.046)
Class dummy: 2	0.643*** (0.226)	-0.097 (0.185)	-0.845 (0.902)

So far, the determinants of freight rates have been explored and found that freight volumes explain the bulk of freight rate variations. To check the robustness these arguments, an additional specification is explored. To analyze the gaps in freight rates between back and front haul, all variables have been converted to ratio. The results are provided in Table 5. They confirm again the economies of density from the negative sign in the coefficient of ratio of log of freight volume. This means that if the gap in freight volumes is larger, the freight volume at the numerator is larger than the one at the denominator and the freight rates for the numerator are much lower. Such tendency may be widened if the per capita GDP of the origin (of numerator) is comparatively larger. Interestingly, road distance is not statistically significant, suggesting that the degree of distance economy may be symmetric for a pair of UA.

Table 5. Inter-freight market: freight volumes and freight rates (ratio)

Notes: Robust standard errors are clustered at pairs of origin-destination prefecture. Detailed results are shown in the Appendix. The number of stars indicate the statistical significance at *** p<0.01, ** p<0.05, * and p<0.1.

6. RESULTS AND DISCUSSION

H1: The longer the distance, the lower the freight rates

This relationship is statistically significant. It is explained by the fixed/variable cost composition of road transport. The share of fixed cost per tk is lower for flows conveyed over longer distances. Road distance is negatively correlated with freight rates, as shown in Appendix 1 and 2.

H2: The larger the UA, the higher the intra-urban freight rate

This is explained by the nature of cargo and its value, which is different depending on the size of the city. Road congestion, which is highly dependent on the size and the population density of the urban area, is usually higher in large urban areas. Last but not least, labor costs and price index are also higher in large urban areas, which means that road transport companies should support higher costs, which are at least partly reflected in freight rates.

This relationship has not been verified through the regression analysis. At the highest level of urban hierarchy, intra-urban freight rates are surprisingly cheaper when controlling for population and GDP per capita effects. This is because at such places, there is higher demand for freight volumes. Top levels of UA have larger population and higher per capita GDP. As there are positive correlations of freight volumes with population size and per capita GDP and there is a presence of economies of scale, resulted freight rates are not necessarily lower in small UA.

H3: Shipping downwards is more expensive than upwards

This relationship is not statistically significant. This is explained by the easiness for road transport companies to find backhaul cargo at large urban areas as compared to small ones. Appendix 3 shows that the downward character of flows is not statistically significant after controlling freight volume and regional characteristics. The difference in freight rates results from freight volumes and not from the downward or upward direction of flows.

H4: The wider the size gap between origin and destination UA, the wider the freight rate gap

This relationship is statistically significant. This is explained by the easiness for road transport companies to find backhaul cargo at large urban areas as compared to small ones. The wider the size gap in population, the wider the gap in freight volumes. Consequently, the freight rate gap can be larger.

H5: The larger is the volume, the lower are the freight rates

This relationship is statistically significant. This can be explained by economies of scale in transportation and by a higher level of competition between truck companies as well. It has been verified in all of the analysis.

H6: The characteristics of the origin UA have a stronger impact on freight rates than the characteristics of destination UA

This relationship is statistically significant. This is maybe related to the business characteristics in Japan, a country in which shippers usually assume the transport costs until the establishment of the consignee (Cost, Insurance, Freight). These variables are critical in determination of the freight rates.

7. CONCLUSION

This paper has explored the relationship between freight flows and rates and the position of urban areas within the Japanese urban hierarchy. The joint consideration of the size of the urban area and of patterns of upward and downwards flows provided a very useful framework for understanding inter-urban freight rates in Japan. It has focused on the reasons which could lead to the differences in freight rates. It showed that freight rates between urban areas are largely determined by freight volumes and distance. Beyond these two large sources of explanation, other factors play non-negligible roles as well. Differences in the size of the urban areas of origin and destination also impacts freight rates. Therefore, shipping cargo from small to large urban areas is cheaper than on the opposite direction. When there is a wide population gap between the urban areas of origin and destination, there is also a wide gap between front haul and back haul freight rates. Finally, other characteristics such the economic performance of urban areas of origin and destination, measured by their GDP per capita, plays a role in the formation of freight rates. The characteristics of the origin UA turned to be more important than those of the destination UA. This could be a regional specificity, since Japanese shippers usually include transport costs in the price of the goods they sell (Cost, Insurance, Freight).

1279 RAILWAY INFRASTRUCTURE OF NORTH EAST INDIA: PROSPECTS AND POSSIBILITIES

ABSTRACT

Indian Railway (IR) is the fourth largest railways systems in the world after USA, China and Russia. The main motto of the India Railway is the cost effective mode of mass transportation for both freight and passenger. Indian Railway is the life line of the country which covers mostly all states. The Northeast India has unique strategical location, geographical isolation and geo-political value which comprises of the eight sister states of Arunachal Pradesh, Assam, Manipur, Meghalaya, Mizoram, Nagaland, Tripura and Sikkim. The total area of the region is about 262192 km² and about 36 per cent International Border to total International Boundary is located here. North Eastern States are sharing the International Border with Bangladesh, Bhutan, China, Tibet and Myanmar. Due to locational isolation alongwith physical, social, economical and political factors like undulating topography, tribal movement, social unrest, central-state relation, political instability, cultural dynamics, land acquisition related issues etc. of North Eastern States make this region lack behind. Transport network was developed by the British ruler for excavating the natural resources of the region because this region was a major source of hydrocarbons, especially natural gas and oil, coal, limestone and bamboo etc. Transport network played an important role not only for India's national security but likewise to the feeling of wholeness in diversity that characterises its power. Railway transportation can transform the partially economic situation of the region. This paper deals with present conditions of railway transport system in North Eastern Region of India and hindrance of railway system within the region and highlight on the future prospect. Secondary data has been collected from office of the Zonal Railway Manager, Malegaon, Guwahati; Personnel Railway Manager, Northeast Frontier Railway, Malegaon, Guwahati; Chief Commercial Inspector, Lumding, Assam. A detailed examination of railway records was carried out to understand the developmental process of railway in this region and helps to recognize the role of Political, Social, Economical and Technological factors in the development railway transportation in North Eastern States. ArcGIS and QGIS have been used for analysed the regional disparity in terms of physiographic and infrastructural features. Some statistical tool has been used for quantify the collected data by applying SPSS. Findings suggest widespread inequality in railway infrastructure and service among the North Eastern States. Railway system of this region going through a challenging phase and railway network having a virtual space integrated regional development.

1568 SOCIAL AND ECONOMIC INTER-REGIONAL EFFECTS OF HSR SYSTEMS: A REVIEW FOR TURKISH HSR LINES

ABSTRACT

High Speed Railway investment projects require economically significant financial resources and take so much time to build the systems. Moreover, these systems need to be implemented after intensive and fussy social and economic feasibility because of its both regional and inter-regional great impacts and costs. In this study, HSR systems are, which either implemented or constructed and planned, in Turkey, evaluated from the point of passenger and freight transportation, logistic activities and regional developments. Transport data and development indicators analysis in terms of their spatial distribution and synthesis according as their regional and inter-regional relations. GIS program are used to make the analysis and synthesis. As well, other countries which use HSR systems in transportation mode or plan to construct the system, are examined in connection with their relation from Asia to Europa vice versa. According as the study, it is seen that HSR services strengthened the connections between Europe and Asia, especially in terms of time and distance issues. At the same time, while the transportation infrastructure of the region is getting stronger, the international and inter-regional connections of the country are also increasing. Moreover, countries which are located on the HSR lines, benefit positively from the systems, on the other hand, countries that are located outside of the systems, cannot benefit in terms of the economic and social mobility that the system creates. So far, the study shows that HSR lines is going to be one of the key linkage between the countries and regions from the point of transportation modes.

1098 AGGLOMERATION AND FIRM WAGE INEQUALITY: EVIDENCE FROM CHINA

ABSTRACT

China is experiencing rapid urbanization with the steady emergence of large cities, leading to policy discussions of the role of large cities in the country’s development. While the consensus is that agglomeration plays an important role in economic development and large cities can act as engines of economic growth, there is relatively little empirical knowledge of the effects of agglomeration on inequality. In this study, we apply panel data from a micro firm-level survey and from city-level data to investigate whether there is causal relationship between agglomeration and establishment wage dispersion in China. Given potential endogeneity of city size, we employ an instrumental variable regression (IV) approach. We find strong evidence that agglomeration has significant effects on wage dispersion in the short run and long run. The link between agglomeration and wage dispersion is heterogeneous across regions. The spatial distinct results appear to be due to differing stages of development. Our results are consistent with the two-sided sorting models in that the most productive and least productive firms are moving from inland cities to the coast. Keywords: agglomeration, wage dispersion, city size, China

1342 SCOPE OF AIRPORT-ORIENTED DEVELOPMENT (AOD) FOR INDIAN AIRPORTS - A DISTRIBUTION ASSESSMENT USING SPATIAL ECONOMETRICS MODELS

ABSTRACT

Principally, the cities have developed around a central core of transportation and logistics. Starting from seaports to rivers and canals, from railways to roadways, and finally around airways. Today, airport is more than just a hub for human movement. It is a driver of business location, economic growth, and global integration. To position metropolitan regions on a global scale and enhance their ability to compete with other regions, policy-makers undertake major investments in the form of large-scale development projects, and airport-oriented development (AOD) is one of them. AOD can be analysed as “ecosystem of business”, which includes airports, airlines, passengers, governments, local communities, and regional economies. Region’s economic scenario is a key factor for the growth in air service demand and the vice-versa also holds true, as air transportation can be a strategic cause and facilitator of a region’s economic growth. The major catalytic impact caused by airports is generation and enhancement of regional economic competitiveness by promoting export activities, tourism activities, market connectivity, boosting business operations and productivity, and influencing companies’ location and investment decisions. Airports have layers of impacts at spatial, environmental, economic, social, and network level. However, the intricate role of airports in the economy has made the science of impact analysis more complicated as the relationship between regional economic growth and spatial changes is complex and causal. Moreover, less attention is given to the relationship between air transport, spatial effects, and economic development. Numerous studies attempt to evaluate the regional impacts of airports by economic assessment tools. Other researches have generally focused on financial efficiency and productivity, while neglecting the role of space or location and spatial effects in the study of airport activity. Here, spatial econometrics comes into the picture which is a powerful tool for the analysis of spatial relationships. Regional observations are linked to a location and it is commonly observed that data collected for regions in space are not independent, but rather positively spatially dependent, which means that observations from one location tend to exhibit values similar to those from nearby locations. Spatial econometric models allow to account for dependence among these observations. It is important to understand the spatial correlations that may exist on airports as the connectivity of India's airports is majorly complementary than competitive and establishes a balance of competition and cooperation. Also, India's airports have recently undergone several reforms and it is important to analyse the spatial distribution of airports taking into consideration the factors that explain their distribution. Thus, an analysis of the cost of airports with their observed spatial characteristics, is justified, as it may help clarify the role that networks play, and allow for analysis that proposes optimal controls. The paper analyses the cost function of Indian airports using various direct and modified variables and alternative spatial models to review the scope of airport-oriented development (AOD) in Indian setting.

1393 DISTINGUISHING PRODUCTIVITY DIFFERENCE FROM AGGLOMERATION AND SELECTION EFFECT: EVIDENCE FROM INDONESIAN MANUFACTURING FIRMS

ABSTRACT

This study examines the productivities differences between Indonesian manufacturing firms in small and large cities. While a large of literature studied the agglomeration and selection effects on firms separately, this study tests those two effects simultaneously by using a new quantile approach developed by Combes (2012). By using the data of Indonesian manufacturing firms census from 1990 to 2014 data, we find a strong evidence of agglomeration benefit for firms in the large cities than those are in the small cities. However, we find a stronger selection effect in small cities than the larger cities. The average productivities of firms in the above-median of employment density are 18.2 percent higher than those below median, while the minimum productivities to enter the market are 0.6 percent higher in the below-median cities. The results are robust to different spatial definition of city size and scale. When we breakdown the manufacturing firms into 24 sectors, we find that firms in 19 sectors are better-off from the agglomeration effect, while five sectors suggest non-statistically significant. In contrast, there are 11 sectors that suggest selection effect while the rest are not statistically significant. We conclude that natural resources endowment and the quality of local infrastructure drive our results.

1415 THE IMPLICATIONS OF INDUSTRIAL ROBOTICS LABOR DEMAND FOR METROPOLITAN ECONOMIES IN THE UNITED STATES

ABSTRACT

Questions about how automation is changing the nature of work and the composition of the workforce are taking on new urgency in the age of robotics and artificial intelligence. However, the question of where these changes will have the greatest impacts is largely un-examined. While effects of technological change have a global reach, some local economies will be more affected by technology-related labor disruptions than others, depending on the particularities of their industry structure, production processes, and supply chains. This research is a component of a larger project funded by the NSF National Robotics Initiative. It focuses on local economies in the U.S., specifically on metropolitan economies and employs actual data about robotics labor demand. This approach stands in contrast to other recent estimates that infer the effects of robot use based on sales data and industry structure (e.g. Acemoglu & Autor, 2011).

ABSTRACT

There has been growing academic interest in understanding how cultural attributes of a region and local production systems are deeply inter-related so as to shape its cultural industries, and thereby, cultural economy of the region. The latter is one of the rapidly growing economies in the world. As neo-classical economic theories of agglomeration and Marshallian industrial district fail to suitably map the dynamics of cultural and creative industries, the concept of cultural economic geography has emerged. In the latter case, cultural factors result into significant sources of regional differentiation and competitive advantage in globalized economies. This has found its application, particularly, in developing countries where traditional cultural industries and their creative resources are largely rooted in regional culture, agrarian societies, and mostly operate from both urban and rural areas where they have existed over generations. To examine this phenomenon in Indian scenario, silk weaving industry of Varanasi District has been selected. Over generations, local weavers have mastered the art of weaving with silk on handlooms producing 'Banarasi' brocades and 'sarees' which have secured geographical indication rights, thus, supporting the link between the product and its place of production which spans Varanasi and five adjoining districts. Though the trade in silk products is centered in Varanasi city, production is spread across the district (1,535 sqkm) with more than 60% of approx. 14,000 handloom weaving households living in tight-knit clusters dotting the rural hinterland. Such a regional scale of operations in this industry, which thrives on traditional artisanal skills and tacit knowledge, is realized by the presence of strong informal networks of dense inter-personal and inter-organizational relations among a variety of actors who are directly or indirectly involved in the industry. Organizational hierarchy among weavers and allied workers and its evolution, factors affecting their location decisions, and specificities of the value-chain have been studied. To map the dynamics of network relations, a questionnaire-based survey has been conducted with a representative sample of handloom weavers from Varanasi District, seeking information on their primary and secondary connections in the industry. Further, Social Network Analysis has been employed to describe various structural aspects of these networks; thus, establishing the significance of such informal networks in operations of the traditional silk weaving industry in the city-region. Thus, this paper re-establishes the significance of studying the region as a unit, wherein economic transactions are not only facilitated by competitive advantage extended by economies of agglomeration, but also by creative advantage accruing from economies of scope in terms of informal exchange of traditional knowledge and cultural diversity across dense networks.

Keywords: cultural economy, cultural industrial cluster, handloom industry, social network analysis

INTRODUCTION

In recent decades culture-led development strategy has found increasing attention of policy makers as well as scholars across the world. Developed countries, like the United Kingdom, Australia, the USA, Hong Kong, have created dedicated governmental infrastructure to bolster the share of 'cultural and/or creative industries' in local economy. This may be explained by the lower share of production of crafts in these countries, as compared to technology-intensive, post-industrial, and service-oriented creative economic activities, like advertising, media, TV, etc. Moreover, a number of contextually developed 'creativity indices' are being used by several governments in the developed world to monitor the growth of these industries, which build a rapidly growing sector. Recently, developing countries are also following suit. However, there lies a difference between them and their counterparts from the developed world, which need be identified and worked on carefully; hence, the need for further research.

Figure 1 Classification of cultural and creative industries (UNESCO, 2013)

Before studying the difference, it is important to introduce the basic terminology. Although wide semantic ambiguity exists in the definitions of 'cultural and creative industries'; broadly speaking, industries with production and consumption processes having a 'symbolic and expressive element at their core' have been classified as cultural

industries (UNESCO, 2013); for instance, arts (performing, visual, and literary) and crafts. Whereas industries ‘requiring creativity, skill and talent, with the potential for wealth, and job creation through exploitation of their intellectual property’ have been identified under the broader set of creative industries (DCMS, 2001); e.g. advertising, film and media, publishing, and even software development.

The difference lies in the observation that cultural industries are deeply rooted in local context, culture, and communities; whereas creative industries are purely looking at activities protected under law related to Intellectual Property Rights (UNCTAD, 2010). Unlike creative industries exploiting individual creativity, traditional cultural industries build upon creativity which is a collective good of artisan communities. As individual creative acts cannot be disentangled from collective values and knowledge (i.e. local traditions), these can’t be protected under the existing legal framework. This is why traditional cultural industries fail to comply with the conceptual definition of creative industries. Hence, it is important to make the distinction between these two industrial sectors, particularly in the context of developing countries, as both require different contexts to grow and their economic contributions are also different.

Additionally, creative industries need entrepreneurial climate (e.g. start-up environs), economic diversification, soft institutional factors (such as tolerance, urban amenities, social diversity), and urbanization economies (enabling information flow and cross-fertilization of ideas) to grow; whereas traditional cultural industries operate largely in rural areas where they have existed over generations with hereditary skill transfer (Fahmi, Koster, & Van Dijk, 2016). Thus, the factors affecting location decision of workers in both creative and traditional cultural industries widely differ.

Hence, there is a need to freshly identify factors affecting location decisions of artisans engaged in traditional cultural industries, particularly in developing country scenarios; which are different from those active in relation to creative industries. This paper tries to address this gap, through a focused discussion on regional networks in case of silk-weaving industry spread across Varanasi district, which is essentially a traditional cultural industry where the skills are passed on over generations.

Before detailing out the empirical case, it might be helpful to discuss factors which help build a conducive environment for cultural industries, in general, to grow and sustain. The next section deliberates upon the same.

PLACE, CULTURE, AND ECONOMY

Unlike in other manufacturing industries, processes of cultural production and consumption are highly rooted to the place where they originate. In fact, local ‘traditions, norms and sensibilities actively shape the structures and strategies of business operations in the cultural economy and the design of final outputs’ (Scott, 2000). ‘The particular traditions, conventions, and skills that exist in any given urban area help to infuse local products with an exclusive aura that can be imitated by firms in other places but never completely reproduced’, notes Scott (2006). Distinctive place-based characteristics of products – be it technology- or crafts-intensive, utilitarian or cultural – increases their chance of continued competitive success, as consumers value them for both qualitative aspects and price-efficiency (Scott, 2006). On one hand, elements of place enter into the design specifications of products; and on the other, changing symbologies of outputs get assimilated into cultural assets of places where they are made. Since cultural economy is a site of dense inter-firm transactions, involving both traded and untraded interdependencies, it demands mutual proximity; thus, bringing in the component of geography in the discourse of cultural economy. The conceptual diagram (fig. 2) by Evans (2004) may be referred in this regard.

Figure 2 Triad of symbiotic relationship between Place, Culture & Economy

This understanding of the recursive relationship between place and cultural production had resulted into increased scholarly attention to identify local factors which help create a conducive environment for cultural industries. This led to development of various conceptual frameworks which take spatiality into account, namely ‘Creative City’ (Landry & Bianchini, 1995), ‘Cultural Economy of Cities and Creative Field’ (Scott, 1997), ‘Creative Milieu’ (Landry, 2000), ‘Creative Atmosphere’ (Lazzeretti, Boix, & Capone, 2009), ‘Creative Economic Geography’ (Flew, 2010).

Besides market forces of production and consumption, a lot of other factors influence the economy of traditional cultural products (such as indigenously developed arts and crafts); for instance, protection and suitable adaptation of traditional artisanal knowledge – which is at the core of cultural production. Instead of in professional training institutions, such

skill-sets are typically passed from one generation to the next in an artisan family. This is why networks disseminating tacit knowledge become significant in the study of cultural industries; hence, are being discussed in the next section.

NETWORKS IN CULTURAL INDUSTRIES

Artisan communities, generally, live in tight geographical clusters for both competitive and creative advantages. Competitive advantages refer to benefits generating out to agglomeration effect, i.e. economies of scale, as is witnessed in Marshallian industrial districts. On the other hand, creative advantages are generated in terms of flow of knowledge through web of informal face-to-face interactions among individual members of the artisan community.

However, scholars have noted that benefits of clustering are not simply generated out of mere co-location of enterprises; rather it need be complemented by development of collaborative networks (Comunian, 2012; van Heur, 2009). This is why, most of the studies on cultural economic geography have identified network of dense inter-firm transactions as one of the key determinants of a conducive environment. This is besides the concentration of skilled labour with local sensibilities, and cultural diversity of local population. The latter parameter might not be relevant for traditional cultural industries, as such artisan communities are largely homogenous in general.

To better explain the significance of inter-firm networks in study of traditional cultural industries, it may be noted that the knowledge involved in artisanal production is highly informal, or tacit, in nature. This is because such knowledge gets disseminated only through informal face-to-face interactions; unlike codified knowledge which can be demonstrated, and transferred geographically (and historically) through various media. Typically, artisanal skills are deeply protected within the artisan community or the family, and are transferred over generations by the virtue of heredity, and not by institution-based learning.

Another aspect of networks in traditional cultural industries is the fact that inter-firm transactions are both traded and untraded in character. Unlike in a typical manufacturing sector, such transactions are highly informal in character with no formal contract being signed, and wherein mutual trust and reciprocity are corner-stones of the practice. In this case, trust can be inter-personal and/ or inter-organizational in nature.

Social Network Analysis (SNA) is one of the number of tools and techniques which have been used to measure the strength of networking involved in cultural industries. In a study by Lee (2015), 'connectivity' and 'quality of information' have been identified as indicators of networks that actively promote knowledge spill-over and learning.

Equipped with this basic understanding of the relevance of studying networks w.r.t. traditional cultural industries, the following sections elaborate on local regional networks which are in action in case of traditional occupation of silk-weaving in Varanasi.

SILK WEAVING – A TRADITIONAL OCCUPATION

Varanasi is a repository of varied locally produced cultural products which have bagged geographical indication tags, such as handwoven silk products, wooden toys and lacquerware, pottery, *zardozi* (i.e. embroidered fabric), and others. These are also sources of livelihood of a sizeable share of its population. Of them, silk-weaving is the largest employer in the city-region, and hence, the focus of this paper.

Over generations, weavers of Varanasi have mastered the art of weaving silk products on handloom; particularly 'saree' (a traditional women's garment) and brocade laced with 'zari' (i.e. fine threads of silver and/or gold). Even the finished product - 'Banarasi Saree' - is named after the region, i.e. Banaras, or Varanasi. Thus, 'Banarasi Saree' is good example of a cultural product wherein the place of production becomes a unique component of the product, and vice versa.

Over centuries, silk-weaving has been a family-owned enterprise held on privately-owned handlooms set at respective houses. Although, typically, an adult male member of the family operates the loom, other members of the household are also engaged in the process; thereby turning it into a household industry. To consider the specificities of this industry, it is rather important to study the weaving process in practice, prevailing organizational hierarchy among weavers. The same has been briefly discussed in following sections.

Weaving process in Varanasi

Following are basic dimensions governing the variety of Banarasi Sarees.

1. Type of yarn (natural, synthetic, and blended)
2. Patterns of weave (based on the various arrangements of warp and weft)
3. Techniques of weaving (hand- or machine-driven)
4. Design motifs (traditional or modern); e.g., *butidar, jangla, jamdani, tanchoi, jamawar, etc.*

Weaving process may be broadly classified into three phases of production, i.e. pre-loom, on-loom, and post-loom operations. Following steps are typically followed for silk weaving in Varanasi (Bajpai, 2015; Textiles Committee & HWA, 2007) (refer fig. 3).

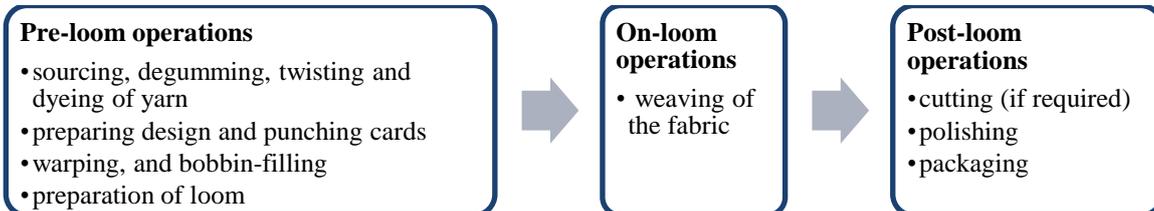

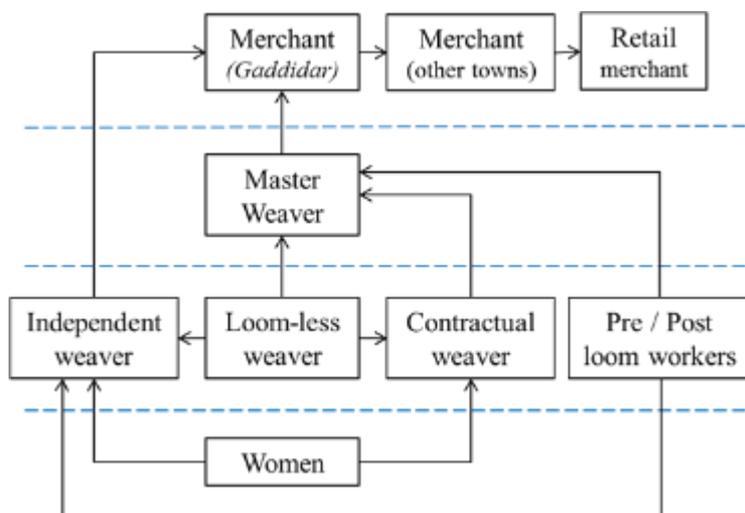

Figure 45 Weaving process in Varanasi - adapted from (Textiles Committee & HWA, 2007) (photos: author)

Thus, silk weaving involves a large array of skilled workers or artisans required at different stages of production; each being completed at different workshops instead of a single large factory.

Organizational hierarchy of weavers in Varanasi

Organisational structure of the weaving community in Varanasi has been explained by Basole (2015) (refer fig. 4). Weavers are broadly classified into following groups.

Independent weaver	: One who independently works on his loom housed at his residence, employs raw materials, and sells finished product in the market.
Contractual weaver	: One whose services are being hired by a master weaver; works on his loom housed at his residence. Master weaver provides for raw materials (yarn and design).
Loom-less weaver	: One who doesn't own any loom, thus, weaves on a loom housed at the employer's residence/workshop; provided with raw materials and work.
Master weaver (<i>girhasta</i> in Hindi)	: One who may or may not weave himself, but employs one or more weavers, either at his residence / workshop, or on contract.

Source: adapted from Basole (2015)

Figure 4 Organization of actors in weaving industry

Presently, about 95% of handloom weavers work as a wage-earner (i.e. loom-less or contractual weaver). Rest of the weavers (i.e. independent weavers) engage in production either in anticipation of demand or against a prior order (Textiles Committee & HWA, 2007). Both independent and contractual weavers employ loom-less weavers as and when required, if they have idle loom capacity and/or require extra labour to meet demand pressures. Womenfolk typically performs allied tasks, such as, winding of yarn (*'naari-baana'*) and cutting in respective households.

Almost all business transactions in this industry are informal in nature. Following transactions are typically held in production process of a Banarasi Saree.

1. Merchant or trader (*gaddidar* in Hindi) places order with a master-weaver (or, *girhasta*). The trader might also pay an advance amount to the master-weaver to buy yarn and other raw-materials, develop design by hiring services of a designer (which may, or may not, be brought to the trader for approval).
2. Once the design is ready, the master weaver places order for graphing and punching cards to be fitted to a jacquard machine.

3. Next, the master-weaver hires an adequate no. of contractual and/or loom-less weavers to enable production. Hired weavers may work on looms set up by the master-weaver at a workshop, or may work on individually owned looms at respective houses.
4. Upon completion, the weaver returns the finished product to the master-weaver, who would further send it to the trader.

A rigid hierarchical differentiation has set in within the weaving community where once independent class of weavers has become highly dependent upon the ones in upper echelons of the community, i.e. master weavers (*girhasta*) and merchants (*gaddidar*). The occupational structure has changed over years with diversification of labour; massive shift from handlooms to power-looms; labour emigration from Varanasi to textile factories beyond the region; and the rise of contractual weavers.

Such changes are altering the social structure of weaving community in Varanasi. Previously, almost everyone in a weaver’s household had been engaged in processes ancillary to weaving. Now, increasingly, pre- and post-loom operations are getting outsourced; thus, changing the familial and social relations.

As noted by Schütte & Kreutzmann (2015), the count of independent weavers is fast declining. Contractual and loom-less weavers are the weakest and most vulnerable among all in the hierarchy; since they neither have any command on the design nor on the pricing of the product they weave. Increasing reliance of weavers on *gaddidar* and/or *girhasta* for supply of raw materials and design (owing to their weak economic situation), drives them into relationship of dependency.

Regional networks in weaving industry

As per the records of the Geographical Indications Registry of Chennai, production of the registered product ‘Banarasi Brocade and Sarees’ is spread across five districts, having the highest share in Varanasi district (refer fig. 5). About 87% of the handloom weaving households and 88% of the handloom weavers in the region are located in Varanasi district, with Varanasi city being the major hub for production and trading.

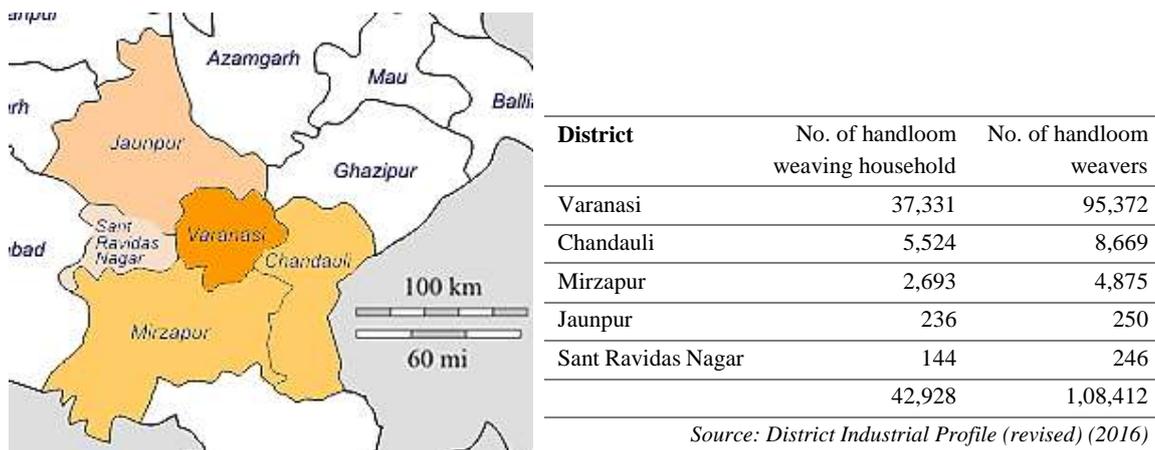

Figure 46 Regional spread of Banarasi brocade and saree industry

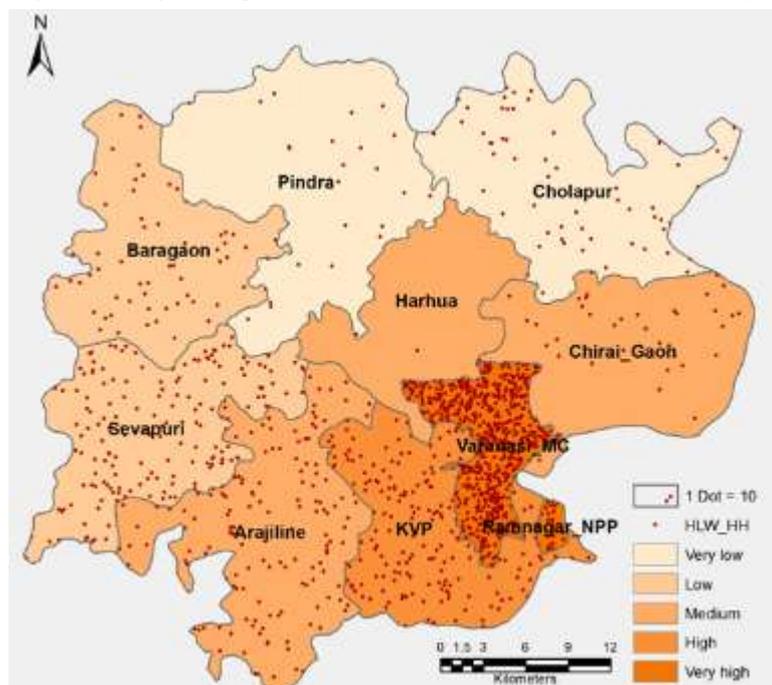

Figure 47 Distribution of handloom weaving households across blocks in Varanasi district (source: author; dot density refers to density distribution of handloom weaving households, and the choropleth map refers to no. of households as per Census of India 2011)

As per a draft report of the baseline survey of Varanasi Handloom Mega Cluster conducted in 2015-16 by the Office of Assistant Commissioner, Handloom and Textile industries of the State Government of Uttar Pradesh, about 42% of the handloom weaving households in the district are located within the municipal limits of Varanasi Municipal Corporation. Rest of the households are spread across the rural hinterland in concentrated pockets, particularly, in southern blocks of the district, namely, Kashi Vidya Peeth (which encapsulates the municipal area from three sides), Sevapuri, Arajiline, and (refer fig. 6).

Though the production is decentralized across the region, trading is highly concentrated in few wholesale markets located at the heart of Varanasi city, namely, at Chowk, Gol Ghar, and Madanpura; and also in Lohta lying just outside the municipal limits towards the west. This may be explained by the hierarchical structure of the weaving community, briefly discussed in a previous section, and structure of spatial networks of business transactions spread over the region.

CONCEPTUAL FRAMEWORK

In order to further explore the network of inter-relationships between weavers and allied workers, a number of pilot surveys and field visits were conducted in selected pockets in Varanasi city and its rural hinterland. Based on the initial observations, a paper-based questionnaire was developed.

The paper-based questionnaire survey was primarily intended at identifying both professional and social networks of weavers, and physically map those connections to identify the spatial dimension. Various types of weavers – those who directly work on the loom – were respondents of the survey, excluding those who are engaged in either pre- or post-loom operations. The questionnaire included following broad sections.

Section	To identify:
Occupational details	Type and quantum of production; type of infrastructure involved (i.e. loom)
Professional network	Professional connections of the weaver; frequency and length (in years); physical distance / proximity and level of trust with each of the connections
Social network	Participation in weaving by family members and relations; source of financial support; sense of belongingness and social participation of the weaver
Governance	Level of governmental intervention
Miscellaneous	Migration pattern (type of job and location); aspirations for the future

Broadly, respondents were asked to identify individuals with whom they interact professionally. Proximity of the individual (km), average frequency of interactions (no. of days per month), and the length of connection (in years) were noted for each tie. Further, this information was fed to a visualization interface (NodeXL) to draw network graph for a sample cluster. The graph was interpreted based on knowledge obtained from both literature and observations from the field.

From a part of the ongoing paper-based questionnaire survey, descriptive results w.r.t. networks are being discussed in following sections of this paper, followed by discussion of a sample cluster of Adampura in Varanasi city.

RESULTS AND DISCUSSION

Informal networks

As mentioned in a previous section, weavers in Varanasi are increasingly getting relegated to the status of contractual labour. In the prevalent system, most of the weavers are provided with requisite raw materials (i.e. yarn and design) by a master weaver or a trader, as per order. They are required to weave and deliver the woven product back against which they get paid as per the contract. Of the small sample set of 32 respondents from Adampura Zone in Varanasi city being interviewed, about 72% of handloom weavers have been contractual, whereas only handful are working independently, i.e. they employ their own labour, capital, and sell the finished product in the market. Rest are master weavers, each contracting work to about three to six weavers, who work either at their respective households, or those who are loom-less and travel to work in a workshop ('*kar-khana*' in Hindi) set up by the employer. There are contractual weavers who have been working on contracts from a single master weaver for the past fifteen years, whereas there are many who keep on switching from one to another every second or third year. Thus, there is neither any formal employment, nor even a formal contract involved in such transactions, which are largely based on mutual trust.

Proximity of connections

Although inter-firm networks are spread across a large city-region, ties between weavers and traders and/or allied workers are typically local, i.e. with high proximity. In other words, weavers and allied individuals often form locally dense non-overlapping cliques connected by few distant actors. Such a network structure may be classified as 'small-worlds' (Giuliani & Pietrobelli, 2011).

Most of the weavers living in dense urban areas of Varanasi have reported that distances covered for different transactions lie within a range of 500 m to 2 km. In rural areas, the range is around 2 to 5 km, with less frequent ties spanning for 10 km or more (e.g. services offered by a trader, or one who punches cards, or a designer). Hence, it is important to assess physical distances, since local ties are supposed to offer creative advantages of clustering (by

promoting frequent informal interactions); whereas distant ties are expected to generate competitive advantages resulting out of specialization.

Frequency of interactions

Besides the physical distance or geographical proximity, it is also important to assess the frequency of interactions while measuring the strength of networking ties. Respondents mostly reported high frequency in meeting their professional aides over both professional and non-professional interactions, given the concentration of weaving households in areas where they mostly live.

Contractual weavers usually meet their respective master weavers / traders over three to four times in a month, as and when they require additional yarn for weft, and also to deliver the finished product. However, the services of a yarn supplier, warper, and dyer are required by an independent weaver only once in one-and-half to two months, as and when the warp is consumed, since four to six sarees may be woven out of a typical roll of warp.

Strength of ties

Strong inter-relationships between weavers may also be explained by the fact that the weaving community in Varanasi is not only an occupational group, but largely a ‘biradari’, i.e. a caste-based community, where 60% to 95% of the weavers belong to Momin Ansari group of Muslim community. (However, it may be noted that weavers mostly refrain from having professional ties with their in-laws.) Thus, a deep cultural sense of belonging adds to inter-personal trust which is crucial for such networks.

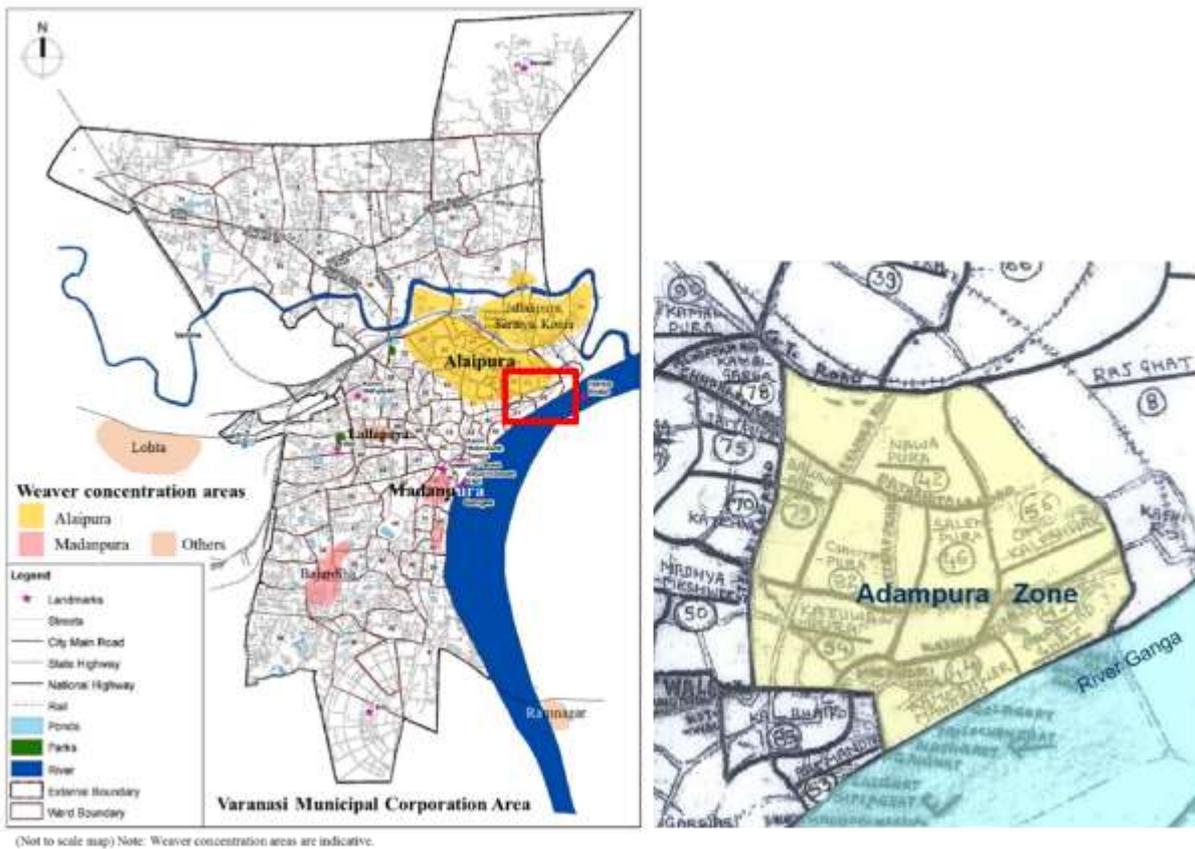

Figure 48 Adampura Zone: (left) Weaver concentration areas in Varanasi municipal area; (right) Adampura Zone identified on municipal ward map (indicative) (adapted by author from various sources and field observations)

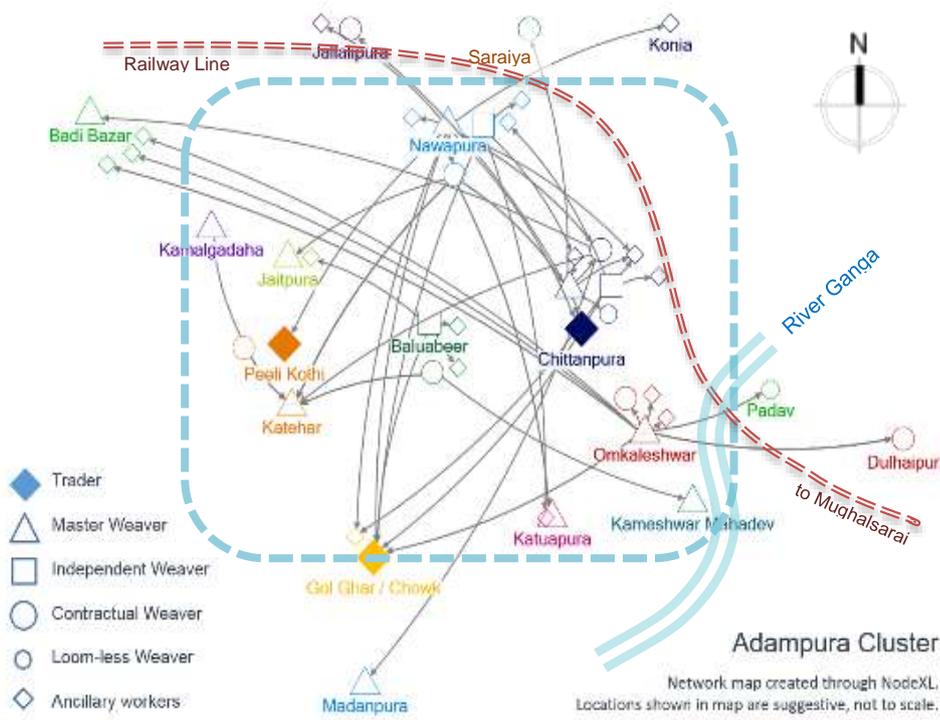

Figure 49 Map of professional network among weavers in Adampura Zone / Cluster (source: author)

Case of Adampura Zone in Varanasi

In order to describe the spatiality of inter-connections in the weaving community of Varanasi, Adampura Zone has been discussed in following paragraphs. Adampura is one of the prime weaving concentration area in the city of Varanasi under the jurisdiction of Adampura Police Station. It includes the following municipal wards with high density of weaving households: Nawapura, Chittanpura, Omkaleshwar, Baluabeer, and Katuapura (refer fig. 7). These wards are majorly comprised of following neighbourhoods, namely Fulwariya, Chittanpura, Pathani Tola, Alampura, Omkaleshwar, Koyla Bazar, and Dulligarhi. These are complemented by adjoining neighbourhoods of Katehar Mohalla and Jaitpura; and the entire belt is collectively known as Peeli Kothi – which is a hub of trading, under the auspices of several elite traders and exporters from the area.

About 32 weavers from Adampura Zone were interviewed. A basic network diagram has been prepared from the connections reported by these respondents (refer fig. 8). Nodes have been grouped as per the type of worker in distinct neighbourhoods. Following aspects may be noted from the map: Gol Ghar / Chowk, Peeli Kothi, and Chittanpura are trading hubs showing high centralities; whereas Nawapura and Chittanpura both are clusters of a range of weavers and allied workers (i.e. warper, dyer, punch card maker, etc.). Omkaleshwar towards the east receives contractual and loom-less weavers from Padav and Dulhaipur which are located across the river. Similarly, areas across the railway line - Jallalipura, Saraiyan, and Konia - are hubs of contractual and loom-less weavers and allied workers. Badi Bazar in the west is a hub of raw materials (i.e. yarn, dye).

Thus, it is evident from the above discussion that spatial information helps to assess various structural properties of a network, namely centralities, proximity, strength of ties, and nature of dependence. Hence, networks of business transactions in traditional cultural industries shall be assessed in relation to physical attributes of various actors and their inter-connections.

CONCLUSION

Traditional cultural industries are largely craft-based and practised by artisan communities. These industries thrive upon skill-sets getting passed on over generations and being protected within the community. Transfer of such tacit knowledge demands a strong network of inter-firm and inter-personal relationships. Since artisans live in tight-knit geographical clusters associated with strong social ties and a strong sense of belonging, spatial dimension of such networks gain significance in assessing the strength of such interconnections.

The case of Varanasi's silk weaving industry is a good example in this regard, highlighting the importance of trusted and reciprocal inter-relationships in sustenance of professional ties. Also, these networks have given shape to a particular organizational hierarchical structure embedded in the weaving community which has a pre-dominant bias on contract-based employment, albeit informal in nature.

The study is being further expanded to individually explore many such 'small-world' networks spread across the city region. This will enable the researcher to assess the network structure at a regional scale and examine the differences between properties of networks in urban and rural pockets. Further examination may be conducted to assess how

various exogenous and/or endogenous factors are affecting these network structures, such as rampant increase in mechanization in weaving industry resulting into faster and larger production; increasing migration of weavers from on-loom to pre- or post-loom operations; and rising emigration of weavers from Varanasi to distant regions.

1553 SHARED AUTOMATED VEHICLES AND EMPLOYMENT AGGLOMERATION: INTEGRATING URBANSIM WITH AGENT-BASED TRANSPORTATION SIMULATION MODEL

Wenwen Zhang¹, Subhrajit Guhathakurta²

¹School of Public and International Affairs, Virginia Tech, Blacksburg, USA

²Center for Spatial Planning Analytics and Visualization, Georgia Tech, Atlanta, USA

ABSTRACT

Increasing use of shared automated vehicles (SAVs), a promising future transportation system, will likely change transportation costs and land accessibility, and eventually the spatial distribution of employment. The variations in employment location decisions will, in turn, alter the spatial distribution of opportunities to incubate new businesses and expand existing services, with significant implications for reorienting the economic structure and competitiveness of a region. However, few studies have explored the potential changes in employment location choices in an SAV dominant scenario. This study addresses this gap in the literature by simulating the employment agglomeration patterns with the help of an integrated urban simulation model and an agent-based SAV dynamic ridesharing model. The results show that SAV will accelerate the existing deindustrialization trends by significantly reducing the travel costs and enhancing land accessibility.

Key words: Shared Automated Vehicles, Employment Agglomeration, Commercial and Industrial Land, Agent-based Simulation

INTRODUCTION

Shared Autonomous Vehicles (SAVs), envisioned as a ubiquitous transit system, have generated significant attention and discussion in recent years (Collie, Rose, Choraira, & Wegscheider, 2017). While the technology is still under development and legal issues remain, small-scale SAV projects are already implemented in cities worldwide (NuTonomy, 2016; Siegel, Robert, 2016). A wealth of literature has demonstrated the feasibility (Kornhauser, 2013), affordability (Burns, Jordan, & Scarborough, 2013), and reduced environmental impacts (Fagnant & Kockelman, 2014; Greenblatt & Saxena, 2015) of the system when compared with private vehicle ownership (Zhang, Guhathakurta, & Khalil, 2018) and current ride-sourcing mobility services.

However, the long-term impacts of this promising future travel mode on urban land use have not been adequately researched (Guerra, 2016). Although some SAV studies have explored the influence of the system on urban parking (Zhang & Guhathakurta, 2017; Zhang, Guhathakurta, Fang, & Zhang, 2015) and residential location choices (Zhang, 2017), to authors best knowledge, no study, to date, has explored how SAVs will influence commercial and industrial land uses. Hence, there is a pressing need to extend the current employment/industrial location choice theories by examining how employment agglomeration patterns will change with the proliferation of SAVs. This study integrates employment location and relocation choice models in UrbanSim (Waddell & Ulfarsson, 2003) with an SAV simulation model (Zhang & Guhathakurta, 2017) to explore changes in employment agglomeration patterns in an SAV dominated future. The results enhance our existing understanding of the spatial distribution of employment by industry sectors under an SAV dominated scenario.

The rest of the paper is organized as follows. Section 2 revisits existing employment location choices theories and the literature on the impacts of SAVs. In Section 3, we introduce the integrated model framework, implementation methods, and data sources. Section 4 summarizes model results, which are validated and verified in Section 5. Section 6 concludes by highlighting the main findings and discusses model limitations as well as potential future research endeavors.

PRIOR WORK

There is an extensive literature examining how transportation-related factors influence employment location choice in metropolitan areas. Weber (1929) formulated the theory of industry location, proposing that firms locate in places that minimize the transportation costs of materials and products. The spatial theory of firm location choices was pioneered by Losch's idealized hexagonal markets, which distributed firms according to their demand potential (Losch, 1954) and by Christaller's work on central place and hierarchy of cities (Christaller, 1933). Both Losch and Christaller provided conceptual frameworks explaining the role of accessibility to raw materials and markets in firm location choices.

The co-locating phenomenon of firms, which was not addressed in the initial models, was later explained in the theoretical literature on agglomeration economies. This line of theory suggests that the returns to scale are not constant, but rather increase for firms that cluster with other firms. The extent of scale economies vary by the type of agglomerating firms, particularly with respect to whether they are within the same industry sector, complementary to the sector, or in other sectors (Marshall, 2009). The localization economies are realized when firms in the same industry sector agglomerate, which offers at least three benefits including access to buyer-supplier networks, labor market pooling, and knowledge spillovers (Fujita & Thisse, 2003; Krugman, Cooper, & Srinivasan, 1995). Meanwhile, multiple factors may prevent extremely high density of firms. These factors are associated with adverse externalities caused by agglomeration, such as congestion, pollution, and high rents in the urban centers. Recent empirical models, also include other amenities, such as government policies and local tax as drivers of agglomeration (Waddell & Ulfarsson, 2003).

The existing location theories suggest accessibility to resources and amount of developable land play an essential role in firm location choices. The introduction of SAVs as a new form of urban mobility service will inarguably change firms' accessibility to human capital and markets as well as the availability of land in the region. Therefore, this travel mode would inevitably lead to shifts in employment location choices. First, SAVs will increase firms' accessibility to labor by reducing the transportation costs. Several studies suggest that the mobility service provided by SAV system will be more affordable compared with privately owned vehicles and even some public transit services. The mile based cost for SAV ranges from €13-50/mile according to recent articles and commercial assessment reports (Albright, Bell, Schneider, & Nyce, 2016; Barclays, 2016; Bridges, 2015; Burns et al., 2013). The cost of SAVs varies depending on the assumptions in technology development, future insurance rate, maintenance frequency, vehicle fuel type, as well as the density of travel demand. In the most optimistic estimation, where electric SAV system fulfills the travel demand, the system costs approximately €13/mile and can still anticipate 30% of marginal profits (Bridges, 2015). Although the estimated cost of SAVs varies significantly among studies, even the highest estimated cost of SAV (€50/mile) is well below the current cost for an average sedan, which is estimated at €75/mile (AAA, 2016).

Beyond the mile-based cost reduction, SAVs can further reduce transportation costs by enabling multi-tasking in vehicles. Given that the burden of driving is eliminated in self-driving cars, the in-vehicle travel time (IVTT) may not be a nuisance to drivers, as they can be productive or just relax in cars. Therefore, it is anticipated that the primary travel time costs in the era of SAVs will be the out-of-vehicle travel time (OVTT) costs, i.e., waiting time costs. In other words, the accessibility to destinations or resources is no longer an inversed function of distance, but instead negatively associated OVTT costs and discounted IVTT costs. The average waiting time costs may vary throughout the city, depending on the distribution of available SAVs. Although the SAVs can relocate to balance the distribution of services in the city, the OVTT costs in higher density districts are expected to be lower. This indicates that compactly developed zones may turn out to be more accessible to various markets and resources in the region.

Moreover, SAVs may also change the spatial patterns of developable land by eliminating a significant amount of parking lots in urban areas. Simulation results from both hypothetical and real-world network-based model settings all suggest that over 90% of the parking lots can be eliminated in the SAV scenario (Zhang et al., 2015; International Transport Forum, 2015; Zhang & Guhathakurta, 2017). Additionally, the reduction in parking land is unlikely to be uniformly distributed in the city. More reduction is anticipated in areas with high land values, given SAVs are programmed to park in zones that minimize total parking expenses (Zhang & Guhathakurta, 2017). This suggests that more land may be available for development in areas with comparatively higher land values, such as urban core and commercial sub-centers, where currently a considerable amount of land is zoned as parking spaces to meet the minimum parking requirements.

In sum, prior studies conceptually support our hypothesis that SAVs will fundamentally change the employment location choices by reducing transportation costs and land availability in urban areas. This study seeks to quantify the potential changes in employment distribution patterns in a SAV dominated scenario.

METHODS AND DATA

Model Development

This study uses a three-step model framework, which integrates employment location and relocation choice models in UrbanSim with an agent-based SAV simulation model, to examine changes in employment agglomeration patterns in a SAV dominant scenario. First, the preferences in employment location choice by industry sectors are estimated using Multinomial Logit models (MNL). Second, the explanatory variables in the MNL models, especially the accessibility to human capital and density of available commercial and industrial land, are updated using outputs from the SAV simulation model (i.e., reductions in commute costs and parking spaces). Finally, changes in employment location choices by industry sector are simulated using the employment relocation choice models in UrbanSim. The following sections discusses the steps mentioned.

Step 1: Employment Location Choice Models

The aggregated MNL models, i.e., the Transportation Analysis Zone (TAZ) level models, are applied to reveal preferences for employment location choices. In addition to the selected relocation TAZ, additional nine TAZs with commercial or industrial land are randomly sampled as alternatives for each job in the model. In other words, each relocating job has 10 alternative TAZs to select from. The probability of a job n choosing to locate in TAZ i can be expressed as:

$$P_{ni} = \frac{e^{V_{ni}}}{\sum_{j=1}^{10} e^{V_{nj}}} \tag{1}$$

The utility of job n choosing TAZ i , denoted as V_{ni} , in the above equation can be expressed using a linear combination of independent variables as follow:

$$V_{ni} = \beta_1 HC_{edu,i} + \beta_2 A_i + \beta_3 L_i + \beta_4 X_i + \epsilon_{ni} \tag{2}$$

Where, $HC_{edu,i}$ are vectors measuring TAZ i 's regional accessibility to human capital with education attainment, edu . A_i represents localization and agglomeration features, such as employment counts by sector and firm density, in TAZ i . L_i is the density of available commercial/industrial land in TAZ i . X_i are vectors of transportation infrastructure, built environment, and local policy and economic conditions in TAZ i . $\beta_1, \beta_2, \beta_3$, and β_4 are vectors of estimated coefficients. ϵ_{ni} is the unobserved random utility component for each decision maker n given TAZ i , which is independent and identically Gumbel-distributed.

$HC_{edu,i}$ features are estimated using Equations (3)-(6). $HC_{edu,i}$ are defined as the sum of all available labors with education attainment, edu (i.e., $pop_{edu,j}$) weighted by the generalized transportation cost (i.e., $e^{-TC_{ij}}$) across all TAZs (i.e., J TAZs) in the region. TC_{ij} is the transportation costs between TAZ i and j , including the travel time costs ($time\ cost_{ij}$) and vehicle costs ($vehicle\ cost_{ij}$). The time costs are estimated by multiplying the sum of OVTT costs (incurred at trip origins and destinations [i.e., $OVTT_i$ and $OVTT_j$]) and IVTT costs (incurred between origins and destinations [i.e., $IVTT_{i,j}$]) by average hourly salary. Vehicle costs ($vehicle\ cost_{ij}$) are estimated by multiplying the shortest distance between TAZ i and j (i.e., $dist_{ij}$) with the average vehicle cost per mile, including both vehicle ownership and operational costs. The average vehicle cost is the weighted average of mile-based costs. The weights are estimated based on the composition of regional vehicle inventory.

$$HC_{edu,i} = \sum_{j=1}^J pop_{edu,j} * e^{-TC_{ij}} \tag{3}$$

$$TC_{ij} = time\ cost_{ij} + vehicle\ cost_{ij} \tag{4}$$

$$time\ cost_{ij} = (OVTT_i + OVTT_j + IVTT_{i,j}) * average\ job\ salary \tag{5}$$

$$vehicle\ cost_{ij} = dist_{ij} * cost\ per\ mile \tag{6}$$

Step 2: Labor Accessibility and Land Availability in the Era of SAVs

A discrete-event simulation model is applied to examine possible impacts of SAVs on land accessibility and urban parking. The SAV model simulates a scenario in which urban residents give up private vehicle ownership and rely exclusively on the SAV system to fulfill their daily travel demand. The model generates urban travel demand – trips, using Origin and Destination (OD) pairs obtained from OD matrices derived from local travel demand models. Travel departure times are simulated to follow the distributions obtained from the local travel survey. Upon receiving clients' calls for vehicles, the system assigns the closest available SAV to fulfill the request. Clients will be put on a waiting list if all vehicles are occupied and be prioritized for assignment once an SAV is freed up. After dropping off clients, SAVs will either be assigned to serve waiting clients, cruise to underserved areas, if in a surplus area, or park directly. The first simulation day will be used as a "warm-up" period to determine the required SAV fleet size to serve the study area. Results from the second and subsequent simulation days will be used to analyze average waiting time and system-wide parking demand. See Zhang et al. (2017) for more details regarding the conceptual SAV model and model implementation algorithms.

The SAV simulation model outputs are used to update the values of two sets of independent variables: (1) human capital accessibility variables ($HC_{edu,i}$) and (2) density of available commercial and industrial spaces (L_i). The human capital accessibility will be improved significantly, due to the reduction in commute costs introduced by SAVs. Human capital accessibility will be updated using Equations (7)-(10) in the era of SAVs. The time costs will be a linear function of OVTT costs at both ends of the trip and a discounted (i.e., α) IVTT cost. Given the uncertainty in the perception of reduced IVTT costs, α ranging from 0% to 50% are examined in this study, as existing literature estimated the value of travel time to as approximately 25% to 50% of prevailing salary (Litman, 2008). Furthermore, the average vehicle cost per mile will be replaced by the SAV cost per mile, 30 cents/mile (i.e., the average of existing estimations, ranging from 13-50 cents/mile).

$$HC_{edu,i} = \sum_{j=1}^J pop_{edu,j} * e^{-TC'_{ij}} \tag{7}$$

$$TC'_{ij} = time\ cost'_{ij} + vehicle\ cost'_{ij} \tag{8}$$

$$time\ cost'_{ij} = (OVTT_i + OVTT_j + \alpha * IVTT_{i,j}) * average\ job\ salary \tag{9}$$

$$vehicle\ cost'_{ij} = dist_{ij} * SAV\ cost\ per\ mile \tag{10}$$

Simulation studies suggest that SAV may be able to eliminate over 90% of urban parking spaces (Zhang & Guhathakurta, 2017). The redundant parking spaces hold the potential to be converted into rentable commercial or industrial spaces. The most recent Atlanta parking inventory report indicates the average area of parking space in Atlanta is approximately 300 square feet (CAP, 2014). Therefore, the updated density of available land in TAZ i can be estimated as follow:

$$L'_i = L_i + \delta * Parking_i * 300 / Area_i \tag{11}$$

Where, $Parking_i$ is the unused parking spaces in TAZ i based on the output of SAV simulation model. The parking lots reduction potentials depend heavily on the market penetration of SAVs. The coefficient δ indicates the percentage of parking spaces that will be transformed into rentable spaces, primarily due to the changes in the zoning ordinance, developers' preferences, and the market demand, which are not modeled in this study. Instead, this study conducts sensitivity tests with parking space conversion rates, δ , ranging from 25% to 90%.

Step 3: Simulate Employment Relocation using UrbanSim

The employment relocation choices are simulated iteratively over multiple years. At the beginning of each simulation year, the model first identifies the relocating jobs and then assigns the relocating jobs to TAZs with the highest utility value, calculated based on employment location choice models. The relocation jobs include (1) new employment in the region, which is generated based on the control totals in the region and (2) existing jobs that decide to relocate, which are randomly selected from all jobs in the region according to the average relocation rates by industry sectors. For each new or relocating job, a choice set of ten TAZs are randomly pooled, and utilities for the sampled TAZs are calculated using the coefficients from the employment location choice MNL model and the updated independent variables, as shown in Equations (12)-(13).

$$P_{n,i,k} = \frac{e^{V_{n,i,k}}}{\sum_{j=1}^{10} e^{V_{n,j,k}}} \quad (12)$$

$$V_{n,i,k} = \beta_1 HC_{edu,i} + \beta_2 A_{i,k} + \beta_3 L_{i,k} + \beta_4 X_i + \epsilon_{n,i} \quad (13)$$

Where, $P_{n,i,k}$ is the probability for relocating job n to select alternative i in the simulation year k ; $V_{n,i,k}$ is the utility of alternative i in simulation year k to firm n ; $HC_{edu,i}$ is the accessibility of TAZ i to human capital with education attainment, edu , after the introduction of SAVs; $L_{i,k}$ is the updated density of available commercial and industrial land at the beginning of simulation year k ; $A_{i,k}$ is the updated localization effects at TAZ i , at the beginning of simulation year k .

The final choice is simulated by selecting the TAZ with the highest utility. By the end of simulation year k , the TAZ level agglomeration features, $A_{i,k}$, and available land features, $L_{i,k}$, will be updated to $A_{i,k+1}$ and $L_{i,k+1}$ and will be used to calculate $V_{n,i,k+1}$ and $P_{n,i,k+1}$ in simulation year $k + 1$. This agent-based employment relocation choice model is implemented using UrbanSim (Waddell & Ulfarsson, 2003).

Two scenarios, i.e., Business as Usual (BAU) and SAV scenarios, of employment relocation choice model are developed. The BAU scenario is implemented using the current TAZ level variables. The SAV scenario is implemented with updated access to human capitals and commercial and industrial land density variables. For both scenarios, the relocation of employment is simulated for five years. The results from BAU and SAV models are eventually compared to examine the possible impacts of SAVs on regional employment agglomeration patterns.

Model Simplification and Assumptions

There are several assumptions and simplifications embedded in the developed model, which are summarized as follows:

- 1) No change in the travel patterns, i.e., no induced travel demand and no variations in the travel behaviors (e.g., OD matrices and trip departure time distribution);
- 2) Potential changes in the traffic condition is not modeled in this study. some studies suggest that AVs will induce travel demand (Harper, Hendrickson, Mangones, & Samaras, 2016). However, multiple simulation studies also suggest that AVs may significantly increase road capacity (Shladover, Su, & Lu, 2012; Tientrakool, Ho, & Maxemchuk, 2011). Therefore, it remains unclear whether the existing congestion during peak hours may deteriorate or mitigate in the era of AV;
- 3) It assumes a 100% market penetration rate and the heterogeneity in the preferences for SAVs is not considered. The purpose of this study is not to examine how the employment location choices may change in the transition period, but how the location choices may evolve in an SAV dominated scenario;
- 4) Land use types will remain the same in the SAV scenario, i.e., there will be no conversion between commercial/industrial land and other types of land.
- 5) Changes in potential parking land conversion and IVTT costs are introduced as exogenous variables. We conducted sensitivity tests with different parking land conversion rates (from 25%-90%) and discounted IVTT costs (from 0% to 50%) in the model verification and validation section to determine how these variables may influence model outputs.

Model Implementation and Data

Step 1: Employment Location Choice Model Implementation

2010 and 2015 ESRI business data, with geocoded firm locations, are used to develop employment location choice models by industrial sector. There are 164,494 and 204,906 businesses in 2010 and 2015 dataset respectively. The datasets contain attributes, such as business names, business types, firm locations, and the number of employees. In the 2015 ESRI data, approximately 92,767 firms locate on residential parcels, indicating that these businesses are home-based. These businesses are typically small, with only one or two employees. In this study, home-based businesses (i.e., businesses with less than three employees or located on residential parcels) are filtered out, given that they are most likely to be self-employed businesses and a different set of factors may influence their location choices. Finally, firms that either started after 2010 or relocated between 2010 and 2015 are considered as firms who made location choices and are included in the estimation of MNL models. 70,086 firms or 563,129 jobs are used to estimate the employment location choice model.

The businesses are divided into eight industrial sectors based on Standard Industrial Classification (SIC) code to develop models separately. Different models are estimated for each sector, as most empirical employment location choice models suggest that firms from different sectors inherit significantly different location preferences (Waddell & Ulfarsson, 2003). Table 1 presents the classification of industry sectors based on the SIC code and the employment count.

Table 1: Number of New or Relocated Business by Industry Sector

Industry Sectors	2-Digit SIC Code	Number of Jobs	Count of Firms	Average Size
Construction	15 - 17	13,258	1,224	10.8
Manufacturing	20 - 39	24,551	1,705	14.4
TCU	40 - 49	34,555	3,237	10.7
Wholesale	50 - 51	15,326	2,441	6.3
Retail	52 - 58	209,483	7,085	29.6
FIRE	60 - 67	43,815	3,188	13.7
Services	70 - 89	191,357	17,055	11.2
Public	91 - 99	30,784	2,272	13.5
Total		563,129	70,086	14.7

Table 2 tabulates the descriptive statistics and data sources for all considered independent variables, such as accessibility to human capital, agglomeration economy/diseconomy, land availability, transportation infrastructure access, built environment, local tax policies, and other county-level policy factors, in firm location choice models.

Table 2: Summary of Independent Variables in Employment Location Choice Model

Variable Type	Variables	Min	Max	Average	Std. Dev.	Data Source
Human Capital/ Market Size ($HC_{edu,i}$)	Access to Population with Bachelors	0	44.47	1.96	3.79	Calculated by Authors, using data from Census Bureau

Businesses need human capital to undertake production and other revenue-generating activities. Thus, the accessibility to skilled labor plays an important role in the choice of firm location (Basile, Castellani, & Zanfei, 2009; Mota & Brandão, 2013). In this study, the accessibilities to the population by different level of education attainment ($HC_{edu,i}$), estimated using Equations (3)-(6), are used to measure TAZ level access to human capital. The time costs are associated with travel time and average hourly salary by industrial sector, obtained from the Bureau of Labor Statistics. The vehicle costs are estimated by multiplying the travel distance by the average vehicle costs per mile. The average mile-based vehicle cost is the weighted average costs. The weights are calculated using regional vehicle composition profile obtained from the Atlanta 2011 travel survey and 2016 AAA's vehicle cost report.

Theories regarding agglomeration and localization economies suggest that firms can realize benefits by co-locating and sharing raw materials, skilled labor pools, markets, and infrastructure (Marshall, 2009). While the theory of scale diseconomy indicates that the negative externalities stemming from the high density may prevent firms from agglomerating. The negative effects include congestion, server competition, and an insufficient amount of critical infrastructure. The agglomeration related variables (A_i) used in this study include TAZ level employment by sectors, job density, and average employment size. Given the theory of agglomeration economy and diseconomy, the correlations

between firm location choice and the agglomeration variables are not linear (Bhat, Paleti, & Singh, 2014). Therefore, squared terms of these variables are also considered to reflect the phenomenon of diseconomy when the density becomes too high. Agglomeration variables are estimated from 2010 Esri business data.

The probability of a firm to locate in a TAZ i is also determined by the availability of rentable commercial/industrial spaces. The land availability variable (Li) for the year 2010 is generated by aggregating CoStar’s building level rentable space data to TAZ level. The data is normalized by the area of TAZs to reflect the intensity of available land in TAZs.

Transportation infrastructure and built environment features also affect firm location choices (Bhat et al., 2014). Adjacency to various types of transportation infrastructures, including states expressways, highways, and airports, are examined in different models. Additionally, built environment features, such as population density, walkability (using WalkScore), percent of four-way, three-way intersections, and cul-de-sacs, are also tested to determine whether TAZs with better infrastructure and more compact and diverse development patterns are more appealing to firms in the study area.

The county-specific variables, such as property tax, Location Quotient (LQ), and county binary dummies, are also examined in the models. County property tax is included because prior empirical studies suggest property tax can influence firm location choice via the supply of rentable spaces (Guimaraes, Figueiredo, & Woodward, 2004; Jofre-Monseny & Solé-Ollé, 2010). LQ index is calculated by County to measure the specialization effects. LQ is defined as the percentage of businesses from a certain industry sector for each county divided by the national percentage of the businesses in the same sector. The index is calculated using the Equation below:

$$LQ_{i,j} = \frac{B_{i,j}/TotB_j}{B_{i,nation}/TotB_{nation}} \tag{14}$$

Where, $LQ_{i,j}$ denotes LQ for industry sector i in County j ; $B_{i,j}$ denotes total number of businesses in industry sector i in County j ; $TotB_j$ denotes total number of businesses in County j ; $B_{i,nation}$ denotes total number of businesses in industry sector i in the nation; $TotB_{nation}$ denotes total number of businesses in the nation.

LQ index specifically captures the effect of localization economy (Gabe & Bell, 2004). A county may have a high localization economy if the proportion of a specific industry sector is significantly higher than the national average. Based on the theory of localization economy, firms from the same sector may decide to collocate to have better access to specialized human capital and market.

Other unobservable county-level variables are included in the location choice model by introducing county specific binary variables. The coefficients of these dummy variables will capture the mean effect of unobserved county factors in firm location choices.

Step 2: SAV Simulation Model Implementation

The SAV simulation model is implemented using OD matrices and transportation network from Atlanta Regional Commissions (ARC)’s travel demand model. There are 1,593 TAZs and 9 million vehicle trips in the 10-county study area. The trip departure time distribution is obtained from the weighted 2011 ARC travel survey. The travel demand peaks between 7-8 AM and 5-6 PM. ARC’s travel demand model also provides the link level travel speed, which varies by time of the day, including morning peak, noon, evening peak and night.

Results from 50 rounds of warm-up running tests suggest approximately 367,160 vehicles will be sufficient to serve the 10-county travel demand, i.e., more than 99% of the clients can be picked up within 15 minutes after calling for services. The average waiting time is 7.13 minutes for the entire region. The average waiting time increases to 10.59 during the evening peak hours. The results also show that each SAV can serve, on average, 24.5 trips on a daily basis. Additionally, increasing the fleet size is not going to improve the system performance significantly. An SAV system with 5% more vehicles (i.e., 18,358 additional SAVs) can only reduce the average waiting time by 0.32 minutes to 6.81 minutes. Therefore, in this study, the total fleet size parameter is fixed at 367,160 vehicles for all simulation runs. The expected waiting time for clients departing from different TAZs is calculated using results from all model runs. The TAZ-level average waiting time is then used to update commute costs in the era of SAVs, based on Equations (7)-(10). The discount for IVTT is first set to 0% in the model. The sensitivity tests show the simulation results with discount factors set as 25% and 50%.

Step 3: Employment Relocation Model Implementation in UrbanSim

This study implements employment relocation model using the employment transition and employment relocation models in UrbanSim. The employment transition model in UrbanSim first generates new firms based on regional employment control totals across industry sectors from ARC. The employment relocation model then selects a random sample of existing firms to relocate in the region, based on the average relocation rates by industry sectors. The relocation rates are calculated using Esri 2011 and 2015 data, as tabulated in Table 3. UrbanSim relocation choice model then allocates both the new and relocating firms into TAZs. The probabilities of selecting TAZs for relocation are computed using the estimated employment location choice models from Step 1. Jobs will be eventually assigned to TAZs with the highest probability scores.

Table 3: Annual Relocation Rate by Industry Sector

Industry Sector	Relocated Jobs (2010-2015)	Total Jobs	Annual Relocation Rate
-----------------	----------------------------	------------	------------------------

Construction	13,258	95,302	2.8%
Manufacture	24,551	137,726	3.6%
TCU	34,555	105,843	6.5%
Wholesale	15,326	105,431	2.9%
Retail	209,483	426,851	9.8%
FIRE	43,815	154,192	5.7%
Services	191,357	825,865	4.6%
Public	30,784	155,144	4.0%
Total	563,129	2,006,354	5.6%

MODEL RESULTS AND ANALYSIS

Existing Firm Location Preferences

The estimated firm location choice models are tabulated in Table 4 by industry sector. The final models only include significant variables. The models exclude alternative specific constants and base alternative. Therefore, the estimated coefficients can be directly interpreted with respect to the direction of change in the utility and can also be compared with other coefficients across models. Unstandardized independent variables are used in the models because despite the absolute values of human capital access and commercial/industrial land density variables vary dramatically between SAVs and BAU scenarios, the difference between standardized variables are quite small, rendering it hard to examine the impact of SAVs. The coefficients for standardized variables (i.e., Betas) are also provided in the table for references.

The results tabulated in Table 4 are consistent with the existing theories and empirical studies of firm location choices. Human capital or market size variables ($HC_{edu,i}$) are significant in models for several industry sectors. The signs of the estimated coefficients, however, are not consistent. For instance, jobs in FIRE sector prefer to locate in TAZs with higher access to the population with bachelor or above education attainment. For businesses in services and public sectors, TAZs with better access to the overall labor pool (i.e., population above 25) turn out to be more appealing. Meanwhile, construction and TCU sectors tend to locate in TAZs with less access to the population with higher education attainment and lower median income.

Manufacture, retail, and wholesale jobs are not sensitive to access to human capital.

The agglomeration economy or diseconomy related variables (A_i), such as industry- specific employment and squared version of the variables, are significant and with expected signs across all the models. The results show that the utility function is an inverted “U” shape parabolic curve with respect to the industry-specific employment count. This suggests that when the density is low, firms agglomerate in TAZs with comparatively larger sector-specific employment. However,

when the employment density in the TAZ reaches a certain threshold, the TAZ turns out to be less appealing to businesses to avoid fierce competitions. The model also suggests that firms prefer to co-locate in TAZs with larger total employment density, as the signs for the estimated coefficients of job density (log transformed) are positive and the estimations are significant across different sectors.

The results also support the localization economy theory, which suggests that jobs from different sectors agglomerate to achieve mutual benefits. Manufacturing jobs tend to be positively associated with jobs in TCU, wholesale, and FIRE sectors. Construction sector jobs are more likely to coexist with jobs from manufacturing, TCU, wholesale, and FIRE sectors.

TCU employment agglomerates with manufacturing, construction, and wholesale businesses and is not significantly correlated with retail, FIRE, service, nor Public jobs. Jobs in the Wholesale sector prefers to locate in TAZs with more construction employment and less FIRE employment. Jobs in the retail sector are negatively associated with jobs from the construction, TCU, and Public sectors, however, are positively correlated with jobs from the FIRE sector. FIRE jobs coexist with employment in the service sector and are negatively correlated with jobs from the TCU, wholesale, and public sectors. Service jobs are negatively associated with almost all types of jobs, except for FIRE jobs, which turns out to be not significant. Jobs in the public sector are negatively associated with the manufacturing, wholesale, and services jobs when controlling for all the other independent variables. The localization economy, however, is not as dominant as the urbanization economy, as the correlations of jobs across sectors are sometimes non-significant or even negative. The localization economy, to some extent, relies heavily on the design of local zoning ordinance.

Land availability (*Li*) is also a critical factor in firm location decision-making, as it is significant in most models, except for the retail sector. Jobs in the manufacturing, construction, TCU, and wholesale sectors prefer to locate in TAZ with lower commercial/industrial land density. While the estimations for the commercial/industrial density are 0.064, 0.017, and 0.010 for FIRE, services, and public sectors respectively, indicating these jobs prefer to locate in TAZs with more intensive commercial or industrial activities. This may occur because manufacturing, construction, TCU, and wholesale sectors need sufficient spaces for storage and for machines to operate. Additionally, many construction and transportation (e.g., freight) firms tend to locate in suburban and even rural areas, although their services are delivered primarily in urbanized districts.

Transportation infrastructure variables including distance to highway and expressway exit are negatively correlated with TAZ utility, which is also consistent with most location theories. Proximity to expressway exits is critical to location decision for jobs in the wholesale sector. Distance to highway turns out to be important for manufacturing, construction, TCU, and public sectors. For jobs in retail, FIRE, and services sectors, estimations for both distances to expressway exits, and highway are negative and significant, indicating both factors are considered as critical in location decision process.

Built environment characteristics, such as average land value, population density, and entropy index, are significant for the majority of sectors. Manufacturing, construction, and TCU jobs prefer TAZ with lower land value to reduce operating expenses. Public sector prefers TAZs with higher average land value. This is because businesses in the public sector are more likely to obtain Tax exemptions from the government. Jobs in the retail sector tend to follow the distribution of consumers by locating in TAZs with higher population density. Meanwhile, jobs in the manufacturing sector prefer to locate in zones with less population density, because zoning ordinance typically separates residential neighborhoods with manufacturers to prevent nuisances. Finally, most sectors prefer TAZs with more diversified land use profile, as the estimated coefficients for entropy index are positive for most sectors, except for FIRE and public sectors.

Finally, some county-specific dummy variables are significant in different models.

Location quotient and tax rate variables are not significant in the final models. Manufacturing, construction, TCU, and wholesale jobs tend to locate in peripheral counties, such as Clayton, Douglas, Fayette, Henry, and Rockdale. Meanwhile, Retail, FIRE, Services, and public jobs prefer counties such as Cobb, DeKalb, and Fulton. The results also show that Cobb County is more attractive to almost all jobs across sectors, with positive and significant coefficients in all models.

In summary, the results show that: 1) Sectors, such as manufacturing, construction, TCU, and wholesale prefer to locate in TAZs that is further from the downtown area; 2) Sectors, such as FIRE, services, and public sectors choose to locate in inner city and carry out more intensive economic activities; 3) Retail sector relies heavily on the market size at the TAZ level and therefore tend to follow the distribution of population.

Labor accessibility and Land Availability in the era of SAV

In the SAV dominated scenario, the accessibilities to different labor pools are updated using average waiting time outputs from the SAV simulation model, based on Equations (7)- (10). After the introduction of SAV, the accessibilities to the population with bachelor or above degrees, on average, doubled in the region, due to the remarkable reduction in transportation costs. However, the improvement is not evenly distributed, as shown in Figure 1 (left), as the percent of improvement in the peripheral areas is higher than the downtown area. This is because the current accessibility to human capital in the remote areas is quite poor. However, despite the smaller percentage increase in downtown area, the increase in absolute magnitude peaks in compact zones (see Figure 1 right). Such changes in accessibility is consistent with results from a Switzerland Study (Meyer, Becker, Bosch, Axhausen, 2017). Further, the accessibility to bachelors degree holders increases more in the northern TAZs, compared to the southern part of the region, because more people with bachelor or higher education attainment live in the northern part of the region.

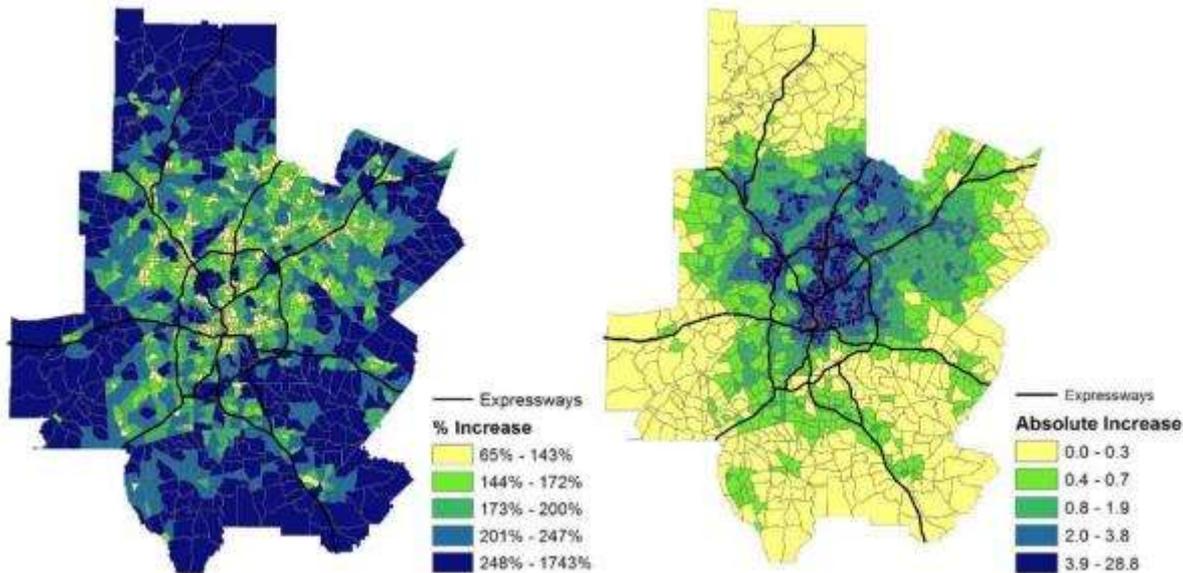

Figure 1: Change in Access to Population with Bachelor or Higher Education under SAV scenario

The number of parking spaces in existing commercial or industrial properties are obtained from the CoStar Group, Inc. Assuming that 90% of the unused parking spaces in the SAV simulation model can be converted to commercial or industrial land use, the corresponding land use density variables are then updated using Equation (11). The updated spatial distribution of commercial and industrial land density is illustrated in Figure 2 (right). On average, the commercial and industrial square feet density increase by 10.7%. The density increases most significantly in the downtown area and TAZs adjacent to highways and expressways, where the existing parking land density is comparatively higher.

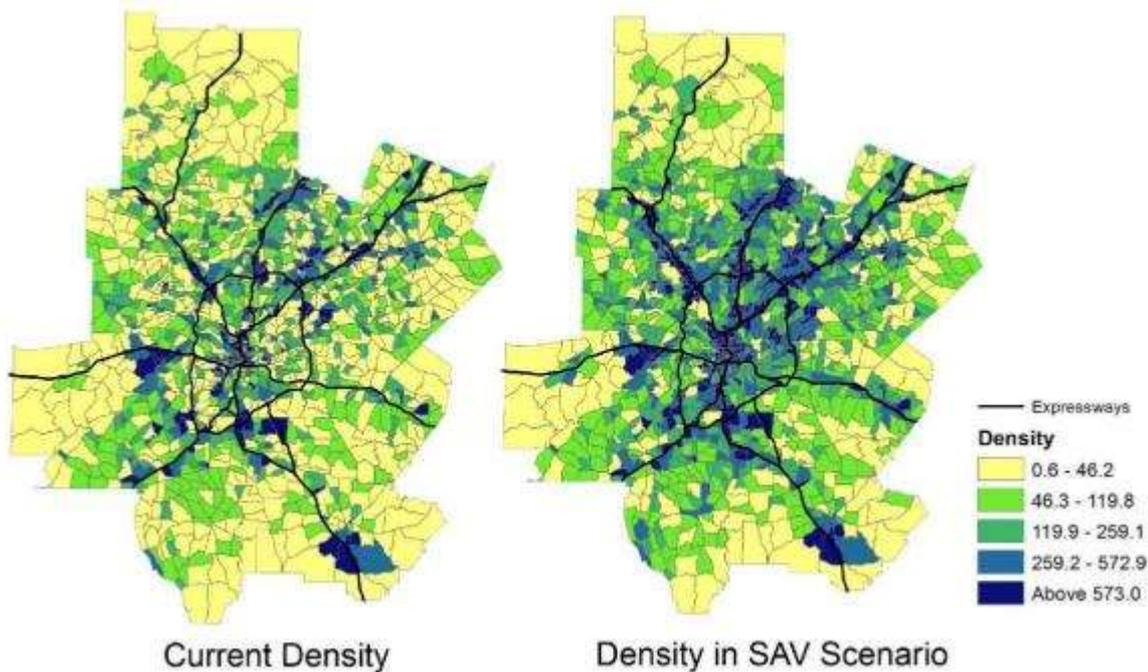

Figure 2: Changes in Available Commercial and Industrial Land Density

New Employment Agglomeration Patterns

The estimated MNL models, baseline independent variables in the BAU scenario, and updated independent variables in the SAV scenarios are input into the UrbanSim model to generate results for BAU and SAV scenarios. The model is set to run from the simulation year 2010 to 2015 to examine possible changes between the two scenarios. The output for 2015 employment in incorporated cities are then aggregated by different existing land use intensities, including downtown, inner city, inner ring suburban and outer ring suburban areas. The classification of incorporated cities in the Atlanta metropolitan region is made based on the built year of structures, density, and dependency of automobiles (Lee, 2005)²³⁰. The classification results are shown in Figure 3.

²³⁰ Lee (2005) classified Atlanta metropolitan area into downtown, inner city, inner ring suburban, and outer ring suburban based on the dominance of built year of structures, density, and dependency of automobiles. For instance, inner ring suburb refers to communities that are low density, single-family areas, which were typically developed between 1950 - 1969. The primary transportation access mode is automobile. More detailed classification methodology can be found in Lee's dissertation Section 3.2.2 (pp. 80-94)

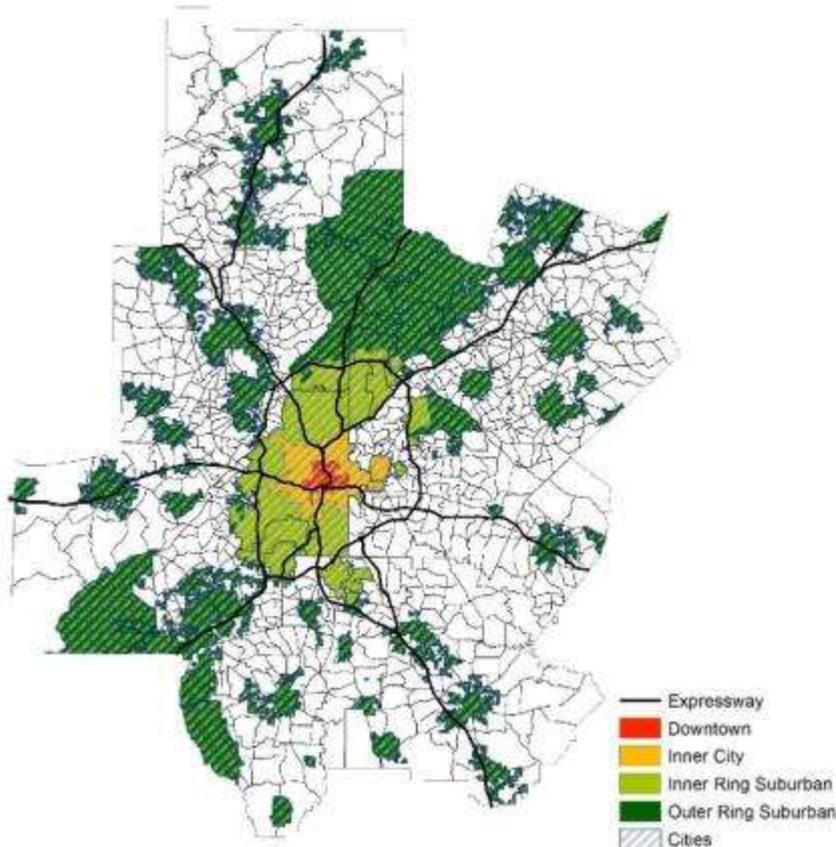

Figure 3: Cities Classification by Land Use Intensity

The simulation results from the BAU and SAV scenarios by industry sectors are tabulated in Table 5. The results suggest that SAVs may exaggerate the current migration trend for commercial and industrial economic activities in the region. In the SAV scenario, sectors, such as construction, manufacturing, TCU, and wholesale, are more likely to relocate to suburban areas, as the job density for these sectors decreases significantly in downtown and inner-city areas, while the job density in the inner ring and outer ring suburban areas increases in the SAV scenario compared to the BAU scenario. Construction jobs are most likely to relocate to inner ring suburban areas. Manufacturing, TCU, and wholesale job densities tend to grow the most in cities located in the outer ring suburban areas.

Employment in FIRE, Service, and public sectors are likely to concentrate more in cities, located in downtown and inner-city areas. The job density in the downtown area increases by 11.8%, 1.4% and 3.1% for FIRE, service, and public sectors respectively in the SAV scenario compared to the BAU scenario. For these sectors, the densities of jobs reduce most significantly in the inner ring suburban areas, ranging from 5.9% to 7.8%.

Retail job density increases in cities across the region, except for the inner ring suburban area. The inner-city area may experience a significant increase in retail density by approximately 4.8%. The retail job density in the downtown area also increases by approximately 0.8%.

Meanwhile, unlike FIRE, service, and public sectors, the job density for retail sector also increases slightly in outer ring suburban areas by 0.6%. This is because retail sectors tend to follow the spatial distribution of the market. The retail employment density in inner ring suburban area seems to level off, as it only increases by 0.02%.

Table 5: Job Density by Industry Sector across Scenarios

Industry Sectors	Scenarios	Downtown	Inner City	Inner Suburban	RingOuter Suburban	Ring
